# Table of Contents

## Introduction to Manual

### Manual Contents

The contents of the CUBRID Database Management System (CUBRID DBMS) product manual are as follows:

- **Introduction to CUBRID:** This chapter provides a description of the structure and characteristics of the CUBRID DBMS.
- **Installing and Upgrading:** This chapter explains how to install and run CUBRID, configure environment variables and ports, perform upgrades, migrate databases in an HA environment, and uninstall CUBRID.
- **Getting Started:** The “Getting Started with CUBRID” provides users with a brief explanation on what to do when first starting CUBRID. The chapter contains information on how to install and execute the system, used ports on accessing to CUBRID and provides simple explanations on the CUBRID query tools.
- **CSQL Interpreter:** CSQL is an application that allows you to use SQL statements through a command-driven interface. This chapter explains how to use the CSQL Interpreter and associated commands.
- **CUBRID SQL:** This chapter describes SQL syntaxes such as data types, functions and operators, data retrieval or table manipulation. The chapter also provides SQL syntaxes used for indexes, triggers, partitioning, serial and user information changes, etc.
- **CUBRID Procedural Language:** This chapter describes the procedural language extension provided by CUBRID for using stored procedures and stored functions. Stored procedures and functions help handle complex business logic that is difficult to implement with SQL alone and simplify data manipulation tasks.
- **CUBRID Management:** This chapter provides instructions on how to create, drop, back up, restore and migrate a database, configuring globalization, and executing CUBRID HA. Also it includes instructions on how to use the **cubrid** utility, which starts and stops the server, broker, and CUBRID Manager server, etc. Also, this chapter provides instructions on setting system

parameters that may influence the performance. It provides information on how to use the configuration file for the server and broker, and describes the meaning of each parameter.

- **CUBRID HA:** This chapter explains how the High Availability (HA) feature is applied in CUBRID. It keeps databases synchronized at all times across multiple servers, and if a failure occurs on the active server, another server automatically takes over the service.
- **CUBRID SHARD:** This chapter explains the sharding feature in CUBRID, which horizontally partitions and distributes data across physically separate databases. CUBRID SHARD is used to distribute and process large volumes of data and high throughput workloads that exceed the capacity of a single database instance.
- **CUBRID Security:** This chapter describes the CUBRID security features such as packet encryption, ACL(Access Control List), authorization, and TDE(Transparent Data Encryption).
- **API Reference:** The “Performance Tuning” chapter provides instructions on setting system parameters that may influence the performance. This chapter provides information on how to use the configuration file for the server and broker, and describes the meaning of each parameter.
- **Release Notes:** This chapter provides a description of additions, changes, improvements and bug fixes.

## Glossary

CUBRID is an object-relational database management system (ORDBMS), which supports object-oriented concepts such as inheritance. In this manual, relational database terminologies are also used along with object-oriented terminologies for better understanding. Object-oriented terminologies such as class, instance and attribute is used to describe concepts including inheritance, and relational database terminologies are mainly used to describe common SQL syntax.

| Relational Database | CUBRID            |
|---------------------|-------------------|
| table               | class, table      |
| column              | attribute, column |
| record              | instance, record  |

| Relational Database | CUBRID            |
|---------------------|-------------------|
| data type           | domain, data type |

## Manual Conventions

The following table provides conventions on definitions used in the CUBRID Database Management System product manual to identify “statements,” “commands” and “reference within texts.”

| Convention      | Description                                                                                                                                               | Example                                          |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| <i>Italics</i>  | <i>Italics</i> type represents variable names and user-defined values (system, database, table, column and file) in examples.                             | <i>persistent</i> :<br><i>stringVariableName</i> |
| <b>Boldface</b> | <b>Boldface</b> type represents names such as the member function name, class name, constants, CUBRID keyword or names such as other required characters. | <b>fetch</b> ( ) member function                 |
| Constant Width  | Constant Width type represents segments of code example or describes a command’s execution and results.                                                   | csql database_name                               |
| UPPER-CASE      | UPPER-CASE represents the CUBRID keyword (see <b>Boldface</b> ).                                                                                          | <b>SELECT</b>                                    |

| Convention                             | Description                                                                                                                                               | Example                              |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Single Quotes ( ' ' )                  | Single quotes ( ' ' ) are used with braces and brackets and represent the necessary sections of a syntax. Single quotes are also used to enclose strings. | { ' const_list ' }                   |
| Brackets ( [ ] )                       | Brackets ( [ ] ) represents optional parameters or keywords.                                                                                              | [ <b>ONLY</b> ]                      |
| Vertical bar (   )                     | Vertical bar (   ) represents that one or another option can be specified.                                                                                | [ <b>COLUMN</b>   <b>ATTRIBUTE</b> ] |
| A parameter enclosed by braces ( { } ) | A parameter enclosed by braces represents that one of those parameters must be specified in a statement syntax.                                           | <b>CREATE { TABLE   CLASS }</b>      |
| A value enclosed by braces ( { } )     | A value enclosed by braces an element consisting of collection.                                                                                           | { 2, 4, 6 }                          |
| Braces with ellipsis ( { } ... )       | Braces before an ellipsis represents that a parameter can be repeated.                                                                                    | {, class_name }...                   |
| Angle brackets ( < > )                 | Angle brackets represent a single key or a series of key strokes.                                                                                         | <Ctrl+n> }...                        |

## Version Name and Version String Conventions

Rules for version naming and string since CUBRID 10.0 are as follows:

- Version name: CUBRID M.m Patch p (Major version, Minor version, Patch version if necessary)  
CUBRID 10.1 Patch 1 (CUBRID 10.1 P1 in short)
- Version string: M.m.p.build\_number (Major version, Minor version, Patch version, Build number)  
10.2.0.8787-a31ea42

Build number consists of two parts which are separated by a hyphen. The former is the number of changes from the base revision, which monotonically increases. The later is the SHA-1 hash of the build built.

Rules for version naming and string since CUBRID 9.0 are as follows:

- Version name: CUBRID M.m Patch p (Major version, Minor version, Patch version if necessary)  
CUBRID 9.2 Patch 1 (CUBRID 9.2 P1 in short)
- Version string: M.m.p.build\_number (Major version, Minor version, Patch version, Build number)  
9.2.1.0012

Rules for version naming and string before CUBRID 9.0 are as follows:

- Version name: CUBRID 2008 RM.m Patch p (2008 for Major version, Minor version, Patch version, Build number) CUBRID 2008 R4.1 Patch 1
- Version string: 8.m.p.build\_number (Major version, Minor version, Patch version, Build number)  
8.4.1.1001

## Introduction to CUBRID

This chapter explains the architecture and features of CUBRID. CUBRID is an object-relational database management system (DBMS) consisting of the database server, the broker, and the CUBRID Manager. It is optimized for Internet data services, and provides various user-friendly features.

This chapter covers the following topics:

- System Architecture: This page contains information about database volume structure, server process, broker process, interface modules, etc.

- Features of CUBRID: This page contains information about transaction, backup and recovery, partitioning, index, HA, Java stored procedure, click counter, relational data model extension, etc.

## System Architecture

### Process Structure

CUBRID is an object-relational database management system (DBMS) consisting of the database server, the broker, and the CUBRID Manager.

- As the core component of the CUBRID database management system, the database server stores and manages data in multi-threaded client/server architecture. The database server processes the queries requested by users and manages objects in the database. The CUBRID database server provides seamless transactions using locking and logging methods even when multiple users use the database at once. It also supports database backup and restore for the operation.
- The broker is a CUBRID-specific middleware that relays the communication between the database server and external applications. It provides functions including connection pooling, monitoring, and log tracing and analysis.
- The CUBRID Manager is a GUI tool that allows users to remotely manage the database and the broker. It also provides the Query Editor, a convenient tool that allows users to execute SQL queries on the database server.
- The CUBRID procedural language (PL) server is a server that compiles and executes stored procedures and functions requested from the database server.

## Database Volume Structure

The following diagram illustrates the CUBRID database volume structure. As you can see, the database is divided into three volumes: permanent, temporary and backup. This chapter will examine each volume and its characteristics.

For commands to create, add or delete the database volume, see [createdb](#), [addvoldb](#) and [deletedb](#).

## Permanent Volume

### Data Volumes

Permanent data volumes are database volumes that exists permanently once they are created.

It usually stores data that needs to be persistent after database restart or crash. The possible types of permanent data are:

- Tables (rows and multimedia data) are internally stored into heap files and heap overflow files, one file for each table.
- Indexes (keys and multimedia data) are internally stored into b-tree files and b-tree overflow files, one file for each index.
- System data is internally stored into several types of files: file tracker, vacuum data, dropped files tracker, and class names hash.

User can specifically assign some permanent data volumes to store temporary data. These volumes are permanent in the sense that they are never destroyed, but behave similarly to [Temporary Volume](#).

### **Note**

If you have used older CUBRID version, you may know that we used to have several types of permanent data volumes: **generic**, **data** and **index**. This classification is deprecated, and although these options are still allowed for **cubrid createdb** and **cubrid addvoldb** commands, the created volumes will be no different and they will store any type of permanent data. The volume purpose is only classified into permanent data and temporary data.

## Control File

The control file contains the volume, backup and log information in the database.

- **Volume Information:** The information that includes names, locations and internal volume identifiers of all the volumes in the database. When the database restarts, the CUBRID reads the volume information control file. It records a new entry to that file when a new database volume is added.
- **Backup Information:** Locations of all the backups for data, index, and generic volumes are recorded to a backup information control file. This control file is maintained where the log files are managed.
- **Log Information:** This information contains names of all active and archive logs. With the log information control file, you can verify the archive log information. The log information control file is created and managed at the same location as the log files.

Control files include the information about locations of database volumes, backups and logs. Since these files will be read when the database restarts, users must not modify them arbitrarily.

## Active Log

Active log is a log that contains recent changes to the database. If a problem occurs, you can use active and archive logs to restore the database completely up to the point of the last commit before the occurrence of the fault.

## Double Write Buffer File

Double write buffer file stores copies of data pages being flushed to disk as a protection against I/O errors. A detailed description of this file can be found in [Database Volume](#) section.

## TDE Key File

TDE (Transparent Data Encryption) key file contains keys for database encryption. The keys in the file are managed using the TDE utility. For more information on this, see [File-based Master Key Management](#) and [TDE Utility](#).

## Temporary Volume

Temporary data volume has the opposite meaning to the permanent volume. That is, the temporary volume is a storage file created temporarily which gets destroyed when the server process terminates. These volumes are used to store intermediate and final results of query processing and sorting.

These files provide space to store intermediary and final results of queries. Based on the size of required temporary data, it will be first stored in memory (the space size is determined by the system parameter **temp\_file\_memory\_size\_in\_pages** specified in **cubrid.conf**). Exceeding data has to be stored on disk.

Database will usually create and use temporary volumes to allocate disk space for temporary data. They user may however assign permanent database volumes with the purpose of storing temporary data using by running **cubrid addvoldb -p temp** command. If such volumes exist, they will have priority over temporary volumes when disk space is allocated for temporary data.

The examples of queries that can use temporary data are as follows:

- Queries creating the resultset like **SELECT**
- Queries including **GROUP BY** or **ORDER BY**
- Queries including a subquery
- Queries executing sort-merge join
- Queries including the **CREATE INDEX** statement

To have complete control on the disk space used for temporary data and to prevent it from consuming all system disk space, our recommendation is to:

- create permanent database volumes in advance to secure the required space for temporary data
- limit the size of the space used in the temporary volumes when a queries are executed by setting **temp\_file\_max\_size\_in\_pages** parameter in **cubrid.conf** (there is no limit by default).

Once temporary temp volume is created, it is maintained until a database restarts and its size cannot be reduced. It is recommended to make temporary temp volume automatically delete by restarting a database if its size is too big.

- **File name of the temporary volumes:** The file name format of a temporary volume is *db\_name\_tnum*, where *db\_name* is the database name and *num* is the volume identifier. The volume identifier is decremented by 1 from 32766.
- **Configuring the temporary volume size:** The number of temporary volumes to be created is determined by the system depending on the space size needed for processing transactions. However, users can limit the total temporary volume size by configuring the

**temp\_file\_max\_size\_in\_pages** parameter value in the system parameter configuration file (**cubrid.conf**). The default value is -1, which means it can be created as long as free space is available. If the **temp\_file\_max\_size\_in\_pages** parameter value is configured to 0, no temporary volumes will be created, and the system will have to rely exclusively on permanent volumes assigned for temporary data.

- **Configuring storing location of temporary volumes:** By default, temporary volumes are created where the first database volume was created. However, you can specify a different directory to store temporary volumes by configuring the **temp\_volume\_path** parameter value.
- **Deleting temporary volumes:** Temporary volumes exist only while the database is running. Therefore, you must not delete the temporary volumes when running servers. They are deleted when database servers are normally terminated. When database servers are abnormally terminated, temporary volumes are deleted on servers restart.

#### Note

Normally, permanent volumes are used to store permanent data, and temporary volumes are used to store temporary data. You can assign permanent volumes to store temporary data, but temporary volumes will never store permanent data!

## Archive Log

Archive log is a volume to store logs continuously created after exhausting available active log space that contains recent changes. If the value of system parameter **log\_max\_archives** is larger than 0, the archive log volume will be generated only after exhausting available active log volume space. The initial value is set to 0 when installing CUBRID. The number of archive log files is kept on the storage by setting the value of **log\_max\_archives**. The unnecessary archive log files should be deleted for getting the free space by the configuration of **log\_max\_archives**, but this value should be set properly to use for restoring the database.

To get more information on the above, see [Managing Archive Logs](#).

## Background Archive Log

Background archive log is a volume used in the background with log archiving temporarily before creating archive logs. It is created as the same volume size as active log and stored.

## Backup Volume

Backup volume is a database snapshot; based on such backup and log volumes, you can restore transactions to a certain point of time.

You can use the **cubrid backupdb** utility to copy all the data needed for database restore, or configure the **backup\_volume\_max\_size\_bytes** parameter value in the database configuration file (**cubrid.conf**) to adjust the backup volume partitioning size.

## Database Server

### Database Server Process

Each database has a single server process. The server process is the core component of the CUBRID database server, and handles a user's requests by directly accessing database and log files. The client process connects to the server process via TCP/IP communication. Each server process creates threads to handle requests by multiple client processes. System parameters can be configured for each database, that is, for each server process. The server process can connect to as many client processes as specified by the **max\_clients** parameter value.

### Master Process

The master process is a broker process that allows the client process to connect to and communicate with the server process. One master process runs for each host. (To be exact, one master process exists for each connection port number specified in the **cubrid.conf** system parameter file.) While the master process listens on the TCP/IP port specified, the client process connects to the master process through that port. The master process changes a socket to server port so that the server process can handle connection.

### Execution Mode

All CUBRID programs except the server process have two modes: client/server mode and standalone mode.

- In client/server mode, applications access server processes by operating themselves as client processes.
- In standalone mode, applications include functionalities of server processes so that the applications can access database files by themselves.

For example, database creation and restore utilities run in standalone mode so they can use the database exclusively by denying the access by multiple users. Another example is that the CSQL Interpreter can either connect to the server process in client/server mode or execute SQL statements by accessing the database in standalone mode. Note that one database cannot be accessed simultaneously by server processes and standalone programs.

## Broker

The broker is a middleware that allows various application clients to connect to the database server. As shown below, the CUBRID system, which includes the broker, has multi-layered

architecture consisting of application clients, `cub_broker`, `cub_cas`, and `cub_server` (database server).

## Application Client

The interfaces that can be used in application clients include C-API (CCI, CUBRID Call Interface), ODBC, JDBC, PHP, Python, Ruby, OLE DB, ADO.NET, Node.js, etc.

## `cub_cas`

`cub_cas` (CUBRID Common Application Server and broker application server (CAS in short)) acts as a common application server used by all the application clients that request connections. `cub_cas` also acts as the database server's client and provides the connection to the database server upon the client's request. The number of `cub_cas`(s) running in the service pool can be specified in the **`cubrid_broker.conf`** file, and this number is dynamically adjusted by `cub_broker`.

`cub_cas` is a program linked to the CUBRID database server's client library and functions as a client module in the database server process (`cub_server`). In the client module, tasks such as query parsing, optimization, execution plan creation are performed.

## `cub_broker`

**`cub_broker`** relays the connection between the application client and the `cub_cas`. That is, when an application client requests access, the **`cub_broker`** checks the status of the **`cub_cas`** through the shared memory, and then delivers the request to an accessible **`cub_cas`**. It then returns the processing results of the request from the **`cub_cas`** to the application client.

The **cub\_broker** also manages the server load by adjusting the number of **cub\_cas** (s) in the service pool and monitors and manages the status of the **cub\_cas**. If the **cub\_broker** delivers the request to **cub\_cas** but the connection to **cub\_cas** 1 fails because of an abnormal termination, it sends an error message about the connection failure to the application client and restarts **cub\_cas** 1. Restarted **cub\_cas** 1 is now in a normal stand-by mode, and will be reconnected by a new request from a new application client.

### Shared Memory

The status information of the **cub\_cas** is stored in the shared memory, and the **cub\_broker** refers to this information to relay the connection to the application client. With the status information stored in the shared memory, the system manager can identify which task the **cub\_cas** is currently performing or which application client's request is currently being processed.

## Interface Module

CUBRID provides various Application Programming Interfaces (APIs). The following APIs are supported by CUBRID as follows:

- JDBC: A standard API used to create database applications in Java.
- ODBC: A standard API used to create database applications on Windows. ODBC driver is written based on CCI library.
- OLE DB: An API used to create COM-based database applications on Windows. OLE DB provider is written based on CCI library.
- PHP: CUBRID provides a PHP interface module to create database applications in the PHP environment. PHP driver is written based on CCI library.
- CCI: CCI is a C language interface provided by CUBRID. The interface module is provided as a C library.

All interface modules access the database server through the broker. The broker is a middleware that allows various application clients to connect to the database server. When it receives a request from an interface module, it calls a native C API provided by the database server's client library.

## CUBRID Characteristics

### Transaction Support

CUBRID supports the following features to completely ensure the atomicity, consistency, isolation and durability in transactions.

- Supporting commit, rollback, savepoint per transaction
- Ensuring transaction consistency in the event of system or database failure
- Ensuring transaction consistency between replications
- Supporting multiple granularity locking of databases, tables and records
- Resolving deadlocks automatically

### Database Backup and Restore

A database backup is the process of copying CUBRID database volumes, control files and log files; a database restore is the process of restoring the database to a certain point in time using backup files, active logs and archive logs copied by the backup process. For a restore, there must be the same operating system and the same version of CUBRID installed as in the backup environment. The backup methods which CUBRID supports include online, offline and incremental backups; the restore methods include restore using incremental backups as well as partial and full restore.

### Table Partitioning

Partitioning is a method by which a table is divided into multiple independent logical units. Each logical unit is called a partition, and each partition is divided into a different physical space. This will lead performance improvement by only allowing access to the partition when retrieving records. CUBRID provides three partitioning methods:

- Range partitioning: Divides a table based on the range of a column value
- Hash partitioning: Divides a table based on the hash value of a column
- List partitioning: Divides a table based on the column value list

### Supports a Variety of Index Functions

CUBRID supports the following index functions to utilize indexes while executing a variety of conditional queries.

- Descending Index Scan: Descending Index Scan is available only with Ascending Index Scan, without creating separate descending indexes.
- Covering Index: When the column of a **SELECT** list is included in the index, the requested data can be obtained with an index scan.
- **ORDER BY** clause optimization: If the required record sorting order is identical to the order of indexes, no additional sorting is required (Skip ORDER BY).

- **GROUP BY** clause optimization: If all columns in the **GROUP BY** clause are included in the indexes, they are available to use while executing queries. Therefore, no additional sorting is required (Skip GROUP BY).

## HA feature

CUBRID provides High Availability(HA) feature to minimize system down time while continuing normal operation of server in the event of hardware, software, or network failure. The structure of CUBRID HA is shared-nothing. CUBRID monitors its system and status on a real time basis with the CUBRID Heartbeat and performs failover when failure occurs. It follows the two steps below to synchronize data from the master database server to slave database server.

- A transaction log multiplication step where the transaction log created in the database server is replicated in real time to another node
- A transaction log reflection step where data is applied to the slave database server through the analysis of the transaction log being replicated in real time

## Stored Procedure

A stored procedure is a method to decrease the complexity of applications and to improve the reusability, security and performance through the separation of database logic and middleware logic. CUBRID supports the SQL extension language PL/CSQL and can also be written in the general-purpose language Java. To use the stored procedure feature, the procedural language server must be running. (See [CUBRID Procedural Language Server](#)) For more details on stored procedures, refer to [CUBRID Procedural Language](#).

## Click Counter

In the Internet environment, it is common to store and keep counting information like page view in the database to track search history.

The above scenario is generally implemented by using the **SELECT** and **UPDATE** statements; SELECT retrieves the data and UPDATE increases the number of clicks for the retrieved queries.

This approach can cause significant performance degradation due to increased lock contention for **UPDATE** when a number of **SELECT** statements are executed against the same data.

To address this issue, CUBRID introduces the new concept of the Click Counter that will support optimized features in the Web in terms of usability and performance, and provides the `INCR()` function and the **WITH INCREMENT FOR** statement.

## Extending the Relational Data Model

### • Collection

For the relational data model, it is not allowed that a single column has multiple values. In CUBRID, however, you can create a column with several values. For this purpose, collection data

types are provided in CUBRID. The collection data type is mainly divided into **SET**, **MULTISET** and **LIST**; the types are distinguished by duplicated availability and order.

- **SET**: A collection type that does not allow the duplication of elements. Elements are stored without duplication after being sorted regardless of their order of entry.
- **MULTISET**: A collection type that allows the duplication of elements. The order of entry is not considered.
- **LIST**: A collection type that allows the duplication of elements. Unlike with **SET** and **MULTISET**, the order of entry is maintained.

## • JSON

JavaScript Object Notation (JSON) has become the de facto standard for data-interchanging. JSON, one of the semi-structured data, is not allowed to reside in the relational data model. In CUBRID, however, you can create and query JSON documents using [SQL functions for JSON](#). you can define a [JSON data type](#) column and stores a JSON document into the column.

## • Inheritance

Inheritance is a concept to reuse columns and methods of a super class (table) in those of a sub class. CUBRID supports reusability through inheritance. By using inheritance provided by CUBRID, you can create a super class with some common columns and then create a sub class inherited from the super class with some unique columns added. In this way, you can create a database model which can minimize the number of columns.

# Installing and Upgrading

For information about ports used by CUBRID, please refer to [Port Setting](#) section; in Linux, every configuration except for **APPL\_SERVER\_PORT** is same as Windows.

You can download various CUBRID tools and drivers in <https://www.cubrid.org/downloads>.

## Installing and Running CUBRID

### Supported Platforms and System Requirements

The platforms supported by CUBRID and hardware/software requirements for the installation are as follows:

| Supported Platforms                                                                                                                                            | Required Memory | Required Disk Space |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------------------|
| <ul style="list-style-type: none"> <li>• Windows 64 Bit Windows 7 or higher</li> <li>• Linux family 64 Bit(Linux kernel 2.4, glibc 2.3.4 or higher)</li> </ul> | 1GB or more     | 2GB or more(*)      |

(\*): Requires a 500MB of free disk space on the initial installation; requires approximately 1.5GB of free disk space with a database creating with default options.

CUBRID Admin Client is not automatically installed when installing the CUBRID package. For this reason, if you require CUBRID Admin you must install it separately. The CUBRID can be downloaded from <http://ftp.cubrid.org>.

A variety of drivers such as JDBC, ODBC and PHP can also be downloaded from <http://ftp.cubrid.org>.

For more information on the CUBRID engine, tools, and drivers, see <https://www.cubrid.org>.

## Compatibility

### Application Compatibility

- Applications that use JDBC, PHP or CCI APIs from 2008 R4.1 or higher version of CUBRID can access the CUBRID 11.4 database. However, you must link the CUBRID 11.4 library or use the driver to use the added/improved features of JDBC, PHP or CCI interfaces. In order to use **Date/Time Types with Timezone** which are introduced as 10.0, users should upgrade drivers.
- Drivers lower version than 10.2 interpret JSON type columns as Varchar.
- Note that query results may differ from those given in the earlier version because new reserved words have been added, and the specifications for some queries have been changed.
- An application that is developed by using the GLO class can be used after it is converted to an application or schema suitable to the BLOB or CLOB type.

### CUBRID Admin Compatibility

- CUBRID Admin guarantees backward compatibility with the servers using CUBRID 10.0 or higher and uses the CUBRID JDBC driver that matches each server version. However, you must use a CUBRID Admin that is higher than CUBRID servers in version in order to utilize all the features

of CUBRID Admin. The CUBRID JDBC driver is included in the \$CUBRID/jdbc directory when CUBRID is installed(\$CUBRID on Linux, %CUBRID% on Windows).

#### **Note**

Old version users should upgrade all of driver, broker, DB server; Data migration should be done because 11.3 or early version's DB volume is not compatible with 11.4 version. For upgrade and data migration, see [Upgrade](#).

### **Interoperability between CUBRID DB server and broker**

- If the CUBRID DB server and its broker server are operated separately, CUBRID version between them should be the same, but if just the patch version is different, their interoperability is guaranteed.

For example, 2008 R4.1 Patch1 broker is compatible with 2008 R4.1 Patch 10 DB server, but not compatible with 2008 R4.3 DB server. 9.1 Patch 1 broker is compatible with 9.1 Patch 10 DB server, but not compatible with 9.2 DB server.

- Even if the operating systems are different, their interoperability is guaranteed if the bit version of a DB server is identical to the bit version of a broker server.

For example, the 64-bit DB server for Linux is interoperable with the 64-bit broker server for Windows.

For the relation between DB server and broker, see [Introduction to CUBRID](#).

## **Installing and Running CUBRID on Linux**

### **Checklist before Installing**

Check the following before installing CUBRID for Linux.

- glibc version

Only supports glibc 2.3.4 or later. The glibc version can be checked as follows:

```
%rpm -q glibc
```

- 64-bit

As 10.0, CUBRID supports only 64-bit Linux. You can check the version as follows:

```
% uname -a
Linux host_name 2.6.32-696.20.1.el6.x86_64 #1 SMP Fri Jan 26
17:51:45 UTC 2018 x86_64 x86_64 x86_64 GNU/Linux
```

Make sure to install the CUBRID 64-bit version on 64-bit Linux.

- The libraries that should be added.

- Curses Library (rpm -q ncurses)

CUBRID is packaged with version 5 of Curses library. If you have the latest version and you are not able to downgrade your system, you may need to install the ncurses-compat-libs package.

- gcrypt Library (rpm -q libgcrypt)

- stdc++ Library (rpm -q libstdc++)

- Check if the mapping between host names and IP addresses are correct in the /etc/hosts file.

If host names and IP addresses are matched incorrectly, DB server cannot be started normally. Therefore, check if they are correctly mapped.

## Installing CUBRID

The installation program consists of shell scripts that contain binary; thus it can be installed automatically. The following example shows how to install CUBRID with the “CUBRID-11.4-latest-Linux.x86\_64.sh” file on the Linux.

```
$ sh CUBRID-11.4-latest-Linux.x86_64.sh
Do you agree to the above license terms? (yes or no) : yes
Do you want to install this software(CUBRID) to the default(/home1/
cub_user/CUBRID) directory? (yes or no) [Default: yes] : yes
Install CUBRID to '/home1/cub_user/CUBRID' ...
In case a different version of the CUBRID product is being used in
other machines,
please note that the CUBRID 11.4 servers are only compatible with
the CUBRID 11.4 clients and vice versa.
Do you want to continue? (yes or no) [Default: yes] : yes
Copying old .cubrid.sh to .cubrid.sh.bak ...
```

CUBRID has been successfully installed.

demodb has been successfully created.

If you want to use CUBRID, run the following commands

```
$ . /home1/cub_user/.cubrid.sh
$ cubrid service start
```

As shown in the example above, after installing the downloaded file (CUBRID-11.4-latest-Linux.x86\_64.sh), you must run `.cubrid.sh` (or `.cubrid.csh`) according to your shell environment to set the environment variables required to use the CUBRID database. Additionally, to automatically set these variables upon login, you need to manually register `.cubrid.sh` (or `.cubrid.csh`) in a shell startup file such as `.bashrc` (or `.cshrc`), depending on your shell environment.

```
$ . /home1/cub_user/.cubrid.sh
```

After CUBRID is installed, you can start CUBRID Manager server and CUBRID broker as follows.

```
$ cubrid service start
```

When you want to check whether CUBRID Manager server and CUBRID broker works well, you can use **grep** command in Linux as follows.

```
$ ps -ef | grep cub_
cub_user 15200 1 0 18:57 00:00:00 cub_master
cub_user 15205 1 0 18:57 pts/17 00:00:00 cub_broker
cub_user 15210 1 0 18:57 pts/17 00:00:00 query_editor_cub_cas_1
cub_user 15211 1 0 18:57 pts/17 00:00:00 query_editor_cub_cas_2
cub_user 15212 1 0 18:57 pts/17 00:00:00 query_editor_cub_cas_3
cub_user 15213 1 0 18:57 pts/17 00:00:00 query_editor_cub_cas_4
cub_user 15214 1 0 18:57 pts/17 00:00:00 query_editor_cub_cas_5
cub_user 15217 1 0 18:57 pts/17 00:00:00 cub_broker
cub_user 15222 1 0 18:57 pts/17 00:00:00 broker1_cub_cas_1
cub_user 15223 1 0 18:57 pts/17 00:00:00 broker1_cub_cas_2
cub_user 15224 1 0 18:57 pts/17 00:00:00 broker1_cub_cas_3
cub_user 15225 1 0 18:57 pts/17 00:00:00 broker1_cub_cas_4
cub_user 15226 1 0 18:57 pts/17 00:00:00 broker1_cub_cas_5
cub_user 15229 1 0 18:57 00:00:00 cub_auto start
cub_user 15232 1 0 18:57 00:00:00 cub_js start
```

### Installing CUBRID (rpm File)

You can install CUBRID by using rpm file that is created on CentOS 6. The way of installing and uninstalling CUBRID is the same as that of using general rpm utility. While CUBRID is being installed, a new system group (cubrid) and a user account (cubrid) are created. After installation is complete, you should log in with a cubrid user account to start a CUBRID service.:

```
$ rpm -Uvh CUBRID-11.4-latest-Linux.x86_64.rpm
```

When rpm is executed, CUBRID is installed in the “cubrid” home directory (`/opt/cubrid`) and related configuration file (`cubrid.[c]sh`) is installed in the `/etc/profile.d` directory. Note that *demodb* is not automatically installed. Therefore, you must executed `/opt/cubrid/demo/`

make\_cubrid\_demo.sh with “cubrid” Linux ID. When installation is complete, enter the code below to start CUBRID with “cubrid” Linux ID.

```
$ cubrid service start
```

#### Note

##### • RPM and dependency

You must check RPM dependency when installing with RPM. If you ignore (--nodeps) dependency, it may not be executed.

##### • cubrid account and DB exists even if you remove RPM package

Even if you remove RPM, user accounts and databases that are created after installing, you must remove it manually, if needed.

##### • Running CUBRID automatically in Linux when the system is started

When you use SH package to install CUBRID, the cubrid script will be included in the \$CUBRID/share/init.d directory. In this file, you can find the environment variable, **CUBRID\_USER**. You should change this variable to the Linux account with which CUBRID has been installed and register it in /etc/init.d, then you can use service or chkconfig command to run CUBRID automatically when the Linux system is started.

When you use RPM package to install CUBRID, the cubrid script will be included in /etc/init.d. But you still need to change the environment variable, \$CUBRID\_USER from “cubrid” script file.

##### • In /etc/hosts file, check if a host name and an IP address mapping is normal

If a host name and an IP address is abnormally mapped, you cannot start DB server. Therefore, you should check if they are normally mapped.

## Upgrading CUBRID

When you specify an installation directory where the previous version of CUBRID is already installed, a message which asks to overwrite files in the directory will appear. Entering **no** will stop the installation.

```
Directory '/home1/cub_user/CUBRID' exist!  
If a CUBRID service is running on this directory, it may be
```

```
terminated abnormally.  
And if you don't have right access permission on this  
directory(subdirectories or files), install operation will be failed.  
Overwrite anyway? (yes or no) [Default: no] : yes
```

Choose whether to overwrite the existing configuration files during the CUBRID installation. Entering **yes** will overwrite and back up them as extension .bak files.

```
The configuration file (.conf or .pass) already exists. Do you want  
to overwrite it? (yes or no) : yes
```

For more information on upgrading a database from a previous version to a new version, see [Upgrade](#).

## Configuring Environment

You can modify the environment such as service ports etc. edit the parameters of a configuration file located in the **\$CUBRID/conf** directory. See [Installing and Running CUBRID on Windows](#) for more information.

## Installing CUBRID Interfaces

You can download interface modules such as CCI, JDBC, PHP, ODBC, OLE DB, ADO.NET, Ruby, Python and Node.js from <https://www.cubrid.org/downloads>.

A simple description on each driver can be found on [API Reference](#).

## Installing CUBRID Tools

You can download various tools including CUBRID Admin and CUBRID Migration Toolkit from <https://www.cubrid.org/downloads>.

# Installing and Running CUBRID on Windows

## Checklist before Installing

You should check the below before installing CUBRID for Windows.

- 64-bit

CUBRID supports only 64-bit Windows. You can check the version by selecting [My Computer] > [System Properties]. Make sure to install a CUBRID 64-bit version on 64-bit Windows.

10.1 would be the last release of 32-bit Windows.

## Installation Process

### Step 1: Specifying the directory to install

### Step 2: Creating a sample database

To create a sample database, it requires about 1.5GB disk space.

### Step 3: Completing the installation

CUBRID Service Tray appears on the right bottom.

#### Note

CUBRID Service is automatically started when the system is rebooted. If you want to stop the when the system is rebooted, change the “Start parameters” of “CUBRIDService” as “Stop”; “Control Panel > Administrative Tools > Services” and double-clicking “CUBRIDService”, then pop-up window will be shown.

## Checklist After Installation

- Whether the start of CUBRID Service Tray or not

If CUBRID Service Tray is not automatically started when starting a system, confirm the following.

- Check if Task Scheduler is started in [Start button] > [Control panel] > [Administrative Tools] > [Services]; if not, start Task Scheduler.
- Check if CUBRID Service Tray is registered in [Start button] > [All Programs] > [Startup]; if not, register CUBRID Service Tray.

## Upgrading CUBRID

To install a new version of CUBRID in an environment in which a previous version has already been installed, select [CUBRID Service Tray] > [Exit] from the menu to stop currently running services, and then remove the previous version of CUBRID. Note that when you are prompted with “Do you want to delete all the existing version of databases and the configuration files?” you must select “No” to protect the existing databases.

For more information on upgrading a database from a previous version to a new version, see [Upgrade](#).

## Configuring Environment

You can change configuration such as service ports to meet the user environment by changing the parameter values of following files which are located in the **%CUBRID%\conf** directory. If a firewall has been configured, the ports used in CUBRID need to be opened.

- **cm.conf**

A configuration file for CUBRID Manager. The port that the Manager server process uses is called **cm\_port** and its default value is **8001**.

- **cubrid.conf**

A configuration file for server. You can use it to configure the following values: database memory, the number threads based on the number of concurrent users, communication port between broker and server, etc. The port that a master process uses is called **cubrid\_port\_id** and its default value is 1523. For details, see [cubrid.conf Configuration File and Default Parameters](#).

- **cubrid\_broker.conf**

A configuration file for broker. You can use it to configure the following values: broker port, the number of application servers (CAS), SQL LOG, etc. The port that a broker uses is called **BROKER\_PORT**. A port you see in the drivers such as JDBC is its corresponding broker's port. **APPL\_SERVER\_PORT** is a port that a broker application server (CAS) uses and it is added only in Windows. The default value is **BROKER\_PORT** +1. The number of ports used is the same as the number of CAS, starting from the specified port's number plus 1. For details, see [Parameter by Broker](#). For example, if the value of **APPL\_SERVER\_PORT** is 35000 and the maximum number of CASes by **MAX\_NUM\_APPL\_SERVER** is 50, then listening ports on CASes are 35000, 35001, ..., 35049. For more details, see [Parameter by Broker](#).

The **CCI\_DEFAULT\_AUTOCOMMIT** broker parameter is supported since 2008 R4.0. The default value in the version is **OFF** and it is later changed to **ON**. Therefore, users who have upgraded from 2008 R4.0 to 2008 R4.1 or later versions should change this value to **OFF** or configure the auto-commit mode to **OFF**.

## Installing CUBRID Interfaces

You can download interface modules such as CCI, JDBC, PHP, ODBC, OLE DB, ADO.NET, Ruby, Python and Node.js from <https://www.cubrid.org/downloads>.

A simple description on each driver can be found on [API Reference](#).

## Installing CUBRID Tools

You can download various tools including CUBRID Admin and CUBRID Migration Toolkit from <https://www.cubrid.org/downloads>.

## Installing with a Compressed Package

### Installing CUBRID with tar.gz on Linux

#### Checklist before Installing

Check the following before installing CUBRID for Linux.

- glibc version

Only supports glibc 2.3.4 or later. The glibc version can be checked as follows:

```
%rpm -q glibc
```

- 64-bit

As 10.0, CUBRID supports only 64-bit Linux. You can check the version as follows:

```
% uname -a
Linux host_name 2.6.18-53.1.14.el5xen #1 SMP Wed Mar 5 12:08:17 EST
2008 x86_64 x86_64 x86_64 GNU/Linux
```

Make sure to install the CUBRID 64-bit version on 64-bit Linux.

- The libraries that should be added.

- Curses Library (rpm -q ncurses)

CUBRID is packaged with version 5 of Curses library. You may need to install ncurses-compat-libs package if your system has newer version and downgrade is not possible.

- gcrypt Library (rpm -q libgcrypt)

- stdc++ Library (rpm -q libstdc++)

- Check if the mapping between host names and IP addresses are correct in the /etc/hosts file.

If host names and IP addresses are matched incorrectly, DB server cannot be started normally. Therefore, check if they are correctly mapped.

#### Installation Process

##### Specifying the Directory to Install

- Decompress the compressed file to the directory to install.

```
tar xvfz CUBRID-11.4-latest-Linux.x86_64.tar.gz /home1/cub_user/
```

CUBRID directory is created under /home1/cub\_user/ and files are created under CUBRID directory.

### Specifying Environment Variables

1. Add below environment variables to a shell script which is run automatically and located under the home directory of a user.

You may have to create a directory for **\$CUBRID\_DATABASES**. You can designate any directory you have enough permission.

The below is an example to add environment variables to .bash\_profile when you run on the bash shell.

```
export CUBRID=/home1/cub_user/CUBRID
export CUBRID_DATABASES=$CUBRID/databases
```

2. Add CUBRID JDBC library file name to the **CLASSPATH** environment variable.

```
export CLASSPATH=$CUBRID/jdbc/cubrid_jdbc.jar:$CLASSPATH
```

3. Add CUBRID bin directory to **PATH** environment variables.

```
export PATH=$CUBRID/bin:$PATH
```

### Creating DB

- Move to the directory to create DB on the console and create DB.

```
cd $CUBRID_DATABASES
mkdir testdb
cd testdb
cubrid createdb --db-volume-size=128M --log-volume-size=128M testdb en_US
```

### Auto-starting when Booting

- “cubrid” script is included in the **\$CUBRID/share/init.d** directory. Change the value of **\$CUBRID\_USER** environment variable into the Linux account which installed

CUBRID and register this script to **/etc/init.d**; then you can start automatically by using “service” or “chkconfig” command.

### Auto-starting DB

- To start DB automatically when you booting a system, change the below in **\$CUBRID/conf/cubrid.conf**.

```
[service]
service=server, broker, manager
server=testdb
```

- In the “service” parameter, processes to be auto-started are specified.
- In the “server” parameter, DB name to be auto-started is specified.

For environment setting, tools installation and interfaces installation after CUBRID installation, see [Installing and Running CUBRID on Linux](#).

## Installing CUBRID with zip on Windows

### Checklist before Installing

Check below list before installing CUBRID database of Windows version.

- 64bit

CUBRID supports only 64-bit Windows. You can check the version by selecting [My Computer] > [System Properties]. Make sure to install a CUBRID 64-bit version on 64-bit Windows.

#### Warning

10.1 would be the last release of 32-bit Windows.

## Installation Process

### Specifying the Directory to Install

- Decompress the compressed file to the directory to install.

```
C:\CUBRID
```

- You may have to create a directory for **\$CUBRID\_DATABASES**. You can designate any directory you have enough permission.

## Specifying Environment Variables

1. Select [Start button] > [Computer] > (click right mouse button) > [Properties] > [Advanced system settings] > [Environment Variables].
2. Click [New ...] under the system variables and add system variables as below.

```
CUBRID = C:\CUBRID
CUBRID_DATABASES = %CUBRID%\databases
```

3. Add CUBRID JDBC library name to **CLASSPATH** system variable.

```
%CUBRID%\jdbc\cubrid_jdbc.jar
```

4. Add CUBRID bin and ccibin directory to **Path** system variable.

```
%CUBRID%\cci\bin;%CUBRID%\bin
```

### Note

Setting environment variables for using CUBRID can be conveniently configured by using the batch file (cubrid\_env.bat) below.  
C:\CUBRID\share\windows\_scripts\cubrid\_env.bat

## Creating DB

- Run **cmd** command and open the console; move to the directory to create DB and create DB.

```
cd C:\CUBRID\databases
md testdb
cd testdb
c:\CUBRID\databases\testdb>cubrid createdb --db-volume-size=128M --log-volume-size=128M testdb en_US
```

## Auto-starting when Booting

- To start CUBRID automatically when booting the Windows system, CUBRID Service should be registered to Windows Service.

1. Register CUBRID Service to Windows Service.

```
C:\CUBRID\bin\ctrlService.exe -i C:\CUBRID\bin
```

2. The below shows how to start/stop CUBRID Service.

```
C:\CUBRID\bin\ctrlService.exe -start/-stop
```

### Auto-starting DB

- To start DB when booting on Windows, change below in C:\CUBRID\conf\cubrid.conf.

```
[service]
service=server, broker, manager
server=testdb
```

- Specify the processes to start automatically on the “service” parameter.
- Specify the DB name to start automatically on the “server” parameter.

### Removing from Service

- To remove registered CUBRID Service, run the following.

```
C:\CUBRID\bin\ctrlService.exe -u
```

### Registering CUBRID Service Tray

Since CUBRID Service Tray is not automatically registered when installing CUBRID with zip file, it is required to register manually if you want CUBRID Service Tray.

1. Create a link of C:\CUBRID\bin\CUBRID\_Service\_Tray.exe in [Start button] > [All Programs] > [Startup].
2. Input “regedit” in [Start button] > [Accessories] > [Run] to run a registry editor.
3. Create CUBRID folder under [Computer] > [HKEY\_LOCAL\_MACHINE] > [SOFTWARE].
4. Create [cmclient] folder under [CUBRID] folder(Edit > New > Key) and add below items(Edit > New > String Value).

| Name      | Type   | Data                    |
|-----------|--------|-------------------------|
| ROOT_PATH | REG_SZ | C:\CUBRID\cubridmanager |

5. Create [cmserver] folder under [CUBRID] folder(Edit > New > Key) and add below items(Edit > New > String Value).

| Name      | Type   | Data      |
|-----------|--------|-----------|
| ROOT_PATH | REG_SZ | C:\CUBRID |

6. Create [CUBRID] folder under [CUBRID] folder(Edit > New > Key) and add below items(Edit > New > String Value).

| Name      | Type   | Data      |
|-----------|--------|-----------|
| ROOT_PATH | REG_SZ | C:\CUBRID |

7. When rebooting Windows, CUBRID Service Tray is created under right side.

### Checklist After Installation

- Whether the start of CUBRID Service Tray or not

If CUBRID Service Tray is not automatically started when starting a system, confirm the following.

- Check if Task Scheduler is started in [Start button] > [Control panel] > [Administrative Tools] > [Services]; if not, start Task Scheduler.
- Check if CUBRID Service Tray is registered in [Start button] > [All Programs] > [Startup]; if not, register CUBRID Service Tray.

For environment setting, tools installation and interfaces installation after CUBRID installation, see [Installing and Running CUBRID on Windows](#).

#### Note

If CUBRID is installed as a zip file, it may not be executed because there is no DLL required to execute CUBRID. In this case, you need to install Microsoft Visual C++ Redistributable.

- **Microsoft Visual C++ Redistributable**

<https://visualstudio.microsoft.com/downloads/>

## Configuring Environment Variables

The following environment variables need to be set in order to use the CUBRID. The necessary environment variables are automatically set when the CUBRID system is installed or can be changed, as needed, by the user.

### CUBRID Environment Variables

- **CUBRID**: The default environment variable that designates the location where the CUBRID is installed. This variable must be set accurately since all programs included in the CUBRID system uses this environment variable as reference.
- **CUBRID\_DATABASES**: The environment variable that designates the location of the **databases.txt** file. The CUBRID system stores the absolute path of database volumes in the **\$CUBRID\_DATABASES/databases.txt** file. See [databases.txt File](#).
- **CUBRID\_MSG\_LANG**: The environment variable that specifies the language used for usage and error messages in CUBRID. The initial value upon start is undefined, and if not defined, it is set to **en\_US**. Available values for the environment variable are **en\_US**, **en\_US.utf8**, **ko\_KR.euckr**, and **ko\_KR.utf8**.

#### Note

- A user of CUBRID Manager should specify **CUBRID\_MSG\_LANG**, an environment variable of DB server node into **en\_US** to print out messages normally after running database related features. However, database related features are run normally and just the output messages are broken when **CUBRID\_MSG\_LANG** is not **en\_US**.
- To apply the changed **CUBRID\_MSG\_LANG**, CUBRID system of DB server node should be restarted(cubrid service stop, cubrid service start).

- **CUBRID\_TMP**: The environment variable that specifies the location where CUBRID stores temporary files. There are two types of temporary files: regular files and UNIX domain sockets. If specified, temporary files are created in the directory specified in the environment variable CUBRID\_TMP.
  - **Regular files**: Temporary files are created by utilities such as **plandump** in addition to the database server and csql. If this environment variable is not set, the following directory is used.
    - Linux: /tmp

- Windows: C:\Windows\TEMP
- **UNIX Domain Socket files:** If this environment variable is not set, UNIX Domain sockets will be created in the following directories for each process (Applicable to **Linux** only and does not apply to **Windows**):
  - cub\_master: **/tmp**
  - cub\_broker process: **\$CUBRID/var/CUBRID SOCK**
  - cub\_pl process: **\$CUBRID/var/CUBRID SOCK**

### **Note**

- The **java.io.tmpdir** option within the **stored\_procedure\_vm\_options** specifies the directory where temporary files for the cub\_pl process (the built-in Java VM) are created. If the **CUBRID\_TMP** environment variable is set, the value of **java.io.tmpdir** is ignored, and the directory specified by CUBRID\_TMP will be used instead.
- To set this environment variable in Windows, you must add the CUBRID\_TMP key to the registry (refer **%CUBRID%\share\windows\_scripts\cubrid\_env.bat**).

**CUBRID\_TMP** value has some constraints, which are as follows:

- Since the maximum length of the UNIX socket path is 108, when a path longer than 108 is entered in **\$CUBRID\_TMP**, an error is displayed.

```
$ export CUBRID_TMP=/home1/testusr/cubrid=/tmp/
12345678901234567890123456789012345678901234567890123456789012345678
9012345678901234567890123456789
$ cubrid server start apricot

The $CUBRID_TMP is too long. (/home1/testusr/cubrid=/tmp/
12345678901234567890123456789012345678901234567890123456789012345678
9012345678901234567890123456789)
```

- When the relative path is entered, an error is displayed.

```
$ export CUBRID_TMP=./var
$ cubrid server start testdb

The $CUBRID_TMP should be an absolute path. (./var)
```

**CUBRID\_TMP** can be used to avoid the following problems that can occur at the default path of the UNIX domain socket that CUBRID uses.

- **/tmp** is used to store the temporary files in Linux. If the system administrator periodically and voluntarily cleans the space, the UNIX domain socket may be removed. In this case, configure **\$CUBRID\_TMP** to another path, not **/tmp**.
- The maximum length of the UNIX socket path is 108. When the installation path of CUBRID is too long and the **\$CUBRID/var/CUBRID SOCK** path that store the UNIX socket path for cub\_broker exceeds 108 characters, the broker cannot be executed. Therefore, the path of **\$CUBRID\_TMP** must not exceed 108 characters.

The above mentioned environment variables are set when the CUBRID is installed. However, the following commands can be used to verify the setting.

- Linux

```
% printenv CUBRID
% printenv CUBRID_DATABASES
% printenv CUBRID_MSG_LANG
% printenv CUBRID_TMP
```

- Windows

```
C:\> set CUBRID
```

## OS Environment

- **PATH**: In the Linux environment, the directory **\$CUBRID/bin**, which includes a CUBRID system executable file, must be included in the **PATH** environment variable.
- **LD\_LIBRARY\_PATH**: In the Linux environment, **\$CUBRID/lib** and **\$CUBRID/cci/lib**, which is the CUBRID system's dynamic library file (libjvm.so), must be included in the **LD\_LIBRARY\_PATH** (or **SHLIB\_PATH** or **LIBPATH**) environment variable.
- **Path**: In the Windows environment, the **%CUBRID%\bin** and **%CUBRID%\cci\bin**, which is a directory that contains CUBRID system's execution file, must be included in the **Path** environment variable.

### Note

- In the Linux environment, you can control the heap memory allocation behavior of **CUBRID's memory manager (GLIB memory manager)** through the following environment variable

settings. For more details, refer to: [https://www.gnu.org/software/libc/manual/html\\_node/Malloc-Tunable-Parameters](https://www.gnu.org/software/libc/manual/html_node/Malloc-Tunable-Parameters).

| Environment variables   | Descriptions                                                                                                                     | Default         |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|-----------------|
| MALLOC_MMAP_MAX_        | Specifies the maximum number of memory blocks that may be allocated via the <code>mmap()</code> .                                | 65536           |
| MALLOC_MMAP_THRESH_OLD_ | Specifies the size threshold for deciding whether to use the <code>mmap()</code> system call for memory allocation.              | 128 KiB         |
| MALLOC_TOP_PAD_         | Specifies the size of additional memory padding to be maintained at the top of the heap.                                         | 0               |
| MALLOC_TRIM_THRESHOLD_  | Specifies the threshold for deciding whether freed memory is released back to the kernel. Released if the threshold is exceeded. | 128 KiB         |
| MALLOC_ARENA_MAX        | Specifies the maximum number of memory arenas that a process is allowed to create.                                               | 8 times of core |

- In the installation package, `.cubrid.sh` (or `.cubrid.csh`) sets the **MALLOC\_TRIM\_THRESHOLD\_** value to 0, while the other environment variables are commented out.

### **Note**

- In Linux environments, the **LD\_PRELOAD** environment variable can be used to override the default memory manager used by CUBRID.
- However, replacing the memory manager may cause unexpected behavior during CUBRID operation, so it should be done with careful consideration.
- The scripts in the installation package (`.cubrid.sh` and `.cubrid.csh`) include the **LD\_PRELOAD** environment variable, but it is commented out by default.

```
ex) export LD_PRELOAD=/usr/lib64/jemalloc.so.1
```

- THP (Transparent Huge Pages) is a Linux kernel feature (supported since kernel version 2.6.38) that is enabled by default in many Linux environments to improve memory management efficiency. It automatically combines small memory pages (4 KB) into larger pages (typically 2 MB), thereby reducing TLB (Translation Lookaside Buffer) overhead.

However, in DBMS environments such as CUBRID, the automatic memory compaction and page migration mechanisms of THP may lead to increased system CPU usage (sys CPU) and memory allocation latency, which can negatively impact performance. Therefore, to ensure stable and predictable service behavior, disabling THP by setting it to never is strongly recommended.

- Checking THP Enablement Status

```
ex) [root]# cat /sys/kernel/mm/transparent_hugepage/
enabled
[always] madvise never
disabled) [root]# echo never > /sys/kernel/mm/
transparent_hugepage/enabled
```

- Checking THP Defragmentation Status

```
ex) [root]# cat /sys/kernel/mm/transparent_hugepage/defrag
always madvise [never]
```

```
disabled) [root]# echo never > /sys/kernel/mm/
transparent_hugepage/defrag
```

## Configuring the Environment Variable

### For Windows

If the CUBRID system has been installed on Windows, then the installation program automatically sets the necessary environment variable. Select [System Properties] in [My Computer] and select the [Advanced] tab. Click the [Environment Variable] button and check the setting in the [System Variable]. The settings can be changed by clicking on the [Edit] button. See the Windows help for more information on how to change the environment variable on Windows.

### For Linux

If the CUBRID system has been installed on Linux, the installation program automatically creates the **.cubrid.sh** or **.cubrid.csh** file and makes configurations so that the files are automatically called from the installation account's shell log-in script. The following is the contents of **.cubrid.sh** environment variable configuration that was created in an environment that uses sh, bash, etc.

```
CUBRID=/home1/cub_user/CUBRID
CUBRID_DATABASES=/home1/cub_user/CUBRID/databases
```

```
ld_lib_path=`printenv LD_LIBRARY_PATH`

if [ "$ld_lib_path" = "" ]
then
    LD_LIBRARY_PATH=$CUBRID/lib:$CUBRID/cci/lib
else
    LD_LIBRARY_PATH=$CUBRID/lib:$CUBRID/cci/lib:$LD_LIBRARY_PATH
fi

SHLIB_PATH=$LD_LIBRARY_PATH
LIBPATH=$LD_LIBRARY_PATH
PATH=$CUBRID/bin:$CUBRID/cubridmanager:$PATH

export CUBRID
export CUBRID_DATABASES
export LD_LIBRARY_PATH
export SHLIB_PATH
export LIBPATH
export PATH
```

## Language & Charset Setting

The language and the charset that will be used in the CUBRID DBMS is specified after the database name when DB is created(e.g. cubrid createdb testdb ko\_KR.utf8). The following are examples of values that can currently be set as a language and a charset.

- **en\_US.iso88591**: English ISO-88591 encoding(.iso88591 can be omitted)
- **ko\_KR.euckr**: Korean EUC-KR encoding
- **ko\_KR.utf8**: Korean UTF-8 encoding(.utf8 can be omitted)
- **de\_DE.utf8**: German UTF-8 encoding
- **es\_ES.utf8**: Spanish UTF-8 encoding
- **fr\_FR.utf8**: French UTF-8 encoding
- **it\_IT.utf8**: Italian UTF-8 encoding
- **ja\_JP.utf8**: Japanese UTF-8 encoding
- **km\_KH.utf8**: Cambodian UTF-8 encoding
- **tr\_TR.utf8**: Turkish UTF-8 encoding(.utf8 can be omitted)
- **vi\_VN.utf8**: Vietnamese UTF-8 encoding
- **zh\_CN.utf8**: Chinese UTF-8 encoding

- **ro\_RO.utf8**: Romanian UTF-8 encoding

Language and charset setting of CUBRID affects read and write data. The language is used for messages displayed by the program.

For more details related to charset, locale and collation settings, see [An Overview of Globalization](#).

## Port Setting

If ports are closed, the ports used by CUBRID should be opened.

The following table summarizes the ports used by CUBRID. Each port on the listener that waits for connection from the opposite side should be opened.

To open the ports for a specific process on the Linux firewall, follow the guide described for the corresponding firewall program.

If available ports for Windows are used, you cannot know which port will be opened. In this case, enter “firewall” in the “Control Panel” of the Windows menu and then choose “Windows Firewall> Allow a program or functionality through Windows Firewall” and then add the program for which port should be opened.

This method can be used for the case that it is difficult to specify a specific port in Windows. This method is recommended since it is safer to add a program to the Allowed programs list than to open a port without specifying a program on the Windows firewall.

- Add “%CUBRID%\bin\cub\_broker.exe” to open all ports for cub\_broker.
- Add “%CUBRID%\bin\cub\_cas.exe” to open all ports for CAS.
- Add “%CUBRID%\bin\cub\_master.exe” to open all ports for cub\_master.
- Add “%CUBRID%\bin\cub\_server.exe” to open all ports for cub\_server.
- **Add “%CUBRID%\bin\cub\_cmserver.exe” to open all ports for the CUBRID Manager.**
  - Add “%CUBRID%\bin\cub\_pl.exe” to open all ports for the CUBRID PL server (cub\_pl).

If you use CUBRID for Linux at the broker machine or the DB server machine, all of Linux ports should be opened. If you use CUBRID for Windows at the broker machine or the DB server machine, all of Linux ports should be opened or the related processes should be added to the program list allowed for the Windows firewall.

| Label       | Listener           | Requester   | Linux Port     | Windows Port                                              | Firewall Port Setting           | Description           |
|-------------|--------------------|-------------|----------------|-----------------------------------------------------------|---------------------------------|-----------------------|
| Default use | cub_broker         | application | BROKER_PORT    | BROKER_PORT                                               | Open                            | One-time connection   |
|             | CAS                | application | BROKER_PORT    | APPL_SERVER_PORT<br>~<br>(APP_SERVER_PORT + # of CAS - 1) | Open                            | Keep connected        |
|             | cub_master         | CAS         | cubrid_port_id | cubrid_port_id                                            | Open                            | One-time connection   |
|             | cub_server         | CAS         | cubrid_port_id | A random available port                                   | Linux: Open<br>Windows: Program | Keep connected        |
|             | Client machine(*)  | cub_server  | ECHO(7)        | ECHO(7)                                                   | Open                            | Periodical connection |
|             | Server machine(**) | CAS, CSQL   | ECHO(7)        | ECHO(7)                                                   | Open                            | Periodical connection |
| HA use      | cub_broker         | application | BROKER_PORT    | Not supported                                             | Open                            | One-time connection   |

| Label              | Listener            | Requester                        | Linux Port     | Windows Port  | Firewall Port Setting | Description                                |

|                    | CAS                 | application                      | BROKER_PORT    | Not supported | Open                  | Keep connected                             |
|                    | cub_master          | CAS                              | cubrid_port_id | Not supported | Open                  | One-time connection                        |
|                    | cub_master (slave)  | cub_master (master)              | ha_port_id     | Not supported | Open                  | Periodical connection, check the heartbeat |
|                    | cub_master (master) | cub_master (slave)               | ha_port_id     | Not supported | Open                  | Periodical connection, check the heartbeat |
|                    | cub_server          | CAS                              | cubrid_port_id | Not supported | Open                  | Keep connected                             |
| Client machine(*)  | cub_server          |                                  | ECHO(7)        | Not supported | Open                  | Periodical connection                      |
| Server machine(**) |                     | CAS, CSQL, copylogdb, applylogdb | ECHO(7)        | Not supported | Open                  | Periodical connection                      |

| Label       | Listener       | Requester   | Linux Port            | Windows Port          | Firewall Port Setting | Description    |
|-------------|----------------|-------------|-----------------------|-----------------------|-----------------------|----------------|
| Manager use | Manager server | application | 8001                  | 8001                  | Open                  |                |
| PL use      | cub_pl         | cub_server  | stored_procedure_port | stored_procedure_port | Open                  | Keep connected |

(\*): The machine which has the CAS, CSQL, copylogdb, or applylogdb process

(\*\*): The machine which has the cub\_server

The detailed description on each classification is given as follows.

## Default Ports for CUBRID

The following table summarizes the ports required for each OS, based on the listening processes. Each port on the listener should be opened.

| Listener   | Requester   | Linux port     | Windows port                                         | Firewall Port Setting | Description         |
|------------|-------------|----------------|------------------------------------------------------|-----------------------|---------------------|
| cub_broker | application | BROKER_PORT    | BROKER_PORT                                          | Open                  | One-time connection |
| CAS        | application | BROKER_PORT    | APPL_SERVER_PORT ~ (APPL_SERVER_PORT + # of CAS - 1) | Open                  | Keep connected      |
| cub_master | CAS         | cubrid_port_id | cubrid_port_id                                       | Open                  | One-time connection |

| Listener           | Requester  | Linux port     | Windows port            | Firewall Port Setting           | Description           |
|--------------------|------------|----------------|-------------------------|---------------------------------|-----------------------|
| cub_server         | CAS        | cubrid_port_id | A random available port | Linux: Open<br>Windows: Program | Keep connected        |
| Client machine(*)  | cub_server | ECHO(7)        | ECHO(7)                 | Open                            | Periodical connection |
| Server machine(**) | CAS, CSQL  | ECHO(7)        | ECHO(7)                 | Open                            | Periodical connection |

(\*): The machine which has the CAS or CSQL process

(\*\*): The machine which has the cub\_server

#### Note

In Windows, you cannot specify the ports to open because CAS randomly specifies the ports as accessing the cub\_server. In this case, add “%CUBRID%\bin\cub\_server.exe” to “Windows Firewall > Allowed programs”.

As the server process (cub\_server) and the client processes (CAS, CSQL) cross-check if the opposite node is normally running or not by using the ECHO(7) port, you should open the ECHO(7) port if there is a firewall. If the ECHO port cannot be opened for both the server and the client, set the `check_peer_alive` parameter value of the cubrid.conf to none.

The relation of connection between processes is as follows:

```
application - cub_broker
              -> CAS   - cub_master
                  -> cub_server
```

- application: The application process
- cub\_broker: The broker server process. It selects CAS to connect with the application.

- CAS: The broker application server process. It relays the application and the cub\_server.
- cub\_master: The master process. It selects the cub\_server to connect with the CAS.
- cub\_server: The database server process

The symbols of relation between processes and the meaning are as follows:

- - : Indicates that the connection is made only once for the initial.
- ->, <- : Indicates that the connection is maintained. The right side of -> or the left side of <- is the party that the arrow symbol indicates. The party that the arrow symbol indicates is the listener which listens to the opposite process.
- (master): Indicates the master node in the HA configuration.
- (slave): Indicates the slave node in the HA configuration.

The connection process between the application and the DB is as follows:

1. The application tries to connect to the cub\_broker through the broker port (BROKER\_PORT) set in the cubrid\_broker.conf.
2. The cub\_broker selects a connectable CAS.
3. The application and CAS are connected.

In Linux, established TCP connection between the **BROKER** and the client will be passed to the **CAS**. Therefore, there is no need for an additional network port for the application to connect to the CAS. However, in **Windows**, when an application connects to a BROKER, the BROKER delivers the network port number to connect to the available CAS to the application. After the client closes the current connection with the BROKER, it connects to the CAS with the received network port number from the BROKER. If the **APPL\_SERVER\_PORT** parameter is not set, the network port used by the first CAS becomes BROKER\_PORT + 1.

For example, if the BROKER\_PORT is 33000 and the APPL\_SERVER\_PORT value has not been set in Windows, the ports used between the application and CAS are as follows:

- The port used to connect the application to the CAS(1): 33001
  - The port used to connect the application to the CAS(2): 33002
  - The port used to connect the application to the CAS(3): 33003
4. CAS sends a request of connecting with the cub\_server to the cub\_master through the cubrid\_port\_id port set in the cubrid.conf.
  5. CAS and the cub\_server are connected.

In Linux, you should use the `cubrid_port_id` port as CAS is connected to the `cub_server` through the Unix domain socket. In Windows, CAS is connected to the `cub_server` through a random available port as the Unix domain socket cannot be used. If the DB server is running in Windows, a random available port is used between the broker machine and the DB server machine. In this case, note that the operation may not be successful if a firewall blocks the port for the process between the two machines.

6. After that, CAS keeps connection with the `cub_server` even if the application is terminated until the CAS restarts.

## Ports for CUBRID HA

The CUBRID HA is supported in Linux only.

The following table summarizes the ports required for each OS, based on the listening processes. Each port on the listener should be opened.

| Listener               | Requester              | Linux port     | Firewall Setting | Port | Description                                |
|------------------------|------------------------|----------------|------------------|------|--------------------------------------------|
| cub_broker             | application            | BROKER_PORT    | Open             |      | One-time connection                        |
| CAS                    | application            | BROKER_PORT    | Open             |      | Keep connected                             |
| cub_master             | CAS                    | cubrid_port_id | Open             |      | One-time connection                        |
| cub_master<br>(slave)  | cub_master<br>(master) | ha_port_id     | Open             |      | Periodical connection, check the heartbeat |
| cub_master<br>(master) | cub_master<br>(slave)  | ha_port_id     | Open             |      | Periodical connection, check the heartbeat |

| Listener           | Requester                        | Linux port     | Firewall Setting | Port | Description           |
|--------------------|----------------------------------|----------------|------------------|------|-----------------------|
| cub_server         | CAS                              | cubrid_port_id | Open             |      | Keep connected        |
| Client machine(*)  | cub_server                       | ECHO(7)        | Open             |      | Periodical connection |
| Server machine(**) | CAS, CSQL, copylogdb, applylogdb | ECHO(7)        | Open             |      | Periodical connection |

(\*): The machine which has the CAS, CSQL, copylogdb, or applylogdb process

(\*\*): The machine which has the cub\_server

As the server process (cub\_server) and the client processes (CAS, CSQL, copylogdb, applylogdb, etc.) cross-check if the opposite node is normally running or not by using the ECHO(7) port, you should open the ECHO(7) port if there is a firewall. If the ECHO port cannot be opened for both the server and the client, set the `ref:check_peer_alive <check_peer_alive>` parameter value of the `cubrid.conf` to none.

The relation of connection between processes is as follows:

```

application - cub_broker
              -> CAS   - cub_master(master) <-> cub_master(slave)
                    -> cub_server(master)   cub_server(slave) <-
applylogdb(slave)
                                     <-----
copylogdb(slave)
```

- cub\_master(master): the master process on the master node in the CUBRID HA configuration. It checks if the peer node is alive.
- cub\_master(slave): the master process on the slave node in the CUBRID HA configuration. It checks if the peer node is alive.
- copylogdb(slave): the process which copies the replication log on the slave node in the CUBRID HA configuration
- applylogdb(slave): the process which applies the replication log on the slave node in the CUBRID HA configuration

For easy understanding for the replication process from the master node to the slave node, the applylogdb and copylogdb on the master node and CAS on the slave node have been omitted.

The symbols of relation between processes and the meaning are as follows:

- - : Indicates that the connection is made only once for the initial.
- ->, <- : Indicates that the connection is maintained. The right side of -> or the left side of <- is the party that the arrow symbol indicates. The party that the arrow symbol indicates is the listener which listens to the opposite process.
- (master): Indicates the master node in the HA configuration.
- (slave): Indicates the slave node in the HA configuration.

The connection process between the application and the DB is identical with **Default Ports for CUBRID**. This section describes the connection process between the master node and the slave node when the master DB and the slave DB are configured 1:1 by the CUBRID HA.

1. The ha\_port\_id set in the cubrid\_ha.conf is used between the cub\_master(master) and the cub\_master(slave).
2. The copylogdb(slave) sends a request for connecting with the master DB to the cub\_master(master) through the port set in the cubrid\_port\_id of the cubrid.conf on the slave node. Finally, the copylogdb(slave) is connected with the cub\_server(master).
3. The applylogdb(slave) sends a request for connecting with the slave DB to the cub\_master(slave) through the port set in the cubrid\_port\_id of the cubrid.conf on the slave node. Finally, the applylogdb(slave) is connected with the cub\_server(slave).

On the master node, the applylogdb and the copylogdb run for the case that the master node is switched to the slave node.

## Ports for CUBRID Manager Server

The following table summarizes the ports, based on the listening processes, used for CUBRID Manager server. The ports are identical regardless of the OS type.

| Listener       | Requester   | Port | Firewall Port Setting |
|----------------|-------------|------|-----------------------|
| Manager server | application | 8001 | Open                  |

- The port used when the CUBRID Manager client accesses the CUBRID Manager server process is **cm\_port** of the cm.conf. The default value is 8001.

## Ports for CUBRID Procedural Language (PL) Server

The following table summarizes the ports, based on the listening processes, used for CUBRID Procedural Language (PL) server. The ports are identical regardless of the OS type.

| Listener | Requester  | Port                  | Firewall Port Setting |
|----------|------------|-----------------------|-----------------------|
| cub_pl   | cub_server | stored_procedure_port | Open                  |

Behavior according to the OS type and the **stored\_procedure\_uds** setting in **cubrid.conf**

- Linux
  - If **stored\_procedure\_uds** is set to **yes**, a UNIX domain socket is used and a TCP socket is not used.
  - If **stored\_procedure\_uds** is set to **no**, a TCP socket is used, and the port is determined by the **stored\_procedure\_port** setting.
- Windows
  - Windows does not support UNIX domain sockets.
  - Therefore, regardless of the **stored\_procedure\_uds** setting, a TCP socket is used, and the port is determined by the **stored\_procedure\_port** setting.

### Note

The port used for communication between the CUBRID Procedural Language server (cub\_pl) and cub\_server is specified by **stored\_procedure\_port** in **cubrid.conf**. The default value is 0, which means that a random available port will be assigned.

## Upgrade

### Cautions during upgrade

#### Changes

Please confirm [11.4 Changes](#) in the release notes.

## Saving the Existing Configuration File

- Save the configuration files in the **\$CUBRID/conf** directory (**cubrid.conf**, **cubrid\_broker.conf** and **cm.conf**) and the DB location file (**databases.txt**) in the **\$CUBRID\_DATABASES** directory.

## Checking New Reserved Words

- You can check whether reserved words are being used or not by applying the CUBRID 11.4 reserved word detection script, **check\_reserved.sql**, which is distributed through the CUBRID installation package or [http://ftp.cubrid.org/CUBRID\\_Engine/11.4/](http://ftp.cubrid.org/CUBRID_Engine/11.4/). If the reserved words are being used as identifiers, the identifiers must be modified. See [Identifier](#).

## Configuring environment variables of CUBRID\_MSG\_LANG

- **CUBRID\_LANG** and **CUBRID\_CHARSET** environment variables are no more used, and the language and the charset should be configured during creating DB. **CUBRID\_MSG\_LANG** is used when displaying the messages of utilities or errors. If **CUBRID\_MSG\_LANG** is not configured, it follows the language and the charset specified when creating DB.

## Changing schema

- 9.0 Beta or earlier version user which had used not ISO-8859-1 charset but EUC-KR charset or UTF-8 charset, should change the schema. In the earlier version of 9.0 Beta, the precision of **CHAR** or **VARCHAR** was specified as byte size. From 9.0 Beta, the precision is specified as character length.

## Adding/Keeping locales

- If you have locales to want to add, add them into **\$CUBRID/conf/cubrid\_locales.txt** file and run **make\_locale** script. For more details, see [Locale Setting](#).
- If you want to keep the old version's locale, add the old version's locale to **\$CUBRID/conf/cubrid\_locales.txt** file and run **make\_locale** script, and specify the old locale when running **"cubrid createdb"** command.

## DB migration

- Since the DB volume of CUBRID 11.3 and earlier versions are not compatible with the DB volume of CUBRID 11.4, it should be migrated with **cubrid unloaddb/loaddb** utility. For more detail procedure, see [DB migration](#).
- CUBRID 2008 R3.1 and later don't support GLO and the LOB type replaces the GLO feature. For this reason, applications or schemas that use GLO must be modified to be compatible with LOB.

### Note

In 2008 R4.0 or before, TIMESTAMP '1970-01-01 00:00:00'(GMT) is the minimum value of TIMESTAMP, but in 2008 4.1 or later, it is recognized as zerodate and TIMESTAMP '1970-01-01 00:00:01'(GMT) is the minimum value of TIMESTAMP.

### Compatibility table

| Vesion | 11.4 | 11.3 | 11.2 | 11.0 | 10.2 | 10.1 | 10.0 |
|--------|------|------|------|------|------|------|------|
| 11.4   | 0    |      |      |      |      |      |      |
| 11.3   |      | 0    | 0    |      |      |      |      |
| 11.2   |      | 0    | 0    |      |      |      |      |
| 11.0   |      |      |      | 0    |      |      |      |
| 10.2   |      |      |      |      | 0    |      |      |
| 10.1   |      |      |      |      |      | 0    |      |
| 10.0   |      |      |      |      |      |      | 0    |

### Reconfiguring environments for replication or HA

- From 2008 R4.0, the replication feature is no longer supported; therefore, it is recommended to reconfigure the DB migration and HA environment for systems in which previous replication versions are used. In addition, for systems that use Linux Heartbeat-based HA feature, which is provided in CUBRID 2008 R2.0 and 2008 R2.1, you must reconfigure to DB migration and the CUBRID Heartbeat-based HA environment for better operational stability(see [Database Migration under HA Environment](#)).
- To reconfigure the HA environment configuration, see [CUBRID HA](#) in the manual.

## Stored Function/Procedure

- To use stored functions/procedures, the CUBRID procedural language server (cub\_pl) is started by default and is managed by the database server. Therefore, even if the procedural language server is stopped, it will be automatically restarted by the database server.
- If you do not want to run the CUBRID procedural language server, set the **stored\_procedure** parameter in **cubrid.conf** to **no** and restart. In this case, the PL/CSQL and Java stored procedure functions cannot be used.

## Upgrading from CUBRID 9.2/9.3/10.0/10.1/10.2/11.0/11.2/11.3 to CUBRID 11.4

Users who are using versions CUBRID 9.2/9.3/10.0/10.1/10.2/11.0/11.2/11.3 should install 11.4 in the different directory, migrate the databases to 11.4 and modify parameter values in the previous environment configuration file.

### DB migration

The following table shows how to perform the migration using the reserved word detection script, check\_reserved.sql, which is separately distributed from [http://ftp.cubrid.org/CUBRID\\_Engine/11.4/](http://ftp.cubrid.org/CUBRID_Engine/11.4/) and the cubrid unloaddb/loaddb utilities. (See [unloaddb](#) and [loaddb](#))

| Step                                                 | Linux Environment                                                                                                                                                                                                                                                             | Windows Environment       |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| Step C1: Stop CUBRID Service                         | % cubrid service stop                                                                                                                                                                                                                                                         | Stop CUBRID Service Tray. |
| Step C2: Execute the reserved words detection script | Execute the following command in the directory where the reserved word detection script is located.<br><br>Execute migration or identifier modification by checking the detection result (For the allowable identifier).<br><br>% csql -S -u dba -i check_reserved.sql testdb |                           |
| Step C3: Unload the earlier version of the DB        | Store the databases.txt file and the configuration files under the conf directory of the earlier version in a separate directory (C3a).<br><br>Execute the cubrid unloaddb utility and store the file generated at this point in a separate directory (C3b).                  |                           |

| Step                                                                          | Linux Environment                                                                                                                                                                                                                                                                                                                                                                                         | Windows Environment                                                                                                                                                               |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                               | <pre>% cubrid unloaddb -S -u dba testdb</pre> <p>Delete the existing database (C3c).</p> <pre>% cubrid deletedb testdb</pre>                                                                                                                                                                                                                                                                              | <p>Uninstall the earlier version of CUBRID.</p>                                                                                                                                   |
| Step C4: Install new version                                                  | See <a href="#">Installing and Running CUBRID</a>                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                   |
| <b>Step C5: Database creation and data loading</b>                            | <p>Go to the directory where you want to create a database, and create one. At this time, be cautious about locale setting(*). (C5a)</p> <pre>% cd \$CUBRID/databases/testdb</pre> <pre>% cubrid createdb testdb en_US</pre> <p>Execute the cubrid loaddb utility with the stored files in (C3b). (C5b)</p> <pre>% cubrid loaddb -u dba -s testdb_schema -d testdb_objects -i testdb_indexes testdb</pre> |                                                                                                                                                                                   |
| <b>Step C6: Back up the new version of the DB</b>                             | <pre>% cubrid backupdb -S testdb</pre>                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                   |
| <b>Step C7: Configure the CUBRID environment and start the CUBRID Service</b> | <p>Modify the configuration file. At this point, partially modify the configuration files from the earlier version stored in step (C3a) to fit the new version.</p> <p>(For configuring system parameter, see <a href="#">Parameter</a></p>                                                                                                                                                               | <p>Start the service by selecting CUBRID Service Tray &gt; [Service Start].</p> <p>Start the database server from the command prompt.</p> <pre>% cubrid server start testdb</pre> |

| Step | Linux Environment                    | Windows Environment |
|------|--------------------------------------|---------------------|
|      | configuration and System Parameters) |                     |
|      | % cubrid service start               |                     |
|      | % cubrid server start testdb         |                     |

## Parameter configuration

### **cubrid.conf**

- The minimum size of **log\_buffer\_size** is changed from 48KB(3\*1page, 16KB=1page) into 2MB(128\*1page, 16KB=1page); therefore, this value should be larger than the changed minimum size.

## Upgrading from CUBRID 9.1 to CUBRID 11.4

Users who are using versions CUBRID 9.1 should install 11.4 in the different directory, migrate databases to 11.4 and modify parameter values in the previous environment configuration file.

## DB migration

Please refer [DB migration](#) for migration steps.

## Parameter configuration

### **cubrid.conf**

- The minimum size of **log\_buffer\_size** is changed from 48KB(3\*1page, 16KB=1page) into 2MB(128\*1page, 16KB=1page); therefore, this value should be larger than the changed minimum size.
- The value of **sort\_buffer\_size** should be configured as 2G or less since the maximum value of sort\_buffer\_size is 2G.
- In the following parameters, the old parameters will be deprecated and the new parameters are recommended to use. The value in the parenthesis is the unit of the value when the unit is

omitted, and the new parameters can specify the unit after the value. For details, see each parameter's explanation in [System Parameters](#)

| Old parameters(unit)                   | New parameters(unit)            |
|----------------------------------------|---------------------------------|
| lock_timeout_in_secs(sec)              | lock_timeout(msec)              |
| checkpoint_every_npages(page_count)    | checkpoint_every_size(byte)     |
| checkpoint_interval_in_mins(min)       | checkpoint_interval(msec)       |
| max_flush_pages_per_second(page_count) | max_flush_size_per_second(byte) |
| sync_on_nflush(page_count)             | sync_on_flush_size(byte)        |
| sql_trace_slow_msecs(msec)             | sql_trace_slow(msecs)           |

### cubrid\_broker.conf

- In **KEEP\_CONNECTION** parameter, OFF value should be changed as **ON** or **AUTO** since **OFF** setting value is no longer used.
- **SELECT\_AUTO\_COMMIT** should be deleted since this parameter is no longer used.
- The value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** should be 2,097,151 or less since the maximum value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is 2,097,151.

### Environment variable

- **CUBRID\_CHARSET** is removed, and now **CUBRID\_CHARSET** is used for configuring the charset of database and **CUBRID\_MSG\_LANG** is used for configuring the charset of messages for utilities and errors.

#### Warning

When you create database, a language and a charset must be specified. It affects the length of string type, string comparison operation, etc. The specified charset when creating database cannot be changed later, so you should be careful when specifying it.

For charset, locale and collation setting, see [An Overview of Globalization](#).

## Upgrading From CUBRID 2008 R4.1/R4.3/R4.4 To CUBRID 11.4

Users who are using a version of CUBRID 2008 R4.1, R4.3 or R4.4 should install 11.4 in the different directory, migrate databases to 11.4 and modify parameter values in the existing environment configuration file.

### DB migration

Please refer [DB migration](#) for migration steps.

(\*): The user which uses CUBRID 2008 R4.x or before should be cautious for determining a locale(language and charset). For example, when the user which used the language as ko\_KR(Korean) and the charset as utf8 processes DB migration, the locale should be set as “cubrid createdb testdb ko\_KR.utf8”. If the locale is not built-in locale, you should run make\_locale(.sh) command first. For more details, see [Locale Setting](#).

- You should be careful about the change of the space for storing about the multibyte character. For example, in 2008 R4.3, **CHAR(6)** means **CHAR** type with 6 bytes size, but from 9.3, **CHAR(6)** means **CHAR** type with 6 characters. In utf8 charset, Korean uses 3 bytes per 1 character, so **CHAR(6)** has 18 bytes. Therefore, more disk space is required.
- If you used utf8 charset in CUBRID 2008 R4.x or before, you should set the charset as utf8 when you run “cubrid createdb”. If not, retrieval queries or string functions are unable to work properly.

### Parameter configuration

#### **cubrid.conf**

- The minimum size of **log\_buffer\_size** is changed from 48KB(3\*1page, 16KB=1page) into 2MB(128\*1page, 16KB=1page); therefore, this value should be larger than the changed minimum size.
- The value of **sort\_buffer\_size** should be configured as 2G or less since the maximum value of **sort\_buffer\_size** is 2G.
- **single\_byte\_compare** should be deleted since this parameter is no longer used.
- **intl\_mbs\_support** should be deleted since this parameter is no longer used.

- **lock\_timeout\_message\_type** should be deleted since this parameter is no longer used.
- In the following parameters, the old parameters will be deprecated and the new parameters are recommended to use. the value in the parenthesis is the unit of the value when the unit is omitted, and the new parameters can specify the unit after the value. For details, see each parameter's explanation in [System Parameters](#)

| Old parameters(unit)                   | New parameters(unit)            |
|----------------------------------------|---------------------------------|
| lock_timeout_in_secs(sec)              | lock_timeout(msec)              |
| checkpoint_every_npages(page_count)    | checkpoint_every_size(byte)     |
| checkpoint_interval_in_mins(min)       | checkpoint_interval(msec)       |
| max_flush_pages_per_second(page_count) | max_flush_size_per_second(byte) |
| sync_on_nflush(page_count)             | sync_on_flush_size(byte)        |
| sql_trace_slow_msecs(msec)             | sql_trace_slow(msecs)           |

### cubrid\_broker.conf

- In **KEEP\_CONNECTION** parameter, **OFF** value should be changed as **ON** or **AUTO** since **OFF** setting value is no longer used.
- **SELECT\_AUTO\_COMMIT** should be deleted since this parameter is no longer used.
- The value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** should be 2,097,151 or less since the maximum value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is 2,097,151.

### Environment variable

- **CUBRID\_LANG** is removed; now the language and the charset of database is set when creating DB, and **CUBRID\_MSG\_LANG** is used for configuring the charset of messages for utilities and errors.

 **Warning**

When you create database, the language and the charset of database should be specified. It affects the length of string type, string comparison operation, etc. The specified charset when creating database cannot be changed later, so you should be careful when specifying it.

For charset, locale and collation setting, see [An Overview of Globalization](#).

## Upgrading From CUBRID 2008 R4.0 or Earlier Versions To CUBRID 11.4

Users who are using versions CUBRID 2008 R4.0 or earlier should install 11.4 in the different directory, migrate databases to 11.4 and modify parameter values in the existing environment configuration file.

### DB migration

Do the same procedures with [DB migration](#). If you use GLO classes, you must modify applications and schema in order to use **BLOB** or **CLOB** types, since GLO classes are not supported in 2008 R3.1. If this modification is not easy, it is not recommended to perform the migration.

### Parameter configuration

#### **cubrid.conf**

- The minimum size of **log\_buffer\_size** is changed from 48KB(3\*1page, 16KB=1page) into 2MB(128\*1page, 16KB=1page); therefore, this value should be larger than the changed minimum size.
- The value of **sort\_buffer\_size** should be configured as 2G or less since the maximum value of **sort\_buffer\_size** is 2G.
- **single\_byte\_compare** should be deleted since this parameter is no longer used.
- **intl\_mbs\_support** should be deleted since this parameter is no longer used.
- **lock\_timeout\_message\_type** should be deleted since this parameter is no longer used.
- Because the default value of **thread\_stacksize** has been changed from 100K to 1M, it is recommended that users who have not configured this value check memory usage of CUBRID-associative processes.
- Because the minimum value of **data\_buffer\_size** has been changed from 64K to 16M, users who have configured this value less than 16M must change the value equal to or greater than 16M.

- In the following parameters, the old parameters will be deprecated and the new parameters are recommended to use. the value in the parenthesis is the unit of the value when the unit is omitted, and the new parameters can specify the unit after the value. For details, see each parameter's explanation in [System Parameters](#)

| Old parameters(unit)                   | New parameters(unit)            |
|----------------------------------------|---------------------------------|
| lock_timeout_in_secs(sec)              | lock_timeout(msec)              |
| checkpoint_every_npages(page_count)    | checkpoint_every_size(byte)     |
| checkpoint_interval_in_mins(min)       | checkpoint_interval(msec)       |
| max_flush_pages_per_second(page_count) | max_flush_size_per_second(byte) |
| sync_on_nflush(page_count)             | sync_on_flush_size(byte)        |

### cubrid\_broker.conf

- In **KEEP\_CONNECTION** parameter, **OFF** value should be changed as **ON** or **AUTO** since **OFF** setting value is no longer used.
- **SELECT\_AUTO\_COMMIT** should be deleted since this parameter is no longer used.
- The value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** should be 2,097,151 or less since the maximum value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is 2,097,151.
- The minimum value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is 1024M. It is recommended that users who configure **APPL\_SERVER\_MAX\_SIZE** configure this value less than the value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT**.
- Because the default value of **CCI\_DEFAULT\_AUTOCOMMIT** has been changed to **ON**, users who have not configured this value should change it to **OFF** if they want to keep auto commit mode.

### cubrid\_ha.conf

- Users who have configured the **ha\_apply\_max\_mem\_size** parameter value more than 500 must the value to 500 or less.

## Environment variable

- **CUBRID\_LANG** is removed; now the language and the charset of database is set when creating DB, and **CUBRID\_MSG\_LANG** is used for configuring the charset of messages for utilities and errors.

### Warning

When you create database, the language and the charset of database should be specified. It affects the length of string type, string comparison operation, etc. The specified charset when creating database cannot be changed later, so you should be careful when specifying it.

For charset, locale and collation setting, see [An Overview of Globalization](#).

## Database Migration under HA Environment

### HA migration from CUBRID 2008 R2.2 or higher to CUBRID 11.4

In the scenario described below, the current service is stopped to perform an upgrade in an environment in which a broker, a master DB and a slave DB are operating on different servers.

| Step                                           | Description                                                                                                                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Steps C1-C6: Perform <b>DB migration</b>       | Run the CUBRID upgrade and database migration in the master node, and back up the new version's database on the master node.                                                      |
| Step C7: Install new version in the slave node | <p>Delete the previous version of the database from the slave node and install a new version.</p> <p>For more information, see <a href="#">Installing and Running CUBRID</a>.</p> |

**Step C8: Restore the backup copy of the master node**

| Step                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>in the slave node</p>                                                                      | <p>Restore the new database backup copy (testdb_bk*) of the master node, which is created in step H6 , to the slave node.</p> <pre>% scp user1@master:\$CUBRID/ databases/databases.txt \$CUBRID/databases/.  % cd ~/DB/testdb  % scp user1@master:~/DB/ testdb/testdb_bk0v000 .  % scp user1@master:~/DB/ testdb/testdb_bkvinf .  % cubrid restoredb testdb</pre> |
| <p><b>Step C9: Reconfigure HA environment and start</b></p> <p>HA mode</p>                    | <p>In the master node and the slave node, set the CUBRID environment configuration file (cubrid.conf) and the HA environment configuration file (cubrid_ha.conf)</p> <p>See <a href="#">Creating Databases and Configuring Servers</a>.</p>                                                                                                                        |
| <p><b>Step C10: Install new version in the broker server,</b></p> <p>and start the broker</p> | <p>For more information about installation, see <a href="#">Installing and Running CUBRID</a>.</p> <p>Start the broker in the Broker server. See <a href="#">Configuring and Starting Broker, and Verifying the Broker Status</a>.</p> <pre>% cubrid broker start</pre>                                                                                            |

## HA Migration from CUBRID 2008 R2.0/R2.1 to CUBRID 11.4

If you are using the HA feature of CUBRID 2008 R2.0 or 2008 R2.1, you must upgrade the server version, migrate the database, set up a new HA environment, and then change the Linux

Heartbeat auto start setting used in 2008 R2.0 or 2008 R2.1. If the Linux Heartbeat package is not needed, delete it.

Perform steps C1~C10 above, then perform step C11 below:

| Step                                                                     | Description                                                                                                                                                                             |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step C11: Change the previous Linux heartbeat auto start settings</b> | <p>Perform the following task in the master and slave nodes from a root account.</p> <pre>[root@master ~]# chkconfig --del heartbeat // Performing the same job in the slave node</pre> |

## Uninstalling CUBRID

### Uninstalling CUBRID in Linux

#### Uninstalling CUBRID of SH package or compressed package

To uninstall SH package(file extension of installing package is .sh) or compressed package(file extension of installing package is .tar.gz), proceed the following steps.

- Remove databases after stopping CUBRID service.

Remove all created databases after stopping CUBRID service.

For example, if there are testdb1, testdb2 as databases, do the following commands.

```
$ cubrid service stop
$ cubrid deletedb testdb1
$ cubrid deletedb testdb2
```

- Remove CUBRID engine.

Remove \$CUBRID and its subdirectories.

```
$ echo $CUBRID
/home1/user1/CUBRID

$ rm -rf /home1/user1/CUBRID
```

- Remove auto-starting script.

If you stored cubrid script in /etc/init.d directory, remove this file.

```
cd /etc/init.d
rm cubrid
```

### Uninstalling CUBRID of RPM package

If you have installed CUBRID in RPM package, you can uninstall CUBRID by “rpm” command.

- Remove databases after stopping CUBRID service.

Remove all created databases after stopping CUBRID service.

For example, if there are testdb1, testdb2 as databases, do the following commands.

```
$ cubrid service stop
$ cubrid deletedb testdb1
$ cubrid deletedb testdb2
```

- Remove CUBRID engine.

```
$ rpm -q cubrid
cubrid-9.2.0.0123-el5.x86_64

$ rpm -e cubrid
warning: /opt/cubrid/conf/cubrid.conf saved as /opt/cubrid/conf/
cubrid.conf.rpmsave
```

- Remove auto-starting script.

If you stored cubrid script in /etc/init.d directory, remove this file.

```
cd /etc/init.d
rm cubrid
```

### Uninstalling CUBRID in Windows

Choose “CUBRID” in “Control panel > Uninstall a program” and uninstall it.

# Getting Started

This chapter contains useful information on starting CUBRID; also it provides brief instructions on how to use the CSQL Interpreter and GUI tools.

CUBRID provides various tools for you to use easily through GUI. You can download them from <https://www.cubrid.org/downloads>.

If you use the following tools which CUBRID provides, you can use CUBRID features easily through GUI.

- CUBRID Manager
- CUBRID Migration Toolkit

CUBRID also provides various drivers such as JDBC, CCI, PHP, PDO, ODBC, OLE DB, ADO.NET, Perl, Python, and Ruby (see API Reference).

## Starting the CUBRID Service

Configure environment variables and language, and then start the CUBRID service. For more information on configuring environment variables and language, see [CUBRID Services](#).

### Shell Command

The following shell command can be used to start the CUBRID service and the *demodb* included in the installation package.

```
% cubrid service start

@ cubrid master start
++ cubrid master start: success

@ cubrid broker start
++ cubrid broker start: success

@ cubrid manager server start
++ cubrid manager server start: success

% cubrid server start demodb

@ cubrid server start: demodb
```

This may take a long time depending on the amount of recovery works to do.

CUBRID 11.4

```
++ cubrid server start: success
```

```
@ cubrid server status
```

```
Server demodb (rel 11.4, pid 31322)
```

## CUBRIDService or CUBRID Service Tray

On the Windows environment, you can start or stop a service as follows:

- Go to [Control Panel] > [Performance and Maintenance] > [Administrator Tools] > [Services] and select the CUBRIDService to start or stop the service.

- In the system tray, right-click the CUBRID Service Tray. To start CUBRID, select [Service Start]; to stop it, select [Service Stop].

Selecting [Service Start] or [Service Stop] menu would be like executing cubrid service start or cubrid service stop in a command prompt; this command runs or stops the processes configured in service parameters of cubrid.conf.

- If you click [Exit] while CUBRID is running, all the services and process in the server stop.

### Note

An administrator level (SYSTEM) authorization is required to start/stop CUBRID processes through the CUBRID Service tray; a login level user authorization is required to start/stop them with shell commands. If you cannot control the CUBRID processes on the Windows Vista or later version environment, select [Execute as an administrator (A)] in the [Start] > [All Programs] > [Accessories] > [Command Prompt]) or execute it by using the CUBRID Service

Tray. When all processes of CUBRID Server stops, an icon on the CUBRID Service tray turns out gray.

## Creating Databases

You can create databases by using the **cubrid createdb** utility and execute it where database volumes and log volumes are located. If you do not specify additional options such as **--db-volume-size** or **--log-volume-size**, 1.5 GB volume files are created by default (data volume is set to 512 MB, active log is set to 512 MB, and background archive log is set to 512 MB).

```
% cd testdb
% cubrid createdb testdb en_US
% ls -l

-rw----- 1 cubrid dbms 536870912 Jan 11 15:04 testdb
-rw----- 1 cubrid dbms 536870912 Jan 11 15:04 testdb_lgar_t
-rw----- 1 cubrid dbms 536870912 Jan 11 15:04 testdb_lgat
-rw----- 1 cubrid dbms      176 Jan 11 15:04 testdb_lginf
-rw----- 1 cubrid dbms      183 Jan 11 15:04 testdb_vinf
```

In the above, *testdb* represents a data volume file, *testdb\_lgar\_t* represents a background archive log file, *testdb\_lgat* represents an active log file, *testdb\_lginf* represents a log information file, and *testdb\_vinf* represents a volume information file.

For details on volumes, see [Database Volume Structure](#) . For details on creating volumes, see [createdb](#). It is recommended to classify and add volumes based on purpose by using the **cubrid addvoldb** utility. For details, see [addvoldb](#).

## Starting Database

You can start a database process by using the **cubrid server** utility.

```
% cubrid server start testdb
```

To have *testdb* started upon startup of the CUBRID service (cubrid service start), configure *testdb* in the **server** parameter of the **cubrid.conf** file.

```
% vi cubrid.conf

[service]

service=server,broker,manager
server=testdb
```

# Query Tools

# CSQL Interpreter

The CSQL Interpreter is a program used to execute the SQL statements and retrieve results in a way that CUBRID supports. The entered SQL statements and the results can be stored as a file. For more information, see [Introduction to the CSQL Interpreter](#) and [CSQL Execution Mode](#).

CUBRID also provides a GUI-based program called “CUBRID Manager”. You can execute all SQL statements and retrieve results in the query editor of CUBRID Manager. For more information, see [Management Tools](#).

This section describes how to use the CSQL Interpreter on the Linux environment.

## Starting the CSQL Interpreter

You can start the CSQL program in the shell as shown below. At the initial installation, **PUBLIC** and **DBA** users are provided and the passwords of the users not set. If no user is specified while the CSQL Interpreter is executed, **PUBLIC** is used for log-in.

```
% csql demodb

CUBRID SQL Interpreter

Type `;help' for help messages.

csql> ;help

=== <Help: Session Command Summary> ===

All session commands should be prefixed by `;' and only blanks/
tabs
can precede the prefix. Capitalized characters represent the
minimum
abbreviation that you need to enter to execute the specified
command.

;REAd    [<file-name>]      - read a file into command buffer.
;Write   [<file-name>]      - (over)write command buffer into a
file.
;Append  [<file-name>]      - append command buffer into a file.
;PRINT   [<file-name>]      - print command buffer.
```

```

;SHELL                - invoke shell.
;CD                   - change current working directory.
;EXit                 - exit program.

;Clear                - clear command buffer.
;EDIT [format/fmt]    - invoke system editor [after
formatter] with command buffer.
;LIST                 - display the content of command
buffer.

;RUN                  - execute sql in command buffer.
;Xrun                 - execute sql in command buffer,
                        and clear the command buffer.

;COMmit               - commit the current transaction.
;ROLLback              - roll back the current transaction.
;AUTocommit [ON|OFF]  - enable/disable auto commit mode.
;REStart              - reconnect to the current database
in a CSQL session.
;CHECKpoint            - execute the checkpoint(CSQL with --
sysadm only).
;Killtran              - check transaction status
information or end a specific transaction.(CSQL with --sysadm only).

;SHELL_Cmd [shell-cmd] - set default shell, editor, print,
pager and formatter
;EDITOR_Cmd [editor-cmd] command to new one, or display the
current
;PRINT_Cmd [print-cmd] one, respectively.
;PAGER_cmd [pager-cmd]
;FORMatter_cmd [formatter-cmd]

;DATE                  - display the local time, date.
;DATAbase              - display the name of database being
accessed.
;SCHEMA class-name    - display schema information of a
class.
;TRIGGER ['*'|trigger-name] - display trigger definition.
;GET system_parameter - get the value of a system parameter.
;SET system_parameter=value - set the value of a system parameter.
;STRING-width [width] - set width that each column which is
a string type is displayed.
;COLUMN-width [name]=[width]- set width that a specific column is
displayed.
;PLAN [simple/detail/off] - show query execution plan.
;INFO <command>        - display internal information.
;TIME [ON/OFF]         - enable/disable to display the query
                        execution time.

;LINE-output [ON/OFF] - enable/disable to display each
value in a line
;HISTORYList           - display list of the executed
queries.
;HISTORYRead <history_num> - read entry on the history number

```

```

into command buffer.
;TRAcE [ON/OFF] [text/json] - enable/disable sql auto trace.
;SIngleline [ON|OFF]       - enable/disable single-line mode.
;CONnect username [dbname | dbname@hostname]
                             - connect to the current or other
databases as a username.
;.Hist [ON/OFF]            - start/stop collecting statistics
information in CSQL(available DBA only).
;.Clear_hist               - clear the CSQL statistics
information in the buffer.
;.Dump_hist                - display the CSQL statistics
information in CSQL.
;.X_hist                   - display the CSQL statistics
information in CSQL with statistics data initialized.
;HElp                      - display this help message.

```

## Running SQL with CSQL

After the CSQL has been executed, you can enter the SQL into the CSQL prompt. Each SQL statement must end with a semicolon (;). Multiple SQL statements can be entered in a single line. You can find the simple usage of the session commands with the ;help command. For more information, see [Session Commands](#).

```

% csql demodb

csql> SELECT SUM(n) FROM (SELECT gold FROM participant WHERE
nation_code='KOR'
csql> UNION ALL SELECT silver FROM participant WHERE
nation_code='JPN') AS t(n);

=== <Result of SELECT Command in Line 2> ===

      sum(n)
=====
          82

1 rows selected. (0.106504 sec) Committed.

csql> ;exit

```

## Management Tools

|                          | Summary of features                                                                                                                                                                                                                                                                                                                                                                                                                      | Downloads of the recent files                     |

## Running SQL with CUBRID Manager

CUBRID Manager is the client tool that you should download and run. It is a Java application which requires JRE or JDK 1.6 or higher.

1. Download and install the latest CUBRID Manager file. CUBRID Manager is compatible with CUBRID DB engine 2008 R2.2 or higher version. It is recommended to upgrade to the latest version periodically; it supports the auto-update feature. (CUBRID FTP: [http://ftp.cubrid.org/CUBRID\\_Tools/CUBRID\\_Manager](http://ftp.cubrid.org/CUBRID_Tools/CUBRID_Manager) )
2. Start CUBRID service on the server. CUBRID Manager server should be started for CUBRID Manager client to access to DB. For more information, see [CUBRID Manager Server](#).

```
C:\CUBRID> cubrid service start
++ cubrid service is running.
```

3. After the installation of CUBRID Manager, register host information on the [File > Add Host] menu. To register the host, you should enter host address, connection port (default: 8001), and CUBRID Manager user name/password and install the JDBC driver of the same version with DB engine (supporting auto-driver-search/auto-update).
4. Choose the host on the left tree and perform the CUBRID Manager user (=host user) authentication. The default ID/password is admin/admin.
5. Create a new database as clicking the right mouse button on the database node, or try to connect as choosing the existing database on the bottom of the host node. At this time, do the DB user's login. The default db user is "dba", and there is no password.
6. Run SQL on the access DB and confirm the result. The host, DB and table list are displayed on the left side, and the query editor and the result window is shown on the right side. You can reuse the SQLs which have been succeeded with [SQL History] tab and compare the multiple results of several DBs as adding the DBs for the comparison of the result with [Multiple Query] tab.

## Migrating schema/data with CUBRID Migration Toolkit

CUBRID Migration Toolkit is a tool to migrate the data and the schema from the source DB (MySQL, Oracle, and CUBRID) to the target DB (CUBRID). It is also Java applications which require JRE or JDK 1.6 or later. You should download separately. (CUBRID FTP: [http://ftp.cubrid.org/CUBRID\\_Tools/CUBRID\\_Migration\\_Toolkit](http://ftp.cubrid.org/CUBRID_Tools/CUBRID_Migration_Toolkit) )

It is useful in case of switching from other DB into CUBRID, in case of migrating into other hardware, in case of migrating some schema and data from the operating DB, in case of upgrading CUBRID version, and in case of running the batch jobs. The main features are as follows:

- Supports the tools/some schema and data migration
- Available to migrate only the desired data as running several SQLs
- Executable without suspending of operation as supporting online migration through JDBC
- Available offline migration with CSV, SQL, CUBRID loaddb format data
- Available to run directly on the target server as extracting the run-script of migration
- Shorten the batch job time as reusing the migration run-script.

## Drivers

The drivers supported by CUBRID are as follows:

- CUBRID JDBC driver ([Downloads JDBC](#))
- CUBRID CCI driver ([Downloads CCI](#))
- CUBRID PHP driver ([Downloads PHP](#))
- CUBRID PDO driver ([Downloads PDO](#))
- CUBRID ODBC driver ([Downloads ODBC](#))
- CUBRID ADO.NET driver ([Downloads ADO.NET](#))
- CUBRID Perl driver ([Downloads Perl](#))
- CUBRID Python driver ([Downloads Python](#))
- CUBRID Ruby driver ([Downloads Ruby](#))
- CUBRID Node.js driver ([Downloads Node.js](#))

Among above drivers, JDBC and CCI drivers are automatically downloaded while CUBRID is being installed. Thus, you do not have to download them manually.

# CSQL Interpreter

To execute SQL statements in CUBRID, you need to use either a Graphical User Interface(GUI)-based CUBRID Manager or a console-based CSQL Interpreter.

CSQL is an application that allows users to use SQL statements through a command-driven interface. This section briefly explains how to use the CSQL Interpreter and associated commands.

## Introduction to the CSQL Interpreter

### A Tool for SQL

The CSQL Interpreter is an application installed with CUBRID that allows you to execute in an interactive or batch mode and viewing query results. The CSQL Interpreter has a command-line interface. With this, you can store SQL statements together with their results to a file for a later use.

The CSQL Interpreter provides the best and easiest way to use CUBRID. You can develop database applications with various APIs (e.g. JDBC, ODBC, PHP, CCI, etc.; you can use the CUBRID Manager, which is a management and query tool provided by CUBRID. With the CSQL Interpreter, users can create and retrieve data in a terminal-based environment.

The CSQL Interpreter directly connects to a CUBRID database and executes various tasks using SQL statements. Using the CSQL Interpreter, you can:

- Retrieve, update and delete data in a database by using SQL statements
- Execute external shell commands
- Store or display query results
- Create and execute SQL script files
- Select table schema
- Retrieve or modify parameters of the database server system
- Retrieve database information (e.g. schema, triggers, queued triggers, workspaces, locks, and statistics)

### A Tool for DBA

A database administrator(**DBA**) performs administrative tasks by using various administrative utilities provided by CUBRID; a terminal-based interface of CSQL Interpreter is an environment where **DBA** executes administrative tasks.

It is also possible to run the CSQL Interpreter in standalone mode. In this mode, the CSQL Interpreter directly accesses database files and executes commands including server process properties. That is, SQL statements can be executed to a database without running a separate database server process. The CSQL Interpreter is a powerful tool that allows you to use the database only with a **csql** utility, without any other applications such as the database server or the brokers.

## Executing CSQL

### CSQL Execution Mode

#### Interactive Mode

With CSQL Interpreter, you can enter and execute SQL statements to handle schema and data in the database. Enter statements in a prompt that appears when running the **csql** utility. After executing the statements, the results are listed in the next line. This is called the interactive mode.

#### Batch Mode

You can store SQL statements in a file and execute them later to have the **csql** utility read the file. This is called the batch mode..

#### Standalone Mode

In the standalone mode, CSQL Interpreter directly accesses database files and executes commands including server process functions. That is, SQL statements can be sent and executed to a database without a separate database server process running for the task. Since the standalone mode allows only one user access at a given time, it is suitable for management tasks by Database Administrators (**DBAs**).

#### Client/Server Mode

CSQL Interpreter usually operates as a client process and accesses the server process.

#### System Administration Mode

You can use this mode when you run checkpoint through CSQL interpreter or exit the transaction monitoring. Also, it allows one connection on CSQL interpreter even if the server access count exceeds the value of **max\_clients** system parameter. In this mode, allowed connection count by CSQL interpreter is only one.

```
csql -u dba --sysadm demodb
```

## Using CSQL (Syntax)

### Connecting to Local Host

Execute the CSQL Interpreter using the **csql** utility. You can set options as needed. To set the options, specify the name of the database to connect to as a parameter. The following is a **csql** utility statement to access the database on a local server:

```
csql [options] database_name
```

### Connecting to Remote Host

The following is a **csql** utility syntax to access the database on a remote host:

```
csql [options] database_name@remote_host_name
```

Make sure that the following conditions are met before you run the CSQL Interpreter on a remote host.

- The CUBRID installed on the remote host must be the same version as the one on the local host.
- The port number used by the master process on the remote host must be identical to the one on the local host.
- You must access the remote host in client/server mode using the **-C** option.

### Example

The following example shows how to access the **demodb** database on the remote host with the IP address 192.168.1.3 and calls the **csql** utility.

```
csql -C demodb@192.168.1.3
```

## CSQL Options

To display the option list in the prompt, execute the **csql** utilities without specifying the database name as follows:

```
$ csql
A database-name is missing.
interactive SQL utility, version 11.4
usage: csql [OPTION] database-name[@host]

valid options:
```

```

-S, --SA-mode           standalone mode execution
-C, --CS-mode           client-server mode execution
-u, --user=ARG          alternate user name
-p, --password=ARG      password string, give "" for none
-e, --error-continue    don't exit on statement error
-i, --input-file=ARG    input-file-name
-o, --output-file=ARG   output-file-name
-s, --single-line       single line oriented execution
-c, --command=ARG       CSQL-commands
-l, --line-output       display each value in a line
-r, --read-only         read-only mode
-t, --plain-output      display results in a script-friendly
format (only works with -c and -i)
-q, --query-output      display results in a query-friendly
format (only work with -c and -i)
-d, --loaddb-output     display results in a loaddb-friendly
format (only work with -c and -i)
-N, --skip-column-names do not display column names in
results (only works with -c and -i)
--string-width          display each column which is a string
type in this width
--no-auto-commit        disable auto commit mode execution
--no-pager              do not use pager
--no-single-line        turn off single line oriented
execution
--no-trigger-action     disable trigger action
--delimiter=ARG        delimiter between columns (only work
with -q)
--enclosure=ARG        enclosure for a result string (only
work with -q)

```

For additional information, see <http://www.cubrid.org>

## Options

### -S, --SA-mode

The following example shows how to connect to a database in standalone mode and execute the **csql** utility. If you want to use the database exclusively, use the **-S** option. If **csql** is running in standalone mode, it is impossible to use another **csql** or utility. If both **-S** and **-C** options are omitted, the **-C** option will be specified.

```
csql -S demodb
```

### -C, --CS-mode

The following example shows how to connect to a database in client/server mode and execute the **csql** utility. In an environment where multiple clients connect to the database, use the **-C** option. Even when you connect to a database on a remote host in client/server

mode, the error log created during **csql** execution will be stored in the **cub.err** file on the local host.

```
csql -C demodb
```

### **-i, --input-file=ARG**

The following example shows how to specify the name of the input file that will be used in a batch mode with the **-i** option. In the **infile** file, more than one SQL statement is stored. Without the **-i** option specified, the CSQL Interpreter will run in an interactive mode.

```
csql -i infile demodb
```

### **-o, --output-file=ARG**

The following example shows how to store the execution results to the specified file instead of displaying on the screen. It is useful to retrieve the results of the query performed by the CSQL Interpreter afterwards.

```
csql -o outfile demodb
```

### **-u, --user=ARG**

The following example shows how to specify the name of the user that will connect to the specified database with the **-u** option. If the **-u** option is not specified, **PUBLIC** that has the lowest level of authorization will be specified as a user. If the user name is not valid, an error message is displayed and the **csql** utility is terminated. If there is a password for the user name you specify, you will be prompted to enter the password.

```
csql -u DBA demodb
```

### **-p, --password=ARG**

The following example shows how to enter the password of the user specified with the **-p** option. Especially since there is no prompt to enter a password for the user you specify in a batch mode, you must enter the password using the **-p** option. When you enter an incorrect password, an error message is displayed and the **csql** utility is terminated.

```
csql -u DBA -p *** demodb
```

### **-s, --single-line**

As an option used with the **-i** option, it executes multiple SQL statement one by one in a file with the **-s** option. This option is useful to allocate less memory for query execution and each SQL statement is separated by semicolons (;). If it is not specified, multiple SQL statements are retrieved and executed at once.

```
csql -s -i infile demodb
```

### **-c, --command=ARG**

The following example shows how to execute more than one SQL statement from the shell with the **-c** option. Multiple statements are separated by semicolons (;).

```
csql -c "select * from olympic;select * from stadium" demodb
```

### **-l, --line-output**

With **-l** option, you can display the values of SELECT lists by line. If **-l** option is omitted, all SELECT lists of the result record are displayed in one line.

```
csql -l demodb
```

### **-e, --error-continue**

The following example shows how to ignore errors and keep execution even though semantic or runtime errors occur with the **-e** option. However, if any SQL statements have syntax errors, query execution stops after errors occur despite specifying the **-e** option.

```
$ csql -e demodb

csql> SELECT * FROM aaa;SELECT * FROM athlete WHERE code=10000;

In line 1, column 1,

ERROR: before ' ;SELECT * FROM athlete WHERE code=10000; '
Unknown class "aaa".

=== <Result of SELECT Command in Line 1> ===

      code  name                gender
nation_code  event
=====
10000  'Aardewijn Pepijn'  'M'
'NED'    'Rowing'

1 rows selected. (0.006433 sec) Committed.
```

### **-r, --read-only**

You can connect to the read-only database with the **-r** option. Retrieving data is only allowed in the read-only database; creating databases and entering data are not allowed.

```
csql -r demodb
```

### **-t, --plain-output**

It only shows column names and values and works with **-c** or **-i** option. Each column and value is separated by a tab and a new line, a tab and a backslash which are included in results are replaced by 'n', 't' and '\ for each. This option is ignored when it is given with **-l** option.

```
$ csql demodb -c "select * from athlete where code between 12762 and 12765" -t
```

| code  | name                  | gender | nation_code | event     |
|-------|-----------------------|--------|-------------|-----------|
| 12762 | O'Brien Dan           | M      | USA         | Athletics |
| 12763 | O'Brien Leah          | W      | USA         | Softball  |
| 12764 | O'Brien Shaun William | M      | AUS         | Cycling   |
| 12765 | O'Brien-Amico Leah    | W      | USA         | Softball  |

### **-q, --query-output**

This option displays the result for easy use in insert queries, only show column names and values, and works with **-c** or **-i** option. Each column name and value are separated by a comma or a single character of the **--delimiter** option; and all results except for numeric types are enclosed by a single quote or a single character of the **--enclosure** option. If the enclosure is a single quote, the single quote in the results is replaced with two ones. It is ignored when it is given with **-l** option.

```
$ csql demodb -c "select * from athlete where code between 12762 and 12765" -q
```

```
code,name,gender,nation_code,event
12762,'O'Brien Dan','M','USA','Athletics'
12763,'O'Brien Leah','W','USA','Softball'
12764,'O'Brien Shaun William','M','AUS','Cycling'
12765,'O'Brien-Amico Leah','W','USA','Softball'
```

```
$ csql demodb -c "select * from athlete where code between 12762 and 12765" -q --delimiter="," --enclosure="\""
```

```
code,name,gender,nation_code,event
12762,"O'Brien Dan","M","USA","Athletics"
12763,"O'Brien Leah","W","USA","Softball"
12764,"O'Brien Shaun William","M","AUS","Cycling"
12765,"O'Brien-Amico Leah","W","USA","Softball"
```

### **-d, --loaddb-output**

This option displays the result for easy use in loaddb utility, only show column names and values, and works with **-c** or **-i** option. Each column name and value are separated by a space; and all results except for numeric types are enclosed by a single quote. The single quote in the results is replaced with two ones and the result of the enum type is outputted by an index instead of a value. This option is ignored when it is given with **-l** option.

```
$ csql demodb -c "select * from athlete where code between 12762
and 12765" -d

%class [ ] ([code] [name] [gender] [nation_code] [event])
12762 'O''Brien Dan' 'M' 'USA' 'Athletics'
12763 'O''Brien Leah' 'W' 'USA' 'Softball'
12764 'O''Brien Shaun William' 'M' 'AUS' 'Cycling'
12765 'O''Brien-Amico Leah' 'W' 'USA' 'Softball'
```

### **-N, --skip-column-names**

It will hide column names from the results. It only works with **-c** or **-i** option and is usually used with **-t -q** or **-d** option. This option is ignored when it is given with **-l** option.

```
$ csql demodb -c "select * from athlete where code between 12762
and 12765" -d -N

12762 'O''Brien Dan' 'M' 'USA' 'Athletics'
12763 'O''Brien Leah' 'W' 'USA' 'Softball'
12764 'O''Brien Shaun William' 'M' 'AUS' 'Cycling'
12765 'O''Brien-Amico Leah' 'W' 'USA' 'Softball'
```

### **--no-auto-commit**

The following example shows how to stop the auto-commit mode with the **--no-auto-commit** option. If you don't configure **--no-auto-commit** option, the CSQL Interpreter runs in an auto-commit mode by default, and the SQL statement is committed automatically at every execution. Executing the **;Autocommit** session command after starting the CSQL Interpreter will also have the same result.

```
csql --no-auto-commit demodb
```

### **--no-pager**

The following example shows how to display the execution results by the CSQL Interpreter at once instead of page-by-page with the **--no-pager** option. The results will be output page-by-page if **--no-pager** option is not specified.

```
csql --no-pager demodb
```

**--no-single-line**

The following example shows how to keep storing multiple SQL statements and execute them at once with the **;xr** or **;ru** session command. If you do not specify this option, SQL statements are executed without **;xr** or **;ru** session command. Singleline command will also have the same result.

```
csql --no-single-line demodb
```

**--sysadm**

This option should be used together with **-u dba**. It is specified when you want to run CSQL in a system administrator's mode.

```
csql -u dba --sysadm demodb
```

**--write-on-standby**

This option should be used together with a system administrator's mode option (**--sysadm**). **dba** which run CSQL with this option can write directly to the standby DB (slave DB or replica DB). However, the data to be written directly to the replica DB are not replicated.

```
csql --sysadm --write-on-standby -u dba testdb@localhost
```

**Note**

Please note that replication mismatch occurs when you write the data directly to the replica DB.

**--no-trigger-action**

If you specify this option, triggers of the queries executed in this CSQL are not triggered.

**--delimiter=ARG**

This option should be used together with **-q** and a single character is specified in the argument to separate the column name and value. If multiple characters are specified, the first character is used without displaying an error. (include special characters such as **\t** and **\n**)

**--enclosure=ARG**

This option should be used together with **-q** and a single character is specified in the argument to enclose all values except for numeric types. If multiple characters are specified, the first character is used without displaying an error.

## Session Commands

In addition to SQL statements, CSQL Interpreter provides special commands allowing you to control the Interpreter. These commands are called session commands. All the session commands must start with a semicolon (;).

Enter the **;help** command to display a list of the session commands available in the CSQL Interpreter. You don't need to type the full session command; the CSQL Interpreter recognizes commands as long as you input the minimum number of characters needed to uniquely identify the command from others. Session commands are not case-sensitive.

CSQL recognizes SQL string literals, comments, and identifiers (see: [lexical rules](#)). Specifically:

- String literals enclosed in single quotes
- Comments marked by `--`, `/*`, or `/**`
- Identifiers enclosed in double quotes, brackets, or backticks

Strings within these are recognized only as strings and lose any special meaning they might have outside, and this applies to session commands as well. For example, `'exit'` within a string literal, comment, or identifier below is not recognized as a session command but only as a string.

```
csql> select * from table_a where col = ';exit';
...
csql> select * from table_b /* ;exit on no results */;
...
csql> create table table_c([;exit] int);
...
```

Except in interactive mode CSQL, if the first character of a command line is a semicolon, it is recognized as a session command even if it is within a string literal, comment, or identifier.

```
csql> select * from table_a where col = '
csql> ;exit      <-- CSQL exit
...
csql> select * from table_b /*
csql> ;exit      <-- CSQL exit
...
csql> create table table_c([
csql> ;exit      <-- CSQL exit
...
```

This exception is necessary to allow operations such as exiting CSQL (**;exit**), continuing to edit in an editor (**;edit**), or clearing the query buffer (**;clear**) to be performed at any edit position.

```

;DATABASE - display the name of database being
accessed.
;Schema class-name - display schema information of a class.
;TRIGGER ['*'|trigger-name] - display trigger definition.
;Get system_parameter - get the value of a system parameter.
;SET system_parameter=value - set the value of a system parameter.
;STRING-width [width] - set width that each column which is a
string type is displayed.
;COLUMN-width [name]=[width] - set width that a specific column is
displayed.
;PLAN [simple/detail/off] - show query execution plan.
;INFO <command> - display internal information.
;TIME [ON/OFF] - enable/disable to display the query
execution time.
;SERVER-output [ON/OFF] - enable/disable displaying server
messages stored in DBMS_OUTPUT buffer.
;LINE-output [ON/OFF] - enable/disable to display each value
in a line
;HISTORYlist - display list of the executed queries.
;HISTORYread <history_num> - read entry on the history number into
command buffer.
;TRACE [ON/OFF] [text/json] - enable/disable sql auto trace.
;SINGLEline [ON/OFF] - enable/disable single-line mode.
;CONNECT username [dbname | dbname@hostname]
- connect to the current or other
databases as a username.
;.Hist [ON/OFF] - start/stop collecting statistics
information in CSQL(available DBA only).
;.Clear_hist - clear the CSQL statistics information
in the buffer.
;.Dump_hist - display the CSQL statistics
information in CSQL.
;.X_hist - display the CSQL statistics
information in CSQL with statistics data initialized.
;HELP - display this help message.

```

### Reading SQL statements from a file (;REAd)

The **;REAd** command reads the contents of a file into the buffer. This command is used to execute SQL commands stored in the specified file. To view the contents of the file loaded into the buffer, use the **;List** command.

```

csql> ;read nation.sql
The file has been read into the command buffer.
csql> ;list
insert into "sport_event" ("event_code", "event_name",
"gender_type", "num_player") values
(20001, 'Archery Individual', 'M', 1);
insert into "sport_event" ("event_code", "event_name",
"gender_type", "num_player") values

```

```
20002, 'Archery Individual', 'W', 1);  
....
```

### Storing SQL statements into a file (;Write)

The **;Write** command stores the contents of the query buffer into a file. This command is used to store queries that you entered or modified in the CSQL Interpreter.

```
csql> ;write outfile  
Command buffer has been saved.
```

### Appending to a file (;APpend)

This command appends the contents of the current query buffer to an **outfile** file.

```
csql> ;append outfile  
Command buffer has been saved.
```

### Executing a shell command (;SHELL)

The **;SHELL** session command calls an external shell. Starts a new shell in the environment where the CSQL Interpreter is running. It returns to the CSQL Interpreter when the shell terminates. If the shell command to execute with the **;SHELL\_Cmd** command has been specified, it starts the shell, executes the specified command, and returns to the CSQL Interpreter.

```
csql> ;shell  
% ls -al  
total 2088  
drwxr-xr-x 16 DBA cubrid 4096 Jul 29 16:51 .  
drwxr-xr-x 6 DBA cubrid 4096 Jul 29 16:17 ..  
drwxr-xr-x 2 DBA cubrid 4096 Jul 29 02:49 audit  
drwxr-xr-x 2 DBA cubrid 4096 Jul 29 16:17 bin  
drwxr-xr-x 2 DBA cubrid 4096 Jul 29 16:17 conf  
drwxr-xr-x 4 DBA cubrid 4096 Jul 29 16:14 cubridmanager  
% exit  
csql>
```

### Registering a shell command (;SHELL\_Cmd)

The **;SHELL\_Cmd** command registers a shell command to execute with the **SHELL** session command. As shown in the example below, enter the **;shell** command to execute the registered command.

```
csql> ;shell_c ls -la  
csql> ;shell
```

```
total 2088
drwxr-xr-x 16 DBA cubrid 4096 Jul 29 16:51 .
drwxr-xr-x  6 DBA cubrid 4096 Jul 29 16:17 ..
drwxr-xr-x  2 DBA cubrid 4096 Jul 29 02:49 audit
drwxr-xr-x  2 DBA cubrid 4096 Jul 29 16:17 bin
drwxr-xr-x  2 DBA cubrid 4096 Jul 29 16:17 conf
drwxr-xr-x  4 DBA cubrid 4096 Jul 29 16:14 cubridmanager
csql>
```

The OS environment variable(CUBRID\_CSQSQL\_SHELL or SHELL; CUBRID\_CSQSQL\_SHELL is used if both environment variables are set) may be registered and used in advance.

```
$ export CUBRID_CSQSQL_SHELL='ls -la'
or
$ export SHELL='ls -la'
```

### Registering a pager command (;Pager\_cmd)

The ;Pager\_cmd command registers a pager command to display the query result. The way of displaying is decided by the registered command. The default is **more**. Also **cat** and **less** can be used. But ;Pager\_cmd command works well only on Linux.

When you register pager command as more, the query result shows by page and wait until you press the space key.

```
csql>;pager more
```

When you register pager command as cat, the query result shows all in one display without paging.

```
csql>;pager cat
```

When you redirect the output with a file, the total query result will be written on the file.

```
csql>;pager cat > output.txt
```

If you register pager command as less, you can forward, backward the query result. Also pattern matching on the query result is possible.

```
csql>;pager less
```

The keyboard commands used on the **less** are as follows.

- Page UP, b: go up to one page. (backwording)
- Page Down, Space: go down to one page (forwarding)
- /string: find a sting on the query results
- n: find the next string
- N: find the previous string
- q: quit the paging mode.

### Changing the current working directory (;CD)

This command changes the current working directory where the CSQL Interpreter is running to the specified directory. If you don't specify the path, the directory will be changed to the home directory.

```
csql> ;cd /home1/DBA/CUBRID
Current directory changed to /home1/DBA/CUBRID.
```

### Exiting the CSQL Interpreter (;EXit)

This command exits the CSQL Interpreter.

```
csql> ;ex
```

### Clearing the query buffer (;Clear)

The **;Clear** session command clears the contents of the query buffer.

```
csql> ;clear
csql> ;list
```

### Displaying the contents of the query buffer (;List)

The **;List** session command lists the contents of the query buffer that have been entered or modified. The query buffer can be modified by **;READ** or **;Edit** command.

```
csql> ;list
```

### Executing SQL statements (;RUN)

This command executes SQL statements in the query buffer. Unlike the **;Xrun** session command described below, the buffer will not be cleared even after the query execution.

```
csql> ;run
```

### Clearing the query buffer after executing the SQL statement (**;Xrun**)

This command executes SQL statements in the query buffer. The buffer will be cleared after the query execution.

```
csql> ;xrun
```

### Committing transaction (**;COMmit**)

This command commits the current transaction. You must enter a commit command explicitly if it is not in auto-commit mode. In auto-commit mode, transactions are automatically committed whenever SQL is executed.

```
csql> ;commit  
Execute OK. (0.000192 sec)
```

### Rolling back transaction (**;ROLLback**)

This command rolls back the current transaction. Like a commit command (**;COMmit**), it must enter a rollback command explicitly if it is not in auto-commit mode (**OFF**).

```
csql> ;rollback  
Execute OK. (0.000166 sec)
```

### Setting the auto-commit mode (**;AUTocommit**)

This command sets auto-commit mode to **ON** or **OFF**. If any value is not specified, current configured value is applied by default. The default value is **ON**.

```
csql> ;autocommit off  
AUTOCOMMIT IS OFF
```

### Checkpoint Execution (**;CHECKpoint**)

This command executes the checkpoint within the CSQL session. This command can only be executed when a DBA group member, who is specified for the custom option (**-u user\_name**), connects to the CSQL Interpreter in system administrator mode (**--sysadm**).

**Checkpoint** is an operation of flushing all dirty pages except for temp pages within the current data buffer to disks. You can also change the checkpoint interval using a command (`;set parameter_name value`) to set the parameter values in the CSQL session. You can see the examples of the parameter related to the checkpoint execution interval (**checkpoint\_interval** and **checkpoint\_every\_size**). For more information, see [Logging-Related Parameters](#).

```
sysadm> ;checkpoint
Checkpoint has been issued.
```

### Transaction Monitoring Or Termination (;Killtran)

This command checks the transaction status information or terminates a specific transaction in the CSQL session. This command prints out the status information of all transactions on the screen if a parameter is omitted it terminates the transaction if a specific transaction ID is specified for the parameter. It can only be executed when a DBA group member, who is specified for the custom option (`-u user_name`), connects to the CSQL Interpreter in system administrator mode (`--sysadm`).

```
sysadm> ;killtran
Tran index      User name      Host name      Process id
Program name
-----
1(+)           dba           myhost         664
cub_cas
2(+)           dba           myhost         6700
csql
3(+)           dba           myhost         2188
cub_cas
4(+)           dba           myhost         696
csql
5(+)           public        myhost         6944
csql

sysadm> ;killtran 3
The specified transaction has been killed.
```

### Restarting database (;REStart)

A command that tries to reconnect to the target database in a CSQL session. Note that when you execute the CSQL Interpreter in CS (client/server) mode, it will be disconnected from the server. When the connection to the server is lost due to a HA failure and failover to another server occurs, this command is particularly useful in connecting to the switched server while maintaining the current session.

```
csql> ;restart
The database has been restarted.
```

### Displaying the current date (;DATE)

The **;DATE** command displays the current date and time in the CSQL Interpreter.

```
csql> ;date
Tue July 29 18:58:12 KST 2008
```

### Displaying the database information (;DATABASE)

This command displays the database name and host name where the CSQL Interpreter is working. If the database is running, the HA mode (one of those following: active, standby, or maintenance) will be displayed as well.

```
csql> ;database
demodb@cubridhost (active)
```

### Displaying schema information of a class (;Schema)

The **;Schema** session command displays schema information of the specified table. The information includes the table name, its column name and constraints.

```
csql> ;schema event
=== <Help: Schema of a Class> ===
<Class Name>
    event
<Attributes>
    code          INTEGER NOT NULL
    sports        CHARACTER VARYING(50)
    name          CHARACTER VARYING(50)
    gender        CHARACTER(1)
    players       INTEGER
<Constraints>
    PRIMARY KEY pk_event_event_code ON event (code)
```

### Displaying the trigger (;TRIGGER)

This command searches and displays the trigger specified. If there is no trigger name specified, all the triggers defined will be displayed.

```
csql> ;trigger
=== <Help: All Triggers> ===
      trig_delete_contents
```

### Checking the parameter value(;Get)

You can check the parameter value currently set in the CSQL Interpreter using the **;Get** session command. An error occurs if the parameter name specified is incorrect.

```
csql> ;get isolation_level
=== Get Param Input ===
isolation_level="tran_rep_class_commit_instance"
```

### Setting the parameter value (;SET)

You can use the **;SET** session command to set a specific parameter value. Note that changeable parameters can have their values modified. To change the server parameter values, you must have DBA authorization. For information on list of changeable parameters, see [Broker Configuration](#).

```
csql> ;set block_ddl_statement=1
=== Set Param Input ===
block_ddl_statement=1

-- Dynamically change the log_max_archives value in the csql
accessed by dba account
csql> ;set log_max_archives=5
```

### Setting the output width of string (;String-width)

You can use the **;String-width** command to set the output width of character string or BIT string.

**;string-width** session command without a length shows the current setting length. When it is set to 0, the columns will be displayed as it is. If it sets greater than 0, the string typed columns will be displayed with the specified length.

```
csql> SELECT name FROM NATION WHERE NAME LIKE 'Ar%';
'Arab Republic of Egypt'
'Aruba'
'Armenia'
'Argentina'

csql> ;string-width 5
csql> SELECT name FROM NATION WHERE NAME LIKE 'Ar%';
'Arab '
'Aruba'
```

```
'Armen'
'Argen'

csql> ;string-width
STRING-WIDTH : 5
```

### Setting the output width of the column (;COLUMN-width)

You can use the **;COLUMN-width** command to set the output width regardless of its data types. If you don't give a value after **;COL** command, it shows the current setting length. When it sets to 0, the columns will be displayed as it is. If it sets to greater than 0, the columns will be displayed with the specified length.

```
csql> CREATE TABLE tbl(a BIGINT, b BIGINT);
csql> INSERT INTO tbl VALUES(12345678890, 1234567890)
csql> ;column-width a=5
csql> SELECT * FROM tbl;
    12345    1234567890
csql> ;column-width
COLUMN-WIDTH a : 5
```

### Setting the view level of executing query plan (;PLAN)

You can use the **;PLAN** session command to set the view level of executing query plan the level is composed of **simple**, **detail**, and **off**. Each command refers to the following:

- **off**: Not displaying the query execution plan (OPT LEVEL=1)
- **simple**: Displaying the query execution plan in simple version (OPT LEVEL=257)
- **detail**: Displaying the query execution plan in detailed version (OPT LEVEL=513)

For more information. see [Viewing Query Plan](#).

### Setting SQL trace(;trace)

The **;trace** session command specifies if SQL trace result is printed out together with query result or not. When you set SQL trace ON by using this command, the result of query profiling is automatically shown even if you do not run "**SHOW TRACE**;" syntax.

For more information, see [Query Profiling](#).

The command format is as follows.

```
;trace {on | off} [{text | json}]
```

- **on**: set on SQL trace.

- **off**: set off SQL trace.
- **text**: print out as a general TEXT format. If you omit OUTPUT clause, TEXT format is specified.
- **json**: print out as a JSON format.

#### Note

CSQL interpreter which is run in the standalone mode(use -S option) does not support SQL trace feature.

## Displaying information (;Info)

The **;Info** session command allows you to check information such as schema, triggers, the working environment, locks and statistics.

```
csql> ;info lock
*** Lock Table Dump ***
Lock Escalation at = 100000, Run Deadlock interval = 1
Transaction (index 0, unknown, unknown@unknown|-1)
Isolation COMMITTED READ
State TRAN_ACTIVE
Timeout_period -1
.....
```

## Dumping CSQL execution statistics information(;;Hist)

This command is a CSQL session command for starting to collect the statistics information in CSQL. The information is collected only for the currently connected CSQL after “**;;Hist on**” command is entered. Following options are provided for this session command.

- **on**: Starts collecting statistics information for the current connection.
- **off**: Stops collecting statistics information of server.

This command is executable while the **communication\_histogram** parameter in the **cubrid.conf** file is set to **yes**. You can also view this information by using the **cubrid statdump** utility.

After running “**;;Hist on**”, the execution commands such as **;;dump\_hist** or **;;x** must be entered to output the statistics information. After **;;dump\_hist** or **;;x**, all accumulated data are dumped and initiated.

As a reference, you should use **cubrid statdump** utility to check all queries’ statistics information of a database server.

This example shows the server statistics information for current connection. For information on dumped specific items or **cubrid statdump** command, see [statdump](#).

```

csql> ;set communication_histogram=yes
csql> ;.hist on
csql> SELECT name FROM nation LIMIT 5;
csql> ;.x

### Displaying query execution time (;Time)

The **;Time** session command can be set to display the elapsed time to execute the query. It can be set to **ON** or **OFF**. The current setting is displayed if there is no value specified. The default value is **ON**.

The **SELECT** query includes the time of outputting the fetched records. Therefore, to check the execution time of complete output of all records in the **SELECT** query, use the **--no-pager** option while executing the CSQC interpreter.

```
$ csql -u dba --no-pager demodb
csql> ;time ON
csql> ;time
TIME IS ON
```

### Displaying Server Stored Messages (;SERVER-output)

If this value is set to ON, it will output messages stored in the server's DBMS\_OUTPUT buffer. The default value is OFF. The DBMS\_OUTPUT buffer stores messages through calls to DBMS\_OUTPUT.put\_line() or DBMS\_OUTPUT.put() in PL/CSQL stored procedures/functions. After executing an SQL statement, DBMS\_OUTPUT messages are displayed under the '<DBMS\_OUTPUT>' label. If an error occurs during the execution of a stored procedure/function, DBMS\_OUTPUT messages are displayed after all CSQC's default messages, including error messages, regardless of the execution order, so caution is needed. For example, in the case below, the DBMS\_OUTPUT.put\_line() statement is executed before the RETURN statement that causes a ZERO\_DIVIDE exception, but in the output, the DBMS\_OUTPUT message appears after the error message.

```
csql> ;server-output on
SERVER OUTPUT IS ON
csql>
csql> create or replace function late_message return integer as
csql> begin
csql>     DBMS_OUTPUT.put_line('Hello world');
```

```

csql>      return (1/0);  -- ZERO_DIVIDE exception
csql> end;
Execute OK. (0.024973 sec) Committed. (0.000000 sec)

1 command(s) successfully processed.
csql>
csql> select late_message() from dual;

In line 2, column 23,

ERROR: Stored procedure execute error:
      (line 4, column 13) division by zero

<DBMS_OUTPUT>
====
Hello world

0 command(s) successfully processed.

```

### Displaying a column of result record in one line(;LINE-output)

If this value is set to ON, it makes the record display in several lines by column. The default value is OFF, which makes one record display in one line.

```

csql> ;line-output ON
csql> select * from athlete;

=== <Result of SELECT Command in Line 1> ===

<00001> code      : 10999
        name      : 'Fernandez Jesus'
        gender    : 'M'
        nation_code: 'ESP'
        event     : 'Handball'
<00002> code      : 10998
        name      : 'Fernandez Jaime'
        gender    : 'M'
        nation_code: 'AUS'
        event     : 'Rowing'
...

```

### Displaying query history (;HISTORYlist)

This command displays the list that contains previously executed commands (input) and their history numbers.

```

csql> ;historylist
----< 1 >----
select * from nation;

```

```
----< 2 >----
select * from athlete;
```

### Reading input with the specified history number into the buffer (;HISTORYRead)

You can use **;HISTORYRead** session command to read input with history number in the **;HISTORYList** list into the command buffer. You can enter **;run** or **;xrun** directly because it has the same effect as when you enter SQL statements directly.

```
csql> ;historyread 1
```

### Calling the default editor (;EDIT)

This command calls the specified editor. The default editor is **vi** on Linux **Notepad** on Windows environment. Use **;EDITOR\_Cmd** command to specify a different editor.

#### format / fmt

The **format** or **fmt** option allows you to edit after formatting the SQL statement. Formatter registration uses the **;Formatter\_cmd** session command.

```
csql> ;edit
SELECT * FROM t1

csql> ;edit format
SELECT
*
FROM
t1
```

### Specifying the formatter (;Formatter\_cmd)

This command specifies the formatter to be used with **;EDIT** session command. The user can set it up and use it as shown in the example, and the OS environment variable (CUBRID\_CSQF\_FORMATTER or FORMATTER; CUBRID\_CSQF\_FORMATTER is used if both environment variables are set) can be configured in advance for use.

```
csql> ;formatter_cmd /usr/local/bin/fsqf

$ export CUBRID_CSQF_FORMATTER=/home/cubrid/bin/fsqf
or
$ export FORMATTER=/home/cubrid/bin/fsqf
```

**Note**

The use of Free SQL Formatter is recommended.

Download URL: <https://github.com/CUBRID/fsqlf/releases>

**Specifying the editor (;EDITOR\_Cmd)**

This command specifies the editor to be used with **;EDIT** session command. As shown in the example below, you can specify other editor (ex: emacs) which is installed in the system.

```
csql> ;editor_cmd emacs
csql> ;edit
```

The OS environment variable(CUBRID\_CSQLEditor or EDITOR; CUBRID\_CSQLEditor is used if both environment variables are set) may be registered and used in advance.

```
export CUBRID_CSQLEditor=emacs
or
export EDITOR=emacs
```

**Specifying the single line mode (;Singleline)**

This command sets single line mode to **ON** or **OFF** (default value is **ON**). If you type semi-colon(;) and ENTER key in the single line ON mode, SQL statements are executed. If single line mode is set to **OFF**, multiple SQL statements are retrieved and executed at once with the **;xr** or **;ru** session command. If any value is not specified, current configured value is applied by default.

```
csql> ;singleline off
SINGLE IS OFF
csql> ;singleline
SINGLE IS OFF
```

**Switching csql session(;Connect)**

This is a session command to switch the connection to another user without terminating CSQL. The command format is as follows.

- user: Username to connect
- database: Database name to connect (if omitted, currently connected database)
- host: Hostname to connect to (if omitted, localhost)

```
csql> ;connect public
csql> ;connect dba

csql> ;connect public testdb
csql> ;connect dba demodb

csql> ;connect Peter testdb@192.168.0.1
csql> ;connect public demodb@localhost
```

### Warning

1. When ‘;connect’ session command executes, the current CSQL session connection is disconnect regardless of session transition success or not.
2. When CSQL is in system administrator mode, ‘;connect’ session command cannot be used (When entering CSQL with an csql -u dba --sysadm demodb form command).

## CUBRID SQL

This chapter describes SQL syntax such as data types, functions and operators, data retrieval or table manipulation. You can also find SQL statements used for index, trigger, partition, serial and changing user information.

The main topics covered in this chapter are as follows:

- Writing Rules
  - Identifier: Describes how to write, the identifier, string allowed to be used as a name of a table, index, and column.
  - Reserved words: Lists reserved words in CUBRID. To use a reserved word as an identifier, enclose the identifier by using double quotes, backticks (`), or brackets ([]).
  - Comment
  - Literal: Describes how to write constant values.
- Data types: Describes the data types, the format to store data.
- Data Definition Statements: Describes how to create, alter, drop, and rename a table, an index, a view and a serial.

- Operators and Functions: Describes the operators and functions used for query statements.
- Data Manipulation Statements: Describes the SELECT, INSERT, UPDATE, and DELETE statements.
- Query Optimization: Describes the query optimization by using the index, hint, and the index hint syntax.
- Parallel Query Processing: Describes the parallel execution features for processing large amounts of data.
- Partitioning: Describes how to partition one table into several independent logical units.
- Trigger: Describes how to create, alter, drop, and rename a trigger that is automatically executed in response to certain events.
- Class Inheritance: Describes how to inherit the attribute from the parent to the child table (class).
- Database Administration: Describes about user management, SET and SHOW statements.
- User Schema: Describes a logical collection of objects in a database that is created with users.
- System Catalog: Describes the CUBRID system catalog, the internal information of the CUBRID database.

## Writing Rules

### Identifier

#### Guidelines for Creating Identifiers

Table name, index name, view name, column name, user name etc. are included in identifier. The guidelines for creating identifiers are as follows:

- An identifier must begin with a letter; it must not begin with a number or a symbol.
- It is not case-sensitive.
- **Reserved Words** are not allowed.

```
identifier ::= identifier_letter [ { other_identifier } ; ]
identifier_letter ::= upper_case_letter | lower_case_letter
other_identifier ::= identifier_letter | digit | _ | #
digit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

**upper\_case\_letter** ::= A | B | C | D | E | F | G | H | I | J | K | L | M | N | O |  
**lower\_case\_letter** ::= a | b | c | d | e | f | g | h | i | j | k | l | m | n | o |

## Legal Identifiers

### Beginning with a Letter

An identifier must begin with a letter. All other special characters except operator characters are allowed. The following are examples of legal identifiers.

```
a
a_b
ssn#
this_is_an_example_#
```

### Enclosing in Double Quotes, Square Brackets, or Backtick Symbol

Identifiers or reserved keywords shown as below are not allowed. However, if they are enclosed in double quotes, square brackets, or backtick symbol, they are allowed as an exception. Especially, the double quotations can be used as a symbol enclosing identifiers when the **ansi\_quotes** parameter is set to **yes**. If this value is set to **no** double quotations are used as a symbol enclosing character strings. The following are examples of legal identifiers.

```
"select"
"@lowcost"
"low cost"
"abc" "def"
[position]
```

### Warning

Even though identifiers are enclosed in double quotation marks, square brackets, or backticks, they cannot contain square brackets ([ ]) or dots (.).

- Square brackets are used by default to process reserved words when parsing a query inside.
- Dots are used in Path Expressions and JSON, and they are also used to separate schema names and object names.

The following identifiers are not allowed even though they are enclosed in double quotation marks (" ").

```
"he[["o"
"wor]d"
```

```
"hello[]world"  
"hello.world"
```

### Note

From 10.0 version, if a column name which is a reserved word is used together with a “table name (or alias).”, you don’t need to wrap up a column name with a double quotes.

```
CREATE TABLE tbl ("int" int, "double" double);  
  
SELECT t.int FROM tbl t;
```

In the above SELECT query, “int” is a column name which is used together with “t”.

## Illegal Identifiers

Beginning with special characters or numbers

An identifier starting with a special character or a number is not allowed. As an exception, a underline (\_) and a sharp symbol (#) are allowed for the first character.

```
_a  
#ack  
%nums  
2fer  
88abs
```

An identifier containing a space

An identifier that a space within characters is not allowed.

```
col1 t1
```

An identifier containing operator special characters

An identifier which contains operator special characters (+, -, \*, /, %, ||, !, <, >, =, |, ^, &, ~) is not allowed.

```
col+  
col~  
col& &
```

The maximum length of an identifier name

The following table summarizes the maximum byte length allowable for each identifier name. Note that the unit is byte and the number of characters and the bytes are different by the character set used (for example, the length of one Korean character in UTF-8 is 3 bytes).

| Identifier            | Maximum Bytes |
|-----------------------|---------------|
| Database              | 17            |
| User                  | 31            |
| Table                 | 222           |
| Column                | 254           |
| Index                 | 254           |
| Constraint            | 254           |
| Java Stored Procedure | 254           |
| Trigger               | 222           |
| View                  | 222           |
| Serial                | 222           |

 Note

Prior to version 11.2, the maximum length of table, trigger, and serial names were 254 bytes. Since version 11.2, table, trigger, and serial names contain schema names. Therefore, identifier names cannot exceed 222 bytes except for 31 bytes, which is the length of the owner name, and 1 byte, which is the length of the delimiter (.).

### Note

Automatically created constraint name like a name of primary key(pk\_<table\_name>\_<column\_name>) or foreign key(fk\_<table\_name>\_<column\_name>) also does not allow over the maximum name length of the identifier, 254 bytes.

## Reserved Words

The following keywords are previously reserved as a command, a function name or a type name in CUBRID. You are restricted to use these words for a class name, an attribute name, a variable name. Note that these reserved keywords can be used as an identifier when they are enclosed in double quotes, square brackets, or backtick symbol (`).

|          |            |           |
|----------|------------|-----------|
| ABSOLUTE | ACTION     | ACCESS    |
| ADD      | ADD_MONTHS | AFTER     |
| ALL      | ALLOCATE   | ALTER     |
| AND      | ANY        | ARE       |
| AS       | ASC        | ASSERTION |
| AT       | ATTACH     | ATTRIBUTE |

## Comment

There are 3 types of comments. One is a SQL-style which starts with '--', the other is C++ style starts with '//'. Both regards the entire line starts with the comment symbols is a comment line. The C style starts with '/\*' and ends with '\*/'

The following are examples of comments.

- How to use --

```
-- This is a SQL-style comment.
```

- How to use //

```
// This is a C++ style comment.
```

- How to use /\* \*/

```
/* This is a C-style comment.*/
```

```
/* This is an example to use two lines  
as comment by using the C-style. */
```

## Literal

This section describes how to write a literal value in CUBRID.

### Number

There are two ways of writing a number; how to write an exact value and how to write an approximate value.

- An exact number is written as a serial numbers and a dot (.); this input literal is translated as an INT, BIGINT or NUMERIC typed value based on its range.

```
10, 123456789012, 1234234324234.23
```

- An approximate number is written as a serial numbers, a dot (.) and E (scientific notation, multiples of 10); this input literal is translated as a DOUBLE typed value.

```
1.2345E15, 12345E5
```

- ◦ or - symbol can be written in front of a number, and this can be written between E which indicates multiples of 10 and a number.

```
+10.2345, -1.2345E-15
```

### Date/Time

For representing data and time, there are DATE, TIME, DATETIME and TIMESTAMP types; these values can be represented as adding date, time, datetime and timestamp literals (case-insensitive) in front of their strings.

If you use date/time literals, you don't need to use converting functions such as `TO_DATE()`, `TO_TIME()`, `TO_DATETIME()` and `TO_TIMESTAMP()`. However, the writing order of a string which indicates date or time.

- The date literal only allows 'YYYY-MM-DD' or 'MM/DD/YYYY'.

```
date'1974-12-31', date'12/31/1974'
```

- The time literal only allows 'HH:MI:SS', 'HH:MI:SS AM' or 'HH:MI:SS PM'.

```
time'12:13:25', time'12:13:25 AM', time'12:13:25 PM'
```

- The date/time literal used in DATETIME type allows 'YYYY-MM-DD HH:MI:SS[msec AM|PM]' or 'MM/DD/YYYY HH:MI:SS[msec AM|PM]'. msec means milliseconds, which can be written until 3 digits.

```
datetime'1974-12-31 12:13:25.123 AM', datetime'12/31/1974  
12:13:25.123 AM'
```

- The date/time literal used in TIMESTAMP type allows 'YYYY-MM-DD HH:MI:SS[ AM|PM]' or 'MM/DD/YYYY HH:MI:SS[ AM|PM]'.

```
timestamp'1974-12-31 12:13:25 AM', timestamp'12/31/1974 12:13:25 AM'
```

- The literal of date/time with timezone type has the same format as the above, and add an offset or a region name which indicates a timezone information.
  - Add datetimetz, datetimeltz, timestamptz or timestampltz literal at the front of a string to represent each type's value.

```
datetimetz'10/15/1986 5:45:15.135 am +02:30:20';  
datetimetz'10/15/1986 5:45:15.135 am +02:30';  
datetimetz'10/15/1986 5:45:15.135 am +02';  
datetimeltz'10/15/1986 5:45:15.135 am Europe/Bucharest'  
datetimetz'2001-10-11 02:03:04 AM Europe/Bucharest EEST';  
timestampltz'10/15/1986 5:45:15 am Europe/Bucharest'  
timestamptz'10/15/1986 5:45:15 am Europe/Bucharest'
```

- The literal at the front of a string can be replaced with "<date/time type> WITH TIMEZONE" or <date/time type> WITH LOCAL TIME ZONE.

⋮

DATETIME WITH TIMEZONE = datetimetz DATETIME WITH LOCAL TIMEZONE = datetimeltz  
TIMESTAMP WITH TIMEZONE = timestamptz TIMESTAMP WITH LOCAL TIMEZONE =  
timestampltz

```
DATETIME WITH TIME ZONE'10/15/1986 5:45:15.135 am +02';  
DATETIME WITH LOCAL TIME ZONE'10/15/1986 5:45:15.135 am +02';
```

**Note**

- <date/time type> WITH LOCAL TIME ZONE: internally stores UTC time; it is converted as a local (current session) timezone when it is output.
- <date/time type> WITH TIME ZONE: internally stores UTC time and timezone information (decided by a user or a session timezone) when this value is created.

## Bit String

Bit string uses two formats of binary format and hexadecimal format.

Binary format is written as adding B or 0b in front of a number; the input value is a string with 0 and 1 after B, and a number with 0 and 1 after 0b.

```
B'10100000'  
0b10100000
```

Binary number is written by 8 digits; if the input digits are not divided into 8, this value is saved as 0s are attached. For example, B'1' is saved as B'10000000'.

Hexadecimal format is written as adding X or 0x in front of a number; the input value is a string with hexadecimal after X, and a number with hexadecimal after 0x.

```
X'a0'  
0xA0
```

Hexadecimal number is written by 2 digits; if the input digits are not divided into 2, this value is saved as 0s are attached. For example, X'a' is saved as X'a0'.

## Character String

Character string is written as wrapped in single quotes.

- If you want to include a single quote in a string, input it twice serially.

```
SELECT 'You''re welcome.';
```

- An escape using a backslash can be used if you set **no\_backslash\_escapes** in **cubrid.conf** as no. But this default value is yes.

For details, see [Escape Special Characters](#).

- Charset introducer can be located in front of a string, and COLLATE modifier can be located after a string.

For details, see [Charset Introducer](#).

## Collection

In collection types, there are SET, MULTiset and LIST; their values are written as elements are wrapped in braces ({, }).

```
{'c','c','c','b','b','a'}
```

For details, see [Collection Types](#).

## NULL

NULL value means there is no data. NULL is case-insensitive, so it also can be written as null. Please note that NULL value is not 0 in a number type or an empty string ("") in a string type.

# Data Types

## Data Types

### Numeric Types

CUBRID supports the following numeric data types to store integers or real numbers.

| Type                   | Bytes | Min            | Max            | Exact/approx. |
|------------------------|-------|----------------|----------------|---------------|
| <b>SHORT, SMALLINT</b> | 2     | -32,768        | 32,767         | exact numeric |
| <b>INTEGER, INT</b>    | 4     | -2,147,483,648 | +2,147,483,647 | exact numeric |
| <b>BIGINT</b>          | 8     |                |                | exact numeric |

| Type                            | Bytes | Min                                                    | Max                                                    | Exact/approx.                           |
|---------------------------------|-------|--------------------------------------------------------|--------------------------------------------------------|-----------------------------------------|
|                                 |       | -9,223,372,036,854,775,808                             | +9,223,372,036,854,775,807                             |                                         |

Numeric data types are divided into exact and approximate types. Exact numeric data types (**SMALLINT**, **INT**, **BIGINT**, **NUMERIC**) are used for numbers whose values must be precise and consistent, such as the numbers used in financial accounting. Note that even when the literal values are equal, approximate numeric data types (**FLOAT**, **DOUBLE**) can be interpreted differently depending on the system.

CUBRID does not support the UNSIGNED type for numeric data types.

On the above table, two types on the same cell are identical types but it always prints the above type name when you execute **SHOW COLUMNS** statement. For example, you can use both **SHORT** and **SMALLINT** when you create a table, but it prints "SHORT" when you execute **SHOW COLUMNS** statement.

### Precision and Scale

The precision of numeric data types is defined as the number of significant figures. This applies to both exact and approximate numeric data types.

The scale represents the number of digits following the decimal point. It is significant only in exact numeric data types. Attributes declared as exact numeric data types always have fixed precision and scale. **NUMERIC** (or **DECIMAL**) data type always has at

least one-digit precision, and the scale should be between 0 and the precision declared. Scale cannot be greater than precision. For **INTEGER**, **SMALLINT**, or **BIGINT** data types, the scale is 0 (i.e. no digits following the decimal point), and the precision is fixed by the system.

## Numeric Literals

Special signs can be used to input numeric values. The plus sign (+) and minus sign (-) are used to represent positive and negative numbers respectively. You can also use scientific notations. In addition, you can use currency signs specified in the system to represent currency values. The maximum precision that can be expressed by a numeric literal is 255.

## Numeric Coercions

All numeric data type values can be compared with each other. To do this, automatic coercion to the common numeric data type is performed. For explicit coercion, use the **CAST** operator. When different data types are sorted or calculated in a numerical expression, the system performs automatic coercion. For example, when adding a **FLOAT** attribute value to an **INTEGER** attribute value, the system automatically coerces the **INTEGER** value to the most approximate **FLOAT** value before it performs the addition operation.

The following is an example to print out the value of **FLOAT** type when adding the value of **INTEGER** type to the value of **FLOAT** type.

```
CREATE TABLE tbl (a INT, b FLOAT);  
INSERT INTO tbl VALUES (10, 5.5);  
SELECT a + b FROM tbl;
```

```
1.550000e+01
```

This is an example of overflow error occurred when adding two integer values, the following can be an **INTEGER** type value for the result.

```
SELECT 100000000*1000000;
```

```
ERROR: Data overflow on data type integer.
```

In the above case, if you specify one of two integers as the **BIGINT** type, it will determine the result value into the **BIGINT** type, and then output the normal result.

```
SELECT CAST(100000000 AS BIGINT)*1000000;
```

```
10000000000000000
```

#### Warning

Earlier version than CUBRID 2008 R2.0, the input constant value exceeds **INTEGER**, it is handled as **NUMERIC**. However, 2008 R2.0 or later versions, it is handled as **BIGINT**.

## INT/INTEGER

The **INTEGER** data type is used to represent integers. The value range is available is from -2,147,483,648 to +2,147,483,647. **SMALLINT** is used for small integers, and **BIGINT** is used for big integers.

- If a real number is entered for an **INT** type, the number is rounded to zero decimal place and the integer value is stored.
- **INTEGER** and **INT** are used interchangeably.
- **DEFAULT** constraint can be specified in a column of this type.

```
If you specify 8934 as INTEGER, 8934 is stored.
If you specify 7823467 as INTEGER, 7823467 is stored.
If you specify 89.8 to an INTEGER, 90 is stored (all digits after
the decimal point are rounded).
If you specify 3458901122 as INTEGER, an error occurs (if the
allowable limit is exceeded).
```

## SHORT/SMALLINT

The **SMALLINT** data type is used to represent a small integer type. The value range is available is from -32,768 to +32,767.

- If a real number is entered for an **SMALLINT** type, the number is rounded to zero decimal place and the integer value is stored.
- **SMALLINT** and **SHORT** are used interchangeably.
- **DEFAULT** constraint can be specified in a column of this type.

If you specify 8934 **as** SMALLINT, 8934 **is** stored.  
 If you specify 34.5 **as** SMALLINT, 35 **is** stored (all digits after the decimal point are rounded).  
 If you specify 23467 **as** SMALLINT, 23467 **is** stored.  
 If you specify 89354 **as** SMALLINT, an error occurs (if the allowable limit **is** exceeded).

## BIGINT

The **BIGINT** data type is used to represent big integers. The value range is available from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.

- If a real number is entered for a **BIG** type, the number is rounded to zero decimal place and the integer value is stored.
- Based on the precision and the range of representation, the following order is applied.

**SMALLINT** ??\*\*INTEGER\*\* ??\*\*BIGINT\*\* ??\*\*NUMERIC\*\*

- **DEFAULT** constraint can be specified in a column of this type.

If you specify 8934 **as** BIGINT, 8934 **is** stored.  
 If you specify 89.1 **as** BIGINT, 89 **is** stored.  
 If you specify 89.8 **as** BIGINT, 90 **is** stored (all digits after the decimal point are rounded).  
 If you specify 3458901122 **as** BIGINT, 3458901122 **is** stored.

## NUMERIC/DECIMAL

**NUMERIC** or **DECIMAL** data types are used to represent fixed-point numbers. As an option, the total number of digits (precision) and the number of digits after the decimal point (scale) can be specified for definition. The minimum value for the precision  $p$  is 1. When the precision  $p$  is omitted, you cannot enter data whose integer part exceeds 15 digits because the default value is 15. If the scale  $s$  is omitted, an integer rounded to the first digit after the decimal point is returned because the default value is 0.

**NUMERIC [(p[, s])]**

- Precision must be equal to or greater than scale.
- Precision must be equal to or greater than the number of integer digits + scale.
- **NUMERIC**, **DECIMAL**, and **DEC** are used interchangeably.

- To check how the precision and the scale became changed when you operate with **NUMERIC** typed values, see [Arithmetic Operations and Type Casting of Numeric Data Types](#).
- **DEFAULT** constraint can be specified in a column of this type.

If you specify `12345.6789 as NUMERIC`, `12346` is stored (it rounds to the first place after the decimal point since `0` is the default value of scale).

If you specify `12345.6789 as NUMERIC(4)`, an error occurs (precision must be equal to or greater than the number of integer digits).

If you declare `NUMERIC(3,4)`, an error occurs (precision must be equal to or greater than the scale).

If you specify `0.12345678 as NUMERIC(4,4)`, `.1235` is stored (it rounds to the fifth place after the decimal point).

If you specify `-0.123456789 as NUMERIC(4,4)`, `-.1235` is stored (it rounds to the fifth place after decimal point and then prefixes a minus (-) sign).

## FLOAT/REAL

The **FLOAT** (or **REAL**) data type represents floating point numbers.

The ranges of values that can be described as normalized values are from  $-3.402823466E+38$  to  $-1.175494351E-38$ , 0, and from  $+1.175494351E-38$  to  $+3.402823466E+38$ , whereas the values other than normalized values, which are closer to 0, are described as de-normalized values. It conforms to the ANSI/IEEE 754-1985 standard.

The minimum value for the precision  $p$  is 1 and the maximum value is 38. When the precision  $p$  is omitted or it is specified as seven or less, it is represented as single precision (in 7 significant figures). If the precision  $p$  is greater than 7 and equal to or less than 38, it is represented as double precision (in 15 significant figures) and it is converted into **DOUBLE** data type.

**FLOAT** data types must not be used if you want to store a precise value that exceeds the number of significant figures, as they only store the approximate value of any input value over 7 significant figures.

### FLOAT[(p)]

- **FLOAT** is in 7 significant figures.
- Extra cautions are required when comparing data because the **FLOAT** type stores approximate numeric.
- **FLOAT** and **REAL** are used interchangeably.
- **DEFAULT** constraint can be specified in a column of this type.

If you specify `16777217 as FLOAT`, `16777216` is stored and `1.677722e+07` is displayed (if precision is omitted, 8-th digit is rounded up because it is represented as 7 significant figures).  
 If you specify `16777217 as FLOAT(5)`, `16777216` is stored and `1.677722e+07` is displayed (if precision is in seven or less, 8-th digit is rounded up because it is represented as 7 significant figures).  
 If you specify `16777.217 as FLOAT(5)`, `16777.216` is stored and `1.677722e+04` is displayed (if precision is in seven or less, 8-th digit is rounded up because it is represented as 7 significant figures).  
 If you specify `16777.217 as FLOAT(10)`, `16777.217` is stored and `1.677721700000000e+04` is displayed (if precision is greater than 7 and less than or equal to 38, zeroes are added because it is represented as 15 significant figures).

## DOUBLE/DOUBLE PRECISION

The **DOUBLE** data type is used to represent floating point numbers.

The ranges of values that can be described as normalized values are from `-1.7976931348623157E+308` to `-2.2250738585072014E-308`, 0, and from `2.2250738585072014E-308` to `1.7976931348623157E+308`, whereas the values other than normalized values, which are closer to 0, are described as de-normalized values. It conforms to the ANSI/IEEE 754-1985 standard.

The precision *p* is not specified. The data specified as this data type is represented as double precision (in 15 significant figures).

**DOUBLE** data types must not be used if you want to store a precise value that exceeds the number of significant figures, as they only store the approximate value of any input value over 15 significant figures.

- **DOUBLE** is in 15 significant figures.
- Extra caution is required when comparing data because the **DOUBLE** type stores approximate numeric.
- **DOUBLE** and **DOUBLE PRECISION** are used interchangeably.
- **DEFAULT** constraint can be specified in a column of this type.

If you specify `1234.56789 as DOUBLE`, `1234.56789` is stored and `1.234567890000000e+03` is displayed.  
 If you specify `9007199254740993 as DOUBLE`, `9007199254740992` is stored and `9.007199254740992e+15` is displayed.

### Note

MONETARY type is deprecated, and it is not recommended anymore.

## Date/Time Types

Date/time data types are used to represent the date or time (or both together). CUBRID supports the following data types:

| Type             | bytes | Min.                                                   | Max.                                                   | Note                                                                |
|------------------|-------|--------------------------------------------------------|--------------------------------------------------------|---------------------------------------------------------------------|
| <b>DATE</b>      | 4     | 0001-01-01                                             | 9999-12-31                                             | As an exception, DATE '0000-00-00' format is allowed.               |
| <b>TIME</b>      | 4     | 00:00:00                                               | 23:59:59                                               |                                                                     |
| <b>TIMESTAMP</b> | 4     | 1970-01-01 00:00:01 (GMT)<br>1970-01-01 09:00:01 (KST) | 2038-01-19 03:14:07 (GMT)<br>2038-01-19 12:14:07 (KST) | As an exception, TIMESTAMP '0000-00-00 00:00:00' format is allowed. |
| <b>DATETIME</b>  | 8     | 0001-01-01 00:00:0.000                                 | 9999-12-31 23:59:59.999                                | As an exception, DATETIME '0000-00-00 00:00:00' format is allowed.  |

| Type                | bytes | Min.                                                    | Max.                                                   | Note                                                                                                                    |
|---------------------|-------|---------------------------------------------------------|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>TIMESTAMPLTZ</b> | 4     | Depends on<br>timezone<br>1970-01-01<br>00:00:01 (GMT)  | Depends on<br>timezone<br>2038-01-19<br>03:14:07 (GMT) | Timestamp with local<br>timezone. As an exception,<br>TIMESTAMPLTZ'0<br>000-00-00<br>00:00:00'<br>format is<br>allowed. |
| <b>TIMESTAMPPTZ</b> | 8     | Depends on<br>timezone<br>1970-01-01<br>00:00:01 (GMT)  | Depends on<br>timezone<br>2038-01-19<br>03:14:07 (GMT) | Timestamp with timezone.<br>As an exception,<br>TIMESTAMPPTZ<br>'0000-00-00<br>00:00:00'<br>format is<br>allowed.       |
| <b>DATETIMELTZ</b>  | 8     | Depends on<br>timezone<br>0001-01-01<br>00:00:0.000 UTC | Depends on<br>timezone<br>9999-12-31<br>23:59:59.999   | Datetime with local<br>timezone. As an exception,<br>DATETIMELTZ<br>'0000-00-00<br>00:00:00'<br>format is<br>allowed.   |
| <b>DATETIMEPTZ</b>  | 12    | Depends on<br>timezone<br>0001-01-01<br>00:00:0.000 UTC | Depends on<br>timezone<br>9999-12-31<br>23:59:59.999   | Datetime with<br>timezone. As an exception,<br>DATETIMEPTZ<br>'0000-00-00<br>00:00:00'                                  |

| Type | bytes | Min. | Max. | Note               |
|------|-------|------|------|--------------------|
|      |       |      |      | format is allowed. |

## Range and Resolution

- By default, the range of a time value is represented by the 24-hour system. Dates follow the Gregorian calendar. An error occurs if a value that does not meet these two constraints is entered as a date or time.
- The range of year in **DATE** is 0001 - 9999 AD.
- From the CUBRID 2008 R3.0 version, if time value is represented with two-digit numbers, a number from 00 to 69 is converted into a number from 2000 to 2069; a number from 70 to 99 is converted into a number from 1970 to 1999. In earlier than CUBRID 2008 R3.0 version, if time value is represented with two-digit numbers, a number from 01 to 99 is converted into a number from 0001 to 0099.
- The range of **TIMESTAMP** is between 1970-01-01 00:00:01 and 2038-01-19 03 03:14:07 (GMT). For KST (GMT+9), values from 1970-01-01 09:00:01 to 2038-01-19 12:14:07 can be stored. timestamp'1970-01-01 00:00:00' (GMT) is the same as timestamp'0000-00-00 00:00:00'.
- The range of **TIMESTAMPTZ**, **TIMESTAMPTZ** varies with timezone, but the value converted to UTC should be between 1970-01-01 00:00:01 and 2038-01-19 03 03:14:07.
- The range of **DATETIMELTZ**, **DATETIMELTZ** varies with timezone, but the value converted to UTC should be between 0001-01-01 00:00:0.000 and 9999-12-31 23:59:59.999. A value stored in database may no longer be valid if session timezone changes.
- The results of date, time and timestamp operations may depend on the rounding mode. In these cases, for Time and Timestamp, the most approximate second is used as the minimum resolution; for Date, the most approximate date is used as the minimum resolution.

## Coercions

The **Date** / **Time** types can be cast explicitly using the **CAST** operator only when they have the same field. For implicit coercion, see [Implicit Type Conversion](#). The following table shows types that allows explicit coercions. For implicit coercion, see [Arithmetic Operations and Type Casting of DATE/TIME Data Types](#).

### Explicit Coercions

| FROM \ TO | DATE | TIME | DATETIME | TIMESTAMP |
|-----------|------|------|----------|-----------|
| DATE      | -    | X    | O        | O         |
| TIME      | X    | -    | X        | X         |
| DATETIME  | O    | O    | -        | O         |
| TIMESTAMP | O    | O    | O        | -         |

In general, zero is not allowed in **DATE**, **DATETIME**, and **TIMESTAMP** types. However, if both date and time values are 0, it is allowed as an exception. This is useful in terms that this value can be used if an index exists upon query execution of a column corresponding to the type.

- Some functions in which the **DATE**, **DATETIME**, and **TIMESTAMP** types are specified as an argument return different value based on the **return\_null\_on\_function\_errors** system parameter if every input argument value for date and time is 0. If **return\_null\_on\_function\_errors** is yes, **NULL** is returned; if no, an error is returned. The default value is **no**.
- The functions that return **DATE**, **DATETIME**, and **TIMESTAMP** types can return a value of 0 for date and time. However, these values cannot be stored in Date objects in Java applications. Therefore, it will be processed with one of the following based on the configuration of `zeroDateTimeBehavior`, the connection URL property: being handled as an exception, returning **NULL**, or returning a minimum value (see [Configuration Connection](#)).
- If the **intl\_date\_lang** system is configured, input string of `TO_DATE()`, `TO_TIME()`, `TO_DATETIME()`, `TO_TIMESTAMP()`, `DATE_FORMAT()`, `TIME_FORMAT()`, `TO_CHAR()` and `STR_TO_DATE()` functions follows the corresponding locale date format. For details, see [Statement/Type-Related Parameters](#) and the description of each function.
- Types with timezone follow the same conversion rules as their parent type.

#### Note

For literals of date/time types and date/time types with timezone, see [Date/Time](#).

## DATE

The **DATE** data type is used to represent the year (yyyy), month (mm) and day (dd). Supported range is “01/01/0001” to “12/31/9999.” The year can be omitted. If it is, the year value of the current system is specified automatically. The specified input/output types are as follows:

```
date 'mm/dd[/yyyy]'
date '[yyyy-]mm-dd'
```

- All fields must be entered as integer.
- The date value is displayed in the type of ‘MM/DD/YYYY’ in CSQL, and it is displayed in the type of ‘YYYY-MM-DD’ in JDBC application programs and the CUBRID Manager.
- You can store the date value of the system in the **DATE** type by using the `SYS_DATE` (or `SYSDATE`, `CURRENT_DATE`).
- The `TO_DATE()` function is used to convert a character string type into a **DATE** type.
- 0 is not allowed to input in year, month, and day; however, ‘0000-00-00’, which every digit consisting of year, month, and day is 0, is allowed as an exception.
- If the year is two digits and the value is greater than or equal to 70, it is recognized as the 1900s, otherwise it is recognized as the 2000s.
- **DEFAULT** constraint can be specified in a column of this type.

```
DATE'2008-10-31' is displayed as '10/31/2008'.
DATE'10/31' is displayed as '10/31/2011'(if a value for year is
omitted, the current year is automatically specified).
DATE'00-10-31' is displayed as '10/31/2000'.
DATE'0000-10-31' is displayed as an error (a year value should be at
least 1).
DATE'70-10-31' is displayed as '10/31/1970'.
DATE'0070-10-31' is displayed as '10/31/0070'.
```

## TIME

The **TIME** data type is used to represent the hour (hh), minute (mm) and second (ss). Supported range is “00:00:00” to “23:59:59.” Second can be omitted; if it is, 0 seconds is specified. Both 12-hour and 24-hour notations are allowed as an input format. The input format of **TIME** is as follows:

```
time 'hh:mi[:ss] [am | pm]'
```

- All items must be entered as integer.

- AM/PM time notation is used to display time in the CSQL; while the 24-hour notation is used in the CUBRID Manager.
- AM/PM can be specified in the 24-hour notation. An error occurs if the time specified does not follow the AM/PM format.
- Every time value is stored in the 24-hour notation.
- You can store the time value of the system in the **TIME** type by using the `SYS_TIME` (or `SYSTIME`, `CURRENT_TIME`).
- The `TO_TIME()` function is used to return a character string type into a TIME type.
- **DEFAULT** constraint can be specified in a column of this type.

```
TIME'00:00:00' is outputted as '12:00:00 AM'.
TIME'1:15' is regarded as '01:15:00 AM'.
TIME'13:15:45' is regarded as '01:15:45 PM'.
TIME'13:15:45 pm' is stored normally.
TIME'13:15:45 am' is an error (an input value does not match the AM/
PM format).
```

## TIMESTAMP

The **TIMESTAMP** data type is used to represent a data value in which the date (year, month, date) and time (hour, minute, second) are combined. The range of representable value is between GMT '1970-01-01 00:00:01' and '2038-01-19 03:14:07'. The **DATETIME** type can be used if the value is out of range or data in milliseconds is stored. The input format of **TIMESTAMP** is as follows:

```
timestamp'hh:mi[:ss] [am|pm] mm/dd[/yyyy]'
timestamp'hh:mi[:ss] [am|pm] [yyyy-]mm-dd'

timestamp'mm/dd[/yyyy] hh:mi[:ss] [am|pm]'
timestamp'[yyyy-]mm-dd hh:mi[:ss] [am|pm]'
```

- All fields must be entered in integer format.
- If the year is omitted, the current year is specified by default. If the time value (hour/minute/second) is omitted, 12:00:00 AM is specified.
- You can store the timestamp value of the system in the **TIMESTAMP** type by using the `SYS_TIMESTAMP` (or `SYSTIMESTAMP`, `CURRENT_TIMESTAMP`).
- The `TIMESTAMP()` or `TO_TIMESTAMP()` function is used to cast a character string type into a **TIMESTAMP** type.

- 0 is not allowed to input in year, month, and day; however, '0000-00-00 00:00:00', which every digit consisting of year, month, day, hour, minute, and second is 0, is allowed as an exception. GMT timestamp'1970-01-01 12:00:00 AM' or KST timestamp'1970-01-01 09:00:00 AM' is translated into timestamp'0000-00-00 00:00:00'.
- **DEFAULT** constraint can be specified in a column of this type.

```

TIMESTAMP'10/31' is outputted as '12:00:00 AM 10/31/2011' (if the
value for year/time is omitted, a default value is outputted ).
TIMESTAMP'10/31/2008' is outputted as '12:00:00 AM 10/31/2008' (if
the value for time is omitted, a default value is outputted ).
TIMESTAMP'13:15:45 10/31/2008' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'01:15:45 PM 2008-10-31' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'13:15:45 2008-10-31' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'10/31/2008 01:15:45 PM' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'10/31/2008 13:15:45' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'2008-10-31 01:15:45 PM' is outputted as '01:15:45 PM
10/31/2008'.
TIMESTAMP'2008-10-31 13:15:45' is outputted as '01:15:45 PM
10/31/2008'.
An error occurs on TIMESTAMP '2099-10-31 01:15:45 PM' (out of range
to represent TIMESTAMP).

```

## DATETIME

The **DATETIME** data type is used to represent a data value in which the data (year, month, date) and time (hour, minute, second) are combined. The range of representable value is between 0001-01-01 00:00:00.000 and 9999-12-31 23:59:59.999 (GMT). The input format of **TIMESTAMP** is as follows:

```

datetime'hh:mi[:ss[:msec]] [am|pm] mm/dd[/yyyy]'
datetime'hh:mi[:ss[:msec]] [am|pm] [yyyy-]mm-dd'
datetime'mm/dd[/yyyy] hh:mi[:ss[:ff]] [am|pm]'
datetime'[yyyy-]mm-dd hh:mi[:ss[:ff]] [am|pm]'

```

- All fields must be entered as integer.
- If you year is omitted, the current year is specified by default. If the value (hour, minute/second) is omitted, 12:00:00.000 AM is specified.

- You can store the timestamp value of the system in the **DATETIME** type by using the `SYS_DATETIME` (or `SYSDATETIME`, `CURRENT_DATETIME`, `CURRENT_DATETIME()`, `NOW()`) function.
- The `TO_DATETIME()` function is used to convert a string type into a **DATETIME** type.
- 0 is not allowed to input in year, month, and day; however, '0000-00-00 00:00:00', which every digit consisting of year, month, day, hour, minute, and second is 0, is allowed as an exception.
- **DEFAULT** constraint can be specified in a column of this type.

```
DATETIME'10/31' is outputted as '12:00:00.000 AM 10/31/2011' (if the
value for year/time is omitted, a default value is outputted).
DATETIME'10/31/2008' is outputted as '12:00:00.000 AM 10/31/2008'.
DATETIME'13:15:45 10/31/2008' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'01:15:45 PM 2008-10-31' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'13:15:45 2008-10-31' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'10/31/2008 01:15:45 PM' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'10/31/2008 13:15:45' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'2008-10-31 01:15:45 PM' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'2008-10-31 13:15:45' is outputted as '01:15:45.000 PM
10/31/2008'.
DATETIME'2099-10-31 01:15:45 PM' is outputted as '01:15:45.000 PM
10/31/2099'.
```

## CASTing a String to Date/Time Type

### Recommended Format for Strings in Date/Time Type

When you casting a string to Date/Time type by using the `CAST()` function, it is recommended to write the string in the following format: Note that date/time string formats used in the `CAST()` function are not affected by locale which is specified by creating DB.

Also, in `TO_DATE()`, `TO_TIME()`, `TO_DATETIME()`, `TO_TIMESTAMP()` functions, when date/time format is omitted, write the date/time string in the following format.

- **DATE** Type

```
YYYY-MM-DD
MM/DD/YYYY
```

- **TIME** Type

```
HH:MI:SS [AM|PM]
```

- **DATETIME** Type

```
YYYY-MM-DD HH:MI:SS[.msec] [AM|PM]
HH:MI:SS[.msec] [AM|PM] YYYY-MM-DD

MM/DD/YYYY HH:MI:SS[.msec] [AM|PM]
HH:MI:SS[.msec] [AM|PM] MM/DD/YYYY
```

- **TIMESTAMP** Type

```
YYYY-MM-DD HH:MI:SS [AM|PM]
HH:MI:SS [AM|PM] YYYY-MM-DD

MM/DD/YYYY HH:MI:SS [AM|PM]
HH:MI:SS [AM|PM] MM/DD/YYYY
```

## Available Format for Strings in Date/Time Type

`CAST()` function allows the below format for date/time strings.

### Available DATE String Format

```
[year sep] month sep day
```

- 2011-04-20: April 20th, 2011
- 04-20: April 20th of this year

If a separator (*sep*) is a slash (/), strings are recognized in the following order:

```
month/day[/year]
```

- 04/20/2011: April 20th, 2011
- 04/20: April 20th of this year

If you do not use a separator (*sep*), strings are recognized in the following format. It is allowed to use 1, 2, and 4 digits for years and 1 and 2 digits for months. For day, you should always enter 2 digits.

```

YYYYMMDD
YYMMDD
YMMDD
MMDD
MDD

```

- 20110420: April 20th, 2011
- 110420: April 20th, 2011
- 420: April 20th of this year

### Available TIME String Format

```
[hour]:min[:[sec]][.[msec]] [am|pm]
```

- 09:10:15.359 am: 9 hours 10 minutes 15 seconds AM (0.359 seconds will be truncated)
- 09:10:15: 9 hours 10 minutes 15 seconds AM
- 09:10: 9 hours 10 minutes AM
- :10: 12 hours 10 minutes AM

```
[[[[[Y]Y]Y]Y]M]MDD]HHMISS[.[msec]] [am|pm]
```

- 20110420091015.359 am: 9 hours 10 minutes 15 seconds AM
- 0420091015: 9 hours 10 minutes 15 seconds AM

```
[H]HMMSS[.[msec]] [am|pm]
```

- 091015.359 am: 9 hours 10 minutes 15 seconds AM
- 91015: 9 hours 10 minutes 15 seconds AM

```
[M]MSS[.[msec]] [am|pm]
```

- 1015.359 am: 12 hours 10 minutes 15 seconds AM
- 1015: 12 hours 10 minutes 15 seconds AM

```
[S]S[.msec]] [am|pm]
```

- 15.359 am: 12 hours 15 seconds AM
- 15: 12 hours 15 seconds AM

#### Note

: The [H]H format was allowed in CUBRID 2008 R3.1 and the earlier versions. That is, the string '10' was converted to **TIME** '10:00:00' in the R3.1 and the earlier versions, and will be converted to **TIME** '00:00:10' in version R4.0 and later.

### Available DATETIME String Format

```
[year sep] month sep day [sep] [sep] hour [sep min[sep sec[.msec]]]
```

- 04-20 09: April 20th of this year, 9 hours AM

```
month/day[/year] [sep] hour [sep min [sep sec[.msec]]]
```

- 04/20 09: April 20th of this year, 9 hours AM

```
year sep month sep day sep hour [sep min[sep sec[.msec]]]
```

- 2011-04-20 09: April 20th, 2011, 9 hours AM

```
month/day/year sep hour [sep min[sep sec [.[msec]]]
```

- 04/20/2011 09: April 20th, 2011, 9 hours AM

```
YYMMDDH (It is allowed only when time format is one digit.)
```

- 1104209: April 20th, 2011, 9 hours AM

```
YYMMDDHHMI[SS[.msec]]
```

- 1104200910.359: April 20th, 2011, 9 hours 10 minutes AM (0.359 seconds will be truncated)
- 110420091000.359: April 20th, 2011, 9 hours 10 minutes 0.359 seconds AM

```
YYYYMMDDHHMISS[.msec]
```

- 201104200910.359: November 4th, 2020 8 hours 9 minutes 10.359 seconds PM
- 20110420091000.359: April 20th, 2011, 9 hours 10 minutes 0.359 seconds AM

### Available Time-Date String Format

```
[hour]:min[:sec[.msec]] [am|pm] [year-]month-day
```

- 09:10:15.359 am 2011-04-20: April 20th, 2011, 9 hours 10 minutes 15.359 seconds AM
- :10 04-20: April 20th of this year, 12 hours 10 minutes AM

```
[hour]:min[:sec[.msec]] [am|pm] month/day[/[year]]
```

- 09:10:15.359 am 04/20/2011: April 20th, 2011, 9 hours 10 minutes 15.359 seconds AM
- :10 04/20: April 20th of this year, 12 hours 10 minutes AM

```
hour[:min[:sec[.msec]]] [am|pm] [year-]month-day
```

- 09:10:15.359 am 04-20: April 20th of this year, 9 hours 10 minutes 15.359 seconds AM
- 09 04-20: April 20th of this year, 9 hours AM

```
hour[:min[:sec[.msec]]] [am|pm] month/day[/[year]]
```

- 09:10:15.359 am 04/20: April 20th of this year, 9 hours 10 minutes, 15.359 seconds AM
- 09 04/20: April 20th of this year, 9 hours AM

### Rules

*msec* is a series of numbers representing milliseconds. The numbers after the fourth digit will be ignored. The rules for the separator string are as follows:

- You should always use one colon (:) as a separator for the **TIME** separator.
- **DATE** and **DATETIME** strings can be represented as a series of numbers without the separator sep), and non-alphanumeric characters can be used as separators. The **DATETIME** string can be divided into Time and Date with a space.
- Separators should be identical in the input string.
- For the Time-Date string, you can only use colon (:) for a Time separator and hyphen (-) or slash (/) for a Date separator. If you use a hyphen when entering date, you should enter like yyyy-mm-dd; in case of a slash, enter like mm/dd/yyyy.

The following rules will be applied in the part of date.

- You can omit the year as long as the syntax allows it.
- If you enter the year as two digits, it represents the range from 1970-2069. That is, if YY<70, it is treated as 2000+YY; if YY>=70, it is treated as 1900+YY. If you enter one, three or four digit numbers for the year, the numbers will be represented as they are.
- A space before and after a string and the string next to the space are ignored. The am/pm identifier for the **DATETIME** and **TIME** strings can be recognized as part of TIME value, but are not recognized as the am/pm identifier if non-space characters are added to it.

The **TIMESTAMP** type of CUBRID consists of **DATE** type and **TIME** type, and **DATETIME** type consists of **DATE** type and **TIME** type with milliseconds being added to them. Input strings can include Date (**DATE** string), Time (**TIME** string), or both (**DATETIME** strings). You can convert a string including a specific type of data to another type, and the following rules will be applied for the conversion.

- If you convert the **DATE** string to the **DATETIME** type, the time value will be '00:00:00.'
- If you convert the **TIME** string to the **DATETIME** type, colon (:) is recognized as a date separator, so that the **TIME** string can be recognized as a date string and the time value will be '00:00:00.'
- If you convert the **DATETIME** string to the **DATE** type, the time part will be ignored from the result but the time input value format should be valid.

- You can convert the **DATETIME** string to the **TIME** type, and you must follow the following rules.
  - The date and time in the string must be divided by at least one blank.
  - The date part of the result value is ignored but the date input value format should be valid.
  - The year in the date part must be over 4 digits (available to start with 0) or the time part must include hours and minutes ([H]H:[M]M) at least. Otherwise the date part is recognized as the **TIME** type of the [MM]SS format, and the following string will be ignored.
- If one of the units (year, month, date, hour, minute and second) of the **DATETIME** string is greater than 999999, it is not recognized as a number, so the string including the corresponding unit will be ignored. For example, in '2009-10-21 20:9943:10', an error occurs because the value in minutes is out of the range. However, if '2009-10-21 20:1000123:10' is entered, '2009' is recognized as the **TIME** type of the MMSS format, so that **TIME** '00:20:09' will be returned.
- If you convert the time-date string to the **TIME** type, the date part of the string is ignored but the date part format must be valid.
- All input strings including the time part allow [.msec] on conversion, but only the **DATETIME** type can be maintained. If you convert this to a type such as **DATE**, **TIMESTAMP** or **TIME**, the msec value is discarded.
- All conversions in the **DATETIME**, **TIME** string allow English locale following after time value or am/pm specifier written in the current locale of a server.

```
SELECT CAST('420' AS DATE);
```

```
cast('420' as date)
=====
04/20/2012
```

```
SELECT CAST('91015' AS TIME);
```

```
cast('91015' as time)
=====
09:10:15 AM
```

```
SELECT CAST('110420091035.359' AS DATETIME);
```

```
cast('110420091035.359' as datetime)
=====
09:10:35.359 AM 04/20/2011
```

```
SELECT CAST('110420091035.359' AS TIMESTAMP);
```

```
cast('110420091035.359' as timestamp)
=====
09:10:35 AM 04/20/2011
```

## Date/Time Types with Timezone

Date/Time types with timezone are date/time types which can be input or output by specifying timezone. There are two ways of specifying timezone; specifying the name of local zone and specifying the offset of time.

Timezone information are considered in the Date/Time types if TZ or LTZ is followed after the existing Date/Time types; TZ means timezone, and LTZ means local timezone.

- TZ type can be represented as <date/time type> WITH TIME ZONE. This stores UTC time and timezone information (decided by a user or session timezone) when this is created. TZ type requires 4 bytes more to store timezone information.
- LTZ type can be represented as <date/time type> WITH LOCAL TIME ZONE. This stores UTC time internally; when this value is output, this is converted as a value of a local (current session) time zone.

This table describes date/time types to compare date/time types with timezone together.

UTC in the table means Coordinated Universal Time.

| Category | Type | Input               | Store       | Output                             | Description |
|----------|------|---------------------|-------------|------------------------------------|-------------|
| DATE     | DATE | Without<br>timezone | Input value | Absolute<br>(the same<br>as input) | Date        |

| Category  | Type          | Input               | Store                                     | Output                                                 | Description                                                             |
|-----------|---------------|---------------------|-------------------------------------------|--------------------------------------------------------|-------------------------------------------------------------------------|
| DATETIME  | DATETIME      | Without<br>timezone | Input value                               | Absolute<br>(the same<br>as input)                     | Date/time<br>including<br>milliseconds                                  |
|           | DATETIMEZ     | With<br>timezone    | UTC +<br>timezone(region<br>or<br>offset) | Absolute<br>(keep input<br>timezone)                   | Date/time +<br>timezone                                                 |
|           | DATETIMELTZ   | With<br>timezone    | UTC                                       | Relative<br>(transformed<br>by<br>session<br>timezone) | Date/time<br>in the<br>session<br>timezone                              |
| TIME      | TIME          | Without<br>timezone | Input value                               | Absolute<br>(the same<br>as input)                     | Time                                                                    |
| TIMESTAMP | TIMESTAMP     | Without<br>timezone | UTC                                       | Relative<br>(transformed<br>by<br>session<br>timezone) | Input value<br>is<br>translated<br>as a session<br>timezone's<br>value. |
|           | TIMESTAMPZ    | With<br>timezone    | UTC +<br>timezone(region<br>or<br>offset) | Absolute<br>(keep input<br>timezone)                   | UTC +<br>timestamp<br>with<br>timezone                                  |
|           | TIMESTAMPZLTZ | With<br>timezone    | UTC                                       | Relative<br>(transformed<br>by<br>session<br>timezone) | Session<br>timezone.<br>Same as<br>TIMESTAMP's<br>value, but            |

| Category | Type | Input | Store | Output               | Description                                                        |
|----------|------|-------|-------|----------------------|--------------------------------------------------------------------|
|          |      |       |       | session<br>timezone) | timezone<br>specifier is<br>output<br>when this is<br>printed out. |

The other features of date/time types with timezone (e.g. maximum/minimum value, range, resolution) are the same with the features of general date/time types.

#### Note

- On CUBRID, TIMESTAMP is stored as second unit, after Jan. 1, 1970 UTC (UNIX epoch).
- Some DBMS's TIMESTAMP is similar to CUBRID's DATETIME as the respect of saving milliseconds.

To see examples of functions using timezone types, see [Date/Time Functions and Operators](#).

The following shows that the output values are different among DATETIME, DATETIMETZ and DATETIMELTZ when session timezone is changed.

```
-- csql> ;set timezone="+09"
```

```
CREATE TABLE tbl (a DATETIME, b DATETIMETZ, c DATETIMELTZ);
INSERT INTO tbl VALUES (datetime'2015-02-24 12:30',
datetimeetz'2015-02-24 12:30', datetimeltz'2015-02-24 12:30');
```

```
SELECT * FROM tbl;
```

```
12:30:00.000 PM 02/24/2015      12:30:00.000 PM 02/24/2015 +09:
00                          12:30:00.000 PM 02/24/2015 +09:00
```

```
-- csql> ;set timezone="+07"
```

```
SELECT * FROM tbl;
```

```
12:30:00.000 PM 02/24/2015      12:30:00.000 PM 02/24/2015 +09:
00                             10:30:00.000 AM 02/24/2015 +07:00
```

The following shows that the output values are different among `TIMESTAMP`, `TIMESTAMPTZ` and `TIMESTAMPLTZ` when session timezone is changed.

```
-- ;set timezone="+09"
```

```
CREATE TABLE tbl (a TIMESTAMP, b TIMESTAMPTZ, c TIMESTAMPLTZ);
INSERT INTO tbl VALUES (timestamp'2015-02-24 12:30',
timestamp'2015-02-24 12:30', timestamp'2015-02-24 12:30');

SELECT * FROM tbl;
```

```
12:30:00 PM 02/24/2015      12:30:00 PM 02/24/2015 +09:
00                             12:30:00 PM 02/24/2015 +09:00
```

```
-- csql> ;set timezone="+07"
```

```
SELECT * FROM tbl;
```

```
10:30:00 AM 02/24/2015      12:30:00 PM 02/24/2015 +09:
00                             10:30:00 AM 02/24/2015 +07:00
```

### Conversion from string to timestamp types

Conversion from string to `timestamp`/`timestampltz`/`timestamptz` are performed in context for creating timestamp objects from literals.

| From/to                   |  | Timestamp                                                                                           | Timestampltz                                                                                        | Timestamptz                                                                                                             |
|---------------------------|--|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| String (without timezone) |  | Interpret the date/time parts in session timezone. Convert to UTC, encode and store the Unix epoch. | Interpret the date/time parts in session timezone. Convert to UTC, encode and store the Unix epoch. | Interpret the date/time parts in session timezone. Convert to UTC, encode and store the Unix epoch and TZ_ID of session |

| From/to                | Timestamp                                             | Timestamptz                                                            | Timestamptz                                                                                          |
|------------------------|-------------------------------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| String (with timezone) | Error (timezone part is not supported for timestamp). | Convert from value's timezone to UTC. Encode and store the Unix epoch. | Convert from value's timezone to UTC. Encode and store the Unix epoch and TZ_ID of value's timezone. |

### Conversion from string to datetime types

Conversion from string to datetime/datetimetz/datetimetz are performed in context for creating datetime objects from literals.

| From/to                   | Datetime                                             | Datetimetz                                                                                  | Datetimetz                                                                                                      |
|---------------------------|------------------------------------------------------|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| String (without timezone) | Store the parsed values from string.                 | Interpret the date/time parts in session timezone. Convert to UTC and store the new values. | Interpret the date/time parts in session timezone. Convert to UTC and store the new values and TZ_ID of session |
| String (with timezone)    | Error (timezone part is not supported for datetime). | Convert from value's timezone to UTC. Store the new values in UTC reference.                | Convert from value's timezone to UTC. Store the new values in UTC reference TZ_ID of string's timezone.         |

### Conversion of datetime and timestamp types to string (printing of values)

| <b>From/to</b> | <b>String (timezone not printing allowed)</b>                 | <b>String (timezone force print)</b>                                              | <b>String requirement - (no free choice)</b>                                      |
|----------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| TIMESTAMP      | Decode Unix epoch to session timezone and print               | Decode Unix epoch to session timezone and print with session timezone.            | Decode Unix epoch to session timezone and print. Do not print timezone string     |
| TIMESTAMPTZ    | Decode Unix epoch to session timezone and print               | Decode Unix epoch to session timezone and print with session timezone.            | Decode Unix epoch to session timezone and print. Print session timezone.          |
| TIMESTAMPTZ    | Decode Unix epoch to timezone from value and print it.        | Decode Unix epoch to timezone from value and print it; print timezone from value. | Decode Unix epoch to timezone from value and print it; print timezone from value. |
| DATETIME       | Print the stored values.                                      | Print the stored value and session timezone.                                      | Print the stored value. Do not print any timezone.                                |
| DATETIMELTZ    | Convert from UTC to session timezone and print the new value. | Convert from UTC to session timezone and print it. Print session timezone         | Convert from UTC to session timezone and print it. Print session timezone.        |
| DATETIMELTZ    | Convert from UTC to value's timezone and print the new value. | Convert from UTC to value's timezone and print it. Print value's timezone         | Convert from UTC to value's timezone and print it. Print value's timezone.        |

## Timezone Configuration

The below shows the timezone related parameters configured in cubrid.conf. For parameter's configuration, see [cubrid.conf Configuration File and Default Parameters](#).

- **timezone**

Specifies a timezone for a session. The default is a value of **server\_timezone**.

- **server\_timezone**

Specifies a timezone for a server. The default is a timezone of OS.

- **tz\_leap\_second\_support**

Sets for support for leap second as yes or no. The default is no.

## Timezone Function

The following are timezone related functions. For each function's detail usage, click each function's name.

- [DBTIMEZONE\(\)](#)

- [SESSIONTIMEZONE\(\)](#)

- [FROM\\_TZ\(\)](#)

- [NEW\\_TIME\(\)](#)

- [TZ\\_OFFSET\(\)](#)

## Functions with a Timezone Type

All functions which use DATETIME, TIMESTAMP or TIME typed value in their input value, can use timezone typed value.

The below is an example of using timezone typed values, it works the same as the case without timezone. Exceptionally, if the type name ends with LTZ, the output value of this type follows the local timezone's setting (timezone parameter).

On the below example, the default unit of a number is millisecond, which is the minimum unit of DATETIME type.

```
SELECT datetimeltz '09/01/2009 03:30:30 pm' + 1;
```

```
03:30:30.001 PM 09/01/2009 Asia/Seoul
```

```
SELECT datetimeltz '09/01/2009 03:30:30 pm' - 1;
```

```
03:30:29.999 PM 09/01/2009 Asia/Seoul
```

On the below example, the default unit of a number is second, which is the minimum unit of TIMESTAMP type.

```
SELECT timestamptz '09/01/2009 03:30:30 pm' + 1;
```

```
03:30:31 PM 09/01/2009 Asia/Seoul
```

```
SELECT timestamptz '09/01/2009 03:30:30 pm' - 1;
```

```
03:30:29 PM 09/01/2009 Asia/Seoul
```

```
SELECT EXTRACT (hour from datetimetz'10/15/1986 5:45:15.135 am
Europe/Bucharest');
```

```
5
```

A type which the name ends with LTZ follows the setting of local timezone. Therefore, if the value of timezone parameter is set to 'Asia/Seoul', EXTRACT function returns hour value of this timezone.

```
-- csql> ;set timezone='Asia/Seoul'
```

```
SELECT EXTRACT (hour from datetimeltz'10/15/1986 5:45:15.135 am
Europe/Bucharest');
```

```
12
```

## Conversion Functions for Timezone Types

The following are functions converting a string to a date/time typed value, or date/time typed value to a string; The value can include an information like an offset, a zone and a daylight saving.

- `DATE_FORMAT()`
- `STR_TO_DATE()`
- `TO_CHAR()`
- `TO_DATETIME_TZ()`
- `TO_TIMESTAMP_TZ()`

For each function's usage, see the each function's explanation by clicking the function name.

```
SELECT DATE_FORMAT (datetimetz'2012-02-02 10:10:10 Europe/Zurich
CET', '%TZR %TZD %TZh %TZM');
SELECT STR_TO_DATE ('2001-10-11 02:03:04 AM Europe/Bucharest EEST',
'%Y-%m-%d %h:%i:%s %p %TZR %TZD');
SELECT TO_CHAR (datetimetz'2001-10-11 02:03:04 AM Europe/Bucharest
EEST');
SELECT TO_DATETIME_TZ ('2001-10-11 02:03:04 AM Europe/Bucharest
EEST');
SELECT TO_TIMESTAMP_TZ ('2001-10-11 02:03:04 AM Europe/Bucharest');
```

### Note

`TO_TIMESTAMP_TZ()` and `TO_DATETIME_TZ()` functions do the same behaviors with `TO_TIMESTAMP()` and `TO_DATETIME()` functions except that they can have TZR, TZD, TZh and TZM information in their date/time argument.

CUBRID uses the region name of timezone in the IANA(Internet Assigned Numbers Authority) timezone database region; for IANA timezone, see <http://www.iana.org/time-zones>.

## IANA Timezone

In IANA(Internet Assigned Numbers Authority) timezone database, there are lots of codes and data which represent the history of localtime for many representative locations around the globe.

This database is periodically updated to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules. Its management procedure is described in [BCP 175: Procedures for Maintaining the Time Zone Database](#). For more details, see <http://www.iana.org/time-zones>.

CUBRID supports IANA timezone, and a user can use the IANA timezone library in the CUBRID installation package as it is. If you want to update as the recent timezone, update timezone first, compile timezone library, and restart the database.

Regarding this, see [Compiling Timezone Library](#).

## Bit Strings

A bit string is a sequence of bits (1's and 0's). Images (bitmaps) displayed on the computer screen can be stored as bit strings. CUBRID supports the following two types of bit strings:

- Fixed-length bit string (**BIT**)
- Variable-length bit string (**BIT VARYING**)

A bit string can be used as a method argument or an attribute type. Bit string literals are represented in a binary or hexadecimal format. For binary format, append the string consisting of 0's and 1's to the letter **B** or append a value to the **0b** as shown example below.

```
B'1010'  
0b1010
```

For hexadecimal format, append the string consisting of the numbers 0 - 9 and the letters A - F to the uppercase letter **X** or append a value to the **0x**. The following is hexadecimal representation of the same number that was represented above in binary format.

```
X'a'  
0xA
```

The letters used in hexadecimal numbers are not case-sensitive. That is, X'4f' and X'4F' are considered as the same value.

## Length

If a bit string is used in table attributes or method declarations, you must specify the maximum length. The maximum length for a bit string is 1,073,741,823 bits.

## Bit String Coercion

Automatic coercion is performed between a fixed-length and a variable-length bit string for comparison. For explicit coercion, use the `CAST()` operator.

## BIT(*n*)

Fixed-length binary or hexadecimal bit strings are represented as **BIT** (*n*), where *n* is the maximum number of bits. If *n* is not specified, the length is set to 1. If *n* is not specified, the length is set to 1. The bit string is filled with 8-bit unit from the left side. For example, the value of B'1' is the same as the value of B'10000000'. Therefore, it is recommended to declare a length by 8-bit unit, and input a value by 8-bit unit.

### Note

If you input B'1' to the BIT(4) column, it is printed out X'8' on CSQL, X'80' on CUBRID Manager or application program.

- *n* must be a number greater than 0.
- If the length of the string exceeds *n*, it is truncated and filled with 0s.
- If a bit string smaller than *n* is stored, the remainder of the string is filled with 0s.
- **DEFAULT** constraint can be specified in a column of this type.

```
CREATE TABLE bit_tbl(a1 BIT, a2 BIT(1), a3 BIT(8), a4 BIT VARYING);
INSERT INTO bit_tbl VALUES (B'1', B'1', B'1', B'1');
INSERT INTO bit_tbl VALUES (0b1, 0b1, 0b1, 0b1);
INSERT INTO bit_tbl(a3,a4) VALUES (B'1010', B'1010');
INSERT INTO bit_tbl(a3,a4) VALUES (0xaa, 0xaa);
SELECT * FROM bit_tbl;
```

| a1<br>a4 | a2   | a3    |
|----------|------|-------|
| =====    |      |       |
| ====     |      |       |
| X'8'     | X'8' | X'80' |
| X'8'     |      |       |
| X'8'     | X'8' | X'80' |
| X'8'     |      |       |
| NULL     | NULL | X'a0' |
| X'a'     |      |       |
| NULL     | NULL | X'aa' |
| X'aa'    |      |       |

## BIT VARYING(*n*)

A variable-length bit string is represented as **BIT VARYING** (*n*), where *n* is the maximum number of bits. If *n* is not specified, the length is set to 1,073,741,823 (maximum value). *n* is the maximum number of bits. If *n* is not specified, the maximum length is set to 1,073,741,823. The bit string is filled with 8-bit values from the left side. For example, the value of B'1' is the same as the value of B'10000000'. Therefore, it is recommended to declare a length by 8-bit unit, and input a value by 8-bit unit.

### Note

If you input B'1' to the BIT VARYING(4) column, it is printed out X'8' on CSQL, X'80' on CUBRID Manager or application program.

- If the length of the string exceeds *n*, it is truncated and filled with 0s.
- The remainder of the string is not filled with 0s even if a bit string smaller than *n* is stored.
- *n* must be a number greater than 0.
- **DEFAULT** constraint can be specified in a column of this type.

```
CREATE TABLE bitvar_tbl(a1 BIT VARYING, a2 BIT VARYING(8));
INSERT INTO bitvar_tbl VALUES (B'1', B'1');
INSERT INTO bitvar_tbl VALUES (0b1010, 0b1010);
INSERT INTO bitvar_tbl VALUES (0xaa, 0xaa);
INSERT INTO bitvar_tbl(a1) VALUES (0xaaa);
INSERT INTO bitvar_tbl(a2) VALUES (0xaaa);
SELECT * FROM bitvar_tbl;
```

| a1     | a2    |
|--------|-------|
| X'8'   | X'8'  |
| X'a'   | X'a'  |
| X'aa'  | X'aa' |
| X'aaa' | NULL  |
| NULL   | X'aa' |

## Character Strings

CUBRID supports the following two types of character strings:

- Fixed-length character string: **CHAR** (*n*)

- Variable-length character string: **VARCHAR** (*n*)

#### Note

From CUBRID 9.0 version, **NCHAR** and **NCHAR VARYING** is no more supported. Instead, please use **CHAR** and **VARCHAR**.

The following are the rules that are applied when using the character string types.

- In general, single quotations are used to enclose character string. Double quotations may be used as well depending on the value of **ansi\_quotes**, which is a parameter related to SQL statement. If the **ansi\_quotes** value is set to **no**, character string enclosed by double quotations is handled as character string, not as an identifier. The default value is **yes**. For details, [Statement/Type-Related Parameters](#).
- If there are characters that can be considered to be blank (e.g. spaces, tabs, or line breaks) between two character strings, these two character strings are treated as one according to ANSI standard. For example, the following example shows that a line break exists between two character strings.

```
'abc'  
'def'
```

The above two strings and the below string are considered identical.

```
'abcdef'
```

- If you want to include a single quote as part of a character string, enter two single quotes in a row. For example, the character string on the left is stored as the one on the right.

```
'''abcde''fghij'      'abcde'fghij
```

- The maximum size of the token for all the character strings is 16 KB.
- To enter the language of a specific country, we recommend that you to specify the locale when creating DB, then you can change locale by the introducer **CHARSET** (or **COLLATE** modifier). For more information, see [An Overview of Globalization](#).

## Length

Specify the number of a character string.

When the length of the character string entered exceeds the length specified, the excess characters may be truncated in the insert/update operation if the `allow_truncated_string` configuration value is “yes” otherwise error occurs.

For a fixed-length character string type such as **CHAR**, the length is fixed at the declared length. Therefore, the right part (trailing space) of the character string is filled with space characters when the string is stored. For a variable-length character string type such as **VARCHAR**, only the entered character string is stored, and the space is not filled with space characters.

The maximum length of a **CHAR** type to be specified is 268,435,455. The maximum length of a **VARCHAR** type to be specified is 1,073,741,823.

Also, the maximum length that can be input or output in a CSQL statement is 8,192 KB.

#### Note

In the CUBRID version less than 9.0, the length of **CHAR** or **VARCHAR** was not the number of characters, but the byte size.

## Character Set, charset

A character set (charset) is a set in which rules are defined that relate to what kind of codes can be used for encoding when specified characters (symbols) are stored in the computer. The character used by CUBRID can be configured as the **CUBRID\_CHARSET** environment variable. For details, see [An Overview of Globalization](#).

## Collating Character Sets

A collation is a set of rules used for comparing characters to search or sort values stored in the database when a certain character set is specified. For details, see [An Overview of Globalization](#).

## Character String Coercion

Automatic coercion takes place between a fixed-length and a variable-length character string for the comparison of two characters, applicable only to characters that belong to the same character set.

For example, when you extract a column value from a **CHAR** (5) data type and insert it into a column with a **CHAR** (10) data type, the data type is automatically coerced to **CHAR** (10). If you want to coerce a character string explicitly, use the **CAST** operator (See `CAST()`).

## String compression

Variable character type values (VARCHAR(*n*)) may be compressed (using LZ01X algorithm) before being stored in database (heap file, index file or list file). Compression is attempted if size in bytes is at least 255 bytes (this value is predefined and cannot be changed). If the compression is not efficient (compressed value size and its overhead is equal or greater than the original uncompressed value), the value is stored uncompressed. Compression is activated by default and may be disabled by setting the system parameter `enable_string_compression`. The overhead of compression is eight bytes : four for size of compressed buffer and four for the size of expected uncompressed string. Compressed strings are decompressed when they are read from database. To determine if a value is compressed or not, one may use the `DISK_SIZE` function result and compare it with the result of `OCTET_LENGTH` function on the same argument. A smaller value for `DISK_SIZE` (ignoring the value overhead) indicates that compression is used.

## CHAR(*n*)

A fixed-length character string is represented as **CHAR** (*n*), in which *n* represents the number of characters. If *n* is not specified, the value is specified as 1, default value.

When the length of a character string exceeds *n*, they may be truncated in the insert/update operation if the `allow_truncated_string` configuration value is “yes” otherwise error occurs. When character string which is shorter than *n* is stored, white space characters are used to fill up the trailing space.

**CHAR** (*n*) and **CHARACTER** (*n*) are used interchangeably.

### Note

In the earlier versions of CUBRID 9.0, *n* represents byte length, not the number of characters.

- *n* specifies the number of bytes, ranging from 1 to 2048, and defines a fixed-length character type that allocates storage of the specified size.
- Empty quotes ( ' ' ) are used to represent a blank string. In this case, the return value of the **LENGTH** function is not 0, but is the fixed length defined in **CHAR** (*n*). That is, if you enter a blank string into a column with **CHAR** (10), the **LENGTH** is 10; if you enter a blank value into a **CHAR** with no length specified, the **LENGTH** is the default value 1.
- Space characters used as filling characters are considered to be smaller than any other characters, including special characters.

If you specify `'pacesetter' as CHAR(12)`, `'pacesetter '` is stored (a 10-character string plus two white space characters).

If you specify `'pacesetter' as CHAR(10)`, `'pacesetter'` is stored (a 10-character string; two white space characters are truncated).  
 If you specify `'pacesetter' as CHAR(4)`, `'pace'` may be stored or error occurs depending on the configuration value of `allow_truncated_string` (truncated as the length of the character string is greater than 4).  
 If you specify `'p' as CHAR`, `'p'` is stored (if `n` is not specified, the length is set to the default value 1).

- **DEFAULT** constraint can be specified in a column of this type.

## VARCHAR(n)/CHAR VARYING(n)

Variable-length character strings are represented as **VARCHAR** (*n*), where *n* represents the number of characters. If *n* is not specified, the value is specified as 1,073,741,823, the maximum length.

When the length of a character string exceeds *n*, they may be truncated in the insert/update operation if the `allow_truncated_string` configuration value is **yes** or error occurs if not. When character string which is shorter than *n* is stored, for **VARCHAR** (*n*), the length of string used are stored without any trailing spaces.

**VARCHAR** (*n*), **CHARACTER**, **VARYING** (*n*), and **CHAR VARYING** (*n*) are used interchangeably.

### Note

In the earlier versions of CUBRID 9.0, *n* represents byte length, not the number of characters.

- **STRING** is the same as the **VARCHAR** (maximum length).
- *n* is an integer between 1 and 1,073,741,823 (1G).
- Empty quotes ( ' ') are used to represent a blank string. In this case, the return value of the **LENGTH** function is not 0.

If you specify `'pacesetter' as VARCHAR(4)`, `'pace'` may be stored or error occurs depending on the configuration value of `allow_truncated_string` (truncated as the length of the character string is greater than 4).  
 If you specify `'pacesetter' as VARCHAR(12)`, `'pacesetter'` is stored (a 10-character string).  
 If you specify `'pacesetter' as VARCHAR(12)`, `'pacesetter '` is stored (a 11-character string).  
 If you specify `'pacesetter' as VARCHAR(10)`, `'pacesetter'` may be stored or error occurs depending on the configuration value of

```
allow_truncated_string (a 10-character string; two white space
characters can be truncated).
If you specify 'p ' as VARCHAR, 'p ' is stored (if n is not
specified, the default value 1,073,741,823 is used, and the trailing
space is not filled with white space characters).
```

- **DEFAULT** constraint can be specified in a column of this type.

## STRING

**STRING** is a variable-length character string data type. **STRING** is the same as the **VARCHAR** with the length specified as the maximum value. That is, **STRING** and **VARCHAR** (1,073,741,823) have the same value.

## Escape Special Characters

CUBRID supports two kinds of methods to escape special characters. One is using quotes and the other is using backslash (\).

- Escape with Quotes

If you set **no** for the system parameter **ansi\_quotes** in the **cubrid.conf** file, you can use both double quotes (") and single quotes (') to wrap strings. The default value for the **ansi\_quotes** parameter is **yes**, and you can use only single quotes to wrap the string.

- You should use two single quotes (') for the single quotes included in the strings wrapped in single quotes.
- You should use two double quotes (") for the double quotes included in the strings wrapped in double quotes. (when **ansi\_quotes** = **no**)
- You don't need to escape the single quotes included in the string wrapped in double quotes. (when **ansi\_quotes** = **no**)
- You don't need to escape the double quotes included in the string wrapped in single quotes.

- Escape with Backslash

You can use escape using backslash (\) only if you set **no** for the system parameter **no\_backslash\_escapes** in the **cubrid.conf** file. The default value for the **no\_backslash\_escapes** parameter is **yes**. If the value of **no\_backslash\_escapes** is **no**, the following are the special characters.

- \': Single quotes (')
- \": Double quotes (")

- \n : Newline, linefeed character
- \r : Carriage return character
- \t : Tab character
- \\ : Backslash
- \% : Percent sign (%). For details, see the following description.
- \\_ : Underbar (\_). For details, see the following description.

For all other escapes, the backslash will be ignored. For example, “x” is the same as entering only “x”.

**\%** and **\\_** are used in the pattern matching syntax such as **LIKE** to search percent signs and underbars and are used as a wildcard character if there is no backslash. Outside of the pattern matching syntax, “\%” and “\\_” are recognized as normal strings not wildcard characters. For details, see [LIKE](#).

The following is the result of executing Escape if a value for the system parameter **ansi\_quotes** in the **cubrid.conf** file is yes(default), and a value for **no\_backslash\_escapes** is no.

```
-- ansi_quotes=yes, no_backslash_escapes=no
SELECT STRCMP('single quotes test(')', 'single quotes test(\')');
```

If you run the above query, backslash is regarded as an escape character. Therefore, above two strings are the same.

```
      strcmp('single quotes test(')', 'single quotes test(\')')
=====
0
```

```
SELECT
STRCMP('\a\b\c\d\e\f\g|h|i\j\k\l|m\n\o\p\q\r\s\t\u\v\w\x\y\z',
'a\b\c\defghijklm\nopq\r\s\tuvwxyz');
```

If you run the above query, backslash is regarded as an escape character. Therefore, above two strings are the same.

```
      strcmp('abcdefghijklm
s      uvwxyz', 'abcdefghijklm
s      uvwxyz')
=====
0
```

```
SELECT LENGTH('\\');
```

If you run the above query, backslash is regarded as an escape character. Therefore, the length of above string is 1.

```
char_length('\\')
=====
1
```

The following is the result of executing Escape if a value for the system parameter **ansi\_quotes** in the **cubrid.conf** file is yes(default), and a value for **no\_backslash\_escapes** is yes(default). Backslash character is regarded as a general character.

```
-- ansi_quotes=yes, no_backslash_escapes=yes

SELECT STRCMP('single quotes test(')', 'single quotes test(\')');
```

If you run the above query, the quotation mark is regarded as opened, so the below error occurs. If you input this query on the CSQL interpreter's console, it waits the next quotation mark's input.

```
ERROR: syntax error, unexpected UNTERMINATED_STRING, expecting
SELECT or VALUE or VALUES or '('
```

```
SELECT
STRCMP('a\b\c\d\e\f\g\h\i\j\k\l\m\n\o\p\q\r\s\t\u\v\w\x\y\z',
'a\b\c\defghijklm\nopq\r\s\tuvwxyz');
```

If you run the above query, backslash is regarded as a general character. Therefore, the result of the comparison between the above two strings shows different.

```
strcmp('a\b\c\d\e\f\g\h\i\j\k\l\m\n\o\p\q\r\s\t\u\v\w\x\y\z',
'a\b\c\defghijklm\nopq\r\s\tuvwxyz')
=====
=====
-1
```

```
SELECT LENGTH('\\');
```

If you run the above query, backslash is regarded as a general character. Therefore, the length of above string is 2.

```
char_length('\\')
=====
2
```

The following shows the result of executing Escape about the LIKE clause when **ansi\_quotes** is yes and **no\_backslash\_escapes** is no.

```
-- ansi_quotes=yes, no_backslash_escapes=no

CREATE TABLE t1 (a VARCHAR(200));
INSERT INTO t1 VALUES ('aaabbb'), ('aaa%');

SELECT a FROM t1 WHERE a LIKE 'aaa%' ESCAPE '\\';
```

```
a
=====
'aaa%'
```

If you run above query, it returns only one row because '%' character is regarded as a general character.

In the string of LIKE clause, backslash is always regarded as a general character. Therefore, if you want to make the '%' character as a general character, not as a pattern matching character, you should specify that '%' is an escape character by using ESCAPE clause. In the ESCAPE clause, backslash is regarded as an escape character. Therefore, we used two backslashes.

If you want use other character than a backslash as an escape character, you can write the query as follows.

```
SELECT a FROM t1 WHERE a LIKE 'aaa#%' ESCAPE '#';
```

## Comparison Rules

When two string values are compared, the followings are the comparison rules about the behavior of trailing spaces:

- Comparison for trailing space insensitive
- Comparison for trailing space sensitive

### Trailing space insensitive

If the two string values are both fixed-length types (CHAR-type), the comparison ignores trailing spaces as below example. comparing 'abc ' with 'abc ' results equal

## Trailing space sensitive

If two string values are both of variable-length types (VARCHAR-type), the comparison does not ignore trailing spaces as below example. comparing 'abc ' with 'abc ' results 'abc ' greater than 'abc '

## Exceptions

When comparing two string values, if one is a fixed-type and the other is a variable-type, CUBRID follows “trailing space sensitive” rule.

## ENUM Data Type

The **ENUM** type is a data type consisting of an ordered set of distinct constant char literals called enum values. The syntax for creating an enum column is:

```
<enum_type>
: ENUM '(' <char_string_literal_list> ')'
```

```
<char_string_literal_list>
: <char_string_literal_list> ',' CHAR_STRING
| CHAR_STRING
```

The following example shows the definition of an **ENUM** column.

```
CREATE TABLE tbl (
  color ENUM ('red', 'yellow', 'blue', 'green')
);
```

- **DEFAULT** constraint can be specified in a column of this type.

An index is associated to each element of the enum set, according to the order in which elements are defined in the enum type. For example, the *color* column can have one of the following values (assuming that the column allows NULL values) :

| Value | Index Number |
|-------|--------------|
| NULL  | NULL         |
| 'red' | 1            |

| Value    | Index Number |
|----------|--------------|
| 'yellow' | 2            |
| 'blue'   | 3            |
| 'green'  | 4            |

The set of values of an **ENUM** type must not exceed 512 elements and each element of the set must be unique. CUBRID allocates two bytes of storage for each **ENUM** type value because it only stores the index of each value. This reduces the storage space needed which may improve performance.

Either the enum value or the value index can be used when working with **ENUM** types. For example, to insert values into an **ENUM** type column, users can use either the value or the index of the **ENUM** type:

```
-- insert enum element 'yellow' with index 2
INSERT INTO tbl (color) VALUES ('yellow');
-- insert enum element 'red' with index 1
INSERT INTO tbl (color) VALUES (1);
```

When used in expressions, the **ENUM** type behaves either as a **CHAR** type or as a number, depending on the context in which it is used:

```
-- the first result column has ENUM type, the second has INTEGER
type and the third has VARCHAR type
SELECT color, color + 0, CONCAT(color, '') FROM tbl;
```

| color    | color+0 | concat(color, '') |
|----------|---------|-------------------|
| 'yellow' | 2       | 'yellow'          |
| 'red'    | 1       | 'red'             |

When used in type contexts other than **CHAR** or numbers, the enum is coerced to that type using either the index or the enum value. The table below shows which part of an **ENUM** type is used in the coercion:

| Type      | Enum type (Index/Value) |
|-----------|-------------------------|
| SHORT     | Index                   |
| INTEGER   | Index                   |
| BIGINT    | Index                   |
| FLOAT     | Index                   |
| DOUBLE    | Index                   |
| NUMERIC   | Index                   |
| TIME      | Value                   |
| DATE      | Value                   |
| DATETIME  | Value                   |
| TIMESTAMP | Value                   |
| CHAR      | Value                   |
| VARCHAR   | Value                   |
| BIT       | Value                   |
| VARBIT    | Value                   |

## ENUM Type Comparisons

When used in **=** or **IN** predicates of the form (<enum\_column> <operator> <constant>), CUBRID tries to convert the constant to the **ENUM** type. If the coercion fails, CUBRID does not return an error but considers the comparison to be false. This is implemented like this in order to allow index scan plans to be generated on these two operators.

For all other **comparison operators**, the **ENUM** type is converted to the type of the other operand. If a comparison is performed on two **ENUM** types, both arguments are converted to **CHAR** type and the comparison follows **CHAR** type rules. Except for **=** and **IN**, predicates on **ENUM** columns cannot be used in index scan plans.

To understand these rules, consider the following table:

```
CREATE TABLE tbl (
  color ENUM ('red', 'yellow', 'blue', 'green')
);

INSERT INTO tbl (color) VALUES (1), (2), (3), (4);
```

The following query will convert the constant 'red' to the enum value 'red' with index 1

```
SELECT color FROM tbl WHERE color = 'red';
```

```
color
=====
'red'
```

```
SELECT color FROM tbl WHERE color = 1;
```

```
color
=====
'red'
```

The following queries will not return a conversion error but will not return any results:

```
SELECT color FROM tbl WHERE color = date'2010-01-01';
SELECT color FROM tbl WHERE color = 15;
SELECT color FROM tbl WHERE color = 'asdf';
```

In the following queries the **ENUM** type will be converted to the type of the other operand:

```
-- CHAR comparison using the enum value
SELECT color FROM tbl WHERE color < 'pink';
```

```
color
=====
'blue'
'green'
```

```
-- INTEGER comparison using the enum index
SELECT color FROM tbl WHERE color > 3;
```

```
color
=====
'green'
```

```
-- Conversion error
SELECT color FROM tbl WHERE color > date'2012-01-01';
```

```
ERROR: Cannot coerce value of domain "enum" to domain "date".
```

## ENUM Type Ordering

Values of the **ENUM** type are ordered by value index, not by enum value. When defining a column with **ENUM** type, users also define the ordering of the enum values.

```
SELECT color FROM tbl ORDER BY color ASC;
```

```
color
=====
'red'
'yellow'
'blue'
'green'
```

To order the values stored in an **ENUM** type column as **CHAR** values, users can cast the enum value to the **CHAR** type:

```
SELECT color FROM tbl ORDER BY CAST (color AS VARCHAR) ASC;
```

```

color
=====
'blue'
'green'
'red'
'yellow'

```

## Notes

The **ENUM** type is not a reusable type. If several columns require the same set of values, an **ENUM** type must be defined for each one. When comparing two columns of **ENUM** type, the comparison is performed as if the columns were coerced to **CHAR** type even if the two **ENUM** types define the same set of values.

Using the **ALTER ... CHANGE** statement to modify the set of values of an **ENUM** type is only allowed if the value of the system parameter **alter\_table\_change\_type\_strict** is set to yes. In this case, CUBRID uses enum value (the char-literal) to convert values to the new domain. If a value is outside of the new **ENUM** type values set, it is automatically mapped to the empty string("").

```

CREATE TABLE tbl(color ENUM ('red', 'green', 'blue'));
INSERT INTO tbl VALUES('red'), ('green'), ('blue');

```

The following statement will extend the **ENUM** type with the value 'yellow':

```

ALTER TABLE tbl CHANGE color color ENUM ('red', 'green', 'blue',
'yellow');
INSERT into tbl VALUES(4);
SELECT color FROM tbl;

```

```

color
=====
'red'
'green'
'blue'
'yellow'

```

The following statement will change all tuples with value 'green' to value 'red' because the value 'green' cannot be converted the new **ENUM** type:

```

ALTER TABLE tbl CHANGE color color enum ('red', 'yellow', 'blue');
SELECT color FROM tbl;

```

```

color
=====
'red'
''
'blue'
'yellow'

```

The **ENUM** type is mapped to char-string types in CUBRID drivers. The following example shows how to use the **ENUM** type in a JDBC application:

```

Statement stmt = connection.createStatement("SELECT color FROM tbl");
ResultSet rs = stmt.executeQuery();

while(rs.next()) {
    System.out.println(rs.getString());
}

```

The following example shows how to use the **ENUM** type in a CCI application.

```

req_id = cci_prepare (conn, "SELECT color FROM tbl", 0, &err);
error = cci_execute (req_id, 0, 0, &err);
if (error < CCI_ER_NO_ERROR)
{
    /* handle error */
}

error = cci_cursor (req_id, 1, CCI_CURSOR_CURRENT, &err);
if (error < CCI_ER_NO_ERROR)
{
    /* handle error */
}

error = cci_fetch (req_id, &err);
if (error < CCI_ER_NO_ERROR)
{
    /* handle error */
}

cci_get_data (req, idx, CCI_A_TYPE_STR, &data, 1);

```

## BLOB/CLOB Data Types

An External **LOB** type is data to process Large Object, such as text or images. When LOB-type data is created and inserted, it will be stored in a file to an external storage, and the location information of the relevant file (**LOB** Locator) will be stored in the CUBRID database. If the **LOB**

Locator is deleted from the database, the relevant file that was stored in the external storage will be deleted as well. CUBRID supports the following two types of **LOB** :

- Binary Large Object (**BLOB**)
- Character Large Object (**CLOB**)

### Note

#### Terminologies

- **LOB** (Large Object): Large-sized objects such as binaries or text.
- **FBO** (File Based Object): An object that stores data of the database in an external file.
- **External LOB**: An object better known as FBO, which stores **LOB** data in a file into an external DB. It is supported by CUBRID. Internal **LOB** is an object that stores **LOB** data inside the DB.
- **External Storage**: An external storage to store LOB (example : POSIX file system).
- **LOB Locator**: The path name of a file stored in external storage.
- **LOB Data**: Details of a file in a specific location of LOB Locator.

When storing LOB data in external storage, the following naming convention will be applied:

```
{table_name}_{unique_name}
```

- *table\_name* : It is inserted as a prefix and able to store the **LOB** data of many tables in one external storage.
- *unique\_name* : The random name created by the DB server.

**LOB** data is stored in the local file system of the DB server. LOB data is stored in the path specified in the **-lob-base-path option** value of **cubrid createdb**; if this value is omitted, the data will be stored in the [db-vol path]/lob path where the database volume will be created. For more details, see [createdb](#) and [To create and manage LOB storage](#).

If a user change any **LOB** file without using CUBRID API or CUBRID tools, data consistency is not guaranteed.

If a **LOB** data file path that was registered to the database directory file(**databases.txt**) is deleted, please note that database server (**cub\_server**) and standalone utilities will not correctly work.

## BLOB

A type that stores binary data outside the database. The maximum length of **BLOB** data is the maximum file size creatable in an external storage. In SQL statements, the **BLOB** type expresses the input and output value in a bit string. That is, it is compatible with the **BIT** (n) and **BIT VARYING** (n) types, and only an explicit type change is allowed. If data lengths differ from one another, the maximum length is truncated to fit the smaller one. When converting the **BLOB** type value to a binary value, the length of the converted data cannot exceed 1GB. When converting binary data to the **BLOB** type, the size of the converted data cannot exceed the maximum file size provided by the **BLOB** storage.

## CLOB

A type that stores character string data outside the database. The maximum length of **CLOB** data is the maximum file size creatable in an external storage. In SQL statements, the **CLOB** type expresses the input and output value in a character string. That is, it is compatible with the **CHAR** (n), **VARCHAR** (n) types. However, only an explicit type change is allowed, and if data lengths are different from one another, the maximum length is truncated to fit to the smaller one. When converting the **CLOB** type value to a character string, the length of the converted data cannot exceed 1 GB. When converting a character string to the **CLOB** type, the size of the converted data cannot exceed the maximum file size provided by the **CLOB** storage.

## To Create and alter LOB

**BLOB** / **CLOB** type columns can be created/added/deleted by using a **CREATE TABLE** statement or an **ALTER TABLE** statement.

- You cannot create the index file for a **LOB** type column.
- You cannot define the **PRIMARY KEY**, **FOREIGN KEY**, **UNIQUE**, **NOT NULL** constraints for a **LOB** type column. However, **SHARED** property cannot be defined and **DEFAULT** property can only be defined by the **NULL** value.
- **LOB** type column/data cannot be the element of collection type.
- If you are deleting a record containing a **LOB** type column, all files located inside a **LOB** column value (Locator) and the external storage will be deleted. When a record containing a **LOB** type column is deleted in a basic key table, and a record of a foreign key table that refers to the foregoing details is deleted at once, all **LOB** files located in a **LOB** column value (Locator) and the external storage will be deleted. However, if the relevant table is deleted by using a **DROP TABLE** statement, or a **LOB** column is deleted by using an **ALTER TABLE...DROP** statement, only a **LOB** column value (**LOB** Locator) is deleted, and the **LOB** files inside the external storage which a **LOB** column refers to will not be deleted.

```
-- creating a table and CLOB column
CREATE TABLE doc_t (doc_id VARCHAR(64) PRIMARY KEY, content CLOB);

-- an error occurs when UNIQUE constraint is defined on CLOB column
ALTER TABLE doc_t ADD CONSTRAINT content_unique UNIQUE(content);

-- an error occurs when creating an index on CLOB column
CREATE INDEX i_doc_t_content ON doc_t (content);

-- creating a table and BLOB column
CREATE TABLE image_t (image_id VARCHAR(36) PRIMARY KEY, doc_id
VARCHAR(64) NOT NULL, image BLOB);

-- an error occurs when adding a BLOB column with NOT NULL constraint
ALTER TABLE image_t ADD COLUMN thumbnail BLOB NOT NULL;

-- an error occurs when adding a BLOB column with DEFAULT attribute
ALTER TABLE image_t ADD COLUMN thumbnail2 BLOB DEFAULT
BIT_TO_BLOB(X'010101');
```

## To store and update LOB

In a **BLOB** / **CLOB** type column, each **BLOB** / **CLOB** type value is stored, and if binary or character string data is input, you must explicitly change the types by using each `BIT_TO_BLOB()` and `CHAR_TO_CLOB()` function.

If a value is input in a **LOB** column by using an **INSERT** statement, a file is created in an external storage internally and the relevant data is stored; the relevant file path (Locator) is stored in an actual column value.

If a record containing a **LOB** column uses a **DELETE** statement, a file to which the relevant **LOB** column refers will be deleted simultaneously.

If a **LOB** column value is changed using an **UPDATE** statement, the column value will be changed following the operation below, according to whether a new value is **NULL** or not.

- If a **LOB** type column value is changed to a value that is not **NULL** : If a Locator that refers to an external file is already available in a **LOB** column, the relevant file will be deleted. A new file is created afterwards. After storing a value that is not **NULL**, a Locator for a new file will be stored in a **LOB** column value.
- If changing a **LOB** type column value to **NULL** : If a Locator that refers to an external file is already available in a **LOB** column, the relevant file will be deleted. And then **NULL** is stored in a **LOB** column value.

```
-- inserting data after explicit type conversion into CLOB type
column
```

```

INSERT INTO doc_t (doc_id, content) VALUES ('doc-1',
CHAR_TO_CLOB('This is a Dog'));
INSERT INTO doc_t (doc_id, content) VALUES ('doc-2',
CHAR_TO_CLOB('This is a Cat'));

-- inserting data after explicit type conversion into BLOB type
column
INSERT INTO image_t VALUES ('image-0', 'doc-0',
BIT_TO_BLOB(X'000001'));
INSERT INTO image_t VALUES ('image-1', 'doc-1',
BIT_TO_BLOB(X'000010'));
INSERT INTO image_t VALUES ('image-2', 'doc-2',
BIT_TO_BLOB(X'000100'));

-- inserting data from a sub-query result
INSERT INTO image_t SELECT 'image-1010', 'doc-1010', image FROM
image_t WHERE image_id = 'image-0';

-- updating CLOB column value to NULL
UPDATE doc_t SET content = NULL WHERE doc_id = 'doc-1';

-- updating CLOB column value
UPDATE doc_t SET content = CHAR_TO_CLOB('This is a Dog') WHERE
doc_id = 'doc-1';

-- updating BLOB column value
UPDATE image_t SET image = (SELECT image FROM image_t WHERE image_id
= 'image-0') WHERE image_id = 'image-1';

-- deleting BLOB column value and its referencing files
DELETE FROM image_t WHERE image_id = 'image-1010';

```

## To access LOB

When you get a **LOB** type column, the data stored in a file to which the column refers will be displayed. You can execute an explicit type change by using `CAST()` operator, `CLOB_TO_CHAR()` and `BLOB_TO_BIT()` function.

- If the query is executed in CSQL, a column value (Locator) will be displayed, instead of the data stored in a file. To display the data to which a **BLOB** / **CLOB** column refers, it must be changed to strings by `CLOB_TO_CHAR()` function.
- To use the string process function, the strings need to be converted by `CLOB_TO_CHAR()` function.
- You cannot specify a **LOB** column in **\*\* GROUP BY\*\*** clause and **ORDER BY** clause.
- Comparison operators, relational operators, **IN**, **NOT IN** operators cannot be used to compare **LOB** columns. However, **IS NULL** expression can be used to compare whether it is a **LOB** column

value (Locator) or **NULL**. This means that **TRUE** will be returned when a column value is **NULL**, and if a column value is **NULL**, there is no file to store **LOB** data.

- When a **LOB** column is created, and the file is deleted after data input, a **LOB** column value (Locator) will become a state that is referring to an invalid file. As such, using `CLOB_TO_CHAR()`, `BLOB_TO_BIT()`, `CLOB_LENGTH()` and `BLOB_LENGTH()` functions on the columns that have mismatching **LOB** Locator and a **LOB** data file enables them to display **NULL**.

```
-- displaying locator value when selecting CLOB and BLOB column in
CSQL interpreter
SELECT doc_t.doc_id, content, image FROM doc_t, image_t WHERE
doc_t.doc_id = image_t.doc_id;
```

```
doc_id          content          image
=====

```

### Note

- From CUBRID 11.4, the locator, which represents the LOB file path, **changed from an absolute file path to a relative one**. The relative path starts from '**lob-base-path**' in databases.txt. With this change, LOB file path management has become more flexible, and LOB file path problems have been reduced during database moves, backups, and restores.
- For example, if the '**lob-base-path**' path defined in databases.txt is /home1/data1, an example of the locator for each CUBRID version is as follows.
  - **CUBRID 11.4 (relative):** *file:ces\_004/doc\_t.00001366272829040346\_0773*
  - up to CUBRID 11.3 (**absolute**): *file:/home1/data1/ces\_004/doc\_t.00001366272829040346\_0773*
- Due to the locator being stored as a relative path, if '**lob-base-path**' in databases.txt is changed,
  - Previously created LOB data cannot be retrieved.

- To retrieve previously created LOB data, it should be moved to the updated '**lob-base-path**' directory.

```
# example:  
% cp -r /home1/data1/* /home2/data2
```

- LOB data created in CUBRID 11.3 or earlier, even though they store the locator as an absolute file path, can be retrieved in CUBRID 11.4 without any changes.
- Advantages during database moves and restores: Even if the database is moved to another location, there is no need to manually modify the LOB file path because the path is managed based on **lob-base-path**.
- The adoption of the **relative LOB file path** is one of the notable improvements in CUBRID 11.4, and it significantly enhances database management efficiency.

## Functions and Operators for LOB

You can explicitly cast bit/string type to **BLOB/CLOB** type and **BLOB/CLOB** type to bit/string type with `CAST()` operator. For more details, see `CAST()` operator.

```
CAST (<bit_type_column_or_value> AS { BLOB | CLOB })  
CAST (<char_type_column_or_value> AS { BLOB | CLOB })
```

These are the functions for BLOB/CLOB types. For more details, refer [LOB Functions](#).

- `CLOB_TO_CHAR()`
- `BLOB_TO_BIT()`
- `CHAR_TO_CLOB()`
- `BIT_TO_BLOB()`
- `CHAR_TO_BLOB()`
- `CLOB_FROM_FILE()`
- `BLOB_FROM_FILE()`
- `CLOB_LENGTH()`
- `BLOB_LENGTH()`

**Note**

“ <blob\_or\_clob\_column **IS NULL** “: using **IS NULL** condition, it compares the value of **LOB** column(Locator) if it's **NULL** or not. If it's **NULL**, this condition returns **TRUE**.

## To create and manage LOB storage

By default, the **LOB** data file is stored in the <db-volume-path>/lob directory where database volume is created. However, if the lob base path is specified with `createdb -B` option when creating the database, **LOB** data files will be stored in the directory designated. However, if the specified directory does not exist, CUBRID tries to create the directory and display an error message when it fails to create it. For more details, see `createdb -B` option.

```
# image_db volume is created in the current work directory, and a
LOB data file will be stored.
% cubrid createdb image_db en_US

# LOB data file is stored in the "/home1/data1" path within a local
file system.
% cubrid createdb --lob-base-path="file:/home1/data1" image_db en_US
```

You can identify a directory where a LOB file will be stored by executing the cubrid spacedb utility.

```
% cubrid spacedb image_db

Space description for database 'image_db' with pagesize 16.0K. (log
pagesize: 16.0K)

Valid Purpose total_size free_size Vol Name
0 GENERIC 512.0M 510.1M /home1/data1/image_db

Space description for temporary volumes for database 'image_db' with
pagesize 16.0K.

Valid Purpose total_size free_size Vol Name
LOB space description file:/home1/data1
```

To expand or change the **lob-base-path** of the database, change its **lob-base-path** of **databases.txt** file. Restart the database server to apply the changes made to **databases.txt**.

However, even if you change the **lob-base-path** of **databases.txt**, access to the **LOB** data stored in a previous storage is possible.

```
# You can change to a new directory from the lob-base-path of
databases.txt file.
% cat $CUBRID_DATABASES/databases.txt

#db-name      vol-path          db-host      log-path
lob-base-path
image_db      /home1/data1    localhost    /home1/data1
file:/home1/data2
```

Backup/recovery for data files of **LOB** type columns are not supported, while those for meta data(Locator) are supported.

If you are copying a database by using **copydb** utility, you must configure the **databases.txt** additionally, as the **LOB** file directory path will not be copied if the related option is not specified. For more details, see the `copydb -B` and `copydb --copy-lob-path` options.

## Transaction and Recovery

Commit/Rollback for **LOB** data changes are supported. That is, it ensures the validation of mapping between **LOB** Locator and actual **LOB** data within transactions, and it supports recovery during DB errors. This means that an error will be displayed in case of mapping errors between **LOB** Locator and **LOB** data due to the rollback of the relevant transactions, as the database is terminated during transactions. See the example below.

```
-- csql> ;AUTOCOMMIT OFF

CREATE TABLE doc_t (doc_id VARCHAR(64) PRIMARY KEY, content CLOB);
INSERT INTO doc_t VALUES ('doc-10', CHAR_TO_CLOB('This is content'));
COMMIT;
UPDATE doc_t SET content = CHAR_TO_CLOB('This is content 2') WHERE
doc_id = 'doc-10';
ROLLBACK;
SELECT doc_id, CLOB_TO_CHAR(content) FROM doc_t WHERE doc_id =
'doc-10';
```

```
doc_id  content
=====
'doc-10' 'This is content'
```

```
-- csql> ;AUTOCOMMIT OFF
```

```
INSERT INTO doc_t VALUES ('doc-11', CHAR_TO_CLOB ('This is
content'));
COMMIT;
UPDATE doc_t SET content = CHAR_TO_CLOB('This is content 3') WHERE
doc_id = 'doc-11';

-- system crash occurred and then restart server
SELECT doc_id, CLOB_TO_CHAR(content) FROM doc_t WHERE doc_id =
'doc-11';
```

```
-- Error : LOB Locator references to the previous LOB data because
only LOB Locator is rollbacked.
```

### Note

- When selecting **LOB** data in an application through a driver such as JDBC, the driver can get **ResultSet** from DB server and fetch the record while changing the cursor location on **ResultSet**. That is, only Locator, the meta data of a **LOB** column, is stored at the time when **ResultSet** is imported, and **LOB** data that is referred by a File Locator will be fetched from the file Locator at the time when a record is fetched. Therefore, if **LOB** data is updated between two different points of time, there could be an error, as the mapping of **LOB** Locator and actual **LOB** data will be invalid.
- Since backup/recovery is supported only for meta data (Locator) of the **LOB** type columns, an error is likely to occur, as the mapping of **LOB** Locator and LOB data is invalid if recovery is performed based on a specific point of time.
- TO execute **INSERT** the **LOB** data into other device, LOB data referred by the meta data (Locator) of a **LOB** column must be read.
- In a CUBRID HA environment, the meta data (Locator) of a **LOB** column is replicated and data of a **LOB** type is not replicated. Therefore, if storage of a **LOB** type is located on the local machine, no tasks on the columns in a slave node or a master node after failover are allowed.

### Warning

Up to CUBRID 2008 R3.0, Large Objects are processed by using **glo** (Generalized Large Object) classes. However, the **glo** classes has been deprecated since the CUBRID 2008 R3.1. Instead of

it, **LOB** / **CLOB** data type is supported. Therefore, both DB schema and application must be modified when upgrading CUBRID in an environment using the previous version of **glo** classes.

## Collection Types

Allowing multiple data values to be stored in a single attribute is an extended feature of relational database. Each element of a collection is possible to have different data type each other except View. Rest types except BLOB and CLOB can be an element of collection types.

| Type                 | Description                                                              | Definition                                                                | Input Data                | Stored Data               |
|----------------------|--------------------------------------------------------------------------|---------------------------------------------------------------------------|---------------------------|---------------------------|
| <b>SET</b>           | A union which does not allow duplicates                                  | col_name SET<br>VARCHAR(20)<br>or col_name SET<br>(VARCHAR(20))           | {'c','c','c','b','b','a'} | {'a','b','c'}             |
| <b>MULTISET</b>      | A union which allows duplicates                                          | col_name MULTISET<br>VARCHAR(20)<br>or col_name MULTISET<br>(VARCHAR(20)) | {'c','c','c','b','b','a'} | {'a','b','b','c','c','c'} |
| <b>LIST SEQUENCE</b> | or A union which allows duplicates and stores data in the order of input | col_name LIST<br>VARCHAR(20)<br>or col_name LIST<br>(VARCHAR(20))         | {'c','c','c','b','b','a'} | {'c','c','c','b','b','a'} |

As you see the table above, the value specified as a collection type can be inputted with curly braces ('{', '}') each value is separated with a comma (,).

If the specified collection types are identical, the collection types can be cast explicitly by using the **CAST** operator. The following table shows the collection types that allow explicit coercions.

| FROM \ TO | SET | MULTISET | LIST |
|-----------|-----|----------|------|
| SET       | -   | Yes      | Yes  |
| MULTISET  | Yes | -        | No   |
| LIST      | Yes | Yes      | -    |

Collection Types do not support collations. Therefore, Below query returns error.

```
CREATE TABLE tbl (str SET (string) COLLATE utf8_en_ci);
```

```
Syntax error: unexpected 'COLLATE', expecting ',', ' or ')
```

## SET

**SET** is a collection type in which each element has different values. Elements of a **SET** are allowed to have only one data type. It can have records of other tables.

```
CREATE TABLE set_tbl (col_1 SET (CHAR(1)));
INSERT INTO set_tbl VALUES ({'c','c','c','b','b','a'});
INSERT INTO set_tbl VALUES ({NULL});
INSERT INTO set_tbl VALUES ({''});
SELECT * FROM set_tbl;
```

```
col_1
=====
{'a', 'b', 'c'}
{NULL}
{' '}
```

```
SELECT CAST (col_1 AS MULTISET), CAST (col_1 AS LIST) FROM set_tbl;
```

```
cast(col_1 as multiset)  cast(col_1 as sequence)
=====
{'a', 'b', 'c'}  {'a', 'b', 'c'}
```

```
{NULL} {NULL}
{' '} {' '}
```

```
INSERT INTO set_tbl VALUES ('');
```

```
ERROR: Casting '' to type set is not supported.
```

## MULTISET

**MULTISET** is a collection type in which duplicated elements are allowed. Elements of a **MULTISET** are allowed to have only one data type. It can have records of other tables.

```
CREATE TABLE multiset_tbl (col_1 MULTISET (CHAR(1)));
INSERT INTO multiset_tbl VALUES ({'c','c','c','b','b','a'});
SELECT * FROM multiset_tbl;
```

```
col_1
=====
{'a','b','b','c','c','c'}
```

```
SELECT CAST(col_1 AS SET), CAST(col_1 AS LIST) FROM multiset_tbl;
```

```
cast(col_1 as set)  cast(col_1 as sequence)
=====
{'a','b','c'} {'c','c','c','b','b','a'}
```

## LIST/SEQUENCE

**LIST** (= **SEQUENCE**) is a collection type in which the input order of elements is preserved, and duplications are allowed. Elements of a **LIST** are allowed to have only one data type. It can have records of other tables.

```
CREATE TABLE list_tbl (col_1 LIST (CHAR(1)));
INSERT INTO list_tbl VALUES ({'c','c','c','b','b','a'});
SELECT * FROM list_tbl;
```

```
col_1
=====
{'c', 'c', 'c', 'b', 'b', 'a'}
```

```
SELECT CAST(col_1 AS SET), CAST(col_1 AS MULTiset) FROM list_tbl;
```

```
cast(col_1 as set) cast(col_1 as multiset)
=====
{'a', 'b', 'c'} {'a', 'b', 'b', 'c', 'c', 'c'}
```

## JSON Data Type

From CUBRID 10.2, native **JSON** data type is supported as defined by [RFC 7159](#). **JSON** data type offers automatic validation and allows fast access and operations on JSON data.

### Note

Old driver versions connecting to CUBRID 10.2 server interpret a JSON type column as Varchar.

## Creating JSON data

JSON values are automatically converted (parsed) from string format when they're assigned to JSON data type columns.

```
-- assign a string to JSON type column
CREATE TABLE t (id int, j JSON);
INSERT INTO t VALUES (1, '{"a":1}');
SELECT j, TYPEOF(j) FROM t;
```

```
j                                typeof(j)
=====
{'a':1}                          'json'
```

Conversions to JSON can also be forced through **CAST** or by using json keyword before strings.

```
-- cast string to json
SELECT CAST('{"a":1}' as JSON);
```

```
cast('{ "a":1}' as json)
=====
{"a":1}
```

```
-- use json keyword
SELECT json'{ "a":1}', TYPEOF (json'{ "a":1}');
```

```
json '{ "a":1}'          typeof(json '{ "a":1}')
=====
{"a":1}                  'json'
```

JSON data type may also be created using `JSON_OBJECT` and `JSON_ARRAY` functions.

## JSON Validation

Conversion to JSON data does built-in validation and reports an error if the string is not a valid JSON.

```
-- non-quoted string is not a valid json
SELECT json'abc';
```

```
In line 1, column 8,
ERROR: before ' ; '
Invalid JSON: 'abc'.
```

JSON type columns with stricter validation rules can be defined using the [draft JSON Schema standard](#). If you are not familiar with JSON Schema, you may refer to [Understanding JSON Schema](#).

A simple example of how schema can be used:

```
-- set j column to accept only string type JSON's
CREATE TABLE t (id int, j JSON ('{"type": "string"}'));
```

```
-- inserting string type JSON passes schema validation
INSERT into t values (1, '"abc"');
```

```
1 command(s) successfully processed.
```

```
-- inserting object type JSON does not pass schema validation
INSERT into t values (2, '{"a":1}');
```

```
ERROR: before ' ); '
The provided JSON has been invalidated by the JSON schema (Invalid
schema path: #, Keyword: type, Invalid provided JSON path: #)
```

## JSON Value Types

A JSON value must be an object, an array or a scalar (string, number, boolean or null), as defined by [RFC 7159](#).

A table of JSON value types:

| Type   |        | CUBRID JSON type | Description                                            |
|--------|--------|------------------|--------------------------------------------------------|
| Object |        | JSON_OBJECT      | A set of key-value pairs                               |
| Array  |        | JSON_ARRAY       | An array of JSON values                                |
| Scalar | String | STRING           | A quoted string                                        |
|        | Number | INTEGER          | 32-bit signed integer                                  |
|        |        | BIGINT           | 64-bit signed integer                                  |
|        |        | DOUBLE           | Non-integer number or integer bigger than $2^{63} - 1$ |
|        | true   | BOOLEAN          | True boolean value                                     |
|        | false  | BOOLEAN          | False boolean value                                    |

| Type | CUBRID JSON type | Description |
|------|------------------|-------------|
| null | JSON_NULL        | Null value  |

The CUBRID JSON type of a JSON value can be obtained with `JSON_TYPE` function.

## JSON Data Conversions

JSON data types can be obtained by explicit or implicit casting from and to other types.

Casting a JSON value to JSON type may fail if desired type has a schema and converted value does not pass schema validation.

Converting other types to JSON is explained by next table:

| Original type                                                                                                   | CUBRID JSON type                                              |
|-----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| Any string                                                                                                      | String is parsed as JSON data. The result may be of any type. |
| <div><b>Note</b></div> <p>If string codeset is not UTF8, string is first converted to UTF8 and then parsed.</p> |                                                               |
| Short, Integer                                                                                                  | INTEGER                                                       |
| Bigint                                                                                                          | BIGINT                                                        |
| Float, Double                                                                                                   | DOUBLE                                                        |
| Numeric                                                                                                         | DOUBLE                                                        |

Converting JSON data type to other types is explained by next table:

| CUBRID JSON Type | Other accepted types                                                              |
|------------------|-----------------------------------------------------------------------------------|
| JSON_OBJECT      | String with printed JSON                                                          |
| JSON_ARRAY       | String with printed JSON                                                          |
| STRING           | Any type that a string can be converted to                                        |
| INTEGER          | Any type that an integer can be converted to                                      |
| BIGINT           | Any type that a bigint can be converted to                                        |
| DOUBLE           | Any type that a double can be converted to                                        |
| BOOLEAN          | “true” or “false” if converted to string<br>0 or 1 if converted to a numeric type |
| JSON_NULL        | String with printed JSON ‘null’                                                   |

## JSON Paths

JSON Paths provide ways of addressing json elements inside a JSON. Many of the JSON functions require a JSON Path or JSON Pointer argument to define the location inside the JSON where operations are performed. JSON Paths always start with ‘\$’ and may be followed by array indexes, object key tokens and wildcards. If ‘\$’ is followed by no other tokens, then path points to JSON data root.

```

<json_path>::=
  <start_token> [<path_token>] ...

<start_token>::=
  $

<path_token>::=
  <array_access_token> | <object_key_access_token> |

```

```

<wildcard_token>

<array_access_token>::=
    [idx]

<object_key_access_token>::=
    .[key_identifier | "key_str"]

<wildcard_token>::=
    .*|[*]**path_token

```

As an example, relative to `{“a”:[0,1,2,{“b”:5}]}` `$.a[3].b` would mean: “The member having key ‘b’ of the element at index 3 of the member having key ‘a’ of the root” and would address the json value ‘5’; Object\_key\_access\_tokens as key string can be used to express the same key\_identifiers and can also enable using characters that need escaping, e.g. `$.””` can be used to refer to a member having a double quote as a key.

JSON wildcards can be one of three types:

- `.*`, object member access matching wildcards
- `[*]`, array index access matching wildcards
- `**`, matching a sequence of object keys and array indexes. `**` wildcards must be suffixed by a token

Path expressions, like JSON Pointers and JSON text, should be encoded using ASCII or UTF-8 character set. If other character sets are used, a coercion will be done to UTF-8.

## JSON Pointers

JSON Pointers, as defined by <https://datatracker.ietf.org/doc/html/rfc6901> provide an alternative to JSON paths. JSON Pointers, like JSON Paths and JSON text, should be encoded using ASCII or UTF-8 character set. If other character sets are used, a coercion will be done to UTF-8.

```

<json_pointer>::=
    [/path_token] ... [/ -]

```

```

'$.a[10].bb' is equivalent to '/a/10/bb'
'$' is equivalent to ''

```

The special character `-` can be used exclusively as a last path\_token and can be used to address the end of a json\_array.

JSON pointers can be used to address the same path as their corresponding no-wildcards JSON paths.

## Implicit Type Conversion

An implicit type conversion represents an automatic conversion of a type of expression to a corresponding type.

**SET**, **MULTISET**, **LIST** and **SEQUENCE** should be converted explicitly.

If you convert the **DATETIME** and the **TIMESTAMP** types (including types having timezone) to the **DATE** type or the **TIME** type, data loss may occur. If you convert the **DATE** type to the **DATETIME** type or the **TIMESTAMP** type (or types with timezone), the time will be set to '12:00:00 AM.'

Timezone part of values with timezone types has only a reference purpose, their absolute value is stored as UTC reference. When converting from a value of type with timezone to a type without timezone, a conversion is operated as if session timezone is used. When converting from a value of type without timezone to a type with timezone, the conversion takes place considering the session timezone. For more details on converting to/from value with timezone type see [Date/Time Types](#).

If you convert a string type or an exact numeric type to a floating-point numeric type, the value may not be accurate. Because a string type and an exact type use a decimal precision to represent the value, but a floating-point numeric type uses a binary precision.

The implicit type conversion executed by CUBRID is as follows:

**Implicit Type Conversion Table 1**

| From<br>To        | DATE<br>TIME | DATE<br>TIMEL<br>TZ | DATE<br>TIMET<br>Z | DATE | TIME | TIMES<br>TAMP | TIMES<br>TAMP<br>LTZ | TIMES<br>TAMP<br>TZ |
|-------------------|--------------|---------------------|--------------------|------|------|---------------|----------------------|---------------------|
| DATETIME          | -            | 0                   | 0                  | 0    | 0    | 0             | 0                    | 0                   |
| DATETIME<br>MELTZ | 0            | -                   | 0                  | 0    | 0    | 0             | 0                    | 0                   |
| DATETIME<br>METZ  | 0            | 0                   | -                  | 0    | 0    | 0             | 0                    | 0                   |

| From<br>\ To     | DATE<br>TIME | DATE<br>TIMEL<br>TZ | DATE<br>TIMET<br>Z | DATE | TIME | TIMES<br>TAMP | TIMES<br>TAMP<br>LTZ | TIMES<br>TAMP<br>TZ |
|------------------|--------------|---------------------|--------------------|------|------|---------------|----------------------|---------------------|
| DATE             | 0            | 0                   | 0                  | -    |      | 0             | 0                    | 0                   |
| TIME             |              |                     |                    |      | -    |               |                      |                     |
| TIMEST<br>AMP    | 0            | 0                   | 0                  | 0    | 0    | -             | 0                    | 0                   |
| TIMEST<br>AMPLTZ | 0            | 0                   | 0                  | 0    | 0    | 0             | -                    | 0                   |
| TIMEST<br>AMPTZ  | 0            | 0                   | 0                  | 0    | 0    | 0             | 0                    | -                   |
| DOUBL<br>E       |              |                     |                    |      | 0    | 0             | 0                    | 0                   |
| FLOAT            |              |                     |                    |      | 0    | 0             | 0                    | 0                   |
| NUMER<br>IC      |              |                     |                    |      |      | 0             | 0                    | 0                   |
| BIGINT           |              |                     |                    |      | 0    | 0             | 0                    | 0                   |
| INT              |              |                     |                    |      | 0    | 0             | 0                    | 0                   |
| SHORT            |              |                     |                    |      | 0    | 0             | 0                    | 0                   |
| BIT              |              |                     |                    |      |      |               |                      |                     |

| From<br>To | DATE<br>TIME | DATE<br>TIMEL<br>TZ | DATE<br>TIMET<br>Z | DATE | TIME | TIMES<br>TAMP | TIMES<br>TAMP<br>LTZ | TIMES<br>TAMP<br>TZ |

| VARBIT     |              |                     |                    |      |      |               |                      |                     |
| CHAR       | 0            | 0                   | 0                  | 0    | 0    | 0             | 0                    | 0                   |
| VARCHAR    | 0            | 0                   | 0                  | 0    | 0    | 0             | 0                    | 0                   |

#### Limitations when numeric value is changed as **TIME** or **TIMESTAMP** (**TIMESTAMPLTZ**, **TIMESTAMPTZ**)

- All numeric types except for **NUMERIC** type can be converted into **TIME** type; at this time, it represents a value of the remainder which is calculated by dividing the input number into 86,400 seconds(1 day), and the remainder is calculated as seconds.
- All numeric types including **NUMERIC** can be converted into **TIMESTAMP**, **TIMESTAMPLTZ**, **TIMESTAMPTZ** types ; at this time, the input number cannot exceed 2,147,483,647 as the maximum.

**Implicit Type Conversion Table 2**

| From<br>To          | INT | SHORT<br>RT | BIT | VAR<br>BIT | CHAR | VARCHAR | DOUBLE | FLOAT | NUMERIC | BIGINT |
|---------------------|-----|-------------|-----|------------|------|---------|--------|-------|---------|--------|

| VARCHAR   | 0   | 0     | 0      | 0      | 0    | -       | 0     | 0     | 0       | 0      |

## Conversion Rules

### INSERT and UPDATE

The type will be converted to the type of the column affected.

```
CREATE TABLE t(i INT);
INSERT INTO t VALUES('123');

SELECT * FROM t;
```

```
      i
=====
     123
```

## Function

If the parameter value entered in the function can be converted to the specified type, the parameter type will be converted. The strings are converted to numbers because the input parameter expected in the following function is a number.

```
SELECT MOD('123', '2');
```

```
mod('123', '2')
=====
1.0000000000000000e+00
```

You can enter multiple type values in the function. If the type value not specified in the function is delivered, the type will be converted depending on the following priority order.

- Date/Time Type ( **DATETIME** > **TIMESTAMP** > **DATE** > **TIME** )
- Approximate Numeric Type ( **DOUBLE** > **FLOAT** )
- Exact Numeric Type ( **NUMERIC** > **BIGINT** > **INT** > **SHORT** )
- String Type ( **CHAR** > **VARCHAR** )

## Comparison Operation

The following are the conversion rules according to an operand type of the comparison operator.

| operand1 Type | operand2 Type  | Conversion                         |  | Comparison     |
|---------------|----------------|------------------------------------|--|----------------|
| Numeric Type  | Numeric Type   | None                               |  | NUMERIC        |
|               | String Type    | Converts operand2 to <b>DOUBLE</b> |  | NUMERIC        |
|               | Date/Time Type | Converts operand1 to Date/Time     |  | TIME/TIMESTAMP |
| String Type   | Numeric Type   | Converts operand1 to <b>DOUBLE</b> |  | NUMERIC        |

| operand1 Type  | operand2 Type  | Conversion                                   | Comparison     |
|----------------|----------------|----------------------------------------------|----------------|
| Date/Time Type | String Type    | None                                         | String         |
|                | Date/Time Type | Converts operand1 to Date/Time type          | Date/Time      |
|                | Numeric Type   | Converts operand2 to Date/Time               | TIME/TIMESTAMP |
|                | String Type    | Converts operand2 to Date/Time type          | Date/Time      |
|                | Date/Time Type | Converts it to the type with higher priority | Date/Time      |

When Date/Time type and numeric type are compared, see [Limitations when numeric value is changed as TIME or TIMESTAMP](#) of the above table.

There are exceptions when operand1 is string type and operand2 is a value.

| operand1 Type | operand2 Type  | Conversion                           | Comparison |
|---------------|----------------|--------------------------------------|------------|
| String type   | Numeric type   | Converts operand2 to the string type | String     |
|               | Date/Time type | Converts operand2 to the string type | String     |

If operand2 is a set operator( **IS IN**, **IS NOT IN**, **= ALL**, **= ANY**, **< ALL**, **< ANY**, **<= ALL**, **<= ANY**, **>= ALL**, **>= ANY** ), the exception above is not applied.

The following is examples of implicit type conversion in comparison operations.

#### • Numeric Type & String Type Operands

The string type operand will be converted to **DOUBLE**.

```
CREATE TABLE t1(i INT, s STRING);
INSERT INTO t1 VALUES(1,'1'),(2,'2'),(3,'3'),(4,'4'), (12,'12');

SELECT i FROM t1 WHERE i < '11.3';
```

```
      i
=====
      1
      2
      3
      4
```

```
SELECT ('2' <= 11);
```

```
      ('2'<11)
=====
           1
```

#### · String Type & Date/Time Type Operands

The string type operand will be converted to the date/time type.

```
SELECT ('2010-01-01' < date'2010-02-02');
```

```
      ('2010-01-01'<date '2010-02-02')
=====
                                   1
```

```
SELECT (date'2010-02-02' >= '2010-01-01');
```

```
      (date '2010-02-02'>='2010-01-01')
=====
                                   1
```

#### · String Type & Numeric Type Host Variable Operands

The numeric type host variable will be converted to the string type.

```
PREPARE s FROM 'SELECT s FROM t1 WHERE s < ?';
EXECUTE s USING 11;
```

```
      s
=====
      '1'
```

### · String Type & Numeric Type value Operands

The numeric type value will be converted to the string type.

```
SELECT s FROM t1 WHERE s > 11;
```

```
      s
=====
      '2'
      '3'
      '4'
      '12'
```

```
SELECT s FROM t1 WHERE s BETWEEN 11 AND 33;
```

```
      s
=====
      '2'
      '3'
      '12'
```

### · String Type Column & Date/Time Type Value Operands

The date/time type value will be converted to the string type.

```
CREATE TABLE t2 (s STRING);
INSERT INTO t2 VALUES ('01/01/1998'), ('01/01/1999'),
('01/01/2000');
SELECT s FROM t2;
```

```
      s
=====
      '01/01/1998'
```

```
'01/01/1999'
'01/01/2000'
```

```
SELECT s FROM t2 WHERE s <= date'02/02/1998';
```

In the above query, comparison operation is performed by converting date'02/02/1998' into string '02/02/1998'.

```
      s
=====
'01/01/1998'
'01/01/1999'
'01/01/2000'
```

## Range Operation

### · Numeric Type and String Type Operands

The string type operand will be converted to **DOUBLE**.

```
CREATE TABLE t3 (i INT);
INSERT INTO t3 VALUES (1), (2), (3), (4);
SELECT i FROM t3 WHERE i <= ALL {'11', '12'};
```

```
      i
=====
1
2
3
4
```

### · String Type and Date/Time Type Operands

The string type operand will be converted to the date/time type.

```
SELECT s FROM t2;
```

```
      s
=====
'01/01/1998'
```

```
'01/01/1999'
'01/01/2000'
```

```
SELECT s FROM t2 WHERE s <= ALL {date'02/02/1998',date'01/01/2000'};
```

```
s
=====
'01/01/1998'
```

An error will be returned if it cannot be converted to the corresponding type.

## Arithmetic Operation

### • Date/Time Type Operand

If the date/time type operands are given to '-' operator and the types are different from each other, it will be converted to the type with a higher priority. The following example shows that the operand data type on the left is converted from **DATE** to **DATETIME** so that the result of '-' operation of **DATETIME** can be outputted in milliseconds.

```
SELECT date'2002-01-01' - datetime'2001-02-02 12:00:00 am';
```

```
date '2002-01-01'- datetime '2001-02-02 12:00:00 am'
=====
28771200000
```

### • Numeric Type Operand

If the numeric type operands are given and the types are different from each other, it will be converted to the type with the higher priority.

### • Date/Time Type & Numeric Type Operands

If the date/time type and the numeric type operands are given to '+' or '-' operator, the numeric type operand is converted to either **BIGINT**, **INT** or **SHORT**.

### • Date/Time Type & String Type Operands

If a date/time type and a string type are operands, only '+' and '-' operators are allowed. If the '+' operator is used, it will be applied according to the following rules.

- The string type will be converted to **BIGINT** with an interval value. The interval is the smallest unit for operands in the Date/Time type, and the interval for each type is as follows:
  - **DATE** : Days
  - **TIME, TIMESTAMP** : Seconds
  - **DATETIME** : Milliseconds
- Floating-point numbers are rounded.
- The result type is the type of an date/time operand.

```
SELECT date'2002-01-01' + '10';
```

```
date '2002-01-01'+'10'
=====
01/11/2002
```

If the date/time type and a string type are operands and the '-' operator is used, they will be applied according to the following rules.

- If the date/time type operands are **DATE**, **DATETIME** and **TIMESTAMP**, the string will be converted to **DATETIME**; if the date/time operand is **TIME**, the string is converted to **TIME**.
- The result type is always **BIGINT**.

```
SELECT date'2002-01-01'-'2001-01-01';
```

```
date '2002-01-01'-'2001-01-01'
=====
31536000000
-- this causes an error
```

```
SELECT date'2002-01-01'-'10';
```

```
ERROR: Cannot coerce '10' to type datetime.
```

## · Numeric Type & String Type Operands

If a numeric type and a string type are operands, they will be applied according to the following rules.

- Strings will be converted to **DOUBLE** when possible.
- The result type is **DOUBLE** and depends on the type of the numeric operand.

```
SELECT 4 + '5.2';
```

```

              4+'5.2'
=====
9.199999999999999e+00

```

Unlike CUBRID 2008 R3.1 and the earlier versions, the string in the date/time format, that is, the string such as '2010-09-15' is not converted to the date/time type. You can use a literal DATE'2010-09-15' with the date/time type for addition and subtraction operations.

```
SELECT '2002-01-01'+1;
```

```
ERROR: Cannot coerce '2002-01-01' to type double.
```

```
SELECT DATE'2002-01-01'+1;
```

```

date '2002-01-01'+1
=====
01/02/2002

```

## · String Type Operand

If you multiply, divide or subtract both strings, the result returns a **DOUBLE** type value.

```
SELECT '3'*'2';
```

```

              '3'*'2'
=====
6.000000000000000e+00

```

The '+' operator action depends on how to set the system parameter **plus\_as\_concat** in the **cubrid.conf** file. For details, see [Statement/Type-Related Parameters](#).

- If a value for **plus\_as\_concat** is yes (default value), the concatenation of two strings will be returned.

```
SELECT '1'+'1';
```

```
          '1'+'1'
=====
          '11'
```

- If a value for **plus\_as\_concat** is no and two strings can be converted to numbers, the **DOUBLE** type value will be returned by adding the two numbers.

```
SELECT '1'+'1';
```

```
          '1'+'1'
=====
2.0000000000000000e+00
```

An error will be returned if it cannot be converted to the corresponding type.

## Data Definition Statements

### TABLE DEFINITION STATEMENTS

#### CREATE TABLE

##### Table Definition

Use **CREATE TABLE** statement to create a table. A table with the same name as an existing view or synonym cannot be created. Regarding writing table name, see [Identifier](#).

```
CREATE {TABLE | CLASS} [IF NOT EXISTS] [schema_name.]table_name
[<subclass_definition>]
[CLASS ATTRIBUTE (<column_definition>, ...)]
```

```

[([{<table_constraint>}... ,] <column_definition> [{,
{<column_definition> | <table_constraint>}}...])]
[INHERIT <resolution>, ...]
[<table_options>]

    <subclass_definition> ::= {UNDER | AS SUBCLASS OF}
[<schema_name.>]superclass_name, ...

    <column_definition> ::=
        column_name <data_type> [{<default_or_shared_or_ai> |

collation_name] |
        ENCRYPT [=] [AES | ARIA] |
        AUTO_INCREMENT = initial_value

    <index_with_option> ::= {DEDUPLICATE '=' deduplicate_level }

```

- IF NOT EXISTS: If an identically named table already exists, a new table will not be created without an error.
- *schema\_name*: Specifies the schema name(maximum: 31 bytes). If omitted, the schema name of the current session is used.
- *table\_name*: specifies the name of the table to be created (maximum: 222 bytes).
- *column\_name*: specifies the name of the column to be created (maximum: 254 bytes).
- *column\_type*: specifies the data type of the column.
- [**SHARED** value | **DEFAULT** value]: specifies the initial value of the column.

- **ON UPDATE** specifies an expression to update the field when the field's ROW gets updated. For details, see [ON UPDATE](#).
- *<column\_constraint>*: specifies the constraint of the column. Available constraints are **NOT NULL**, **UNIQUE**, **PRIMARY KEY** and **FOREIGN KEY**.
- *<default\_or\_shared\_or\_ai>*: only one of DEFAULT, SHARED, AUTO\_INCREMENT can be used. When AUTO\_INCREMENT is specified, "(seed, increment)" and "AUTO\_INCREMENT = initial\_value" cannot be defined at the same time.
- *table\_comment\_string*: specifies a table's comment
- *column\_comment\_string*: specifies a column's comment.
- *index\_comment\_string*: specifies an index's comment.
- *deduplicate\_level*: specifies the deduplicate level (0 to 14). For details, see [DEDUPLICATE](#).

#### Note

- **DBA** and **DBA** members can create tables in different schemas. If a user is neither **DBA** nor **DBA** member, tables can only be created in the schema of that user.

#### Note

- *deduplicate\_level* is an integer from 0 to 14.
- When this parameter is set to 0, it indicates an index configuration where data deduplication within indexes is not performed. This configuration is the same as that in CUBRID 11.2 or an earlier version.

```
CREATE TABLE olympic2 (
  host_year      INT      NOT NULL PRIMARY KEY,
  host_nation    VARCHAR(40) NOT NULL,
  host_city      VARCHAR(20) NOT NULL,
  opening_date   DATE      NOT NULL,
  closing_date   DATE      NOT NULL,
  mascot        VARCHAR(20),
  slogan         VARCHAR(40),
  introduction    VARCHAR(1500)
);
```

The below adds a comment of a table with ALTER statement.

```
ALTER TABLE olympic2 COMMENT = 'this is new comment for olympic2';
```

The below includes an index comment when you create a table.

```
CREATE TABLE tbl (a INT, index i_t_a (a) COMMENT 'index comment');
```

### Note

#### A CHECK constraint in the table schema

A CHECK constraint defined in the table schema is parsed, but ignored. The reason of being parsed is to support the compatibility when DB migration from other DBMS is done.

```
CREATE TABLE tbl (
  id INT PRIMARY KEY,
  CHECK (id > 0)
)
```

## Column Definition

A column is a set of data values of a particular simple type, one for each row of the table.

```
<column_definition> ::=
  column_name <data_type> [[<default_or_shared_or_ai>] |
  [<on_update>] | [<column_constraint>]] ... [COMMENT 'comment_string']

  <data_type> ::= <column_type> [<charset_modifier_clause>]
  [<collation_modifier_clause>]

  <charset_modifier_clause> ::= {CHARACTER_SET|CHARSET}
  {<char_string_literal>|<identifier>}

  <collation_modifier_clause> ::= COLLATE
  {<char_string_literal>|<identifier>}

  <default_or_shared_or_ai> ::=
    SHARED <value_specification> |
    DEFAULT <value_specification> |
    AUTO_INCREMENT [(seed, increment)]

  <on_update> ::= [ON UPDATE <value_specification>]
```

```
<column_constraint> ::= [CONSTRAINT constraint_name] {NOT NULL |
UNIQUE | PRIMARY KEY | [FOREIGN KEY] [WITH <index_with_option>]
<referential_definition>}
```

## Column Name

How to create a column name, see **Identifier**. You can alter created column name by using the **RENAME COLUMN Clause** of the **ALTER TABLE** statement.

The following example shows how to create the *manager2* table that has the following two columns: *full\_name* and *age*.

```
CREATE TABLE manager2 (full_name VARCHAR(40), age INT );
```

### Note

- The first character of a column name must be an alphabet.
- The column name must be unique in the table.

## Setting the Column Initial Value (SHARED, DEFAULT)

An attribute in a table can be created with an initial **SHARED** or **DEFAULT** value. You can change the value of **SHARED** and **DEFAULT** in the **ALTER TABLE** statement.

- **SHARED** : Column values are identical in all rows. If a value different from the initial value is **INSERTed**, the column value is updated to a new one in every row.
- **DEFAULT** : The initial value set when the **DEFAULT** attribute was defined is stored even if the column value is not specified when a new row is inserted.

The pseudocolumn allows for the **DEFAULT** value as follows.

| DEFAULT Value    | Data Type |
|------------------|-----------|
| SYS_TIMESTAMP    | TIMESTAMP |
| UNIX_TIMESTAMP() | INTEGER   |

| DEFAULT Value                | Data Type |
|------------------------------|-----------|
| CURRENT_TIMESTAMP            | TIMESTAMP |
| SYS_DATETIME                 | DATETIME  |
| CURRENT_DATETIME             | DATETIME  |
| SYS_DATE                     | DATE      |
| CURRENT_DATE                 | DATE      |
| SYS_TIME                     | TIME      |
| CURRENT_TIME                 | TIME      |
| USER, USER()                 | STRING    |
| TO_CHAR(date_time[, format]) | STRING    |
| TO_CHAR(number[, format])    | STRING    |

### Note

When using a function not specified in the table above as a **DEFAULT** value, it is evaluated at the time of table creation and stored as the **DEFAULT** value. Therefore, during an **INSERT**, the default value used for the column is not the function result at the time of **INSERT**, but the value evaluated at the time the table was created. Stored functions cannot be used as **DEFAULT** values, and doing so results in an error.

```
CREATE TABLE default_val_func_test (id INT DEFAULT RAND ());
INSERT INTO default_val_func_test (id) VALUES (1);
INSERT INTO default_val_func_test (id) VALUES (DEFAULT);
```

```
INSERT INTO default_val_func_test (id) VALUES (DEFAULT);

SELECT * FROM default_val_func_test;
```

```
      id
=====
      1
1572882525
1572882525
```

```
CREATE FUNCTION fn_int (a int) return int as begin return a; end;
CREATE TABLE default_val_sp_test (id INT DEFAULT fn_int (1));
```

```
ERROR: before ' ); '
'fn_int(1)' function can not be used in DEFAULT clause.
```

#### Note

In version lower than CUBRID 9.0, the value at the time of **CREATE TABLE** has been saved when the **DATE** value of the **DATE**, **DATETIME**, **TIME**, **TIMESTAMP** column has been specified as **SYS\_DATE**, **SYS\_DATETIME**, **SYS\_TIME**, **SYS\_TIMESTAMP** while creating a table. Therefore, to enter the value at the time of data **INSERT** in version lower than CUBRID 9.0, the function should be entered to the **VALUES** clause of the **INSERT** syntax.

```
CREATE TABLE colval_tbl
(id INT, name VARCHAR SHARED 'AAA', phone VARCHAR DEFAULT
'000-0000');
INSERT INTO colval_tbl (id) VALUES (1), (2);
SELECT * FROM colval_tbl;
```

```
      id  name                      phone
=====
      1  'AAA'                      '000-0000'
      2  'AAA'                      '000-0000'
```

```
--updating column values on every row
INSERT INTO colval_tbl(id, name) VALUES (3, 'BBB');
```

```
INSERT INTO colval_tbl(id) VALUES (4),(5);
SELECT * FROM colval_tbl;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'BBB' | '000-0000' |
| 2  | 'BBB' | '000-0000' |
| 3  | 'BBB' | '000-0000' |
| 4  | 'BBB' | '000-0000' |
| 5  | 'BBB' | '000-0000' |

```
--changing DEFAULT value in the ALTER TABLE statement
ALTER TABLE colval_tbl MODIFY phone VARCHAR DEFAULT '111-1111';
INSERT INTO colval_tbl (id) VALUES (6);
SELECT * FROM colval_tbl;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'BBB' | '000-0000' |
| 2  | 'BBB' | '000-0000' |
| 3  | 'BBB' | '000-0000' |
| 4  | 'BBB' | '000-0000' |
| 5  | 'BBB' | '000-0000' |
| 6  | 'BBB' | '111-1111' |

```
--use DEFAULT TO_CHAR in CREATE TABLE statement
CREATE TABLE t1(id1 INT, id2 VARCHAR(20) DEFAULT
TO_CHAR(12345,'S999999'));
INSERT INTO t1 (id1) VALUES (1);
SELECT * FROM t1;
```

| id1 | id2       |
|-----|-----------|
| 1   | ' +12345' |

The **DEFAULT** value of the pseudocolumn can be specified as one or more columns.

```
CREATE TABLE tbl (date1 DATE DEFAULT SYSDATE, date2 DATE DEFAULT
SYSDATE);
CREATE TABLE tbl (date1 DATE DEFAULT SYSDATE,
ts1 TIMESTAMP DEFAULT CURRENT_TIMESTAMP);
CREATE TABLE t1(id1 INT, id2 VARCHAR(20) DEFAULT
TO_CHAR(12345,'S999999'), id3 VARCHAR(20) DEFAULT TO_CHAR(SYS_TIME,
```

```
'HH24:MI:SS')));
ALTER TABLE t1 add column id4 varchar (20) default
TO_CHAR(SYS_DATETIME, 'yyyy/mm/dd hh:mi:ss'), id5 DATE DEFAULT
SYSDATE;
```

## AUTO INCREMENT

You can define the **AUTO\_INCREMENT** attribute for the column to automatically give serial numbers to column values. This can be defined only for **SMALLINT**, **INTEGER**, **BIGINT** and **NUMERIC(p, 0)** types.

**DEFAULT**, **SHARED** and **AUTO\_INCREMENT** cannot be defined for the same column. Make sure the value entered directly by the user and the value entered by the auto increment attribute do not conflict with each other.

You can change the initial value of **AUTO\_INCREMENT** by using the **ALTER TABLE** statement. For details, see [AUTO\\_INCREMENT Clause](#) of **ALTER TABLE**.

```
CREATE TABLE [schema_name.]table_name (id INT AUTO_INCREMENT[(seed,
increment)]);

CREATE TABLE [schema_name.]table_name (id INT AUTO_INCREMENT)
AUTO_INCREMENT = seed ;
```

- *seed* : The initial value from which the number starts. All integers (positive, negative, and zero) are allowed. The default value is **1**.
- *increment* : The increment value of each row. Only positive integers are allowed. The default value is **1**.

When you use the **CREATE TABLE [schema\_name.]table\_name (id INT **AUTO\_INCREMENT** **AUTO\_INCREMENT** = seed;** statement, the constraints are as follows:

- You should define only one column with the **AUTO\_INCREMENT** attribute.
- Don't use (*seed*, *increment*) and **AUTO\_INCREMENT = seed** together.

```
CREATE TABLE auto_tbl (id INT AUTO_INCREMENT, name VARCHAR);
INSERT INTO auto_tbl VALUES (NULL, 'AAA'), (NULL, 'BBB'), (NULL,
'CCC');
INSERT INTO auto_tbl (name) VALUES ('DDD'), ('EEE');
SELECT * FROM auto_tbl;
```

```
id name
=====
```

```

1  'AAA'
2  'BBB'
3  'CCC'
4  'DDD'
5  'EEE'

```

```

CREATE TABLE tbl (id INT AUTO_INCREMENT, val string) AUTO_INCREMENT
= 3;
INSERT INTO tbl VALUES (NULL, 'cubrid');

SELECT * FROM tbl;

```

```

      id  val
=====
      3  'cubrid'

```

```

CREATE TABLE t (id INT AUTO_INCREMENT, id2 int AUTO_INCREMENT)
AUTO_INCREMENT = 5;

```

ERROR: To avoid ambiguity, the AUTO\_INCREMENT table option requires the table to have exactly one AUTO\_INCREMENT column **and** no seed/increment specification.

```

CREATE TABLE t (i INT AUTO_INCREMENT(100, 2)) AUTO_INCREMENT = 3;

```

ERROR: To avoid ambiguity, the AUTO\_INCREMENT table option requires the table to have exactly one AUTO\_INCREMENT column **and** no seed/increment specification.

#### Note

- Even if a column has auto increment, the **UNIQUE** constraint is not satisfied.
- If **NULL** is specified in the column where auto increment is defined, the value of auto increment is stored.
- Even if a value is directly specified in the column where auto increment is defined, AUTO\_INCREMENT value is not changed.

- **SHARED** or **DEFAULT** attribute cannot be specified in the column in which **AUTO\_INCREMENT** is defined.
- The initial value and the final value obtained by auto increment cannot exceed the minimum and maximum values allowed in the given type.
- Because auto increment has no cycle, an error occurs when the maximum value of the type exceeds, and no rollback is executed. Therefore, you must delete and recreate the column in such cases.

For example, if a table is created as below, the maximum value of A is 32767. Because an error occurs if the value exceeds 32767, you must make sure that the maximum value of the column A does not exceed the maximum value of the type when creating the initial table.

```
CREATE TABLE tb1(A SMALLINT AUTO_INCREMENT, B CHAR(5));
```

## ON UPDATE

An attribute in a table can be created with an automatic update when another attribute of the row is updated. You can change the value of **ON UPDATE** in the **ALTER TABLE** statement. The pseudocolumn allows for the **ON UPDATE** value as follows. Including the attribute in the updated fields will not trigger an update with the specified **ON UPDATE** value.

| DEFAULT Value     | Data Type |
|-------------------|-----------|
| SYS_TIMESTAMP     | TIMESTAMP |
| UNIX_TIMESTAMP()  | INTEGER   |
| CURRENT_TIMESTAMP | TIMESTAMP |
| SYS_DATETIME      | DATETIME  |
| CURRENT_DATETIME  | DATETIME  |

| DEFAULT Value | Data Type |
|---------------|-----------|
| SYS_DATE      | DATE      |

CURRENT\_DATE | DATE

```
CREATE TABLE sales (sales_cnt INTEGER, last_sale TIMESTAMP ON UPDATE
CURRENT_TIMESTAMP, product VARCHAR(100), product_id INTEGER);
INSERT INTO sales VALUES (0, NULL, 'bicycle', 1);

UPDATE sales set sales_cnt = sales_cnt + 1
WHERE product_id = 1;
```

```
ALTER TABLE sales MODIFY last_sale TIMESTAMP; -- removes ON UPDATE
UPDATE sales set sales_cnt = sales_cnt + 1
WHERE product_id = 1; -- last_sale will remain unupdated
```

## Constraint Definition

You can define **NOT NULL**, **UNIQUE**, **PRIMARY KEY**, **FOREIGN KEY** as the constraints. You can also create an index by using **INDEX** or **KEY**.

```
<column_constraint> ::= [CONSTRAINT constraint_name] { NOT NULL |
UNIQUE | PRIMARY KEY | [FOREIGN KEY] [WITH <index_with_option>]
<referential_definition> }

<table_constraint> ::=
{
    {KEY|INDEX} index_name <index_col_desc> |
    [CONSTRAINT [constraint_name]]
    {
        UNIQUE [KEY|INDEX](column_name, ...) |
        PRIMARY KEY (column_name, ...) |
        <referential_constraint>
    }
}

<referential_constraint> ::= FOREIGN KEY [<foreign_key_name>]
(column_name, ...) [WITH <index_with_option>]
<referential_definition>

<referential_definition> ::=
REFERENCES [schema_name.]referenced_table_name
```

```
(column_name, ...) [<referential_triggered_action> ...]

    <referential_triggered_action> ::=
        ON UPDATE <referential_action> |
        ON DELETE <referential_action>

        <referential_action> ::= CASCADE | RESTRICT | NO
ACTION | SET NULL

    <index_with_option> ::= {DEDUPLICATE '=' deduplicate_level}
```

## NOT NULL Constraint

A column for which the **NOT NULL** constraint has been defined must have a certain value that is not **NULL**. The **NOT NULL** constraint can be defined for all columns. An error occurs if you try to insert a **NULL** value into a column with the **NOT NULL** constraint by using the **INSERT** or **UPDATE** statement.

In the following example, if you input NULL value on the *id* column, it occurs an error because *id* column cannot have NULL value.

```
CREATE TABLE const_tbl1(id INT NOT NULL, INDEX i_index(id ASC),
phone VARCHAR);

CREATE TABLE const_tbl2(id INT NOT NULL PRIMARY KEY, phone VARCHAR);
INSERT INTO const_tbl2 VALUES (NULL, '000-0000');
```

```
Putting value 'null' into attribute 'id' returned: Attribute "id"
cannot be made NULL.
```

## UNIQUE Constraint

The **UNIQUE** constraint enforces a column to have a unique value. An error occurs if a new record that has the same value as the existing one is added by this constraint.

You can place a **UNIQUE** constraint on either a column or a set of columns. If the **UNIQUE** constraint is defined for multiple columns, the uniqueness is ensured not for each column, but the combination of multiple columns.

In the following example, the second INSERT statement fails because the value of *id* column is the same as 1 with the value of *id* column in the first INSERT statement.

```
-- UNIQUE constraint is defined on a single column only
CREATE TABLE const_tbl5(id INT UNIQUE, phone VARCHAR);
```

```
INSERT INTO const_tbl5(id) VALUES (NULL), (NULL);
INSERT INTO const_tbl5 VALUES (1, '000-0000');
SELECT * FROM const_tbl5;
```

```
id  phone
=====
NULL NULL
NULL NULL
1   '000-0000'
```

```
INSERT INTO const_tbl5 VALUES (1, '111-1111');
```

```
ERROR: Operation would have caused one or more unique constraint
violations.
```

In the following example, if a **UNIQUE** constraint is defined on several columns, this ensures the uniqueness of the values in all the columns.

```
-- UNIQUE constraint is defined on several columns
CREATE TABLE const_tbl6(id INT, phone VARCHAR, CONSTRAINT UNIQUE
(id, phone));
INSERT INTO const_tbl6 VALUES (1, NULL), (2, NULL), (1, '000-0000'),
(1, '111-1111');
SELECT * FROM const_tbl6;
```

```
id  phone
=====
1   NULL
2   NULL
1   '000-0000'
1   '111-1111'
```

## PRIMARY KEY Constraint

A key in a table is a set of column(s) that uniquely identifies each row. A candidate key is a set of columns that uniquely identifies each row of the table. You can define one of such candidate keys a primary key. That is, the column defined as a primary key is uniquely identified in each row.

By default, the index created by defining the primary key is created in ascending order, and you can define the order by specifying **ASC** or **DESC** keyword next to the column.

```

CREATE TABLE pk_tbl (a INT, b INT, PRIMARY KEY (a, b DESC));

CREATE TABLE const_tbl7 (
    id INT NOT NULL,
    phone VARCHAR,
    CONSTRAINT pk_id PRIMARY KEY (id)
);

-- CONSTRAINT keyword
CREATE TABLE const_tbl8 (
    id INT NOT NULL PRIMARY KEY,
    phone VARCHAR
);

-- primary key is defined on multiple columns
CREATE TABLE const_tbl8 (
    host_year    INT NOT NULL,
    event_code   INT NOT NULL,
    athlete_code INT NOT NULL,
    medal        CHAR (1) NOT NULL,
    score        VARCHAR (20),
    unit         VARCHAR (5),
    PRIMARY KEY (host_year, event_code, athlete_code, medal)
);

```

## FOREIGN KEY Constraint

A foreign key is a column or a set of columns that references the primary key in other tables in order to maintain reference relationship. The foreign key and the referenced primary key must have the same data type. Consistency between two tables is maintained by the foreign key referencing the primary key, which is called referential integrity.

```

[CONSTRAINT constraint_name] FOREIGN KEY [foreign_key_name]
(<column_name_comma_list1>) [WITH <index_with_option>] REFERENCES
[<schema_name.>]referenced_table_name (<column_name_comma_list2>)
[<referential_triggered_action> ...]

    <referential_triggered_action> ::= ON UPDATE
<referential_action> | ON DELETE <referential_action>

    <referential_action> ::= CASCADE | RESTRICT | NO ACTION |
SET NULL

    <index_with_option> ::= {DEDUPLICATE '=' deduplicate_level}

```

- *constraint\_name*: Specifies the name of the table to be created.

- *foreign\_key\_name*: Specifies a name of the **FOREIGN KEY** constraint. You can skip the name specification. However, if you specify this value, *constraint\_name* will be ignored, and the specified value will be used.
- *<column\_name\_comma\_list1>*: Specifies the name of the column to be defined as a foreign key after the **FOREIGN KEY** keyword. The column number of foreign keys defined and primary keys must be same.
- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *referenced\_table\_name*: Specifies the name of the table to be referenced.
- *<column\_name\_comma\_list2>*: Specifies the name of the referred primary key column after the **FOREIGN KEY** keyword.
- *<referential\_triggered\_action>*: Specifies the trigger action that responds to a certain operation in order to maintain referential integrity. **ON UPDATE** or **ON DELETE** can be specified. Each action can be defined multiple times, and the definition order is not significant.
  - **ON UPDATE**: Defines the action to be performed when attempting to update the primary key referenced by the foreign key. You can use either **NO ACTION**, **RESTRICT**, or **SET NULL** option. The default is **RESTRICT**.
  - **ON DELETE**: Defines the action to be performed when attempting to delete the primary key referenced by the foreign key. You can use **NO ACTION**, **RESTRICT**, **CASCADE**, or **SET NULL** option. The default is **RESTRICT**.
- *<referential\_action>*: You can define an option that determines whether to maintain the value of the foreign key when the primary key value is deleted or updated.
  - **CASCADE**: If the primary key is deleted, the foreign key is deleted as well. This option is supported only for the **ON DELETE** operation.
  - **RESTRICT**: Prevents the value of the primary key from being deleted or updated, and rolls back any transaction that has been attempted.
  - **SET NULL**: When a specific record is being deleted or updated, the column value of the foreign key is updated to **NULL**.
  - **NO ACTION**: Its behavior is the same as that of the **RESTRICT** option.
- *deduplicate\_level*: specifies the deduplicate level (0 to 14). For details, see [DEDUPLICATE](#).

For each row R1 of the referencing table, there should be some row R2 of the referenced table such that the value of each referencing column in R1 is either **NULL** or is equal to the value of the corresponding referenced column in R2.

```
-- creating two tables where one is referring to the other
CREATE TABLE a_tbl (
    id INT NOT NULL DEFAULT 0 PRIMARY KEY,
    phone VARCHAR(10)
);

CREATE TABLE b_tbl (
    id INT NOT NULL,
    name VARCHAR (10) NOT NULL,
    CONSTRAINT pk_id PRIMARY KEY (id),
    CONSTRAINT fk_id FOREIGN KEY (id) REFERENCES a_tbl (id)
    ON DELETE CASCADE ON UPDATE RESTRICT
);

INSERT INTO a_tbl VALUES (1,'111-1111'), (2,'222-2222'), (3,
'333-3333');
INSERT INTO b_tbl VALUES (1,'George'),(2,'Laura'), (3,'Max');
SELECT a.id, b.id, a.phone, b.name FROM a_tbl a, b_tbl b WHERE a.id
= b.id;
```

| id | id | phone      | name     |
|----|----|------------|----------|
| 1  | 1  | '111-1111' | 'George' |
| 2  | 2  | '222-2222' | 'Laura'  |
| 3  | 3  | '333-3333' | 'Max'    |

```
-- when deleting primary key value, it cascades foreign key value
DELETE FROM a_tbl WHERE id=3;
```

```
1 row affected.
```

```
SELECT a.id, b.id, a.phone, b.name FROM a_tbl a, b_tbl b WHERE a.id
= b.id;
```

| id | id | phone      | name     |
|----|----|------------|----------|
| 1  | 1  | '111-1111' | 'George' |
| 2  | 2  | '222-2222' | 'Laura'  |

```
-- when attempting to update primary key value, it restricts the operation
UPDATE a_tbl SET id = 10 WHERE phone = '111-1111';
```

```
ERROR: Update/Delete operations are restricted by the foreign key
'fk_id'.
```

#### Note

- In a referential constraint, the name of the primary key table to be referenced and the corresponding column names are defined. If the list of column names are is not specified, the primary key of the primary key table is specified in the defined order.
- The number of primary keys in a referential constraint must be identical to that of foreign keys. The same column name cannot be used multiple times for the primary key in the referential constraint.
- The actions cascaded by reference constraints do not activate the trigger action.
- It is not recommended to use *referential\_triggered\_action* in the CUBRID HA environment. In the CUBRID HA environment, the trigger action is not supported. Therefore, if you use *referential\_triggered\_action*, the data between the master database and the slave database can be inconsistent. For details, see [CUBRID HA](#).

## KEY or INDEX

**KEY** and **INDEX** are used interchangeably. They create an index that uses the corresponding column as a key.

```
CREATE TABLE const_tbl4(id INT, phone VARCHAR, KEY i_key(id DESC,
phone ASC));
```

#### Note

In versions lower than CUBRID 9.0, index name can be omitted; however, in version of CUBRID 9.0 or higher, it is no longer allowed.

## Column Option

You can specify options such as **ASC** or **DESC** after the column name when defining **UNIQUE** or **INDEX** for a specific column. This keyword is specified as store the index value in ascending or descending order.

```
column_name [ASC | DESC]
```

```
CREATE TABLE const_tbl(
  id VARCHAR,
  name VARCHAR,
  CONSTRAINT UNIQUE INDEX(id DESC, name ASC)
);

INSERT INTO const_tbl VALUES('1000', 'john'), ('1000','johnny'),
('1000', 'jone');
INSERT INTO const_tbl VALUES('1001', 'johnny'), ('1001','john'),
('1001', 'jone');

SELECT * FROM const_tbl WHERE id > '100';
```

```
id      name
=====
1001    john
1001    johnny
1001    jone
1000    john
1000    johnny
1000    jone
```

## Table Option

**REUSE\_OID** and **DONT\_REUSE\_OID** are options that specify whether to be referable when creating a table. The two options cannot be used together and can be used with other options. When creating a table without the option, the **REUSE\_OID** table option is used. To change the default option to **DONT\_REUSE\_OID**, you should change the system parameter **create\_table\_reuseoid** to **no**. For detail, see [Statement/Type-Related Parameters](#).

```
<table_options> ::= <table_option> [[,] <table_option> ...]
  <table_option> ::= REUSE_OID | DONT_REUSE_OID |
                    COMMENT [=] 'table_comment_string' |
                    [CHARSET charset_name] [COLLATE
collation_name]
```

## REUSE\_OID

You can specify the **REUSE\_OID** option when creating a table, so that OIDs that have been deleted due to the deletion of records (**DELETE**) can be reused when a new record is inserted (**INSERT**). Such a table is called an OID reusable or a non-referable table.

OID (Object Identifier) is an object identifier represented by physical location information such as the volume number, page number and slot number. By using such OIDs, CUBRID manages the reference relationships of objects and searches, stores or deletes them. When an OID is used, accessibility is improved because the object in the heap file can be directly accessed without referring to the table. However, the problem of decreased reusability of the storage occurs when there are many **DELETE/ INSERT** operations because the object's OID is kept to maintain the reference relationship with the object even if it is deleted.

If you specify the **REUSE\_OID** option when creating a table, the OID is also deleted when data in the table is deleted, so that another **INSERT**ed data can use it. OID reusable tables cannot be referred to by other tables, and OID values of the objects in the OID reusable tables cannot be viewed.

```
-- creating table with REUSE_OID option specified
CREATE TABLE reuse_tbl (a INT PRIMARY KEY) REUSE_OID, COMMENT =
'reuse oid table';
INSERT INTO reuse_tbl VALUES (1);
INSERT INTO reuse_tbl VALUES (2);
INSERT INTO reuse_tbl VALUES (3);

-- an error occurs when column type is a OID reusable table itself
CREATE TABLE tbl_1 (a reuse_tbl);
```

```
ERROR: The class 'reuse_tbl' is marked as REUSE_OID and is non-
referable. Non-referable classes can't be the domain of an attribute
and their instances' OIDs cannot be returned.
```

If you specify **REUSE\_OID** together with the collation of table, it can be placed on before or after **COLLATE** syntax.

```
CREATE TABLE t3(a VARCHAR(20)) REUSE_OID, COMMENT = 'reuse oid
table', COLLATE euckr_bin;
CREATE TABLE t4(a VARCHAR(20)) COLLATE euckr_bin REUSE_OID;
```

### Note

- OID reusable tables cannot be referred to by other tables.

- Updatable views cannot be created for OID reusable tables.
- OID reusable tables cannot be specified as table column type.
- OID values of the objects in the OID reusable tables cannot be read.
- Instance methods cannot be called from OID reusable tables. Also, instance methods cannot be called if a sub class inherited from the class where the method is defined is defined as an OID reusable table.
- OID reusable tables are supported only by CUBRID 2008 R2.2 or above, and backward compatibility is not ensured. That is, the database in which the OID reusable table is located cannot be accessed from a lower version database.
- OID reusable tables can be managed as partitioned tables and can be replicated.
- The updating query with a view can be faced with error when the view includes any OID reusable table.

```
CREATE TABLE t1 (c1 INT) REUSE_OID;
CREATE VIEW v3 AS SELECT c1 FROM t1;

insert into v3(c1) values (1);
```

```
ERROR: Vclass v3 is not updatable. Please check if any of its
related classes are marked as REUSE_OID.
```

## DONT\_REUSE\_OID

Specifying the **DONT\_REUSE\_OID** option when creating the table will create a referable table as opposite to **REUSE\_OID**.

## Charset and Collation

The charset and collation of the table and column can be designated in the **CREATE TABLE** statement. This example specifies the character set and collation for **CREATE TABLE**.

```
CREATE TABLE tblutf8(a int, b int) charset utf8;
CREATE TABLE tblutf8enci(a int, b int) collate utf8_en_ci;

CREATE TABLE tbleuckr(a int, b int) charset euckr collate euckr_bin;
```

```
CREATE TABLE tblcoleuckr(a int, c varchar(100) collate euckr_bin)
charset euckr;

CREATE TABLE tblcol (s1 STRING COLLATE utf8_en_cs,s2 STRING COLLATE
utf8_bin);
CREATE TABLE tblcharcol (col STRING CHARSET utf8) COLLATE utf8_en_ci;
```

Please see [Charset and Collation of Tables](#) or [Charset and Collation of String Literals](#) for details.

## Table's COMMENT

You can write a table's comment as following.

```
CREATE TABLE tbl (a INT, b INT) COMMENT = 'this is comment for table
tbl';
```

To see the table's comment, run the below syntax.

```
SHOW CREATE TABLE table_name;
SELECT class_name, comment from db_class;
SELECT class_name, comment from _db_class;
```

Or you can see the table's comment with ;sc command in the CSQL interpreter.

```
$ csql -u dba demodb

csql> ;sc tbl
```

## Table Encryption (TDE)

You can encrypt a table as follows. For more information on TDE encryption, see [TDE \(Transparent Data Encryption\)](#).

```
CREATE TABLE enc_tbl (a INT, b INT) ENCRYPT = AES;
```

You can specify **AES** or **ARIA** as the encryption algorithm. If omitted as follows, the encryption algorithm specified by the system parameter **tde\_default\_algorithm** is used. The default value is **AES**.

```
CREATE TABLE enc_tbl (a INT, b INT) ENCRYPT;
```

The encryption information is not inherited.

## CREATE TABLE LIKE

You can create a table with the same schema as an existing table by using the **CREATE TABLE ... LIKE** statement. Column attribute, table constraint, index, and encryption information are replicated from the existing table. An index name created from the existing table changes according to a new table name, but an index name defined by a user is replicated as it is. Therefore, you should be careful with a query statement that is supposed to use a specific index created by using the index hint syntax(see [Index Hint](#)).

You cannot create the column definition because the **CREATE TABLE ... LIKE** statement replicates the schema only.

```
CREATE {TABLE | CLASS} [schema_name.]new_table_name LIKE  
[schema_name.]source_table_name;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *new\_table\_name*: A table name to be created
- *source\_table\_name*: The name of the original table that already exists in the database. The following tables cannot be specified as original tables in the **CREATE TABLE ... LIKE** statement.
  - Partition table
  - Table that contains an **AUTO\_INCREMENT** column
  - Table that uses inheritance or methods

```
CREATE TABLE a_tbl (  
  id INT NOT NULL DEFAULT 0 PRIMARY KEY,  
  phone VARCHAR(10)  
);  
INSERT INTO a_tbl VALUES (1,'111-1111'), (2,'222-2222'), (3,  
'333-3333');  
  
-- creating an empty table with the same schema as a_tbl  
CREATE TABLE new_tbl LIKE a_tbl;  
SELECT * FROM new_tbl;
```

There are no results.

```
csql> ;schema a_tbl
```

```

=== <Help: Schema of a Class> ===

<Constraints>

    PRIMARY KEY pk_new_tbl_id ON new_tbl (id)

```

## CREATE TABLE AS SELECT

You can create a new table that contains the result records of the **SELECT** statement by using the **CREATE TABLE...AS SELECT** statement. You can define column and table constraints for the new table. The following rules are applied to reflect the result records of the **SELECT** statement.

- If *col\_1* is defined in the new table and the same column *col\_1* is specified in *select\_statement*, the result record of the **SELECT** statement is stored as *col\_1* value in the new table. Type casting is attempted if the column names are identical but the columns types are different.
- If *col\_1* and *col\_2* are defined in the new table, *col\_1*, *col\_2* and *col\_3* are specified in the column list of the *select\_statement* and there is a containment relationship between all of them, *col\_1*, *col\_2* and *col\_3* are created in the new table and the result data of the **SELECT** statement is stored as values for all columns. Type casting is attempted if the column names are identical but the columns types are different.

- If columns *col\_1* and *col\_2* are defined in the new table and *col\_1* and *col\_3* are defined in the column list of *select\_statement* without any containment relationship between them, *col\_1*, *col\_2* and *col\_3* are created in the new table, the result data of the **SELECT** statement is stored only for *col\_1* and *col\_3* which are specified in *select\_statement*, and **NULL** is stored as the value of *col\_2*.
- Column aliases can be included in the column list of *select\_statement*. In this case, new column alias is used as a new table column name. It is recommended to use an alias because invalid column name is created, if an alias does not exist when a function calling or an expression is used.
- The **REPLACE** option is valid only when the **UNIQUE** constraint is defined in a new table column (*col\_1*). When duplicate values exist in the result record of *select\_statement*, a **UNIQUE** value is stored for *col\_1* if the **REPLACE** option has been defined, or an error message is displayed if the **REPLACE** option is omitted due to the violation of the **UNIQUE** constraint.

```
CREATE {TABLE | CLASS} [schema_name.]table_name
[([{<table_constraint>}... ,] <column_definition> [{,
{<column_definition> | <table_constraint>}...})] [REPLACE] AS
<select_statement>;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: a name of the table to be created.
- *<column\_definition>*: defines a column. If this is omitted, the column schema of **SELECT** statement is replicated; however, the constraint or the **AUTO\_INCREMENT** attribute is not replicated.
- *<table\_constraint>*: defines table constraint.
- *<select\_statement>*: a **SELECT** statement targeting a source table that already exists in the database.
- *<select statement>* can include remote tables like *tbl@server1*.

```
CREATE TABLE a_tbl (
  id INT NOT NULL DEFAULT 0 PRIMARY KEY,
  phone VARCHAR(10)
);
INSERT INTO a_tbl VALUES (1,'111-1111'), (2,'222-2222'), (3,
'333-3333');

-- creating a table without column definition
```

```
CREATE TABLE new_tbl1 AS SELECT * FROM a_tbl;
SELECT * FROM new_tbl1;
```

```

  id  phone
=====
  1   '111-1111'
  2   '222-2222'
  3   '333-3333'
```

```
-- all of column values are replicated from a_tbl
CREATE TABLE new_tbl2 (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  phone VARCHAR
) AS SELECT * FROM a_tbl;

SELECT * FROM new_tbl2;
```

```

  id  phone
=====
  1   '111-1111'
  2   '222-2222'
  3   '333-3333'
```

```
-- some of column values are replicated from a_tbl and the rest is
NULL
CREATE TABLE new_tbl3 (
  id INT,
  name VARCHAR
) AS SELECT id, phone FROM a_tbl;

SELECT * FROM new_tbl3
```

```

  name                                id  phone
=====
  NULL                                1   '111-1111'
  NULL                                2   '222-2222'
  NULL                                3   '333-3333'
```

```
-- column alias in the select statement should be used in the column
definition
CREATE TABLE new_tbl4 (
  id1 INT,
  id2 INT
```

```
) AS SELECT t1.id id1, t2.id id2 FROM new_tbl1 t1, new_tbl2 t2;

SELECT * FROM new_tbl4;
```

| id1 | id2 |
|-----|-----|
| 1   | 1   |
| 1   | 2   |
| 1   | 3   |
| 2   | 1   |
| 2   | 2   |
| 2   | 3   |
| 3   | 1   |
| 3   | 2   |
| 3   | 3   |

```
-- REPLACE is used on the UNIQUE column
CREATE TABLE new_tbl5 (id1 int UNIQUE) REPLACE AS SELECT * FROM
new_tbl4;

SELECT * FROM new_tbl5;
```

| id1 | id2 |
|-----|-----|
| 1   | 3   |
| 2   | 3   |
| 3   | 3   |

You can create a table by selecting data from a remote table as below statement.

```
-- column values are replicated from remote_tbl
CREATE TABLE new_tbl_rem (
  id INT NON NULL;
  phone VARCHAR;
  location VARCHAR;
) AS SELECT id, phone, 'remote' FROM a_tbl@server1 WHERE id < 3;

SELECT * FROM new_tbl_rem;
```

| id | phone      | location |
|----|------------|----------|
| 1  | '111-1111' | 'remote' |
| 2  | '222-2222' | 'remote' |

## ALTER TABLE

You can modify the structure of a table by using the **ALTER** statement. You can perform operations on the target table such as adding/deleting columns, creating/deleting indexes, and type casting existing columns as well as changing table names, column names and constraints. You can also change the initial value of **AUTO\_INCREMENT**. **TABLE** and **CLASS** are used interchangeably **VIEW** and **VCLASS**, and **COLUMN** and **ATTRIBUTE** as well.

```
ALTER [TABLE | CLASS] [schema_name.]table_name <alter_clause> [,
<alter_clause>] ... ;

<alter_clause> ::=
    ADD <alter_add> [INHERIT <resolution>, ...] |
    ADD {KEY | INDEX} <index_name> <index_col_desc> |
    ALTER [COLUMN] column_name SET DEFAULT <value_specification>
|
    DROP <alter_drop> [INHERIT <resolution>, ...] |
    DROP {KEY | INDEX} index_name |
    DROP FOREIGN KEY constraint_name |
    DROP PRIMARY KEY |
    RENAME <alter_rename> [INHERIT <resolution>, ...] |
    CHANGE <alter_change> |
    MODIFY <alter_modify> |
    INHERIT <resolution>, ... |
    AUTO_INCREMENT = <initial_value> |
    COMMENT [=] 'table_comment_string' |
    COMMENT ON {COLUMN | CLASS ATTRIBUTE}
<column_comment_definition> [, <column_comment_definition>] ;

<alter_add> ::=
    [ATTRIBUTE|COLUMN] [(]<class_element>, ...[)] [FIRST|
AFTER old_column_name] |
    CLASS ATTRIBUTE <column_definition>, ... |
    CONSTRAINT <constraint_name> <column_constraint>
(column_name) |
    QUERY <select_statement> |
    SUPERCLASS [schema_name.]superclass_name, ...

<class_element> ::= <column_definition> |
<table_constraint>

<column_constraint> ::= UNIQUE [KEY] | PRIMARY KEY |
FOREIGN KEY

<alter_drop> ::=
    [ATTRIBUTE | COLUMN]
    {
        column_name, ... |
        QUERY [<unsigned_integer_literal>] |
        SUPERCLASS [schema_name.]superclass_name, ... |
        CONSTRAINT constraint_name
```

```

    }

    <alter_rename> ::=
    [ATTRIBUTE | COLUMN]
    {
        old_column_name AS new_column_name |
        FUNCTION OF column_name AS function_name
    }

    <alter_change> ::=
    [COLUMN | CLASS ATTRIBUTE] old_col_name new_col_name
<column_definition>
    [FIRST | AFTER col_name]

    <alter_modify> ::=
    [COLUMN | CLASS ATTRIBUTE] col_name <column_definition>
    [FIRST | AFTER col_name2]

    <table_option> ::=
    CHANGE [COLUMN | CLASS ATTRIBUTE] old_col_name
new_col_name <column_definition>
    [FIRST | AFTER col_name2]
    | MODIFY [COLUMN | CLASS ATTRIBUTE] col_name
<column_definition>
    [FIRST | AFTER col_name2]

    <resolution> ::= column_name OF
[schema_name.]superclass_name [AS alias]

    <index_col_name> ::= column_name [(length)] [ASC | DESC]

    <column_comment_definition> ::= column_name [=]
'column_comment_string'

```

### Note

A column's comment is specified in `<column_definition>` or `<column_comment_definition>`. For `<column_definition>`, see the above [CREATE TABLE syntax](#).

### Warning

The table's name can be changed only by the table owner, **DBA** and **DBA** members. The other users must be granted to change the name by the owner or **DBA** (see [GRANT](#) For details on authorization).

## ADD COLUMN Clause

You can add a new column by using the **ADD COLUMN** clause. You can specify the location of the column to be added by using the **FIRST** or **AFTER** keyword.

```
ALTER [TABLE | CLASS] [schema_name.]table_name
ADD [COLUMN | ATTRIBUTE] [(] <column_definition> [FIRST | AFTER
old_column_name] [)];

    <column_definition> ::=
        column_name <data_type> [[<default_or_shared_or_ai>] |
[<on_update>] | [<column_constraint>]] [COMMENT 'comment_string']

        <data_type> ::= <column_type> [<charset_modifier_clause>]
[<collation_modifier_clause>]

        <charset_modifier_clause> ::= {CHARACTER_SET|CHARSET}
{<char_string_literal>|<identifier>}

        <collation_modifier_clause> ::= COLLATE
{<char_string_literal>|<identifier>}

        <default_or_shared_or_ai> ::=
            SHARED <value_specification> |
            DEFAULT <value_specification> |
            AUTO_INCREMENT [(seed, increment)]

        <on_update> ::= [ON UPDATE <value_specification>]

        <column_constraint> ::= [CONSTRAINT constraint_name] {NOT
NULL | UNIQUE | PRIMARY KEY | [FOREIGN KEY] [WITH
<index_with_option>] <referential_definition>}

        <referential_definition> ::=
            REFERENCES [schema_name.]referenced_table_name
(column_name, ...) [<referential_triggered_action> ...]

        <referential_triggered_action> ::=
            ON UPDATE <referential_action> |
            ON DELETE <referential_action>

        <referential_action> ::= CASCADE | RESTRICT | NO
ACTION | SET NULL

        <index_with_option> ::= {DEDUPLICATE '='
deduplicate_level}
```

- *schema\_name*: specifies the schema name. If omitted, the schema name of the current session is used.

- *table\_name*: specifies the name of a table that has a column to be added.
- *<column\_definition>*: specifies the name(max 254 bytes), data type, and constraints of a column to be added.
- **AFTER** *oid\_column\_name*: specifies the name of an existing column before the column to be added.
- *comment\_string*: specifies a column's comment.
- *deduplicate\_level*: Specifies the deduplicate level (0 to 14). For details, see [DEDUPLICATE](#).

```
CREATE TABLE a_tbl;
ALTER TABLE a_tbl ADD COLUMN age INT DEFAULT 0 NOT NULL COMMENT 'age
comment';
ALTER TABLE a_tbl ADD COLUMN name VARCHAR FIRST;
ALTER TABLE a_tbl ADD COLUMN id INT NOT NULL AUTO_INCREMENT UNIQUE
FIRST;
INSERT INTO a_tbl(age) VALUES(20),(30),(40);

ALTER TABLE a_tbl ADD COLUMN phone VARCHAR(13) DEFAULT
'000-0000-0000' AFTER name;
ALTER TABLE a_tbl ADD COLUMN birthday VARCHAR(20) DEFAULT
TO_CHAR(SYSDATE, 'YYYY-MM-DD');

SELECT * FROM a_tbl;
```

|          | id | name | phone           | age |
|----------|----|------|-----------------|-----|
| birthday |    |      |                 |     |
| =====    |    |      |                 |     |
|          | 1  | NULL | '000-0000-0000' | 20  |
|          |    |      |                 |     |
|          | 2  | NULL | '000-0000-0000' | 30  |
|          |    |      |                 |     |
|          | 3  | NULL | '000-0000-0000' | 40  |
|          |    |      |                 |     |

```
--adding multiple columns
ALTER TABLE a_tbl ADD COLUMN (age1 int, age2 int, age3 int);
```

The result when you add a new column depends on what constraints are added.

- If there is a **DEFAULT** constraint on the newly added column, **DEFAULT** value is inserted.
- If there is no **DEFAULT** constraint and there is a **NOT NULL** constraint, hard default value is inserted when a value of system parameter **add\_column\_update\_hard\_default** is **yes**; however, it returns an error when a value of **add\_column\_update\_hard\_default** is **no**.

The default of `add_column_update_hard_default` is **no**.

Depending on **DEFAULT** constraint and `add_column_update_hard_default`'s value, if they do not violate their constraints, it is possible to add **PRIMARY KEY** constraint or **UNIQUE** constraint.

- If the newly added column when there is no data on the table, or the newly added column with **NOT NULL** and **UNIQUE** data can have **PRIMARY KEY** constraint.
- If you try to add a new column with **PRIMARY KEY** constraint when there is data on the table, it returns an error.

```
CREATE TABLE tbl (a INT);
INSERT INTO tbl VALUES (1), (2);
ALTER TABLE tbl ADD COLUMN (b int PRIMARY KEY);
```

```
ERROR: NOT NULL constraints do not allow NULL value.
```

- If there is data and **UNIQUE** constraint is specified on the newly added data, **NULL** is inserted when there is no **DEFAULT** constraint.

```
ALTER TABLE tbl ADD COLUMN (b int UNIQUE);
SELECT * FROM tbl;
```

| a | b    |
|---|------|
| 1 | NULL |
| 2 | NULL |

- If there is data on the table and **UNIQUE** constraint is specified on the newly added column, unique violation error is returned when there is **DEFAULT** constraint.

```
ALTER TABLE tbl ADD COLUMN (c int UNIQUE DEFAULT 10);
```

```
ERROR: Operation would have caused one or more unique constraint violations.
```

- If there is data on the table and **UNIQUE** constraint is specified on the newly added column, unique violation error is returned when there is **NOT NULL** constraint and the value of system parameter `add_column_update_hard_default` is yes.

```
SET SYSTEM PARAMETERS 'add_column_update_hard_default=yes';
ALTER TABLE tbl ADD COLUMN (c int UNIQUE NOT NULL);
```

```
ERROR: Operation would have caused one or more unique constraint
violations.
```

For **add\_column\_update\_hard\_default** and the hard default, see [CHANGE/MODIFY Clauses](#).

## ADD CONSTRAINT Clause

You can add a new constraint by using the **ADD CONSTRAINT** clause.

By default, the index created when you add **PRIMARY KEY** constraints is created in ascending order, and you can define the key sorting order by specifying the **ASC** or **DESC** keyword next to the column name.

```
ALTER [ TABLE | CLASS | VCLASS | VIEW ] [schema_name.]table_name
ADD <table_constraint> ;

<table_constraint> ::=
{
    {KEY|INDEX} index_name (column_name, ...) |
    [CONSTRAINT [constraint_name]]
    {
        UNIQUE [KEY|INDEX](column_name, ...) |
        PRIMARY KEY (column_name, ...) |
        <referential_constraint>
    }
}

<referential_constraint> ::= FOREIGN KEY [foreign_key_name]
(column_name, ...) <referential_definition>

<referential_definition> ::=
REFERENCES [schema_name.]referenced_table_name
(column_name, ...) [<referential_triggered_action> ...]

<referential_triggered_action> ::=
ON UPDATE <referential_action> |
ON DELETE <referential_action>

<referential_action> ::= CASCADE | RESTRICT | NO
ACTION | SET NULL
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.

- *table\_name*: Specifies the name of a table that has a constraint to be added.
- *constraint\_name*: Specifies the name of a constraint to be added, or it can be omitted. If omitted, a name is automatically assigned(maximum: 254 bytes).
- *foreign\_key\_name*: Specifies a name of the **FOREIGN KEY** constraint. You can skip the name specification. However, if you specify this value, *constraint\_name* will be ignored, and the specified value will be used.
- *<table\_constraint>*: Defines a constraint for the specified table. For details, see [ON UPDATE](#).

```
ALTER TABLE a_tbl ADD CONSTRAINT pk_a_tbl_id PRIMARY KEY(id);
ALTER TABLE a_tbl DROP CONSTRAINT pk_a_tbl_id;
ALTER TABLE a_tbl ADD CONSTRAINT pk_a_tbl_id PRIMARY KEY(id, name
DESC);
ALTER TABLE a_tbl ADD CONSTRAINT u_key1 UNIQUE (id);
```

## ADD INDEX Clause

You can define the index attributes for a specific column by using the **ADD INDEX** clause.

```
ALTER [TABLE | CLASS] [schema_name.]table_name ADD {KEY | INDEX}
index_name (<index_col_name>) ;

<index_col_name> ::= column_name [(length)] [ ASC | DESC ]
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table to be modified.
- *index\_name* : Specifies the name of an index(maximum: 254 bytes). If omitted, a name is automatically assigned.
- *index\_col\_name* : Specifies the column that has an index to be defined. **ASC** or **DESC** can be specified for a column option.

```
ALTER TABLE a_tbl ADD INDEX i1(age ASC), ADD INDEX i2(phone DESC);
```

```
csql> ;schema a_tbl

=== <Help: Schema of a Class> ===

<Class Name>
```

```

a_tbl

<Attributes>

    name          CHARACTER VARYING(1073741823) DEFAULT ''
    phone         CHARACTER VARYING(13) DEFAULT '111-1111'
    age           INTEGER
    id            INTEGER AUTO_INCREMENT NOT NULL

<Constraints>

    UNIQUE u_a_tbl_id ON a_tbl (id)
    INDEX i1 ON a_tbl (age)
    INDEX i2 ON a_tbl (phone DESC)

```

The below is an example to include an index's comment when you add an index with ALTER statement.

```
ALTER TABLE tbl ADD index i_t_c (c) COMMENT 'index comment c';
```

### ALTER COLUMN ... SET DEFAULT Clause

You can specify a new default value for a column that has no default value or modify the existing default value by using the **ALTER COLUMN ... SET DEFAULT**. You can use the **CHANGE** clause to change the default value of multiple columns with a single statement. For details, see the [CHANGE/MODIFY Clauses](#).

```
ALTER [TABLE | CLASS] [schema_name.]table_name ALTER [COLUMN]
column_name SET DEFAULT value ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table that has a column whose default value is to be modified.
- *column\_name* : Specifies the name of a column whose default value is to be modified.
- *value* : Specifies a new default value.

```

csql> ;schema a_tbl

=== <Help: Schema of a Class> ===

<Class Name>

```

```

a_tbl

<Attributes>

    name                CHARACTER VARYING(1073741823)
    phone                CHARACTER VARYING(13) DEFAULT
'000-0000-0000'
    age                 INTEGER
    id                  INTEGER AUTO_INCREMENT NOT NULL

<Constraints>

    UNIQUE u_a_tbl_id ON a_tbl (id)

```

```

ALTER TABLE a_tbl ALTER COLUMN name SET DEFAULT '';
ALTER TABLE a_tbl ALTER COLUMN phone SET DEFAULT '111-1111';

```

```

csql> ;schema a_tbl

=== <Help: Schema of a Class> ===

<Class Name>

    a_tbl

<Attributes>

    name                CHARACTER VARYING(1073741823) DEFAULT ''
    phone                CHARACTER VARYING(13) DEFAULT '111-1111'
    age                 INTEGER
    id                  INTEGER AUTO_INCREMENT NOT NULL

<Constraints>

    UNIQUE u_a_tbl_id ON a_tbl (id)

```

```

CREATE TABLE t1(id1 VARCHAR(20), id2 VARCHAR(20) DEFAULT '');
ALTER TABLE t1 ALTER COLUMN id1 SET DEFAULT TO_CHAR(SYS_DATETIME,
'yyyy/mm/dd hh:mi:ss');

```

```

csql> ;schema t1

=== <Help: Schema of a Class> ===

```

```
<Class Name>
```

```
t1
```

```
<Attributes>
```

```
id1          CHARACTER VARYING(20) DEFAULT
TO_CHAR(SYS_DATETIME, 'yyyy/mm/dd hh:mi:ss')
id2          CHARACTER VARYING(20) DEFAULT ''
```

## AUTO\_INCREMENT Clause

The **AUTO\_INCREMENT** clause can change the initial value of the increment value that is currently defined. However, there should be only one **AUTO\_INCREMENT** column defined.

```
ALTER TABLE [schema_name.]table_name AUTO_INCREMENT = initial_value ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Table name
- *initial\_value* : Initial value to alter

```
CREATE TABLE t (i int AUTO_INCREMENT);
```

```
ALTER TABLE t AUTO_INCREMENT = 5;
```

```
CREATE TABLE t (i int AUTO_INCREMENT, j int AUTO_INCREMENT);
```

```
-- when 2 AUTO_INCREMENT constraints are defined on one table, below
query returns an error.
```

```
ALTER TABLE t AUTO_INCREMENT = 5;
```

ERROR: To avoid ambiguity, the AUTO\_INCREMENT table option requires the table to have exactly one AUTO\_INCREMENT column **and** no seed/increment specification.

## Warning

You must be careful not to violate constraints (such as a **PRIMARY KEY** or **UNIQUE**) due to changing the initial value of **AUTO\_INCREMENT**.

#### Note

If you change the type of **AUTO\_INCREMENT** column, the maximum value is changed, too. For example, if you change INT to BIGINT, the maximum value of **AUTO\_INCREMENT** is changed from the maximum INT into the maximum BIGINT.

## CHANGE/MODIFY Clauses

The **CHANGE** clause changes column name, type, size, and attribute. If the existing column name and a new column name are the same, types, size, and attribute will be changed.

The **MODIFY** clause can modify type, size, and attribute of a column but cannot change its name.

If you set the type, size, and attribute to apply to a new column with the **CHANGE** clause or the **MODIFY** clause, the attribute that is currently defined will not be passed to the attribute of the new column.

When you change data types using the **CHANGE** clause or the **MODIFY** clause, the data can be modified. For example, if you shorten the length of a column, the character string may be truncated if the value of configuration parameter `alter_table_change_type_strict` is set to **no**. But if the parameter value is set to **yes**, the change or modify is not allowed and it returns an error. the configuration parameter `allow_truncated_string` also affect the similar as `alter_table_change_type_strict`.

When changing the type of the column specified **AUTO\_INCREMENT**, it cannot be changed to a column type that is not allowed to used with the **AUTO\_INCREMENT**. For example, if you try to change the column type of “a” from INT to VARCHAR with the ALTER statement as shown below, an error occurs.

```
CREATE a_tbl (a int AUTO_INCREMENT, b VARCHAR);  
ALTER TABLE a_tbl MODIFY COLUMN a VARCHAR;
```

```
ERROR: before ' varchar; '  
The domain of the attribute 'a' having an auto increment constraint  
is invalid.
```

When changing the type of a column specified a default value, if the default value can't be coerced to the changed type, an error occurs as shown in the example below.

```
CREATE TABLE t_def (a bigint default 123456789012, b varchar(20));
ALTER TABLE t_def MODIFY a int;
```

```
ERROR: A domain conflict exists on attribute "a".
```

### Warning

- **ALTER TABLE** *[schema\_name.]table\_name* **CHANGE** *column\_name* **DEFAULT** *default\_value* syntax supported in CUBRID 2008 R3.1 or earlier version is no longer supported.
- When converting a number type to character type, if *alter\_table\_change\_type\_strict=no* and the length of the string is shorter than that of the number, the string is truncated and saved according to the length of the converted character type. If *alter\_table\_change\_type\_strict=yes*, it returns an error.
- If the column attributes like a type, a collation, etc. are changed, the changed attributes are not applied into the view created with the table before the change. Therefore, if you change the attributes of a table, it is recommended to recreate the related views.

```
ALTER [/*+ SKIP_UPDATE_NULL */] TABLE [schema_name.]tbl_name
<table_options> ;

<table_options> ::=
    <table_option>[, <table_option>, ...]

<table_option> ::=
    CHANGE [COLUMN | CLASS ATTRIBUTE] old_col_name
    new_col_name <column_definition>
    [FIRST | AFTER col_name]
    | MODIFY [COLUMN | CLASS ATTRIBUTE] col_name
    <column_definition>
    [FIRST | AFTER col_name]
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *tbl\_name*: specifies the name of the table including the column to change.
- *old\_col\_name*: specifies the existing column name.

- *new\_col\_name*: specifies the column name to change
- *<column\_definition>*: specifies the type, the size, the attribute, and the comment of the column to be changed.
- *col\_name*: specifies the location where the column to change exists.
- **SKIP\_UPDATE\_NULL**: If this hint is added, CUBRID does not check the previous NULLs even if NOT NULL constraint is added. See [SKIP\\_UPDATE\\_NULL](#).

```
CREATE TABLE t1 (a INTEGER);

-- changing column a's name into a1

```

-- change the column's data type (errors)
SET SYSTEM PARAMETERS 'alter_table_change_type_strict=no';

CREATE TABLE t1 (i1 INT);
INSERT INTO t1 VALUES (1), (-2147483648), (2147483647);

ALTER TABLE t1 CHANGE i1 s1 CHAR(4);
SELECT * FROM t1;

```

```

-- hard default values have been placed instead of signaling overflow

s1
=====
'1          '

```

```
'-214'
'2147'
```

### Note

When you change NULL constraint into NOT NULL, it takes a long time by the time updating values into **hard default**; to resolve this problem, CUBRID can skip updating values which already exists by using **SKIP\_UPDATE\_NULL**. However, you should consider that NULL values which do not match with the NOT NULL constraints, can exists.

```
ALTER /*+ SKIP_UPDATE_NULL */ TABLE foo MODIFY col INT NOT NULL;
```

## Changes of Table Attributes based on Changes of Column Type

- **Type Change** : If the value of the system parameter **alter\_table\_change\_type\_strict** is set to no, then changing values to other types is allowed, but if it is set to yes then changing is not allowed. The default value of the parameter is **yes**. You can change values to all types allowed by the **CAST** operator. Changing object types is allowed only by the upper classes (tables) of the objects. Also, if the system parameter **allow\_truncated\_string** is **no** when changing to a string such as **char** or **varchar**, the overflowed string cannot be changed. The default value for the parameter is **no**.
- **NOT NULL**
  - Even though the **NOT NULL** constraint is not specified, it will not be removed from a new table if the constraint is present in the existing table. If you want to remove the constraint **NOT NULL**, specify the **NULL** in the statement.
  - If the **NOT NULL** constraint is specified in the column to change, the result varies depending on the configuration of the system parameter, **alter\_table\_change\_type\_strict**.
    - If **alter\_table\_change\_type\_strict** is set to yes, the column values will be checked. If **NULL** exists, an error will occur, and the change will not be executed.
    - If the **alter\_table\_change\_type\_strict** is set to no, every existing **NULL** value will be changed to a hard default value of the type to change.
- **DEFAULT** : Even though the **DEFAULT** attribute is not specified in the column to change, it will not be removed from a new table if the attribute is present in the existing table. If you want to remove the attribute **DEFAULT**, specify the **DEFAULT NULL** in the statement.

- **COMMENT** : Even though the **COMMENT** attribute is not specified in the column to change, it will not be removed from a new table if the attribute is present in the existing table. If you want to remove the attribute **COMMENT**, specify the **COMMENT** " in the statement.
- **AUTO\_INCREMENT** Even though the **AUTO\_INCREMENT** attribute is not specified in the column to change, it will not be removed from a new table if the attribute is present in the existing table.
  - caution) The **AUTO\_INCREMENT** attribute can not be removed from a new table once the attribute is set by CREATE or ALTER.
- **ON UPDATE** Even though the **ON UPDATE** attribute is not specified in the column to change, it will not be removed from a new table if the attribute is present in the existing table.
  - caution) The **ON UPDATE** attribute can not be removed from a new table once the attribute is set by CREATE or ALTER.
- **FOREIGN KEY** : You cannot change the column with the foreign key constraint that is referred to or refers to.
- Single Column **PRIMARY KEY**
  - If the **PRIMARY KEY** constraint is specified in the column to change, a **PRIMARY KEY** is re-created only in which a **PRIMARY KEY** constraint exists in the existing column and the type is upgraded.
  - If the **PRIMARY KEY** constraint is specified in the column to change but doesn't exist in the existing column, a **PRIMARY KEY** will be created.
  - If a **PRIMARY KEY** constraint exists but is not specified in the column to change, the **PRIMARY KEY** will be maintained.
- Multicolumn **PRIMARY KEY**: If the **PRIMARY KEY** constraint is specified and the type is upgraded, a **PRIMARY KEY** will be re-created.
- Single Column **UNIQUE KEY**
  - If the type is upgraded, a **UNIQUE KEY** will be re-created.
  - If a **UNIQUE KEY** exists in the existing column and it is not specified in the column to change, it will be maintained.
  - If a **UNIQUE KEY** exists in the existing column to change, it will be created.
- Multicolumn **UNIQUE KEY**: If the column type is changed, an index will be re-created.
- Column with a Non-unique Index : If the column type is changed, an index will be re-created.
- Partition Column: If a table is partitioned by a column, the column cannot be changed. Partitions cannot be added.

- Column with a Class Hierarchy : You can only change the tables that do not have a lower class. You cannot change the lower class that inherits from an upper class. You cannot change the inherited attributes.
- Trigger and View : You must redefine triggers and views directly because they are not changed according to the definition of the column to change.
- Column Sequence : You can change the sequence of columns.
- Name Change : You can change names as long as they do not conflict.

### Changes of Values based on Changes of Column Type

The **alter\_table\_change\_type\_strict** parameter determines whether the value conversion is allowed according to the type change. If the value is no, it can be changed when you change a column type or add a **NOT NULL** constraint. The default value is **yes**.

When the value of the parameter, **alter\_table\_change\_type\_strict** is no, it will operate depending on the conditions as follows:

- Overflow occurred while converting numbers or character strings to Numbers: It is determined based on symbol of the result type. If it is negative value, it is specified as a minimum value or positive value, specified as the maximum value and a warning message for records where overflow occurred is recorded in the log. For strings, it will follow the rules stated above after it is converted to **DOUBLE** type. Overflow can also be returned by the parameter **allow\_truncated\_string** setting to **no** if the converted string does not fit the length of the target string type.
- Character strings to convert to shorter ones: The record will be updated to the hard default value of the type that is defined and the warning message will be recorded in a log. Converting to shorter ones is not allowed when the **allow\_truncated\_string** is set to **no**.
- Conversion failure due to other reasons: The record will be updated to the hard default value of the type that is defined and the warning message will be recorded in a log.

If the value of the **alter\_table\_change\_type\_strict** parameter is yes or **allow\_truncated\_string** is set to no, an error message will be displayed and the changes will be rolled back.

The **ALTER CHANGE** statement checks the possibility of type conversion before updating a record but the type conversion of specific values may fail. For example, if the value format is not correct when you convert **VARCHAR** to **DATE**, the conversion may fail. In this case, the hard default value of the **DATE** type will be assigned.

The hard default value is a value that will be used when you add columns with the **ALTER TABLE ... ADD COLUMN** statement, add or change by converting types with the **ALTER TABLE ... CHANGE/**

**MODIFY** statement. The operation will vary depending on the system parameter, **add\_column\_update\_hard\_default** in the **ADD COLUMN** statement.

### Hard Default Value by Type

| Type      | Existence of Hard Default Value | Hard Default Value                         |
|-----------|---------------------------------|--------------------------------------------|
| INTEGER   | Yes                             | 0                                          |
| FLOAT     | Yes                             | 0                                          |
| DOUBLE    | Yes                             | 0                                          |
| SMALLINT  | Yes                             | 0                                          |
| DATE      | Yes                             | date'01/01/0001'                           |
| TIME      | Yes                             | time'00:00'                                |
| DATETIME  | Yes                             | datetime'01/01/0001 00:00'                 |
| TIMESTAMP | Yes                             | timestamp'00:00:01 AM<br>01/01/1970' (GMT) |
| NUMERIC   | Yes                             | 0                                          |
| CHAR      | Yes                             | "                                          |
| VARCHAR   | Yes                             | "                                          |
| SET       | Yes                             | {}                                         |

| Type     | Existence of Hard Default Value | Hard Default Value |
|----------|---------------------------------|--------------------|
| MULTISET | Yes                             | {}                 |
| SEQUENCE | Yes                             | {}                 |
| BIGINT   | Yes                             | 0                  |
| BIT      | NO                              |                    |
| VARBIT   | No                              |                    |
| OBJECT   | No                              |                    |
| BLOB     | No                              |                    |
| CLOB     | No                              |                    |

### Column's COMMENT

A column's comment is specified in `<column_definition>` or `<column_comment_definition>`. `<column_definition>` is located at the end of ADD/MODIFY/CHANGE syntax and `<column_comment_definition>` is located at the end of COMMENT ON COLUMN syntax. To see the meaning of `<column_definition>`, refer to [CREATE TABLE syntax](#) on the above.

In the COMMENT ON COLUMN syntax, you can change column comments by specifying one or more columns. The following example shows how to change a column comment using the COMMENT ON COLUMN statement.

```
ALTER TABLE t1 COMMENT ON COLUMN c1 = 'changed table column c1
comment';
ALTER TABLE t1 COMMENT ON COLUMN c2 = 'changed table column c2
comment', c3 = 'changed table column c3 comment';
```

The below is a syntax to show a column's comment.

```
SHOW CREATE TABLE t1 /* table_name */ ;

SELECT attr_name, class_name, comment
FROM db_attribute
WHERE class_name = t1 /* lowercase_table_name */ ;

SHOW FULL COLUMNS FROM t1 /* table_name */ ;
```

You can see this comment with the “;sc table\_name” command in the CSQL interpreter.

```
$ csql -u dba demodb

csql> ;sc table_name
```

## RENAME COLUMN Clause

You can change the name of the column by using the **RENAME COLUMN** clause.

```
ALTER [TABLE | CLASS | VCLASS | VIEW] [schema_name.] table_name
RENAME [COLUMN | ATTRIBUTE] old_column_name {AS | TO}
new_column_name ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table that has a column to be renamed.
- *old\_column\_name* : Specifies the name of a column.
- *new\_column\_name* : Specifies a new column name after the **AS** keyword(maximum: 254 bytes).

```
CREATE TABLE a_tbl (id INT, name VARCHAR(50));
ALTER TABLE a_tbl RENAME COLUMN name AS name1;
```

## DROP COLUMN Clause

You can delete a column in a table by using the **DROP COLUMN** clause. You can specify multiple columns to delete simultaneously by separating them with commas (,).

```
ALTER [TABLE | CLASS | VCLASS | VIEW] [schema_name.]table_name
DROP [COLUMN | ATTRIBUTE] column_name, ... ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table that has a column to be deleted.
- *column\_name* : Specifies the name of a column to be deleted. Multiple columns can be specified by separating them with commas (,).

```
ALTER TABLE a_tbl DROP COLUMN age1,age2,age3;
```

### DROP CONSTRAINT Clause

You can drop the constraints pre-defined for the table, such as **UNIQUE**, **PRIMARY KEY** and **FOREIGN KEY** by using the **DROP CONSTRAINT** clause. In this case, you must specify a constraint name. You can check these names by using the CSQL command (**;schema table\_name**).

```
ALTER [TABLE | CLASS] [schema_name.]table_name
DROP CONSTRAINT constraint_name ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table that has a constraint to be dropped.
- *constraint\_name* : Specifies the name of a constraint to be dropped.

```
CREATE TABLE a_tbl (
  id INT NOT NULL DEFAULT 0 PRIMARY KEY,
  phone VARCHAR(10)
);

CREATE TABLE b_tbl (
  ID INT NOT NULL,
  name VARCHAR (10) NOT NULL,
  CONSTRAINT u_name UNIQUE (name),
  CONSTRAINT pk_id PRIMARY KEY (id),
  CONSTRAINT fk_id FOREIGN KEY (id) REFERENCES a_tbl (id)
  ON DELETE CASCADE ON UPDATE RESTRICT
);

ALTER TABLE b_tbl DROP CONSTRAINT pk_id;
```

```
ALTER TABLE b_tbl DROP CONSTRAINT fk_id;  
ALTER TABLE b_tbl DROP CONSTRAINT u_name;
```

## DROP INDEX Clause

You can delete an index defined for a column by using the **DROP INDEX** clause. A unique index can be dropped with a **DROP CONSTRAINT** clause.

```
ALTER [TABLE | CLASS] [schema_name.]table_name DROP INDEX  
index_name ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table of which constraints will be deleted.
- *index\_name* : Specifies the name of an index to be deleted.

```
ALTER TABLE a_tbl DROP INDEX i_a_tbl_age;
```

## DROP PRIMARY KEY Clause

You can delete a primary key constraint defined for a table by using the **DROP PRIMARY KEY** clause. You do have to specify the name of the primary key constraint because only one primary key can be defined by table.

```
ALTER [TABLE | CLASS] [schema_name.]table_name DROP PRIMARY KEY ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table that has a primary key constraint to be deleted.

```
ALTER TABLE a_tbl DROP PRIMARY KEY;
```

## DROP FOREIGN KEY Clause

You can drop a foreign key constraint defined for a table using the **DROP FOREIGN KEY** clause.

```
ALTER [TABLE | CLASS] [schema_name.]table_name DROP FOREIGN KEY
constraint_name ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of a table whose constraint is to be deleted.
- *constraint\_name* : Specifies the name of foreign key constraint to be deleted.

```
ALTER TABLE b_tbl ADD CONSTRAINT fk_id FOREIGN KEY (id) REFERENCES
a_tbl (id);
ALTER TABLE b_tbl DROP FOREIGN KEY fk_id;
```

## DROP TABLE

You can drop an existing table by the **DROP** statement. Multiple tables can be dropped with a single **DROP** statement. All rows of table are also dropped. If you also specify **IF EXISTS** clause, no error will be happened even if a target table does not exist.

```
DROP [TABLE | CLASS] [IF EXISTS] <table_specification_comma_list>
[CASCADE CONSTRAINTS] ;

<table_specification_comma_list> ::=
    <single_table_spec> | (<table_specification_comma_list>)

<single_table_spec> ::=
    | [ONLY] [schema_name.]table_name
    | ALL [schema_name.]table_name [( EXCEPT
[schema_name.]table_name, ... )]
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to be dropped. You can delete multiple tables simultaneously by separating them with commas.
- If a super class name is specified after the **ONLY** keyword, only the super class, not the sub classes inheriting from it, is deleted. If a super class name is specified after the **ALL** keyword, the super classes as well as the sub classes inheriting from it are all deleted. You can specify the list of sub classes not to be deleted after the **EXCEPT** keyword.
- If sub classes that inherit from the super class specified after the **ALL** keyword are specified after the **EXCEPT** keyword, they are not deleted.

- Specifies the list of subclasses which are not to be deleted after the **EXCEPT** keyword.
- **CASCADE CONSTRAINTS**: The table is dropped and also foreign keys of other tables which refer this table are dropped.

```
CREATE TABLE b_tbl (i INT);
CREATE TABLE a_tbl (i INT);

-- DROP TABLE IF EXISTS
DROP TABLE IF EXISTS b_tbl, a_tbl;

SELECT * FROM a_tbl;
```

```
ERROR: Unknown class "a_tbl".
```

- If **CASCADE CONSTRAINTS** is specified, the specified table is dropped even if some tables refer the dropping table's primary key; foreign keys of other tables which refer this table are also dropped. However, the data of tables which are referred are not deleted.

The below shows to drop a\_parent table which b\_child table refers. A foreign key of b\_child table also dropped, and the data of b\_child table are kept.

```
CREATE TABLE a_parent (
    id INTEGER PRIMARY KEY,
    name VARCHAR(10)
);
CREATE TABLE b_child (
    id INTEGER PRIMARY KEY,
    parent_id INTEGER,
    CONSTRAINT fk_parent_id FOREIGN KEY(parent_id) REFERENCES
a_parent(id) ON DELETE CASCADE ON UPDATE RESTRICT
);

DROP TABLE a_parent CASCADE CONSTRAINTS;
```

## RENAME TABLE

You can change the name of a table by using the **RENAME TABLE** statement and specify a list of the table name to change the names of multiple tables.

```
RENAME [TABLE | CLASS] [schema_name.]old_table_name {AS | TO}
[schema_name.]new_table_name [{, [schema_name.]old_table_name {AS |
TO} [schema_name.]new_table_name}];
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used. The schema of the table to be changed and the schema of the new table must be the same.
- *old\_table\_name* : Specifies the old table name to be renamed.
- *new\_table\_name* : Specifies a new table name(maximum: 254 bytes).

```
RENAME TABLE a_tbl AS aa_tbl;
RENAME TABLE aa_tbl TO a1_tbl, b_tbl TO b1_tbl;
```

#### Note

The table name can be changed only by the table owner, **DBA** and **DBA** members. The other users must be granted to change the name by the owner or **DBA** (see [GRANT](#) for details about authorization).

## INDEX DEFINITION STATEMENTS

### CREATE INDEX

Creates an index to a specified table by using the **CREATE INDEX** statement. Regarding writing index name, see [Identifier](#).

For how to use indexes on the **SELECT** statement like Using SQL Hint, Descending Index, Covering Index, Index Skip Scan, **ORDER BY** Optimization and **GROUP BY** Optimization, and how to create Filtered Index and Function-based Index, see [Join Methods](#).

```
CREATE [UNIQUE] INDEX index_name ON [schema_name.]table_name
<index_col_desc2> ;

<index_col_desc2> ::=
    {
        ( {column_name | function_name (argument_list)}
[ASC | DESC]
        [{, {column_name | function_name (argument_list)}
```

```
[ASC | DESC]} ...] )
    }
    [WHERE <filter_predicate> ]
    [WITH <index_with_clause> [{,
<index_with_clause>}] ...]
    [INVISIBLE]
    [COMMENT 'index_comment_string']

    <index_with_clause> ::= {ONLINE [PARALLEL parallel_count]}
| <index_with_option>
    <index_with_option> ::= {DEDUPLICATE '=' deduplicate_level}
```

- **UNIQUE:** creates an index with unique values.
- *index\_name*: specifies the name of the index to be created. The index name must be unique in the table.
- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: specifies the name of the table where the index is to be created.
- *column\_name*: specifies the name of the column where the index is to be applied. To create a composite index, specify two or more column names.
- **ASC | DESC:** specifies the sorting order of columns.
- *deduplicate\_level*: specifies the deduplicate level (0 to 14). For details, see [DEDUPLICATE](#).

#### Note

- *deduplicate\_level* is an integer from 0 to 14.
- When this parameter is set to 0, it indicates an index configuration where data deduplication within indexes is not performed. This configuration is the same as that in CUBRID 11.2 or an earlier version.
- *<filter\_predicate>*: defines the conditions to create filtered indexes. When there are several comparison conditions between a column and a constant, filtering is available only when the conditions are connected by using **AND**. Refer to [Filtered Index](#) for more details.
- *function\_name (argument\_list)*: Defines the conditions to create function-based indexes. Regarding this, definitely watch [Function-based Index](#).
- **WITH ONLINE**: creates the index while allowing changes of table data from other transactions. If **PARALLEL** is not specified, the index is created using the transaction thread. *<parallel\_count>* is

the number of threads to be used for creating the index and it must be a integer between 1 and 16.

- **INVISIBLE**: creates the index with its status set to **INVISIBLE**, meaning queries executed will not take into account the index. If **INVISIBLE** is omitted, the index will be created with its status set to **NORMAL\_INDEX**.
- *index\_comment\_string*: specifies a comment of an index.

#### Note

- From CUBRID 9.0, the index name should not be omitted in the CREATE/INDEX statement.
- Prefix index feature is deprecated, so it is not recommended anymore.
- The session and server timezone (**Timezone Parameter**) should not be changed if database contains indexes or function index on columns of type **TIMESTAMP**, **TIMESTAMP WITH LOCAL TIME ZONE** or **DATETIME WITH LOCAL TIME ZONE**.
- The leap second support parameter (**Timezone Parameter**) should not be changed if database contains indexes or function index on columns of type **TIMESTAMP** or **TIMESTAMP WITH LOCAL TIME ZONE**.
- The number of threads from **PARALLEL** option applies only to index loading step. The heap scan step is performed by the transaction thread (single thread). During this process, the rows are collected into batches; when a batch is full (reached 16M in size), it is dispatched to a index loading thread (or pushed in the queue), the collecting process continues. Batch size computing consists of index key size and the row identifier size (8 bytes).
- Under stand-alone mode, the **WITH ONLINE** option is ignored (normal index is created).
- The creation of online index is performed in three stages:
  - Adding index into schema with status **INDEX IS IN ONLINE BUILDING**. This is performed with a **SCH\_M\_LOCK** (like all schema changes) on table. After this, the lock is demoted to **IX\_LOCK**.
  - Populating the index : scanning the heap file into batches, sorting the batches and adding the keys to index. During this step, other transactions can modify table data (index is also updated with data changes from other committed transactions).
  - Updating the index status as **NORMAL INDEX**; this is performed after promoting the table lock back to **SCH\_M\_LOCK** (promotion is guaranteed).

- The online index being built is displayed by SHOW statements from other transactions. It is not visible from other transactions in `_db_index` system table due to MVCC snapshot (other transactions can only see committed entries in this table).
- Transactions running in parallel with online index building which performs operations causing unique violations in index are allowed to commit. The online index will continue to progress and check before final step (setting NORMAL INDEX status in schema) the validity of unique constraint. The index creation will be aborted in case of unique violation. The user needs to restart the operation after making sure the unique constraint is ensured.

The following example shows how to create a descending index.

```
CREATE INDEX gold_index ON participant(gold DESC);
```

The following example shows how to create a multiple column index.

```
CREATE INDEX name_nation_idx ON athlete(name, nation_code) COMMENT  
'index comment';
```

## COMMENT of Index

You can write a comment of an index as following.

```
CREATE TABLE tbl (a int default 0, b int, c int);  
  
CREATE INDEX i_tbl_b on tbl (b) COMMENT 'index comment for i_tbl_b';  
  
CREATE TABLE tbl2 (a INT, index i_tbl_a (a) COMMENT 'index comment',  
b INT);  
  
ALTER TABLE tbl2 ADD INDEX i_tbl2_b (b) COMMENT 'index comment b';
```

A specified comment of an index can be shown by running these statements.

```
SHOW CREATE TABLE table_name;  
SELECT index_name, class_name, comment from db_index where  
class_name ='classname';  
SHOW INDEX FROM table_name;
```

Or you can see the index comments with ;sc command in the CSQL interpreter.

```
$ csql -u dba demodb
csql> ;sc tbl
```

## Online index creation

You can create the index while still allowing other transactions to insert or update the table.

```
CREATE TABLE t1 (i1 int, i2 int);
CREATE INDEX i_t1_i1 on t1 (i1) WITH ONLINE PARALLEL 10;
```

## Displaying online index from other transactions

Other transactions may see the online index with schema related statements:

```
csql> show index in t1;

=== <Result of SELECT Command in Line 1> ===

  Table                               Non_unique  Key_name

```

## DEDUPLICATE

If you use the **DEDUPLICATE** option, you can improve performance of modifying skewed index. The value of this option can be adjusted to mitigate the overflow page's linked list for a specific

key value from being made too long, thereby improving insert/delete/update and vacuum performance. However, since an index column hidden by the system is added, the number of leaf nodes in the index and the height of the b-tree may increase, increasing the size of the index and affecting search performance. In particular, if the index data is uniformly distributed with respect to key values, you are careful to use this option because only the size of the index may increase without improving performance.

If the value of *deduplicate level* is specified as 1 or higher, a hidden index column used internally by the system is added when creating the index. The value of column is used to reduce redundancy so that it is not biased toward a specific key value. A higher *deduplicate level* value, it will be mitigated redundancy and a smaller overflow page for a specific key.

#### Note

- The overflow page have a disadvantage in add, delete, and update performance, but are beneficial in search performance. Therefore, it is better to adjust the length of the overflow page for one key to be within tens or hundreds of pages, rather than setting the *deduplication level* high so that overflow pages are not created when creating an index with that option.

There are two ways to specify *deduplicate level* when creating an index.

#### Implicit method

This method automatically specifies *deduplicate level* when there is no explicit DEDUPLICATE option specified in the SQL statement. This method is affected by the set value of the system parameter **deduplicate\_key\_level**. If **deduplicate\_key\_level** is greater than or equal to 1, *deduplicate level* is automatically set to **deduplicate\_key\_level**.

#### Explicit method

This is a method in which the user explicitly specifies the **DEDUPLICATE** option in the SQL statement. Regardless of the **deduplicate\_key\_level** set value, the *deduplicate level* specified by the user is applied. As in the example below, specify the DEDUPLICATE statement directly.

```
CREATE TABLE tbl (a int default 0, b int, c int);
CREATE INDEX i_tbl_b on tbl (b) WITH DEDUPLICATE=3 COMMENT
'for deduplicate level 3';
CREATE INDEX i_tbl_b_c on tbl (b,c) WITH DEDUPLICATE=7
COMMENT 'for deduplicate level 1';
```

**Warning**

- If **deduplicate\_key\_level** is **-1**, it is internally ignored and not applied even if it is specified explicitly. That is, in this case, all indexes are created with *deduplicate level* as **0**.
- A column name that begins with “**\_dedup\_**” cannot be created.

**Note**

- **When creating an index, if the composition of the key field is guaranteed to be UNIQUE, the DEDUPLICATE specified by the user is ignored and *deduplicate level* is created as 0.**
  - If the columns of index includes all columns of Primary Key or Unique Index.
  - However, except if columns of Primary key or Unique index used as an argument of a function index.

## Allowing multiple indexes on the same column in the same order

Multiple indexes can be defined with all key fields and filter conditions identical except for *deduplicate level*.

```
CREATE TABLE tbl (a int primary key, b int, c int);  
CREATE INDEX idx1 ON tbl(b, c) WITH DEDUPLICATE=3;  
CREATE INDEX idx2 ON tbl(b, c) WITH DEDUPLICATE=5;  
CREATE UNIQUE INDEX idx_uk ON tbl(b);  
CREATE INDEX idx3 ON tbl(b, c) WITH DEDUPLICATE=7;
```

In the example above, idx1 and idx2 have the specified *deduplicate level*. However, since idx3 is guaranteed by idx\_uk that column b is unique, it is created *duplicate level* as **0** and ignore user's specified option.

**Note**

- If an FK already exists with the same index column that differs only in *deduplication level*, it can't be duplicated.
- If columns of index includes a primary key or unique index, indexes that differ only in the *deduplicate level* can't be created. (Even if duplicate indexes are allowed.)

- You cannot change the *deduplicate level* of an index with the ALTER INDEX REBUILD statement. If necessary, delete the index and recreate it.

## OVERFLOW PAGE

### • What is the overflow page?

An index consists of non-leaf nodes and leaf nodes, and a leaf node is composed of a set of index key information. At this time, one index key information is a pair of a key value and a set of record's OIDs corresponding to the key value. If there are many records with a specific key value, the OIDs of all the records can't be stored in the leaf node, so they are separated and managed in a separate page, which is called an overflow page. Also, when even overflow pages are full, new overflow pages are created and these pages are maintained as a linked list.

## ALTER INDEX

The **ALTER INDEX** statement changes the properties of an index. Index is rebuilt unless only comment or status is changed. Rebuilding an index is a job which drops and recreates an index.

The following is a syntax of rebuilding an index.

```
ALTER INDEX index_name ON [schema_name.]table_name {[COMMENT  
index_comment_string] REBUILD} | {COMMENT index_comment_string} |  
VISIBLE | INVISIBLE};
```

- *index\_name*: specifies the name of the index to be altered or rebuilt. The index name must be unique in the table.
- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: specifies the name of the table where the index is rebuilt.
- **REBUILD**: rebuild an index with the same structure as the one already created.
- *index\_comment\_string*: specifies a comment of an index.

**Note**

- From CUBRID 9.0, the index name should not be omitted.
- From CUBRID 10.0, table name should not be omitted.
- From CUBRID 10.0, even if you add column names at the end of a table name, these will be ignored and recreated with the same columns with the previous index.
- From CUBRID 11.4, an error occurs if you add a column name after the table name.

The following is an example of recreating index.

```
CREATE INDEX i_game_medal ON game(medal);  
ALTER INDEX i_game_medal ON game COMMENT 'rebuild index comment'  
REBUILD ;
```

If you want to add or change a comment of the index without rebuilding an index, add a **COMMENT** clause and remove **REBUILD** keyword as follows:

```
ALTER INDEX index_name ON table_name COMMENT 'index_comment_string' ;
```

The below is a syntax to only add or change a comment without rebuilding an index.

```
ALTER INDEX i_game_medal ON game COMMENT 'change index comment' ;
```

The following is a syntax to change the status of an index to **INVISIBLE/VISIBLE**. When an index is set as **INVISIBLE**, queries will be executed as like the index does not exist. In this way, the performance of the index may be tested and the impact of its removal be evaluated without actually dropping the index.

```
CREATE INDEX i_game_medal ON game(medal);  
ALTER INDEX i_game_medal ON game VISIBLE;  
ALTER INDEX i_game_medal ON game INVISIBLE;
```

## DROP INDEX

Use the **DROP INDEX** statement to drop an index. An index also can be dropped with **DROP CONSTRAINT** clause.

```
DROP INDEX index_name ON [schema_name.]table_name ;
```

- *index\_name*: specifies the name of the index to be dropped.
- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: specifies the name of the table whose index is dropped.

#### Warning

From the CUBRID 10.0 version, table name cannot be omitted.

The following is an example of dropping an index:

```
DROP INDEX i_game_medal ON game;
```

## VIEW DEFINITION STATEMENTS

### CREATE VIEW

A view is a virtual table that does not exist physically. You can create a view by using an existing table or a query. **VIEW** and **VCLASS** are used interchangeably.

Use **CREATE VIEW** statement to create a view. A view with the same name as an existing table or synonym cannot be created. Regarding writing view name, see [Identifier](#).

```
CREATE [OR REPLACE] {VIEW | VCLASS} [schema_name.]view_name
[<subclass_definition>]
[(view_column_name [COMMENT 'column_comment_string'], ...)]
[INHERIT <resolution>, ...]
[AS <select_statement>]
[WITH CHECK OPTION]
[COMMENT [=] 'view_comment_string'];

<subclass_definition> ::= {UNDER | AS SUBCLASS OF}
[schema_name.]superclass_name, ...
```

```
<resolution> ::= [CLASS | TABLE] {column_name} OF
[schema_name.]superclass_name [AS alias]
```

- **OR REPLACE:** If the keyword **OR REPLACE** is specified after **CREATE**, the existing view is replaced by a new one without displaying any error message, even when the *view\_name* overlaps with the existing view name.
- *schema\_name:* Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name:* specifies the name of a view to be created. It must be unique in a database.
- *view\_column\_name:* defines the column of a view.
- **AS** *<select\_statement>*: A valid **SELECT** statement must be specified. A view is created based on this.
- **WITH CHECK OPTION:** If this option is specified, the update or insert operation is possible only when the condition specified in the **WHERE** clause of the *<select\_statement>* is satisfied. Therefore, this option is used to disallow the update of a virtual table that violates the condition.
- *view\_comment\_string:* specifies a view's comment.
- *column\_comment\_string:* specifies a column's comment.

```
CREATE TABLE a_tbl (
    id INT NOT NULL,
    phone VARCHAR(10)
);
INSERT INTO a_tbl VALUES(1, '111-1111'), (2, '222-2222'), (3,
'333-3333'), (4, NULL), (5, NULL);

--creating a new view based on AS select_statement from a_tbl
CREATE VIEW b_view AS SELECT * FROM a_tbl WHERE phone IS NOT NULL
WITH CHECK OPTION;
SELECT * FROM b_view;
```

```
      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
```

```
--WITH CHECK OPTION doesn't allow updating column value which
violates WHERE clause
UPDATE b_view SET phone=NULL;
```

```
ERROR: Check option exception on view b_view.
```

The below updates the old view's definition, In addition, this adds a view's comment.

```
--creating view which name is as same as existing view name
CREATE OR REPLACE VIEW b_view AS SELECT * FROM a_tbl ORDER BY id
DESC COMMENT 'changed view';

--the existing view has been replaced as a new view by OR REPLACE
keyword
SELECT * FROM b_view;
```

```

      id  phone
=====
      5  NULL
      4  NULL
      3  '333-3333'
      2  '222-2222'
      1  '111-1111'
```

The below adds a comment to a view's columns.

```
CREATE OR REPLACE VIEW b_view(a COMMENT 'column id', b COMMENT
'column phone') AS SELECT * FROM a_tbl ORDER BY id DESC;
```

## Condition for Creating Updatable VIEW

A virtual table is updatable if it satisfies the following conditions:

- The **FROM** clause must include the updatable table or view only.

In versions lower than CUBRID 9.0, only one updatable table can be included to the **FROM** clause it requires. However, two tables in parentheses like FROM (class\_x, class\_y) can be updated since the two were expressed as one table. In version of CUBRID 9.0 or higher, more than one updatable table is allowed. The **FROM** clause must include only one table or updatable view. However, two tables included in parentheses as in **FROM** (class\_x, class\_y) can be updated because they represent one table.

- A **JOIN** syntax can be included.

**Note**

In versions lower than CUBRID 10.0, you cannot update a view which is created with a **JOIN** syntax.

- The **DISTINCT** or **UNIQUE** statement should not be included.
- The **GROUP BY... HAVING** statement should not be included.
- Aggregate functions such as **SUM** or **AVG** should not be included.
- The entire query must consist of queries that can be updated by **UNION ALL**, not by **UNION**. However, the table should exist only in one of the queries that constitute **UNION ALL**.
- If a record is inserted into a view created by using the **UNION ALL** statement, the system determines into which table the record will be inserted. This cannot be done by the user. To control this, the user must manually insert the row or create a separate view for insertion.

Even when all rules above are satisfied, columns that contains following contents cannot be updated.

- Path expressions (example: *tbl\_name.col\_name*)
- Numeric type column that includes an arithmetic operator

Even though the column defined in the view is updatable, a view can be updated only when an appropriate update authorization is granted on the table included in the **FROM** clause. Also there must be an access authorization to a view. The way to grant an access authorization to a view is the same to grant an access authorization to a table. For details on granting authorization, see [GRANT](#).

## View's COMMENT

You can specify a view's comment as follows.

```
CREATE OR REPLACE VIEW b_view AS SELECT * FROM a_tbl ORDER BY id
DESC COMMENT 'changed view';
```

You can see the specified comment of a view by running this syntax.

```
SHOW CREATE VIEW view_name;
SELECT vclass_name, comment from db_vclass;
```

Or you can see the view's comment with ;sc command which displays the schema in the CSQL interpreter.

```
$ csql -u dba demodb
csql> ;sc b_view
```

Also, you can add a comment for each column of the view.

```
CREATE OR REPLACE VIEW b_view (a COMMENT 'a comment', b COMMENT 'b
comment')
AS SELECT * FROM a_tbl ORDER BY id DESC COMMENT 'view comment';
```

To see how to change a comment of a view, refer to ALTER VIEW syntax on the below.

## ALTER VIEW

### ADD QUERY Clause

You can add a new query to a query specification by using the **ADD QUERY** clause of the **ALTER VIEW** statement. 1 is assigned to the query defined when a virtual table was created, and 2 is assigned to the query added by the **ADD QUERY** clause.

```
ALTER [VIEW | VCLASS] [schema_name.]view_name
ADD QUERY <select_statement>
[INHERIT <resolution> , ...] ;

    <resolution> ::= {column_name} OF [schema_name.]superclass_name
[AS alias]
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name*: specifies the name of a view where the query to be added.
- *<select\_statement>*: specifies the query to be added.

```
SELECT * FROM b_view;
```

```
      id  phone
=====
      1  '111-1111'
```

```

2  '222-2222'
3  '333-3333'
4  NULL
5  NULL

```

```

ALTER VIEW b_view ADD QUERY SELECT * FROM a_tbl WHERE id IN (1,2);
SELECT * FROM b_view;

```

```

      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      4  NULL
      5  NULL
      1  '111-1111'
      2  '222-2222'

```

## AS SELECT Clause

You can change the **SELECT** query defined in the virtual table by using the **AS SELECT** clause in the **ALTER VIEW** statement. This function is working like the **CREATE OR REPLACE** statement. You can also change the query by specifying the query number 1 in the **CHANGE QUERY** clause of the **ALTER VIEW** statement.

```

ALTER [VIEW | VCLASS] [schema_name.]view_name AS <select_statement> ;

```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name*: specifies the name of a view to be modified.
- *<select\_statement>*: specifies the new query statement to replace the **SELECT** statement defined when a view is created.

```

ALTER VIEW b_view AS SELECT * FROM a_tbl WHERE phone IS NOT NULL;
SELECT * FROM b_view;

```

```

      id  phone
=====
      1  '111-1111'

```

```

2  '222-2222'
3  '333-3333'

```

## CHANGE QUERY Clause

You can change the query defined in the query specification by using the **CHANGE QUERY** clause reserved word of the **ALTER VIEW** statement.

```

ALTER [VIEW | VCLASS] [schema_name.]view_name
CHANGE QUERY [integer] <select_statement> ;

```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name*: specifies the name of a view to be modified.
- *integer*: specifies the number value of the query to be modified. The default value is 1.
- *<select\_statement>*: specifies the new query statement to replace the query whose query number is *integer*.

```

--adding select_statement which query number is 2 and 3 for each
ALTER VIEW b_view ADD QUERY SELECT * FROM a_tbl WHERE id IN (1,2);
ALTER VIEW b_view ADD QUERY SELECT * FROM a_tbl WHERE id = 3;
SELECT * FROM b_view;

```

```

      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      4  NULL
      5  NULL
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'

```

```

--altering view changing query number 2
ALTER VIEW b_view CHANGE QUERY 2 SELECT * FROM a_tbl WHERE phone IS
NULL;
SELECT * FROM b_view;

```

```

      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      4  NULL
      5  NULL
      4  NULL
      5  NULL
      3  '333-3333'

```

## DROP QUERY Clause

You can drop a query defined in the query specification by using the **DROP QUERY** of the **ALTER VIEW** statement.

```

ALTER VIEW b_view DROP QUERY 2,3;
SELECT * FROM b_view;

```

```

      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      4  NULL
      5  NULL

```

## COMMENT Clause

You can change a view's comment, columns' comment, or attributes' comment with **COMMENT** clause of **ALTER VIEW** syntax.

```

ALTER [VIEW | VCLASS] [schema_name.]view_name
COMMENT [=] 'view_comment_string' |
COMMENT ON {COLUMN | CLASS ATTRIBUTE} <column_comment_definition> [,
<column_comment_definition>] ;

    <column_comment_definition> ::= column_name [=]
'column_comment_string'

```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name*: Specifies the name of a view to be modified.

- *column\_name*: Specifies the name of a column to be modified.
- *view\_comment\_string*: Specifies a view's comment.
- *column\_comment\_string*: Specifies a column's comment.

The following example shows how to change a view's comments.

```
ALTER VIEW v1 COMMENT = 'changed view v1 comment';
```

You can change the column comment by specifying one or more columns after the ON COLUMN keyword. The following example shows how to change a column's comments.

```
ALTER VIEW v1 COMMENT ON COLUMN c1 = 'changed view column c1 comment';  
ALTER VIEW v1 COMMENT ON COLUMN c2 = 'changed view column c2 comment', c3 = 'changed view column c3 comment';
```

Below is a syntax to show a column's comment. But the SHOW CREATE VIEW statement shows only view comments.

```
SHOW CREATE VIEW v1 /* view_name */ ;  
  
SELECT attr_name, class_name, comment  
FROM db_attribute  
WHERE class_name = 'v1' /* lowercase_view_name */ ;  
  
SHOW FULL COLUMNS FROM v1 /* view_name */ ;
```

You can see this comment with the “;sc view\_name” command in the CSQL interpreter.

```
$ csql -u dba demodb  
  
csql> ;sc v1
```

## DROP VIEW

You can drop a view by using the **DROP VIEW** clause. The way to drop a view is the same as to drop a regular table. If you also specify IF EXISTS clause, no error will be happened even if a target view does not exist.

```
DROP [VIEW | VCLASS] [IF EXISTS] [schema_name.]view_name [{,  
[schema_name.]view_name}] ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *view\_name*: specifies the name of a view to be dropped.

```
DROP VIEW b_view;
```

## RENAME VIEW

You can change the view name by using the **RENAME VIEW** statement.

```
RENAME [VIEW | VCLASS] [schema_name.]old_view_name {AS | TO}  
[schema_name.]new_view_name [{, [schema_name.]old_view_name {AS |  
TO} [schema_name.]new_view_name}] ;
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used. The schema of the view to be changed and the schema of the new view must be the same.
- *old\_view\_name*: specifies the name of a view to be modified.
- *new\_view\_name*: specifies the new name of a view.

The following example shows how to rename a view name to *game\_2004*.

```
RENAME VIEW game_2004 AS info_2004;
```

## SERIAL DEFINITION STATEMENTS

### CREATE SERIAL

Serial is an object that creates a unique sequence number, and has the following characteristics.

- The serial is useful in creating a unique sequence number in multi-user environment.
- Generated serial numbers are not related with table so, you can use the same serial in multiple tables.

- All users including **PUBLIC** can create a serial object. Once it is created, all users can get the number by using **CURRENT\_VALUE(equivalent to CURRVAL)** and **NEXT\_VALUE(equivalent to NEXTVAL)**.
- Only owner of a created serial object and **DBA** can update or delete a serial object. If an owner is **PUBLIC**, all users can update or delete it.

You can create a serial object in the database by using the **CREATE SERIAL** statement. Regarding writing serial name, **Identifier**.

```
CREATE SERIAL [schema_name.]serial_name
[START WITH initial]
[INCREMENT BY interval]
[MINVALUE min | NOMINVALUE]
[MAXVALUE max | NOMAXVALUE]
[CYCLE | NOCYCLE]
[CACHE cached_num | NOCACHE]
[COMMENT 'comment_string'];
```

- *schema\_name*: Specifies the schema name of the serial(maximum: 31 bytes). If omitted, the schema name of the current session is used.
- *serial\_name*: specifies the name of the serial to be generated(maximum: 222 bytes).
- **START WITH initial**: Specifies the initial value of serial. The range of this value is between -1,000,000,000,000,000,000,000,000,000,000(-10<sup>36</sup>) and 9,999,999,999,999,999,999,999,999,999,999(10<sup>37-1</sup>). The default value of ascending serial is 1 and that of descending serial is -1.
- **INCREMENT BY interval**: Specifies the increment of the serial. You can specify any integer between -9,999,999,999,999,999,999,999,999,999,999(-10<sup>37+1</sup>) and 9,999,999,999,999,999,999,999,999,999,999(10<sup>37-1</sup>) except zero at *interval*. The absolute value of the *interval* must be smaller than the difference between **MAXVALUE** and **MINVALUE**. If a negative number is specified, the serial is in descending order otherwise, it is in ascending order. The default value is **1**.
- **MINVALUE**: Specifies the minimum value of the serial. The range of this value is between -1,000,000,000,000,000,000,000,000,000,000(-10<sup>36</sup>) and 9,999,999,999,999,999,999,999,999,999,999(10<sup>37-1</sup>). **MINVALUE** must be smaller than or equal to the initial value and smaller than the maximum value.
- **NOMINVALUE**: 1 is set automatically as a minimum value for the ascending serial, -1,000,000,000,000,000,000,000,000,000,000(-10<sup>36</sup>) for the descending serial.
- **MAXVALUE**: Specifies the maximum number of the serial. The range of this value is between -999,999,999,999,999,999,999,999,999,999(-10<sup>36+1</sup>) and

10,000,000,000,000,000,000,000,000,000,000(10<sup>37</sup>). **MAXVALUE** must be greater than or equal to the initial value and greater than the minimum value.

- **NOMAXVALUE:** 10,000,000,000,000,000,000,000,000,000,000(10<sup>37</sup>) is set automatically as a maximum value for the ascending serial, -1 for the descending serial.
- **CYCLE:** Specifies that the serial will be generated continuously after reaching the maximum or minimum value. When a serial in ascending order reaches the maximum value, the minimum value is created as the next value; when a serial in descending order reaches the minimum value, the maximum value is created as the next value.
- **NOCYCLE:** Specifies that the serial will not be generated anymore after reaching the maximum or minimum value. The default value is **NOCYCLE**.
- **CACHE:** Stores as many serials as the number specified by “cached\_num” in the cache to improve the performance of the serials and fetches a serial value when one is requested. If all cached values are used up, as many serials as “cached\_num” are fetched again from the disk to the memory. If the database server stops accidentally, all cached serial values are deleted. For this reason, the serial values before and after the restart of the database server may be discontinuous. Because the transaction rollback does not affect the cached serial values, the request for the next serial will return the next value of the value used (or fetched) lastly when the transaction is rolled back. The “cached\_num” after the **CACHE** keyword cannot be omitted. If the “cached\_num” is equal to or smaller than 1, the serial cache is not applied.
- **NOCACHE:** Specifies that the serial cache is not used, and serial value is updated for each time. The default value is **NOCACHE**.
- *comment\_string:* specifies a comment of a serial.

```
--creating serial with default values
CREATE SERIAL order_no;

--creating serial within a specific range
CREATE SERIAL order_no START WITH 10000 INCREMENT BY 2 MAXVALUE
20000;

--creating serial with specifying the number of cached serial values
CREATE SERIAL order_no START WITH 10000 INCREMENT BY 2 MAXVALUE
20000 CACHE 3;

--selecting serial information from the db_serial
SELECT name, current_val, increment_val, max_val, min_val, cyclic,
started, cached_num, attr_name FROM db_serial;
```

|            |             |               |         |
|------------|-------------|---------------|---------|
| name       | current_val | increment_val |         |
| max_val    | min_val     | cyclic        | started |
| cached_num | attr_name   |               |         |

```
=====
=====
=====
'order_no'      10006      2      0      1
20000           10000
3              NULL
```

The following example shows how to create the *athlete\_idx* table to store athlete codes and names and then create an instance by using the *order\_no*. *NEXT\_VALUE* increases the serial number and returns its value.

```
CREATE TABLE athlete_idx( code INT, name VARCHAR(40) );
CREATE SERIAL order_no START WITH 10000 INCREMENT BY 2 MAXVALUE
20000;
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Park');
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Kim');
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Choo');
INSERT INTO athlete_idx VALUES (order_no.CURRENT_VALUE, 'Lee');

SELECT * FROM athlete_idx;
```

```
      code  name
=====
10000  'Park'
10002  'Kim'
10004  'Choo'
10004  'Lee'
```

## COMMENT of Serial

The below adds a comment when you create a serial.

```
CREATE SERIAL order_no
START WITH 100 INCREMENT BY 2 MAXVALUE 200
COMMENT 'from 100 to 200 by 2';
```

To see a comment of the serial, run the below syntax.

```
SELECT name, comment FROM db_serial;
```

To change a comment of a serial, see ALTER SERIAL syntax.

## ALTER SERIAL

With the **ALTER SERIAL** statement, you can update the increment of the serial value, set or delete its initial or minimum/maximum values, and set its cycle attribute.

```
ALTER SERIAL [schema_name.]serial_name
[INCREMENT BY interval]
[START WITH initial_value]
[MINVALUE min | NOMINVALUE]
[MAXVALUE max | NOMAXVALUE]
[CYCLE | NOCYCLE]
[CACHE cached_num | NOCACHE]
[COMMENT 'comment_string'];
```

- *schema\_name*: Specifies the schema name of the serial(maximum: 31 bytes). If omitted, the schema name of the current session is used.
- *serial\_name*: specifies the name of the serial to be created(maximum: 222 bytes).
- **INCREMENT BY interval**: specifies the increment of the serial. For the *interval*, you can specify any integer with 38 digits or less except zero. The absolute value of the *interval* must be smaller than the difference between **MAXVALUE** and **MINVALUE**. If a negative number is specified, the serial is in descending order; otherwise, it is in ascending order. The default value is **1**.
- **START WITH initial\_value**: changes the initial value of Serial.
- **MINVALUE**: specifies the minimum value of the serial with 38 digits or less. **MINVALUE** must be smaller than or equal to the initial value and smaller than the maximum value.
- **NOMINVALUE**: 1 is set automatically as a minimum value for the ascending serial; -(10) 36 for the descending serial.
- **MAXVALUE**: specifies the maximum number of the serial with 38 digits or less. **MAXVALUE** must be larger than or equal to the initial value and greater than the minimum value.
- **NOMAXVALUE**: (10) 37 is set automatically as a maximum value for the ascending serial; -1 for the descending serial.
- **CYCLE**: specifies that the serial will be generated continuously after reaching the maximum or minimum value. If the ascending serial reaches the maximum value, the minimum value is generated as the next value. If the descending serial reaches the minimum value, the maximum value is generated as the next value.
- **NOCYCLE**: specifies that the serial will not be generated anymore after reaching the maximum or minimum value. The default is **NOCYCLE**.

- **CACHE**: stores as many serials as the number specified by *integer* in the cache to improve the performance of the serials and fetches a serial value when one is requested. The *integer* after the **CACHE** keyword cannot be omitted. If a number equal to or smaller than 1 is specified, the serial cache is not applied.
- **NOCACHE**: It does not use the serial cache feature. The serial value is updated every time and a new serial value is fetched from the disk upon each request. The default is **NOCACHE**.
- *comment\_string*: specifies a comment of a serial.

```
--altering serial by changing start and incremental values
ALTER SERIAL order_no START WITH 100 MINVALUE 100 INCREMENT BY 2;

--altering serial to operate in cache mode
ALTER SERIAL order_no CACHE 5;

--altering serial to operate in common mode
ALTER SERIAL order_no NOCACHE;
```

#### Warning

In CUBRID 2008 R1.x version, the serial value can be modified by updating the db\_serial table, a system catalog. However, in CUBRID 2008 R2.0 version or above, the modification of the db\_serial table is not allowed but use of the **ALTER SERIAL** statement is allowed. Therefore, if an **ALTER SERIAL** statement is included in the data exported (unloaddb) from CUBRID 2008 R2.0 or above, it is not allowed to import (loaddb) the data in CUBRID 2008 R1.x or below.

#### Warning

When you get the value of **NEXT\_VALUE** after running **ALTER SERIAL**, in the version lower than CUBRID 9.0, the next value of the initial value was returned. From CUBRID 9.0, the setting value of **ALTER\_SERIAL** is returned.

```
CREATE SERIAL s1;
SELECT s1.NEXTVAL;

ALTER SERIAL s1 START WITH 10;

SELECT s1.NEXTVAL;
```

```
-- From 9.0, above query returns 10
-- In the version less than 9.0, above query returns 11
```

The below changes the comment of the serial.

```
ALTER SERIAL order_no COMMENT 'new comment';
```

## DROP SERIAL

With the **DROP SERIAL** statement, you can drop a serial object from the database. If you also specify **IF EXISTS** clause, no error will be happened even if a target serial does not exist.

```
DROP SERIAL [ IF EXISTS ] [schema_name.]serial_name ;
```

- *schema\_name*: Specifies the schema name of the serial. If omitted, the schema name of the current session is used.
- *serial\_name*: Specifies the name of the serial to be dropped.

The following example shows how to drop the *order\_no* serial.

```
DROP SERIAL order_no;
DROP SERIAL IF EXISTS order_no;
```

## Accessing Serial

### Pseudocolumns

You can access and update a serial by serial name and a pseudocolumn pair.

```
[schema_name.]serial_name.CURRENT_VALUE
[schema_name.]serial_name.CURRVAL

[schema_name.]serial_name.NEXT_VALUE
[schema_name.]serial_name.NEXTVAL
```

- *schema\_name*: Specifies the schema name of the serial. If omitted, the schema name of the current session is used.

- `[schema_name.]serial_name.CURRENT_VALUE`, `[schema_name.]serial_name.CURRVAL`: Returns the current serial value.
- `[schema_name.]serial_name.NEXT_VALUE`, `[schema_name.]serial_name.NEXTVAL`: Increments the serial value and returns the result.

The following example shows how to create a table `athlete_idx` where athlete numbers and names are stored and how to create the instances by using a serial `order_no`.

```
CREATE TABLE athlete_idx (code INT, name VARCHAR (40));
CREATE SERIAL order_no START WITH 10000 INCREMENT BY 2 MAXVALUE
20000;
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Park');
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Kim');
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Choo');
INSERT INTO athlete_idx VALUES (order_no.NEXT_VALUE, 'Lee');
SELECT * FROM athlete_idx;
SELECT order_no.CURRENT_VALUE;
```

```
      code  name
=====
10000  'Park'
10002  'Kim'
10004  'Choo'
10006  'Lee'

      serial_current_value(order_no)
=====
10006
```

### Note

When you use a serial for the first time after creating it, **NEXT\_VALUE** returns the initial value. Subsequently, the sum of the current value and the increment are returned.

## Functions

`SERIAL_CURRENT_VALUE([schema_name.]serial_name)`

`SERIAL_NEXT_VALUE([schema_name.]serial_name, number)`

The **Serial** function consists of the **SERIAL\_CURRENT\_VALUE** and **SERIAL\_NEXT\_VALUE** functions.

**Parameters:**

- **schema\_name** – The schema name of the serial
- **serial\_name** – Serial name
- **number** – The number of serials to be obtained

**Return type:**

NUMERIC(38,0)

The **SERIAL\_CURRENT\_VALUE** function returns the current serial value, which is the same value as *serial\_name*.**current\_value**.

This function returns as much added value as interval specified. The serial interval is determined by the value of a **CREATE SERIAL ... INCREMENT BY** statement. **SERIAL\_NEXT\_VALUE** (*serial\_name*, 1) returns the same value as *serial\_name*.**next\_value**.

To get a large amount of serials at once, specify the desired number as an argument to call the **SERIAL\_NEXT\_VALUE** function only once; which has an advantage over calling repeatedly *serial\_name*.**next\_value** in terms of performance.

Assume that an application process is trying to get the number of n serials at once. To perform it, call **SERIAL\_NEXT\_VALUE** (*serial\_name*, N) one time to store a return value and calculate a serial value between (a serial start value) and (the return value). (Serial value at the point of function call) is equal to the value of (return value) - (desired number of serials) \* (serial interval).

For example, if you create a serial starting 101 and increasing by 1 and call **SERIAL\_NEXT\_VALUE** (*serial\_name*, 10), it returns 110. The start value at the point is  $110 - (10 - 1) * 1 = 101$ . Therefore, 10 serial values such as 101, 102, 103, ... 110 can be used by an application process. If **SERIAL\_NEXT\_VALUE** (*serial\_name*, 10) is called in succession, 120 is returned; the start value at this point is  $120 - (10 - 1) * 1 = 111$ .

```
CREATE SERIAL order_no START WITH 101 INCREMENT BY 1 MAXVALUE 20000;  
SELECT SERIAL_CURRENT_VALUE(order_no);
```

```
101
```

```
-- At first, the first serial value starts with the initial serial  
value, 10000. So the 10th serial value will be 10009.  
SELECT SERIAL_NEXT_VALUE(order_no, 10);
```

110

```
SELECT SERIAL_NEXT_VALUE(order_no, 10);
```

120

**Note**

If you create a serial and calls the **SERIAL\_NEXT\_VALUE** function for the first time, a value of (serial interval) \* (desired number of serials - 1) added to the current value is returned. If you call the **SERIAL\_NEXT\_VALUE** function in succession, a value of (serial interval) \* (desired number of serials) added to the current is returned (see the example above).

## SYNONYM DEFINITION STATEMENTS

### CREATE SYNONYM

Create another new name to use for an object that already exists in the database. The user can use the object with the name specified when creating the database object, and can also use the object as a synonym.

1. The user can only create private synonym, and private synonym can only be used in the schema for the user.
2. The information of the created synonym can be found in the **DB\_SYNONYM** system virtual class.
3. If a table or view already exists with the same name, a synonym cannot be created with that name.
4. When creating a synonym, it checks whether the schema of the target object exists, but it does not check whether the target object exists. If the target object does not exist, an error occurs when using a synonym.
5. The user can create a synonym only in the schema of the user, but **DBA** and members of **DBA** can create synonyms by specifying schema.

```
CREATE [OR REPLACE] [PRIVATE] SYNONYM
[schema_name_of_synonym.]synonym_name
FOR [schema_name_of_target.]target_name
[COMMENT 'synonym_comment_string'] ;
```

- **OR REPLACE:** The existing synonym is replaced by a new one without error, even if *synonym\_name* already exists in the schema.
  - The existing synonym are dropped before creating a new one.
- **PRIVATE:** Specifies to create a private synonym. Even if omitted, a private synonym is created by default.
- *schema\_name\_of\_synonym:* Specifies the schema name of the synonym. If omitted, the schema name of the current session is used.
- *synonym\_name:* Specifies the name of the synonym.
- *schema\_name\_of\_target:* Specifies the schema name of the target object. If omitted, the schema name of the current session is used.
- *target\_name:* Specifies the name of the target object.
- *synonym\_comment\_string:* Specifies a comment of a synonym.

#### Warning

The target object of a synonym supports only tables and views. It is possible to use another object as the target object, but an error occurs when using a synonym.

#### Warning

It does not support public synonym yet.

### 1. Private synonym

In the example below, user u1 and user u2 have created a synonym with the same name but use different target objects.

```
call login ('dba') on class db_user;

/* current_user: dba */
```

```

create user u1;
create user u2;

create table t1 (c1 varchar(100));
insert into t1 values ('private synonym for user u1. ');
grant select on t1 to u1;
grant select on t1 to u2;

create table t2 (c1 varchar(100));
insert into t2 values ('private synonym for user u2. ');
grant select on t2 to u1;
grant select on t2 to u2;

```

```

call login ('u1') on class db_user;

/* current_user: u1 */
create synonym s1 for dba.t1;
select * from s1;

```

```

c1
=====
'private synonym for user u1.'

```

```

call login ('u2') on class db_user;

/* current_user: u2 */
create synonym s1 for dba.t2;
select * from s1;

```

```

c1
=====
'private synonym for user u2.'

```

## 2. Synonym information

In the example below, the user can find the information of a synonym in the `DB_SYNONYM` system virtual class.

```

/* There should be the result of example 1. */

call login ('dba') on class db_user;

```

```
/* current_user: dba */
select * from db_synonym;
```

| synonym_name<br>target_name | synonym_owner_name<br>target_owner_name | is_public_synonym<br>comment |
|-----------------------------|-----------------------------------------|------------------------------|
| =====                       | =====                                   | =====                        |
| =====                       | =====                                   | =====                        |

|-----------------------------|-----------------------------------------|------------------------------|
| =====                       | =====                                   | =====                        |
| =====                       | =====                                   | =====                        |
| 's1'                        | 'U2'                                    | 'NO'                         |
| 't2'                        | 'DBA'                                   | NULL                         |

```
/* clean */
```

```
call login ('dba') on class db_user;
```

```
/* current_user: dba */
drop synonym if exists u1.s1;
drop synonym if exists u2.s1;
```

```
drop user u1;
drop user u2;

drop table if exists t1;
drop table if exists t2;
```

### 3. Synonym name

If a table or view already exists with the same name, a synonym cannot be created with that name.

```
call login ('public') on class db_user;

/* current_user: public */
create table t1 (c1 varchar(100));
insert into t1 values ('table for user public.');
```

```
create table s1 (c1 varchar(100));
create view s2 as select * from t1;
```

```
/* Already used as a table name. */
create synonym s1 for t1;
```

```
ERROR: before ' ; '
Class public.s1 already exists.
```

```
/* Already used as a view name. */
create synonym s2 for t1;
```

```
ERROR: before ' ; '
Class public.s2 already exists.
```

```
create synonym s3 for t1;
select * from s3;
```

```
c1
=====
'table for user public.'
```

```
/* clean */
```

```
call login ('public') on class db_user;
```

```
/* current_user: public */
drop synonym if exists s1;
drop synonym if exists s2;
drop synonym if exists s3;
drop view if exists s2;
drop table if exists t1;
drop table if exists s1;
```

#### 4. Synonym for synonym

When creating a synonym, it does not check whether the target object exists, so the user can create a new synonym by specifying an existing synonym as the target object. However, if a synonym is used, the target object of the synonym, which is the target object, is not found again.

```
call login ('public') on class db_user;
```

```
/* current_user: public */
create table t1 (c1 varchar(100));
insert into t1 values ('synonym for synonym.');
```

```
create synonym s1 for t1;
create synonym s2 for s1;
select * from db_synonym;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| 's1'         | 'PUBLIC'           | 'NO'              |
| 't1'         | 'PUBLIC'           | NULL              |
| 's2'         | 'PUBLIC'           | 'NO'              |
| 's1'         | 'PUBLIC'           | NULL              |

```
select * from s2;
```

```
ERROR: before ' ; '
Unknown class "public.s1".
```

```
select * from s1;
```

```
c1
=====
'synonym for synonym.'
```

```
/* clean */

call login ('public') on class db_user;

/* current_user: public */
drop synonym if exists s1;
drop synonym if exists s2;
drop table if exists t1;
```

## 5. Creating schema-specified synonyms

When **DBA** and members of **DBA** create a synonym by specifying a schema, the synonym is created in the specified schema.

```
call login ('dba') on class db_user;

/* current_user: dba */
create user u1;
create user u2;

create table t1 (c1 varchar(100));
insert into t1 values ('private synonym for user u1.');
```

```
grant select on t1 to u1;
grant select on t1 to u2;

create table t2 (c1 varchar(100));
insert into t2 values ('private synonym for user u2.');
```

```
grant select on t2 to u1;
grant select on t2 to u2;

create synonym u1.s1 for dba.t1;
create synonym u2.s1 for dba.t2;

select * from db_synonym;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| =====        | =====              | =====             |
| 's1'         | 'U1'               | 'NO'              |
| 't1'         | 'DBA'              | NULL              |

|      |       |      |
|------|-------|------|
| 's1' | 'U2'  | 'NO' |
| 't2' | 'DBA' | NULL |

```
call login ('u1') on class db_user;

/* current_user: u1 */
select * from s1;
```

```
c1
=====
'private synonym for user u1.'
```

```
call login ('u2') on class db_user;

/* current_user: u2 */
select * from s1;
```

```
c1
=====
'private synonym for user u2.'
```

The user can create a synonym only in the schema of the user.

```
call login ('u1') on class db_user;

/* current_user: u1 */
create synonym u2.s2 for dba.t1;
```

```
ERROR: before ' ; '
DBA, members of DBA group, and owner can perform CREATE SYNONYM.
```

```
/* clean */

call login ('dba') on class db_user;

/* current_user: dba */
drop synonym if exists u1.s1;
drop synonym if exists u2.s1;
drop user u1;
drop user u2;
```

```
drop table if exists t1;  
drop table if exists t2;
```

## ALTER SYNONYM

Change the target object or comment of a synonym. The synonym in use cannot be changed.

```
ALTER [PRIVATE] SYNONYM [schema_name_of_synonym.]synonym_name  
{  
    FOR [<schema_name_of_target>.<target_name>] [COMMENT  
'comment_string'] |  
    COMMENT 'synonym_comment_string'  
} ;
```

- **PRIVATE:** Specifies to alter a private synonym. Even if omitted, a private synonym is created by default.
- *schema\_name\_of\_synonym:* Specifies the schema name of the synonym. If omitted, the schema name of the current session is used.
- *synonym\_name:* Specifies the name of the synonym.
- *schema\_name\_of\_target:* Specifies the schema name of the target object. If omitted, the schema name of the current session is used.
- *target\_name:* Specifies the name of the target object.
- *synonym\_comment\_string:* Specifies a comment of a synonym.

### Warning

When the **ALTER**, **DROP**, **RENAME** statements for a synonym are executed, be careful because all query plans using the target object are deleted from the query plan cache.

However, when the **ALTER** statement is executed, the query plan is not deleted when changing to the same target object or only changing comments.

## Change target object

In the example below, the target object is changed.

```
call login ('public') on class db_user;  
  
/* current_user: public */
```

```

create table t1 (c1 varchar(100));
insert into t1 values ('target table before change.');
```

```

create table t2 (c1 varchar(100));
insert into t2 values ('target table after change.');
```

```

create synonym s1 for t1;
select * from db_synonym;
select * from s1;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| 's1'         | 'PUBLIC'           | 'NO'              |
| 't1'         | 'PUBLIC'           | NULL              |

| c1                            |
|-------------------------------|
| 'target table before change.' |

```

alter synonym s1 for t2;
select * from db_synonym;
select * from s1;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| 's1'         | 'PUBLIC'           | 'NO'              |
| 't2'         | 'PUBLIC'           | NULL              |

| c1                           |
|------------------------------|
| 'target table after change.' |

```

/* clean */

call login ('public') on class db_user;

/* current_user: public */
drop synonym if exists s1;
drop table if exists t1;
drop table if exists t2;
```

## Change comment

In the example below, the user changes the comment of a synonym.

```
call login ('public') on class db_user;

/* current_user: public */
create table t1 (c1 varchar(100));
insert into t1 values ('change comment.');
```

```
create synonym s1 for t1 comment 'It is a synonym for the t1 table.';
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
```

| synonym_name                        | synonym_owner_name | is_public_synonym |
|-------------------------------------|--------------------|-------------------|
| comment                             |                    |                   |
| =====                               |                    |                   |
| =====                               |                    |                   |
| 's1'                                | 'PUBLIC'           | 'NO'              |
| 'It is a synonym for the t1 table.' |                    |                   |

It is possible to change the comment without specifying the target object.

```
alter synonym s1 comment 'the comment was changed.';
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
```

| synonym_name               | synonym_owner_name | is_public_synonym |
|----------------------------|--------------------|-------------------|
| comment                    |                    |                   |
| =====                      |                    |                   |
| =====                      |                    |                   |
| 's1'                       | 'PUBLIC'           | 'NO'              |
| 'the comment was changed.' |                    |                   |

If both the target object and comment are not specified, an error occurs.

```
alter synonym s1;
```

```
ERROR: No options specified for ALTER SYNONYM.
```

To change a comment to **NULL**, change the comment to an empty string.

```
alter synonym s1 comment '';
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| comment      |                    |                   |
| =====        |                    |                   |
| =====        |                    |                   |
| 's1'         | 'PUBLIC'           | 'NO'              |
| NULL         |                    |                   |

```
/* clean */

call login ('public') on class db_user;

/* current_user: public */
drop synonym if exists s1;
drop table if exists t1;
```

## DROP SYNONYM

Drop the synonym. The synonym in use cannot be dropped. Even if a synonym is dropped, the target object is not dropped.

```
DROP [PRIVATE] SYNONYM [IF EXISTS] [schema_name.]synonym_name ;
```

- **PRIVATE:** Specifies to drop a private synonym. Even if omitted, a private synonym is created by default.
- **IF EXISTS:** No error occurs, Even if *synonym\_name* does not exist in the schema.
- *schema\_name:* Specifies the schema name of the synonym. If omitted, the schema name of the current session is used.
- *synonym\_name:* Specifies the name of the synonym.

### Warning

When the **ALTER**, **DROP**, **RENAME** statements for a synonym are executed, be careful because all query plans using the target object are deleted from the query plan cache.

```

call login ('public') on class db_user;

/* current_user: public */
create table t1 (c1 varchar(100));
insert into t1 values ('The target object of the to-be-deleted
synonym.');
```

```

create synonym s1 for t1;
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
select * from s1;
```

```

synonym_name      synonym_owner_name      is_public_synonym
comment
=====
=====
's1'              'PUBLIC'              'NO'
NULL

c1
=====
'The target object of the to-be-deleted synonym.'
```

```

drop synonym s1;
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
```

There are no results.  
0 row selected.

```
select * from s1;
```

```

ERROR: before ' ; '
Unknown class "public.s1".
```

```
select * from t1;
```

```

c1
=====
'The target object of the to-be-deleted synonym.'
```

```
/* clean */  
  
call login ('public') on class db_user;  
  
/* current_user: public */  
drop synonym if exists s1;  
drop table if exists t1;
```

## RENAME SYNONYM

Change the name of the synonym. The name of the synonym in use cannot be changed.

1. The user cannot change the schema of the synonym when renaming a synonym.
2. If a table, view, or synonym already exists with the name to be changed, the name cannot be changed.

```
RENAME [PRIVATE] SYNONYM  
[schema_name_of_old_synonym.]old_synonym_name  
{AS | TO} [schema_name_of_new_synonym.]new_synonym_name ;
```

- **PRIVATE**: Specifies to rename a private synonym. Even if omitted, a private synonym is created by default.
- *schema\_name\_of\_old\_synonym*: Specifies the schema name of the to-be-renamed synonym. If omitted, the schema name of the current session is used.
- *old\_synonym\_name*: Specifies the name of the to-be-renamed synonym.
- *schema\_name\_of\_new\_synonym*: Specifies the schema name of synonym for new name. If omitted, the schema name of the current session is used.
- *new\_synonym\_name*: Specifies the new name of the new-named synonym.

### Warning

When the **ALTER, DROP, RENAME** statements for a synonym are executed, be careful because all query plans using the target object are deleted from the query plan cache.

### 1. Cannot change schema

In the example below, an error occurs when a schema name is specified differently when renamed.

```
call login ('dba') on class db_user;
```

```
/* current_user: dba */
create user u1;
create user u2;
```

```
call login ('u1') on class db_user;
```

```
/* current_user: u1 */
create table t1 (c1 varchar(100));
insert into t1 values ('private synonym for user u1.');
```

```
create synonym s1 for t1;
select synonym_name, synonym_owner_name, is_public_synonym, comment
from db_synonym;
select * from s1;
```

| synonym_name                   | synonym_owner_name | is_public_synonym |
|--------------------------------|--------------------|-------------------|
| comment                        |                    |                   |
| =====                          |                    |                   |
| =====                          |                    |                   |
| 's1'                           | 'U1'               | 'NO'              |
| NULL                           |                    |                   |
| c1                             |                    |                   |
| =====                          |                    |                   |
| 'private synonym for user u1.' |                    |                   |

```
rename synonym s1 as u2.s2;
rename synonym u1.s1 as u2.s2;
```

```
ERROR: before ' ; '
Rename cannot change owner.
```

```
call login ('dba') on class db_user;
```

```
/* current_user: dba */
rename synonym u1.s1 as u2.s2;
```

```
ERROR: before ' ; '

drop user u2;
```

## 2. Name already in use

In the example below, an error occurs because the name to be changed is already in use.

```
call login ('public') on class db_user;

/* current_user: public */
create table t1 (c1 varchar(100));
insert into t1 values ('first table for user u1.');
```

```
create table t2 (c1 varchar(100));
insert into t2 values ('second table for user u1.');
```

```
create table s_t1 (c1 varchar(100));
create table s_v1 as select * from t1;
```

```
create synonym s_s1 for t2;

create synonym s1 for t1;
select * from db_synonym;
select * from s1;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| 's_s1'       | 'PUBLIC'           | 'NO'              |

c1

'first table for user u1.'

```

/* clean */

call login ('public') on class db_user;

/* current_user: public */
drop synonym if exists s1;
drop synonym if exists s2;
drop synonym if exists s_s1;
drop table if exists t1;
drop table if exists t2;
drop table if exists s_t1;
drop table if exists s_v1;

```

## USE SYNONYM

The synonym can be used only if table names and view names are available. When using synonyms, the user must have access authorization to the target object.

1. **GRANT** and **REVOKE** cannot be done for synonyms. If the schema name of a synonym is specified, a synonym existing in another schema can be used.
2. The synonym cannot be used in **ALTER**, **DROP**, **RENAME** statements and **TRUNCATE** statements that change the target object.

### 1. Use synonyms from other schemas

```

call login ('dba') on class db_user;

/* current_user: dba */
create user u1;
create user u2;

```

```
call login ('u1') on class db_user;

/* current_user: u1 */
create table t1 (c1 varchar(100));
insert into t1 values ('first table for user u1. ');
grant select on t1 to u2;

create synonym s1 for t1;
select * from s1;
```

```
c1
=====
'first table for user u1.'
```

```
call login ('u2') on class db_user;

/* current_user: u2 */
select * from s1;
select * from u1.s1;
```

```
ERROR: before ' ; '
Unknown class "u2.s1".
```

```
c1
=====
'first table for user u1.'
```

```
/* clean */

call login ('dba') on class db_user;

/* current_user: dba */
drop synonym if exists u1.s1;
drop table if exists u1.t1;
drop user u1;
drop user u2;
```

## 2. Statements where synonyms cannot be used

```
call login ('public') on class db_user;

/* current_user: public */
```

```
create table t1 (c1 varchar(100));
insert into t1 values ('first table for user public.');
```

```
create synonym s1 for t1;
select * from db_synonym;
select * from s1;
```

| synonym_name | synonym_owner_name | is_public_synonym |
|--------------|--------------------|-------------------|
| target_name  | target_owner_name  | comment           |
| 's1'         | 'PUBLIC'           | 'NO'              |
| 't1'         | 'PUBLIC'           | NULL              |

| c1                             |
|--------------------------------|
| 'first table for user public.' |

```
alter table s1 add column c2 int;
```

```
ERROR: before ' add column c2 int; '
Class public.s1 does not exist.
```

```
drop table s1;
```

```
ERROR: before ' ; '
Class public.s1 does not exist.
```

```
rename table s1 to s2;
```

```
ERROR: before ' ; '
Class public.s1 does not exist.
```

```
truncate s1;
```

```
ERROR: before ' ; '
Class public.s1 does not exist.
```

```
select * from s1;
```

```
c1
=====
'first table for user public.'
```

```
/* clean */

call login ('public') on class db_user;

/* current_user: public */
drop synonym if exists s1;
drop table if exists t1;
drop table if exists s2;
```

## SERVER DEFINITION STATEMENTS

### CREATE SERVER

#### Server Definition

Create remote access information using the **CREATE SERVER** statement. The created server is used to designate a remote server when executing a **SELECT** query using **DBLINK**. For how to use the prepared server, refer to [Remote Table](#).

```
CREATE SERVER <dblink_server_name> (<connect_info>) ;

<dblink_server_name> ::= [owner_name.] server_name

<connect_info> ::=
    <connect_info>, <connect_item>
    | <connect_item>
<connect_item> ::=
    HOST = host_string
    | PORT = port_number
    | DBNAME = db_name
    | USER = user_name
    | PASSWORD = [password_string]
```

```
| PROPERTIES = [properties_string]
| COMMENT = [server_comment_string]
```

- *owner\_name*: Specifies the name of the owner of the server to be created.
- *server\_name*: Specifies the name of the server to be created. (up to 254 bytes)
- *<connect\_info>*: **HOST**, **PORT**, **DBNAME**, and **USER** are mandatory items in the *<connect\_item>* list of access information.
- *<connect\_item>*: It consists of HOST, PORT, DBNAME, USER, PASSWOED, PROPERTIES, and COMMENT items, and the same item cannot be duplicated.
  - *host\_string*: It is the hose name or IP address of the broker server that has DBMS information to be accessed remotely.
  - *port\_number*: The port number of the broker server that has DBMS information to be accessed remotely.
  - *db\_name*: The database name to connect to remotely.
  - *user\_name*: The user name to use when connecting to the database to be accessed remotely.
  - *password\_string*: Password string for *user\_name* used to connect to the database to be accessed remotely.
  - *properties\_string*: A string of property information (up to 2047 bytes) used when connecting to a broker (or gateway) for remote database usage. For detailed attribute information, see [cci\\_connect\\_with\\_url](#)
  - *server\_comment\_string*: Specifies comments about server information. (up to 1023 bytes)

#### Note

*db\_name* and *user\_name* can be written in the form of identifier or string literal.

#### • Example of identifier format

t123db, "123db", 123db, [124db]

#### • Example of string format

't123db', '123db'

**Example 1** The following basic example has the required fields (HOST,PORT,DBNAME,USER) and also contains the PROPERTIES and COMMENT fields.

```
CREATE SERVER dblink_srv1 (  
    HOST='192.168.1.8',  
    PORT=3300,  
    DBNAME=demodb,  
    USER=dba,  
    PASSWORD='password1234',  
    PROPERTIES='?rcTime=600',  
    COMMENT='this is dblink_srv1'  
);
```

**Example 2** The following is an example that includes minimal information when creating a server. It indicates that the remote demodb will be connected to the dev1 account without a password. srv1, srv2, and srv3 have the same information.

```
CREATE SERVER srv1 (  
    HOST='192.168.1.8',  
    PORT=3300,  
    DBNAME=demodb,  
    USER=dev1  
);  
  
CREATE SERVER srv2 (  
    HOST='192.168.1.8',  
    PORT=3300,  
    DBNAME=demodb,  
    USER=dev1,  
    PASSWORD=  
);  
  
CREATE SERVER srv3 (  
    HOST='192.168.1.8',  
    PORT=3300,  
    DBNAME=demodb,  
    USER=dev1,  
    PASSWORD=''  
);
```

**Example 3** The following example specifies the owner when creating the server. In case of CREATE without designating the owner, the current user becomes the owner. Later, you can change the owner using the ALTER SERVER statement. In the example below, the two servers have the same name as srv2, but have different owners as *dba* and *cub*, respectively.

```
-- When the current account is dba  
CREATE SERVER srv2 (  
    HOST='192.168.1.8',  
    PORT=3300,  
    DBNAME=demodb,
```

```

        USER=dev1,
        PASSWORD='dev1-password',
        COMMENT='The owner of this server is dba'
    );

CREATE SERVER cub.srv2 (
    HOST='192.168.1.8',
    PORT=3300,
    DBNAME=demodb,
    USER=dev2,
    PASSWORD='dev2-password',
    COMMENT='The owner of this server is cub.'
);

```

**Example 4** The following is an example of setting up for failover of a remote database by using the `altHosts` attribute in `PROPERTIES` when using a remote database configured in an HA environment. For more information, see [cci\\_connect\\_with\\_url](#)

```

CREATE SERVER dblink_srv1 (
    HOST='192.168.1.8',
    PORT=3300,
    DBNAME=demodb,
    USER=dba,
    PASSWORD='password1234',
    PROPERTIES='?altHosts=192.168.1.9:33000',
    COMMENT='this is dblink_srv1'
);

```

**Example 5** The following is an example of a poor use of the server name (<dblink\_server\_name>).

```

CREATE SERVER srv1 ( HOST='localhost', PORT=3300, DBNAME=demodb,
USER=dev1 );
CREATE SERVER "srv 1" ( HOST='localhost', PORT=3300, DBNAME=demodb,
USER=dev1 );
CREATE SERVER "srv.1" ( HOST='localhost', PORT=3300, DBNAME=demodb,
USER=dev1 );
CREATE SERVER cub.srv1 ( HOST='localhost', PORT=3300, DBNAME=demodb,
USER=dev1 );

CREATE SERVER "cub"."srv 2" ( HOST='localhost', PORT=3300,
DBNAME=demodb, USER=dev1 );
CREATE SERVER [cub].[srv.2] ( HOST='localhost', PORT=3300,
DBNAME=demodb, USER=dev1 );

```

In the above example, creation with “`srv.1`” and `[cub].[srv.2]` names fails. In the case of `cub.srv1`, `cub` will be recognized as the user name and the server name will be recognized as `srv1`.

**Note**

A dot (.) cannot be used for the server name. You cannot use a dot (.) in the server name, even if it is enclosed in quotation marks or [].

## RENAME SERVER

You can change the server name using the **RENAME SERVER** syntax.

```
RENAME SERVER [owner_name.] old_server_name {AS | TO}  
new_server_name ;
```

- *owner\_name*: Specify the owner name of the target server to be renamed.
- *old\_server\_name*: Specify the name of the server to be renamed.
- *new\_server\_name*: Specifies the name of the server to be newly assigned. (up to 254 bytes)

**Note**

Only the owner of the server or members of the ownership group can change the information. In particular, **DBA** or members of **DBA** can change all server information.

Even after the change, the owners remain the same. To change the owner, refer to **ALTER SERVER syntax**.

```
-- When the current account is dba  
RENAME SERVER srv1 AS srv2;  
RENAME SERVER dev1.srv1 AS srv3;
```

Even if the above example is performed under the *dba* account, the owner of *srv2* is not changed and is maintained as *cub*, the owner of the *srv1* server. Also, the owner of the *srv3* server remains *dev1*.

## DROP SERVER

Existing servers can be removed using **DROP SERVER** syntax. If the **IF EXISTS** clause is used together, no error occurs even if the server does not exist.

```
DROP SERVER [IF EXISTS] [owner_name.] server_name ;
```

- *owner\_name*: Specify the owner name of the server to be removed..
- *server\_name*: Specify the name of the server to be removed.

```
DROP SERVER srv1;  
DROP SERVER cub.srv1;  
DROP SERVER IF EXISTS srv2;
```

### Warning

When deleting a user with the DROP USER statement, if there is a server owned by the user, an error is processed and the user is not deleted. First, remove the server owned by the user with the DROP SERVER statement, and then delete the user account.

```
-- When the current account is dba  
csql> create user cub;  
Execute OK. (0.000371 sec) Committed.  
  
1 command(s) successfully processed.  
csql> create server cub.tsrv (HOST='localhost', PORT=3300,  
DBNAME=demdb, USER=dev1);  
Execute OK. (0.000761 sec) Committed.
```

```
1 command(s) successfully processed.  
csql> drop user cub;
```

In the command **from** line 1,

ERROR: Cannot drop the user who owns database objects(class/trigger/  
serial/server etc).

```
0 command(s) successfully processed.  
csql> drop server cub.tsrv;  
Execute OK. (0.000761 sec) Committed.
```

```
1 command(s) successfully processed.  
csql> drop user cub;  
Execute OK. (0.001650 sec) Committed.
```

```
1 command(s) successfully processed.  
csql>
```

In the example above, you can see that the drop user *cub* statement is failing while the *tsrv* server owned by the *cub* account is created. After removing the *cub.tsrv* server, you can see that the *cub* account could be deleted normally..

## ALTER SERVER

You can change the server information by using the **ALTER** statement. You can change the owner of the target server, or update information about HOST, PORT, DBNAME, USER, PASSWOED, PROPERTIES, and COMMENT.

```
ALTER SERVER <dblink_server_name> <alter_server_list> ;

<dblink_server_name> ::= [owner_name.] server_name

<alter_server_list> ::=
    <alter_server_list>, <alter_server_item>
    | <alter_server_item>
<alter_server_item> ::=
    OWNER TO owner_name
    | CHANGE <connect_item>
<connect_item> ::=
    HOST = host_string
    | PORT = port_number
    | DBNAME = db_name
    | USER = user_name
    | PASSWORD = [password_string]
    | PROPERTIES = [properties_string]
    | COMMENT = [server_comment_string]
```

### Note

Only the owner of the server or members of the ownership group can change the information. In particular, **DBA** or **DBA** members can change all server information.

### Warning

It is not possible to update to remove values for HOST, PORT, DBNAME, and USER.

## OWNER TO clause

You can change the owner of the server using the **OWNER TO** clause.

```
ALTER SERVER [owner_name.] server_name OWNER TO new_owner_name ;
```

- *owner\_name*: Specifies the owner name of the target server whose owner is to be changed.
- *server\_name*: Specifies the name of the target server whose owner is to be changed.
- *new\_owner\_name*: Specifies the new owner name.

### Warning

- There is no OWNER TO clause in an ALTER SERVER clause, or it must be specified only once.

```
CREATE SERVER srv1 (HOST='broker-server-name', PORT=3300,  
DBNAME=demodb, USER=dev1);  
ALTER SERVER srv1 OWNER TO usr1;  
ALTER SERVER usr1.srv1 OWNER TO usr2;
```

## CHANGE clause

The **CHANGE** section is used to change the values of HOST, PORT, DBNAME, USER, PASSWOED, PROPERTIES, and COMMENT items.

### Warning

- Multiple CHANGE clauses in one ALTER SERVER statement can be listed by separating them with commas (.). However, at this time, only one CHANGE clause for the same item should be specified.
- Items that were not mentioned when performing the ALTER SERVER syntax do not initialize or delete the value, but retain the existing value.

```
ALTER SERVER [owner_name.] server_name CHANGE <connect_item> [,  
CHANGE <connect_item>] ... ;  
  
    <connect_item> ::=  
        HOST = host_string
```

```

| PORT = port_number
| DBNAME = db_name
| USER = user_name
| PASSWORD = [password_string]
| PROPERTIES = [properties_string]
| COMMENT = [server_comment_string]

```

- *owner\_name*: Specifies the user name of the server to be created.
- *server\_name*: Specifies the name of the server to be created. (up to 254 bytes)
- *host\_string*: It is the host name or IP address of the broker server that has DBMS information to be accessed remotely.
- *port\_number*: The port number of the broker server that has DBMS information to be accessed remotely.
- *db\_name*: The database name to connect to remotely.
- *user\_name*: The user name to use when connecting to the database to be accessed remotely.
- *password\_string*: Password string for *user\_name* used to connect to the database to be accessed remotely.
- *properties\_string*: Property information string used when connecting to the database to be accessed remotely. (up to 2047 bytes)
- *server\_comment\_string*: Specifies comments about server information. (up to 1023 bytes)

```

CREATE SERVER srv1 ( HOST='localhost', PORT=3300, DBNAME=demodb,
USER=dev1 );

ALTER SERVER srv1 CHANGE HOST='127.0.0.1';
ALTER SERVER srv1 CHANGE HOST='127.0.0.1', OWNER TO usr1;
ALTER SERVER srv1 CHANGE USER=dev2, CHANGE PASSWORD='dev2-pawword',
CHANGE PORT=3500;

```

The above example shows that the **CHANGE** clause can be used to list multiple items at once, or it can be used together with the **OWNER TO** clause.

```

ALTER SERVER srv1 CHANGE PORT=;
ALTER SERVER srv1 CHANGE DBNAME=;
ALTER SERVER srv1 CHANGE USER=;
ALTER SERVER srv1 CHANGE HOST=;
ALTER SERVER srv1 CHANGE HOST='';

```

All of the above examples are examples of not supported cases. Since HOST, PORT, DBNAME, and USER, which are essential elements in the configuration of server information, must have values, setting changes that delete values are not supported. In particular, in the case of HOST, setting it to an empty string is also not allowed.

```
ALTER SERVER srv1 CHANGE PASSWORD=;
ALTER SERVER srv1 CHANGE PASSWORD='';

ALTER SERVER srv1 CHANGE PROPERTIES=;
ALTER SERVER srv1 CHANGE PROPERTIES='';

ALTER SERVER srv1 CHANGE COMMENT=;
ALTER SERVER srv1 CHANGE COMMENT='';
```

The above examples are all supported examples. PASSWORD, PROPERTIES, COMMENT, which are not essential elements in the configuration of server information, do not necessarily have a value, so it is possible to change the setting to delete the value.

## STORED FUNCTION/PROCEDURE DEFINITION STATEMENTS

### CREATE PROCEDURE

Create stored procedure using the **CREATE PROCEDURE** statement.

```
CREATE [OR REPLACE] PROCEDURE [schema_name.]procedure_name
([<parameter_definition> [, <parameter_definition>] ...])
[<procedure_properties>]
{IS | AS} LANGUAGE <lang>
    <body>
COMMENT 'procedure_comment';

<parameter_definition> ::= parameter_name [mode] sql_type [ {
DEFAULT | = } <default_expr> ] [COMMENT 'parameter_comment_string']
<lang> ::= [PLCSQL | JAVA]
<mode> ::= IN | OUT | IN OUT | INOUT
<procedure_properties> ::= <authid>
    <authid> ::= AUTHID {DEFINER | OWNER | CALLER | CURRENT_USER}
```

You can use the **OR REPLACE** clause to replace or create a new stored function/procedure.

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.

- *procedure\_name*: Specifies the name of the stored procedure to be created (maximum 222 bytes).
- *parameter\_name*: Specifies the name of the parameter (maximum 254 bytes).
- *sql\_type*: Specifies the data type of the parameter. For available data types, refer to [Supported Data Types of Arguments and Return](#).
- *default\_arg*: Specifies the default value of the parameter. Refer to [Using Default Arguments](#).
- *authid*: Specifies the execution authority of the stored procedure. For more details, refer to [The Difference Between Owner's Rights and Caller's Rights](#).
- *parameter\_comment\_string*: Specifies the comment string for the parameter.
- *body*: Specifies the body of the stored procedure.
- *procedure\_comment*: Specifies the comment string for the stored procedure.

## COMMENT of Stored Procedure

A comment of stored function/procedure can be written at the end of the statement as follows.

```
CREATE FUNCTION Hello() RETURN VARCHAR
AS LANGUAGE JAVA
NAME 'SpCubrid.HelloCubrid() return java.lang.String'
COMMENT 'function comment';
```

A comment of a parameter can be written as follows.

```
CREATE OR REPLACE FUNCTION test(i in int COMMENT 'arg i')
RETURN int AS LANGUAGE JAVA NAME 'SpTest.testInt(int) return int'
COMMENT 'function test';
```

A comment of a stored function/procedure can be shown by running the following syntax.

```
SELECT sp_name, comment FROM db_stored_procedure;
```

A comment for a parameter of a function can be shown by running the following syntax.

```
SELECT sp_name, arg_name, comment FROM db_stored_procedure_args;
```

## Checking the Published Java Stored Procedure Information

You can check the information on the published Java stored procedure. The **db\_stored\_procedure** system virtual table provides the information on stored names and types, return types, number of parameters, Java class specifications, and the owner. The **db\_stored\_procedure\_args** system virtual table provides the information on parameters used in the stored function/procedure.

```
SELECT * FROM db_stored_procedure WHERE sp_type = 'PROCEDURE';
```

```
sp_name          sp_type          return_type
arg_count  lang target          owner
=====
=====
'athlete_add'    'PROCEDURE'
'void'          4
'JAVA' 'Athlete.Athlete(java.lang.String, java.lang.String,
java.lang.String, java.lang.String)' 'DBA'
```

```
SELECT * FROM db_stored_procedure_args WHERE sp_name = 'athlete_add';
```

```
sp_name  index_of  arg_name  data_type  mode
=====
'athlete_add'          0  'name'
'String'              'IN'
'athlete_add'          1  'gender'
'String'              'IN'
'athlete_add'          2  'nation_code'
'String'              'IN'
'athlete_add'          3  'event'
'String'              'IN'
```

## CREATE FUNCTION

Create stored function using the **CREATE FUNCTION** statement.

```
CREATE [OR REPLACE] FUNCTION [schema_name.]function_name
([<parameter_definition> [, <parameter_definition>] ...])
RETURN sql_type
[<function_properties>]
{IS | AS} LANGUAGE <lang>
    <body>

```

- *schema\_name*: Specifies the schema name (up to 31 bytes). If omitted, the schema name of the current session is used.
- *function\_name*: Specifies the name of the stored function to be created (up to 222 bytes).
- *parameter\_name*: Specifies the name of the parameter (up to 254 bytes).
- *sql\_type*: Specifies the data type of the parameter or return value. For available data types, refer to [Supported Data Types of Arguments and Return](#).
- *default\_arg*: Specifies the default value of the parameter. Refer to [Using Default Arguments](#).
- *param\_comment\_string*: Specifies the comment string for the parameter.
- *authid*: Specifies the execution authority of the stored function. For more details, refer to [The Difference Between Owner's Rights and Caller's Rights](#).
- *deterministic*: Specifies whether the stored function is deterministic. For more details, refer to [Use Deterministic Functions](#).
- *body*: Specifies the body of the stored function.
- *function\_comment*: Specifies the comment string for the stored function.

## COMMENT of Stored Function

A comment of stored function/procedure can be written at the end of the statement as follows.

```
CREATE FUNCTION Hello() RETURN VARCHAR
AS LANGUAGE JAVA
NAME 'SpCubrid.HelloCubrid() return java.lang.String'
COMMENT 'function comment';
```

A comment of a parameter can be written as follows.

```
CREATE OR REPLACE FUNCTION test(i in int COMMENT 'arg i')
RETURN int AS LANGUAGE JAVA NAME 'SpTest.testInt(int) return int'
COMMENT 'function test';
```

A comment of a stored function/procedure can be shown by running the following syntax.

```
SELECT sp_name, comment FROM db_stored_procedure;
```

A comment for a parameter of a function can be shown by running the following syntax.

```
SELECT sp_name, arg_name, comment FROM db_stored_procedure_args;
```

### Checking the Published Java Stored Function Information

You can check the information on the published Java stored function. The **db\_stored\_procedure** system virtual table provides the information on stored names and types, return types, number of parameters, Java class specifications, and the owner. The **db\_stored\_procedure\_args** system virtual table provides the information on parameters used in the stored function/procedure.

```
SELECT * FROM db_stored_procedure WHERE sp_type = 'FUNCTION';
```

| sp_name                 | sp_type  | return_type                     |
|-------------------------|----------|---------------------------------|
| hello                   | FUNCTION |                                 |
| STRING                  | 0        | JAVA'SpCubrid.HelloCubrid()     |
| return java.lang.String | DBA      |                                 |
| sp_int                  | FUNCTION |                                 |
| INTEGER                 | 1        | JAVA'SpCubrid.SpInt(int) return |
| int                     | DBA      |                                 |

```
SELECT * FROM db_stored_procedure_args WHERE sp_name = 'sp_int';
```

| sp_name | index_of | arg_name | data_type | mode |
|---------|----------|----------|-----------|------|
| sp_int  | 0        | i        |           |      |
| INTEGER | IN       |          |           |      |

### DROP PROCEDURE

In CUBRID, A stored procedure can be deleted using the **DROP PROCEDURE** statement. Also, you can delete multiple stored procedures at the same time with several *procedure\_names* separated by a comma (,).

```
DROP PROCEDURE procedure_name [{ , procedure_name , ... }];
```

- *procedure\_name*: Specifies the name of procedure to delete

```
DROP PROCEDURE hello, sp_int;
```

A stored procedure can be deleted only by the user who published it or by DBA members. For example, if a **PUBLIC** user published the 'sp\_int' stored procedure, only the **PUBLIC** or **DBA** members can delete it.

## DROP FUNCTION

In CUBRID, A stored function can be deleted using the **DROP FUNCTION** statement. You can also delete multiple stored functions at the same time by specifying several *function\_names* separated by commas (,).

```
DROP FUNCTION function_name [{ , function_name , ... }];
```

- *function\_name*: Specifies the name of function to delete

```
DROP FUNCTION hello, sp_int;
```

A stored function can be deleted only by the user who published it or by DBA members. For example, if a **PUBLIC** user published the 'sp\_int' stored function, only the **PUBLIC** or **DBA** members can delete it.

# Operators and Functions

## Logical Operators

For logical operators, boolean expressions are specified as operands; **TRUE**, **FALSE** or **NULL** is returned as a result. If a boolean value is used in an arithmetic expression, **TRUE** is evaluated to 1 and **FALSE** is evaluated to 0.

### Note

As of version 11.2, using a non-logical value (such as an integer or column) as an operand raises the error "operand must be logical expression." Such a condition must be rewritten with

an explicit comparison: a constant condition like **WHERE 1** as **WHERE 1=1**, and a column condition like **WHERE column\_name** as **WHERE column\_name <> 0**.

The following table shows the logical operators.

### Logical Operators

| Logical Operator       | Description                                                                                                                                                                                                                                   | Condition      |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| <b>AND, &amp;&amp;</b> | If all operands are <b>TRUE</b> , it returns <b>TRUE</b> .                                                                                                                                                                                    | a <b>AND</b> b |
| <b>OR,   </b>          | If none of operands is <b>NULL</b> and one or more operands are <b>TRUE</b> , it returns <b>TRUE</b> . If <b>pipes_as_concat</b> is no that is a parameter related to SQL statements, a double pipe symbol can be used as <b>OR</b> operator. | a <b>OR</b> b  |
| <b>XOR</b>             | If none of operand is <b>NULL</b> and each of operand has a different value, it returns <b>TRUE</b> .                                                                                                                                         | a <b>XOR</b> b |
| <b>NOT, !</b>          | A unary operator. If a operand is <b>FALSE</b> , it returns <b>TRUE</b> . If it is <b>TRUE</b> , returns <b>FALSE</b> .                                                                                                                       | <b>NOT</b> a   |

### Truth Table of Logical Operators

| a           | b           | a AND b     | a OR b      | NOT a        | a XOR b      |
|-------------|-------------|-------------|-------------|--------------|--------------|
| <b>TRUE</b> | <b>TRUE</b> | <b>TRUE</b> | <b>TRUE</b> | <b>FALSE</b> | <b>FALSE</b> |

| a     | b     | a AND b | a OR b | NOT a | a XOR b |
|-------|-------|---------|--------|-------|---------|
| TRUE  | FALSE | FALSE   | TRUE   | FALSE | TRUE    |
| TRUE  | NULL  | NULL    | TRUE   | FALSE | NULL    |
| FALSE | TRUE  | FALSE   | TRUE   | TRUE  | TRUE    |
| FALSE | FALSE | FALSE   | FALSE  | TRUE  | FALSE   |
| FALSE | NULL  | FALSE   | NULL   | TRUE  | NULL    |

## Comparison Operators

Contents

## Comparison Operators

334

The comparison operators compare the operand on the left and on the right, and they return 1 or 0. The operands of comparison operations must have the same data type. Therefore, implicit type casting by the system or implicit type casting by the user is required.

### Syntax 1

```

<expression> <comparison_operator> <expression>

<expression> ::=
    bit_string |
    character_string |
    numeric_value |
    date-time_value |
    collection_value |
    NULL

<comparison_operator> ::=
    = |
    <=> |
    <> |
    != |

```

```

> |
< |
>= |
<=

```

## Syntax 2

```

<expression> IS [NOT] NULL
<logical_expression> IS [NOT] <truth_value>

<expression> ::=
    bit_string |
    character_string |
    numeric_value |
    date-time_value |
    collection_value |
    NULL

<truth_value> ::=
    TRUE |
    FALSE |
    UNKNOWN

<logical_expression> ::=
    <expression> <comparison_operator> <expression> |
    <logical_expression> { AND | OR | XOR } <logical_expression>
|
    NOT <logical_expression>

<comparison_operator> ::=
    = |
    <=> |
    <> |
    != |
    > |
    < |
    >= |
    <=

```

- *<expression>*: Declares an expression to be compared.
  - *bit\_string*: A Boolean operation can be performed on bit strings, and all comparison operators can be used for comparison between bit strings. If you compare two expressions with different lengths, 0s are padded at the end of the shorter one.
  - *character\_string*: When compared by a comparison operator, two character strings must have the same character sets. The comparison is determined by the collation sequence of the character code set. If you compare two character strings with different lengths, blanks

are padded at the end of the shorter one before comparison so that they have the same length.

- *numeric\_value*: The Boolean operator can be performed for all numeric values and any types of comparison operator can be used. When two different numeric types are compared, the system implicitly performs type casting. For example, when an **INTEGER** value is compared with a **DECIMAL** value, the system first casts **INTEGER** to **DECIMAL** before it performs comparison. When you compare a **FLOAT** value, you must specify the range instead of an exact value because the processing of **FLOAT** is dependent on the system.
- *date-time\_value*: If two date-time values with the same type are compared, the order is determined in time order. That is, when comparing two date-time values, the earlier date is considered to be smaller than the later date. You cannot compare date-time values with different type by using a comparison operator; therefore, you must explicitly convert it. However, comparison operation can be performed between DATE, TIMESTAMP, and DATETIME because they are implicitly converted.
- *collection\_value*: When comparing two LISTS (SEQUENCE), comparison is performed between the two elements by user-specified order when LIST was created. Comparison including SET and MULTiset is overloaded to an appropriate operator. You can perform comparison operations on SET, MULTiset, LIST, or SEQUENCE by using a containment operator explained later in this chapter. For details, see [Containment Operators](#).
- **NULL**: The **NULL** value is not included in the value range of any data type. Therefore, comparison between **NULL** values is only allowed to determine if the given value is **NULL** or not. An implicit type cast does not take place when a **NULL** value is assigned to a different data type. For example, when an attribute of **INTEGER** type has a **NULL** and is compared with a floating point type, the **NULL** value is not coerced to **FLOAT** before comparison is made. A comparison operation on the **NULL** value does not return a result.
- *<logical\_expression>*: An expression that evaluates to a boolean (logical) value, such as the result of a comparison (e.g.,  $a = 1$ ) or a logical operation (e.g.,  $(a = 1) \text{ AND } (b = 2)$ ).

The following table shows the comparison operators supported by CUBRID and their return values.

### Comparison Operators

| Comparison Operator | Description                                                                | Predicate      | Return Value |
|---------------------|----------------------------------------------------------------------------|----------------|--------------|
| =                   | A general equal sign. It compares whether the values of the left and right | $1=2$ $1=NULL$ | 0 NULL       |

| Comparison Operator       | Description                                                                                                                                                                     | Predicate                                             | Return Value |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|--------------|
|                           | operands are the same. Returns <b>NULL</b> if one or more operands are <b>NULL</b> .                                                                                            |                                                       |              |
| <code>&lt;=&gt;</code>    | A <b>NULL</b> -safe equal sign. It compares whether the values of the left and right operands are the same including <b>NULL</b> . Returns 1 if both operands are <b>NULL</b> . | <code>1&lt;=&gt;2</code> <code>1&lt;=&gt; NULL</code> | 0 0          |
| <code>&lt;&gt;, !=</code> | The value of left operand is not equal to that of right operand. If any operand value is <b>NULL</b> , <b>NULL</b> is returned.                                                 | <code>1&lt;&gt;2</code>                               | 1            |
| <code>&gt;</code>         | The value of left operand is greater than that of right operand. If any operand value is <b>NULL</b> , <b>NULL</b> is returned.                                                 | <code>1&gt;2</code>                                   | 0            |
| <code>&lt;</code>         | The value of left operand is less than that of right operand. If any operand value is                                                                                           | <code>1&lt;2</code>                                   | 1            |

| Comparison Operator   | Description                                                                                                                                                 | Predicate                   | Return Value |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|--------------|
|                       | <b>NULL, NULL</b> is returned.                                                                                                                              |                             |              |
| <b>&gt;=</b>          | The value of left operand is greater than or equal to that of right operand. If any operand value is <b>NULL, NULL</b> is returned.                         | <code>1&gt;=2</code>        | 0            |
| <b>&lt;=</b>          | The value of left operand is less than or equal to that of right operand. If any operand value is <b>NULL, NULL</b> is returned.                            | <code>1&lt;=2</code>        | 1            |
| <b>IS truth_value</b> | Compares whether the value of the left operand is the same as the truth value of the right. The truth value may be <b>TRUE, FALSE</b> , or <b>UNKNOWN</b> . | <code>(1=1) IS FALSE</code> | 0            |

| Comparison Operator              | Description                                                                                                                                                       | Predicate          | Return Value |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|--------------|
| <b>IS NOT</b> <i>truth_value</i> | Compares whether the value of the left operand differs from the truth value of the right. The truth value may be <b>TRUE</b> , <b>FALSE</b> , or <b>UNKNOWN</b> . | (1=1) IS NOT FALSE | 1            |

### Note

As of version 11.2, the left operand of **IS [NOT] { TRUE | FALSE | UNKNOWN }** must be a logical expression; otherwise the error “operand must be logical expression.” is raised. For example, **1 IS FALSE** must be written as **(1=1) IS FALSE**. For a logical expression, the UNKNOWN truth value is represented as NULL, so **IS [NOT] UNKNOWN** and **IS [NOT] NULL** return the same result.

The following are the examples which use comparison operators.

```

SELECT (1 <> 0); -- 1 is displayed because it is TRUE.
SELECT (1 != 0); -- 1 is displayed because it is TRUE.
SELECT (0.01 = '0.01'); -- An error occurs because a numeric data
type is compared with a character string type.
SELECT (1 = NULL); -- NULL is displayed.
SELECT (1 <=> NULL); -- 0 is displayed because it is FALSE.
SELECT (1.000 = 1); -- 1 is displayed because it is TRUE.
SELECT ('cubrid' = 'CUBRID'); -- 0 is displayed because it is case
sensitive.
SELECT ('cubrid' = 'cubrid'); -- 1 is displayed because it is TRUE.
SELECT (SYSTIMESTAMP = CAST(SYSDATETIME AS TIMESTAMP)); -- 1 is
displayed after casting the type explicitly and then performing
comparison operator.
SELECT (SYSTIMESTAMP = SYSDATETIME); --0 is displayed after casting
the type implicitly and then performing comparison operator.
SELECT (SYSTIMESTAMP <> NULL); -- NULL is returned without
performing comparison operator.
SELECT (SYSTIMESTAMP IS NOT NULL); -- 1 is returned because it is
not NULL.
SELECT ((1 > 0) IS TRUE); -- 1 is displayed because (1 > 0) is TRUE.
SELECT ((1 > 0) IS FALSE); -- 0 is displayed because (1 > 0) is not

```

```
FALSE.
SELECT ((1 > 0) IS UNKNOWN); -- 0 is displayed because (1 > 0) is
not UNKNOWN.
SELECT ((NULL = 1) IS UNKNOWN); -- 1 is displayed because (NULL = 1)
is UNKNOWN.
SELECT ((1 > 0) IS NOT FALSE); -- 1 is displayed because (1 > 0) is
not FALSE.
```

## Arithmetic Operators

### Contents

|                                                                  |            |
|------------------------------------------------------------------|------------|
| <b>Arithmetic Operators</b>                                      | <b>340</b> |
| • Arithmetic Operations and Type Casting of Numeric Data Types   | 342        |
| • Arithmetic Operations and Type Casting of DATE/TIME Data Types | 346        |
| • Behavior related to timezone parameters                        | 349        |

For arithmetic operators, there are binary operators for addition, subtraction, multiplication, or division, and unary operators to represent whether the number is positive or negative. The unary operators to represent the numbers' positive/negative status have higher priority over the binary operators.

```
<expression> <mathematical_operator> <expression>

<expression> ::=
    bit_string |
    character_string |
    numeric_value |
    date-time_value |
    collection_value |
    NULL

<mathematical_operator> ::=
    <set_arithmetic_operator> |
    <arithmetic_operator>

    <arithmetic_operator> ::=
        + |
        - |
        * |
        { / | DIV } |
```

```

{ % | MOD }

<set_arithmetic_operator> ::=
    UNION |
    DIFFERENCE |
    { INTERSECT | INTERSECTION }

```

- *<expression>*: Declares the mathematical operation to be calculated.
- *<mathematical\_operator>*: A operator that performs an operation the arithmetic and the set operators are applicable.
  - *<set\_arithmetic\_operator>*: A set arithmetic operator that performs operations such as union, difference and intersection on collection type operands.
  - *<arithmetic\_operator>*: An operator to perform the four fundamental arithmetic operations.

The following table shows the arithmetic operators supported by CUBRID and their return values.

### Arithmetic Operators

| Arithmetic Operator   Description |                                                          | Operator      | Return Value |
|-----------------------------------|----------------------------------------------------------|---------------|--------------|
| +                                 | Addition                                                 | 1+2           | 3            |
| -                                 | Subtraction                                              | 1-2           | -1           |
| *                                 | Multiplication                                           | 1*2           | 2            |
| /                                 | Division.<br>Returns<br>quotient.                        | 1/2.0         | 0.500000000  |

| Arithmetic Operator   Description | Operator | Return Value                                                                                                          |
|-----------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------|
|                                   |          | be an integer type, and it always returns integer. If an operand is real number, the <b>MOD</b> function can be used. |

Arithmetic Operations and Type Casting of Numeric Data Types

All numeric data types can be used for arithmetic operations. The result type of the operation differs depending on the data types of the operands and the type of the operation. The following table shows the result data types of addition/subtraction/multiplication for each operand type.

Result Data Type by Operand Type

|         | INT           | NUMERIC                              | FLOAT  | DOUBLE |
|---------|---------------|--------------------------------------|--------|--------|
| INT     | INT or BIGINT | NUMERIC                              | FLOAT  | DOUBLE |
| NUMERIC | NUMERIC       | NUMERIC (p and s are also converted) | DOUBLE | DOUBLE |
| FLOAT   | FLOAT         | DOUBLE                               | FLOAT  | DOUBLE |
| DOUBLE  | DOUBLE        | DOUBLE                               | DOUBLE | DOUBLE |

Note that the result type of the operation does not change if all operands are of the same data type but type casting occurs exceptionally in division operations. An error occurs when a denominator, i.e. a divisor, is 0.

The following table shows the total number of digits (*p*) and the number of digits after the decimal point (*s*) of the operation results when all operands are of the **NUMERIC** type.

## Result of NUMERIC Type Operation

| Operation               | Maximum Precision                                                           | Maximum Scale                                                                   |
|-------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| $N(p1, s1) + N(p2, s2)$ | $\max(p1 - s1, p2 - s2) + \max(s1, s2) + 1$                                 |                                                                                 |
| $N(p1, s1) - N(p2, s2)$ | $\max(p1 - s1, p2 - s2) + \max(s1, s2)$                                     |                                                                                 |
| $N(p1, s1) * N(p2, s2)$ | $p1 + p2 + 1$                                                               | $s1 + s2$                                                                       |
| $N(p1, s1) / N(p2, s2)$ | $Pt = (p1 - s1) + s2 + \max(9, \max(s1, s2))$<br>$Pt = (Pt > 38) ? 38 : Pt$ | $St = \max(9, \max(s1, s2))$<br>$St = (Pt > 38) ? \min(9, St - (Pt - 38)) : St$ |

When the arithmetic operator is '/', the result type differs depending on the setting of the system parameter **oracle\_compat\_number\_behavior**. That is, in case of integer/integer, if **oracle\_compat\_number\_behavior** is set to yes, the result type is NUMERIC. Otherwise, it follows the **result data type for each operand type** rule.

### Example

```
--int * int
SELECT 123*123;
```

```
      123*123
=====
      15129
```

```
-- int * int returns overflow error
SELECT (1234567890123*1234567890123);
```

```
ERROR: Data overflow on data type bigint.
```

```

## Arithmetic Operations and Type Casting of DATE/TIME Data Types

If all operands are date/time type, only a subtraction operation is allowed and its return value is **BIGINT**. Note that the unit of the operation differs depending on the types of the operands. Both addition and subtraction operations are allowed in case of date/time and integer types. In this case, operation units and return values are date/time data type.

The following table shows operations allowed for each operand type, and their result types.

### Allowable Operation and Result Data Type by Operand Type

|                  | <b>TIME</b><br>(in<br>seconds)                                     | <b>DATE</b><br>(in<br>day)                                         | <b>TIMESTAMP</b><br>(in seconds)                                        | <b>DATETIME (in<br/>milliseconds<br/>)</b>                             | <b>INT</b>                                                              |
|------------------|--------------------------------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <b>TIME</b>      | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                   | X                                                                  | X                                                                       | X                                                                      | An addition<br>and a<br>subtraction<br>are allowed.<br><b>TIME</b>      |
| <b>DATE</b>      | X                                                                  | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                   | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                        | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                       | An addition<br>and a<br>subtraction<br>are allowed.<br><b>DATE</b>      |
| <b>TIMESTAMP</b> | X                                                                  | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                   | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                        | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                       | An addition<br>and a<br>subtraction<br>are allowed.<br><b>TIMESTAMP</b> |
| <b>DATETIME</b>  | X                                                                  | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                   | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                        | A<br>subtraction<br>is allowed.<br><b>BIGINT</b>                       | An addition<br>and a<br>subtraction<br>are allowed.<br><b>DATETIME</b>  |
| <b>INT</b>       | An addition<br>and a<br>subtraction<br>are allowed.<br><b>TIME</b> | An addition<br>and a<br>subtraction<br>are allowed.<br><b>DATE</b> | An addition<br>and a<br>subtraction<br>are allowed.<br><b>TIMESTAMP</b> | An addition<br>and a<br>subtraction<br>are allowed.<br><b>DATETIME</b> | All<br>operations<br>are allowed.                                       |

**Note**

If any of the date/time arguments contains **NULL**, **NULL** is returned.

### Example

```
-- initial systimestamp value
SELECT SYSDATETIME;
```

```
SYSDATETIME
=====
07:09:52.115 PM 01/14/2010
```

```
-- time type + 10(seconds) returns time type
SELECT (CAST (SYSDATETIME AS TIME) + 10);
```

```
( cast( SYS_DATETIME as time)+10)
=====
07:10:02 PM
```

```
-- date type + 10 (days) returns date type
SELECT (CAST (SYSDATETIME AS DATE) + 10);
```

```
( cast( SYS_DATETIME as date)+10)
=====
01/24/2010
```

```
-- timestamp type + 10(seconds) returns timestamp type
SELECT (CAST (SYSDATETIME AS TIMESTAMP) + 10);
```

```
( cast( SYS_DATETIME as timestamp)+10)
=====
07:10:02 PM 01/14/2010
```

```
-- systimestamp type + 10(milliseconds) returns systimestamp type
SELECT (SYSDATETIME + 10);
```

```
( SYS_DATETIME +10)
=====
07:09:52.125 PM 01/14/2010
```

```
SELECT DATETIME '09/01/2009 03:30:30.001 pm'- TIMESTAMP '08/31/2009
03:30:30 pm';
```

```
datetime '09/01/2009 03:30:30.001 pm'-timestamp '08/31/2009
03:30:30 pm'
=====
86400001
```

```
SELECT TIMESTAMP '09/01/2009 03:30:30 pm'- TIMESTAMP '08/31/2009
03:30:30 pm';
```

```
timestamp '09/01/2009 03:30:30 pm'-timestamp '08/31/2009 03:30:30
pm'
=====
86400
```

### Behavior related to timezone parameters

TIMESTAMP and TIMESTAMP WITH LOCAL TIME ZONE data types stores internally UNIX epoch values (number of seconds elapsed from 1970). When leap second is used (tz\_leap\_second\_support is set to yes, see [Timezone Parameter](#)), they may contain virtual date-time values.

| Virtual date-time   | Unix timestamp |                                              |
|---------------------|----------------|----------------------------------------------|
| 2008-12-31 23:59:58 | -> 79399951    |                                              |
| 2008-12-31 23:59:59 | -> 79399952    |                                              |
| 2008-12-31 23:59:60 | -> 79399953    | -> not real date (introduced by leap second) |
| 2009-01-01 00:00:00 | -> 79399954    |                                              |
| 2009-01-01 00:00:01 | -> 79399955    |                                              |

Arithmetic operations with TIMESTAMP and TIMESTAMPTZ values are performed directly on Unix epoch values. Unix epoch values corresponding to non-existing date/time values are allowed. For this reason, the comparison:

```
SELECT TIMESTAMPTZ'2008-12-31 23:59:59 UTC'=TIMESTAMPTZ'2008-12-31
23:59:59 UTC'+1;
```

```
timestampltz '2008-12-31 23:59:59 UTC'=timestampltz '2008-12-31
23:59:59 UTC'+1
=====
=====

0
```

is equivalent to comparing the Unix timestamps : 79399952 and 79399953. But when same values are used as TIMESTAMPTZ, there is equality:

```
SELECT TIMESTAMPTZ'2008-12-31 23:59:59 UTC'=TIMESTAMPTZ'2008-12-31
23:59:59 UTC'+1;
```

```
timestampltz '2008-12-31 23:59:59 UTC'=timestampltz '2008-12-31
23:59:59 UTC'+1
=====
=====

1
```

The inconsistency arise at display :

```
SELECT TIMESTAMPLTZ'2008-12-31 23:59:59 UTC'+1;
```

```
timestampltz '2008-12-31 23:59:59 UTC'+1
=====
11:59:59 PM 12/31/2008 Etc/UTC UTC
```

Since '2008-12-31 23:59:60 UTC' corresponding to Unix timestamp value 79399953 is not a real date, the immediately preceding value is used. Internally, it is equivalent to the value ('2008-12-31 23:59:60 UTC').

TIMESTAMP WITH TIME ZONE data type contains both a UNIX timestamp and a timezone identifier. Arithmetic on TIMESTAMPTZ is also performed on UNIX timestamp part value, but is followed by an automatic adjusting operation. The presence of timezone identifier (which includes region, offset and daylight saving), requires the TIMESTAMPTZ object to be a valid date-time. The operation timestampltz'2008-12-31 23:59:59 UTC'+1 implies an automatic validation-conversion: instead of (79399953, UTC) which is not a valid date-time the value is automatically converted to (79399952,UTC) which corresponds to '2008-12-31 23:59:59 UTC'.

**After each arithmetic operation implying DATETIMEZ and TIMESTAMPTZ, CUBRID performs an automatic adjustment of result value which involves:**

- adjusting the timezone identifier : adding a number of seconds to a date with timezone may lead to change of internally stored offset rule, daylight saving rule, hence the timezone identifier must be updated
- adjusting the Unix timestamp (only for TIMESTAMPTZ): virtual date-time values (when leap-second is enabled) are always converted to the immediately preceding Unix timestamp value.

## Set Arithmetic Operators

SET, MULTISSET, LIST

To compute union, difference or intersection of collections types (**SET**, **MULTISSET**, and **LIST (SEQUENCE)**), you can use +, -, or \* operators, respectively.

```
<value_expression> <set_arithmetic_operator> <value_expression>

<value_expression> ::=
    collection_value |
    NULL

<set_arithmetic_operator> ::=
    + (union) |
    - (difference) |
    * (intersection)
```

The following table shows a result data type by the operator if collection type is an operand.

### Result Data Type by Operand Type

|                  | SET                | MULTISSET          | LIST                         |
|------------------|--------------------|--------------------|------------------------------|
| SET              | +, -, *: SET       | +, -, *: MULTISSET | +, -, *: MULTISSET           |
| MULTISSET        | +, -, *: MULTISSET | +, -, *: MULTISSET | +, -, *: MULTISSET           |
| LIST (=SEQUENCE) | +, -, *: MULTISSET | +, -, *: MULTISSET | + : LIST -, * :<br>MULTISSET |

The following are the examples which execute arithmetic operations with collection types.

```
SELECT ((CAST ({3,3,3,2,2,1} AS SET))+(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as set))+ ( cast({4, 3, 3, 2} as
multiset)))
=====
{1, 2, 2, 3, 3, 3, 4}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS MULTISET))+(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as multiset))+ ( cast({4, 3, 3, 2} as
multiset)))
=====
{1, 2, 2, 2, 3, 3, 3, 3, 3, 4}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS LIST))+(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as sequence))+ ( cast({4, 3, 3, 2} as
multiset)))
=====
{1, 2, 2, 2, 3, 3, 3, 3, 3, 4}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS SET))-(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as set))- ( cast({4, 3, 3, 2} as
multiset)))
=====
{1}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS MULTISET))-(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as multiset))-( cast({4, 3, 3, 2} as
multiset)))
=====
{1, 2, 3}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS LIST))-(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as sequence))-( cast({4, 3, 3, 2} as
multiset)))
=====
{1, 2, 3}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS SET))*(CAST ({4,3,3,2} AS
MULTISET)));

```
(( cast({3, 3, 3, 2, 2, 1} as set))*( cast({4, 3, 3, 2} as
multiset)))
=====
{2, 3}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS MULTISET))*(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as multiset))*( cast({4, 3, 3, 2} as
multiset)))
=====
{2, 3, 3}
```

```
SELECT ((CAST ({3,3,3,2,2,1} AS LIST))*(CAST ({4,3,3,2} AS
MULTISET)));
```

```
(( cast({3, 3, 3, 2, 2, 1} as sequence))*( cast({4, 3, 3, 2} as
multiset)))
=====
{2, 3, 3}
```

## Assigning Collection Value to Variable

For a collection value to be assigned to a variable, the outer query must return a single row as a result.

The following example shows how to assign a collection value to a variable. The outer query must return only a single row as follows:

```
CREATE TABLE people (
    ssn VARCHAR(10),
    name VARCHAR(255)
);

INSERT INTO people
VALUES ('1234', 'Ken'), ('5678', 'Dan'), ('9123', 'Jones');

SELECT SET(SELECT name
FROM people
WHERE ssn IN {'1234', '5678'})
TO :name_group;
```

## Statement Set Operators

### UNION, DIFFERENCE, INTERSECTION

Statement set operators are used to get union, difference or intersection on the result of more than one query statement specified as an operand. Note that the data types of the data to be retrieved from the target tables of the two query statements must be identical or implicitly castable.

```
query_term statement_set_operator [qualifier] <query_term>
[statement_set_operator [qualifier] <query_term>]];

<query_term> ::=
    query_specification
    subquery
```

#### • *qualifier*

- DISTINCT, DISTINCTROW or UNIQUE(A returned instance is a distinct value.)
- ALL (All instances are returned. Duplicates are allowed.)

- *statement\_set\_operator*
  - UNION (union)
  - DIFFERENCE (difference)
  - INTERSECT | INTERSECTION (intersection)

The following table shows statement set operators supported by CUBRID.

### Statement Set Operators

| Statement Set Operator | Description                              | Note                                                                                                                        |
|------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>UNION</b>           | Union Duplicates are not allowed.        | Outputs all instance results containing duplicates with <b>UNION ALL</b>                                                    |
| <b>DIFFERENCE</b>      | Difference Duplicates are not allowed.   | Same as the <b>EXCEPT</b> operator. Outputs all instance results containing duplicates with <b>DIFFERENCE ALL</b> .         |
| <b>INTERSECTION</b>    | Intersection Duplicates are not allowed. | Same as the <b>INTERSECTION</b> operator. Outputs all instance results containing duplicates with <b>INTERSECTION ALL</b> . |

The following are the examples which execute queries with statement set operators.

```
CREATE TABLE nojoin_tbl_1 (ID INT, Name VARCHAR(32));

INSERT INTO nojoin_tbl_1 VALUES (1, 'Kim');
INSERT INTO nojoin_tbl_1 VALUES (2, 'Moy');
INSERT INTO nojoin_tbl_1 VALUES (3, 'Jonas');
INSERT INTO nojoin_tbl_1 VALUES (4, 'Smith');
INSERT INTO nojoin_tbl_1 VALUES (5, 'Kim');
INSERT INTO nojoin_tbl_1 VALUES (6, 'Smith');
INSERT INTO nojoin_tbl_1 VALUES (7, 'Brown');

CREATE TABLE nojoin_tbl_2 (id INT, Name VARCHAR(32));
```

```

INSERT INTO nojoin_tbl_2 VALUES (5,'Kim');
INSERT INTO nojoin_tbl_2 VALUES (6,'Smith');
INSERT INTO nojoin_tbl_2 VALUES (7,'Brown');
INSERT INTO nojoin_tbl_2 VALUES (8,'Lin');
INSERT INTO nojoin_tbl_2 VALUES (9,'Edwin');
INSERT INTO nojoin_tbl_2 VALUES (10,'Edwin');

```

```

--Using UNION to get only distinct rows
SELECT id, name FROM nojoin_tbl_1
UNION
SELECT id, name FROM nojoin_tbl_2;

```

```

      id  name
=====
      1  'Kim'
      2  'Moy'
      3  'Jonas'
      4  'Smith'
      5  'Kim'
      6  'Smith'
      7  'Brown'
      8  'Lin'
      9  'Edwin'
     10  'Edwin'

```

```

--Using UNION ALL not eliminating duplicate selected rows
SELECT id, name FROM nojoin_tbl_1
UNION ALL
SELECT id, name FROM nojoin_tbl_2;

```

```

      id  name
=====
      1  'Kim'
      2  'Moy'
      3  'Jonas'
      4  'Smith'
      5  'Kim'
      6  'Smith'
      7  'Brown'
      5  'Kim'
      6  'Smith'
      7  'Brown'
      8  'Lin'
      9  'Edwin'
     10  'Edwin'

```

```
--Using DEFFERENCE to get only rows returned by the first query but
not by the second
SELECT id, name FROM nojoin_tbl_1
DIFFERENCE
SELECT id, name FROM nojoin_tbl_2;
```

```
      id  name
=====
      1  'Kim'
      2  'Moy'
      3  'Jonas'
      4  'Smith'
```

```
--Using INTERSECTION to get only those rows returned by both queries
SELECT id, name FROM nojoin_tbl_1
INTERSECT
SELECT id, name FROM nojoin_tbl_2;
```

```
      id  name
=====
      5  'Kim'
      6  'Smith'
      7  'Brown'
```

## Containment Operators

| ● SUBSET                     | 367        |

## ● SUBSETEQ

368

Containment operators are used to check the containment relationship by performing comparison operation on operands of the collection data type. Collection data types or subqueries can be specified as operands. The operation returns **TRUE** or **FALSE** if there is a containment relationship between the two operands of identical/different/subset/proper subset.

```
<collection_operand> <containment_operator> <collection_operand>

<collection_operand> ::=
    <set> |
    <multiset> |
    <sequence> (or <list>) |
    <subquery> |
    NULL

<containment_operator> ::=
    SETEQ |
    SETNEQ |
    SUPERSET |
    SUBSET |
    SUPERSETEQ |
    SUBSETEQ
```

- *<collection\_operand>*: This expression that can be specified as an operand is a single SET-valued attribute, an arithmetic expression containing a SET operator or a SET value enclosed in braces. If the type is not specified, the SET value enclosed in braces is treated as a **LIST** type by default.

Subqueries can be specified as operands. If a column which is not a collection type is searched, a collection data type keyword is required for the subquery like **SET** (*subquery*). The column retrieved by a subquery must return a single set so that it can be compared with the set of the other operands.

If the element type of collection is an object, the OIDs, not its contents, are compared. For example, two objects with different OIDs are considered to be different even though they have the same attribute values.

- **NULL**: Any of operands to be compared is **NULL**, **NULL** is returned.

The description and return values about the containment operators supported by CUBRID are as follows:

### Containment Operators Supported by CUBRID

| Containment Operator  | Description                                          | Predicates               | Return Value |
|-----------------------|------------------------------------------------------|--------------------------|--------------|
| A <b>SETEQ</b> B      | A = B: Elements in A and B are same each other.      | {1,2} SETEQ {1,2,2}      | 0            |
| A <b>SETNEQ</b> B     | A <> B: Elements in A and B are not same each other. | {1,2} SETNEQ {1,2,3}     | 1            |
| A <b>SUPERSET</b> B   | A > B: B is a proper subset of A.                    | {1,2} SUPERSET {1,2,3}   | 0            |
| A <b>SUBSET</b> B     | A < B: A is a proper subset of B.                    | {1,2} SUBSET {1,2,3}     | 1            |
| A <b>SUPERSETEQ</b> B | A >= B: B is a subset of A.                          | {1,2} SUPERSETEQ {1,2,3} | 0            |
| A <b>SUBSETEQ</b> B   | A <= B: A is a subset of B.                          | {1,2} SUBSETEQ {1,2,3}   | 1            |

The following table shows than possibility of operation by operand and type conversion if a containment operator is used.

#### Possibility of Operation by Operand

|                 | SET                | MULTISET           | LIST(=SEQUENCE)                                                         |

sequence.

```

## SETEQ

The **SETEQ** operator returns **TRUE** if the first operand is the same as the second one. It can perform comparison operator for all collection data type.

```
collection_operand SETEQ collection_operand
```

```

--creating a table with SET type address column and LIST type
zip_code column

CREATE TABLE contain_tbl (id INT PRIMARY KEY, name CHAR(10), address
SET VARCHAR(20), zip_code LIST INT);
INSERT INTO contain_tbl VALUES(1, 'Kim', {'country', 'state'},{1, 2,
3});
INSERT INTO contain_tbl VALUES(2, 'Moy', {'country', 'state'},{3, 2,
1});
INSERT INTO contain_tbl VALUES(3, 'Jones', {'country', 'state',
'city'},{1,2,3,4});
INSERT INTO contain_tbl VALUES(4, 'Smith', {'country', 'state',
'city', 'street'},{1,2,3,4});
INSERT INTO contain_tbl VALUES(5, 'Kim', {'country', 'state',
'city', 'street'},{1,2,3,4});
INSERT INTO contain_tbl VALUES(6, 'Smith', {'country', 'state',
'city', 'street'},{1,2,3,5});
INSERT INTO contain_tbl VALUES(7, 'Brown', {'country', 'state',

```

```
'city', 'street'},{}));
```

```
--selecting rows when two collection_operands are same in the WHERE clause
```

```
SELECT id, name, address, zip_code FROM contain_tbl WHERE address  
SETEQ {'country','state', 'city'};
```

```

=====
=====
      3  'Jones              {'city', 'country', 'state'}
{1, 2, 3, 4}

1 row selected.
```

```
--selecting rows when two collection_operands are same in the WHERE clause
```

```
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code  
SETEQ {1,2,3};
```

```

      id  name                address                zip_code
=====
=====
      1  'Kim                {'country', 'state'} {1, 2, 3}

1 rows selected.
```

## SETNEQ

The **SETNEQ** operator returns **TRUE** (1) if a first operand is different from a second operand. A comparable operation can be performed for all collection data types.

```
collection_operand SETNEQ collection_operand
```

```
--selecting rows when two collection_operands are not same in the WHERE clause
```

```
SELECT id, name, address, zip_code FROM contain_tbl WHERE address  
SETNEQ {'country','state', 'city'};
```

```

      id  name                address                zip_code
=====
=====
```

```
1 'Kim      ' {'country', 'state'} {1, 2, 3}
2 'Moy      ' {'country', 'state'} {3, 2, 1}
4 'Smith    ' {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
5 'Kim      ' {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
6 'Smith    ' {'city', 'country', 'state',
'street'} {1, 2, 3, 5}
7 'Brown    ' {'city', 'country', 'state',
'street'} {}

6 rows selected.
```

```
--selecting rows when two collection_operands are not same in the
WHERE clause
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SETNEQ {1,2,3};
```

|              | id           | name   |   | address                      | zip_code  |
|--------------|--------------|--------|---|------------------------------|-----------|
| =====        |              |        |   |                              |           |
|              | 2            | 'Moy   | ' | {'country', 'state'}         | {3, 2, 1} |
|              | 3            | 'Jones | ' | {'city', 'country', 'state'} |           |
| {1, 2, 3, 4} | 4            | 'Smith | ' | {'city', 'country', 'state', |           |
| 'street'}    | {1, 2, 3, 4} |        |   |                              |           |
|              | 5            | 'Kim   | ' | {'city', 'country', 'state', |           |
| 'street'}    | {1, 2, 3, 4} |        |   |                              |           |
|              | 6            | 'Smith | ' | {'city', 'country', 'state', |           |
| 'street'}    | {1, 2, 3, 5} |        |   |                              |           |
|              | 7            | 'Brown | ' | {'city', 'country', 'state', |           |
| 'street'}    | {}           |        |   |                              |           |

SUPERSET

The **SUPERSET** operator returns **TRUE** (1) when a second operand is a proper subset of a first operand; that is, the first one is larger than the second one. If two operands are identical, **FALSE** (0) is returned. Note that **SUPERSET** is not supported if all operands are **LIST** type.

```
collection_operand SUPERSET collection_operand
```

```
--selecting rows when the first operand is a superset of the second
operand and they are not same
```

```
SELECT id, name, address, zip_code FROM contain_tbl WHERE address
SUPERSET {'country','state','city'};
```

```

```
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUPERSET (CAST ({1,2,3} AS SET));
```

```

      id  name                address                zip_code
=====
=====
      3  'Jones              '                {'city', 'country', 'state'}
{1, 2, 3, 4}
      4  'Smith              '                {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
      5  'Kim                '                {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
      6  'Smith              '                {'city', 'country', 'state',
'street'} {1, 2, 3, 5}
```

## SUPERSETEQ

The **SUPERSETEQ** operator returns **TRUE** (1) when a second operand is a subset of a first operand; that is, the first one is identical to or larger than the second one. Note that **SUPERSETEQ** is not supported if an operand is **LIST** type.

```
collection_operand SUPERSETEQ collection_operand
```

```
--selecting rows when the first operand is a superset of the second
operand
SELECT id, name, address, zip_code FROM contain_tbl WHERE address
SUPERSETEQ {'country','state','city'};
```

|              | id           | name   |   | address                      | zip_code |
|--------------|--------------|--------|---|------------------------------|----------|
|              | 3            | 'Jones | ' | {'city', 'country', 'state'} |          |
| {1, 2, 3, 4} | 4            | 'Smith | ' | {'city', 'country', 'state', |          |
| 'street'}    | {1, 2, 3, 4} | 5      | ' | {'city', 'country', 'state', |          |
| 'street'}    | {1, 2, 3, 4} | 6      | ' | {'city', 'country', 'state', |          |
| 'street'}    | {1, 2, 3, 5} | 7      | ' | {'city', 'country', 'state', |          |
| 'street'}    | {}           |        |   |                              |          |

```
--SUPERSETEQ operator cannot be used for comparison between LIST and
LIST type values
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUPERSETEQ {1,2,3};
```

```
ERROR: ' superseteq ' operator is not defined on types sequence and
sequence.
```

```
--Comparing operands with a SUPERSETEQ operator after casting LIST
type as SET type
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUPERSETEQ (CAST ({1,2,3} AS SET));
```

|  | id | name |  | address | zip_code |
|--|----|------|--|---------|----------|
|  |    |      |  |         |          |

```

1  'Kim      '      {'country', 'state'} {1, 2, 3}
3  'Jones    '      {'city', 'country', 'state'}
{1, 2, 3, 4}
4  'Smith    '      {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
5  'Kim      '      {'city', 'country', 'state',
'street'} {1, 2, 3, 4}
6  'Smith    '      {'city', 'country', 'state',
'street'} {1, 2, 3, 5}

```

## SUBSET

The **SUBSET** operator returns **TRUE** (1) if the second operand contains all elements of the first operand. If the first and the second collection have the same elements, **FALSE** (0) is returned. Note that both operands are the **LIST** type, the **SUBSET** operation is not supported.

```
collection_operand SUBSET collection_operand
```

```

--selecting rows when the first operand is a subset of the second
operand and they are not same
SELECT id, name, address, zip_code FROM contain_tbl WHERE address
SUBSET {'country','state','city'};

```

```

      id  name      address      zip_code
=====
1  'Kim      '      {'country', 'state'} {1, 2, 3}
2  'Moy      '      {'country', 'state'} {3, 2, 1}

```

```

--SUBSET operator cannot be used for comparison between LIST and
LIST type values
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUBSET {1,2,3};

```

```

ERROR: ' subset ' operator is not defined on types sequence and
sequence.

```

```

--Comparing operands with a SUBSET operator after casting LIST type
as SET type
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUBSET (CAST ({1,2,3} AS SET));

```

```

      id  name      address      zip_code
=====

```

```
=====
      7  'Brown      '      {'city', 'country', 'state',
'street'} {}
```

## SUBSETEQ

The **SUBSETEQ** operator returns **TRUE** (1) when a first operand is a subset of a second operand; that is, the second one is identical to or larger than the first one. Note that **SUBSETEQ** is not supported if an operand is **LIST** type.

```
collection_operand SUBSETEQ collection_operand
```

```
--selecting rows when the first operand is a subset of the second
operand
SELECT id, name, address, zip_code FROM contain_tbl WHERE address
SUBSETEQ {'country','state','city'};
```

```
      id  name      address      zip_code
=====
=====
      1  'Kim      '      {'country', 'state'} {1, 2, 3}
      2  'Moy      '      {'country', 'state'} {3, 2, 1}
      3  'Jones    '      {'city', 'country', 'state'}
{1, 2, 3, 4}
```

```
--SUBSETEQ operator cannot be used for comparison between LIST and
LIST type values
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUBSETEQ {1,2,3};
```

```
ERROR: ' subseteq ' operator is not defined on types sequence and
sequence.
```

```
--Comparing operands with a SUBSETEQ operator after casting LIST
type as SET type
SELECT id, name, address, zip_code FROM contain_tbl WHERE zip_code
SUBSETEQ (CAST ({1,2,3} AS SET));
```

```
      id  name      address      zip_code
=====
=====
```

```
1 'Kim'      {'country', 'state'} {1, 2, 3}
7 'Brown'    {'city', 'country', 'state',
'street'} {}
```

# BIT Functions and Operators

## Bitwise Operator

A **Bitwise** operator performs operations in bits, and can be used in arithmetic operations. An integer type is specified as the operand and the **BIT** type cannot be specified. An integer of **BIGINT** type (64-bit integer) is returned as a result of the operation. If one or more operands are **NULL**, **NULL** is returned.

The following table shows the bitwise operators supported by CUBRID.

### The bitwise operators

| Bitwise operator | Description                                                  | Expression | Return Value |
|------------------|--------------------------------------------------------------|------------|--------------|
| &                | Performs AND operation in bits and returns a BIGINT integer. | 17 & 3     | 1            |
|                  |                                                              | 17   3     | 19           |

| Bitwise operator      | Description                                                                                                                                  | Expression                 | Return Value |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|--------------|
|                       | Performs OR operation in bits and returns a BIGINT integer.                                                                                  |                            |              |
| <code>^</code>        | Performs XOR operation in bits and returns a BIGINT integer.                                                                                 | <code>17 ^ 3</code>        | 18           |
| <code>~</code>        | A unary operator. It performs complementary operation that reverses (INVERT) the bit order of the operand and returns a BIGINT integer.      | <code>~17</code>           | -18          |
| <code>&lt;&lt;</code> | Performs the operation to shift bits of the left operand as far to the left as the value of the right operand, and returns a BIGINT integer. | <code>17 &lt;&lt; 3</code> | 136          |
| <code>&gt;&gt;</code> | Performs the operation to shift bits of the left operand as far to the right as the value of the right operand, and                          | <code>17 &gt;&gt; 3</code> | 2            |

| Bitwise operator | Description               | Expression | Return Value |
|------------------|---------------------------|------------|--------------|
|                  | returns a BIGINT integer. |            |              |

## BIT\_AND

### BIT\_AND(*expr*)

As an aggregate function, it performs **AND** operations in bits on every bit of *expr*. The return value is a **BIGINT** type. If there is no row that satisfies the expression, **NULL** is returned.

Parameters:

**expr** – An expression of integer type

Return type:

BIGINT

```
CREATE TABLE bit_tbl(id int);
INSERT INTO bit_tbl VALUES (1), (2), (3), (4), (5);
SELECT 18385, BIT_AND(id) FROM bit_tbl WHERE id in(1,3,5);
```

```
18385          bit_and(id)
=====
1              1
```

## BIT\_OR

### BIT\_OR(*expr*)

As an aggregate function, it performs **OR** operations in bits on every bit of *expr*. The return value is a **BIGINT** type. If there is no row that satisfies the expression, **NULL** is returned.

Parameters:

**expr** – An expression of integer type

Return type:

BIGINT

```
SELECT 1|3|5, BIT_OR(id) FROM bit_tbl WHERE id in(1,3,5);
```

| 1 3 5 | bit_or(id) |
|-------|------------|
| ===== | =====      |
| 7     | 7          |

## BIT\_XOR

BIT\_XOR(*expr*)

As an aggregate function, it performs **XOR** operations in bits on every bit of *expr*. The return value is a **BIGINT** type. If there is no row that satisfies the expression, **NULL** is returned.

Parameters:

**expr** – An expression of integer type

Return type:

BIGINT

```
SELECT 1^3^5, BIT_XOR(id) FROM bit_tbl WHERE id in(1,3,5);
```

| 1^3^5 | bit_xor(id) |
|-------|-------------|
| ===== | =====       |
| 7     | 7           |

## BIT\_COUNT

BIT\_COUNT(*expr*)

The **BIT\_COUNT** function returns the number of bits of *expr* that have been set to 1; it is not an aggregate function. The return value is a **BIGINT** type.

Parameters:

**expr** – An expression of integer type

Return type:

BIGINT

```
SELECT BIT_COUNT(id) FROM bit_tbl WHERE id in(1,3,5);
```

```
bit_count(id)
=====
      1
      2
      2
```

## String Functions and Operators

| ● UCASE, UPPER    | 424 |

### Note

In the string functions, if the value of **oracle\_style\_empty\_string** parameter is yes, CUBRID does not separate an empty string and NULL; according to each function, CUBRID regards all of them as NULL or an empty string. For the detail description, see [oracle\\_style\\_empty\\_string](#).

## Concatenation Operator

A concatenation operator gets a character string or bit string data type as an operand and returns a concatenated string. The plus sign (+) and double pipe symbol (||) are provided as concatenation operators for character string data. If **NULL** is specified as an operand, a **NULL** value is returned.

If **pipes\_as\_concat** that is a parameter related to SQL statement is set to **no** (default value: yes), a double pipe (||) symbol is interpreted as an **OR** operator. If **plus\_as\_concat** is set to no (default value: yes), a plus (+) symbol is interpreted as a plus (+) operator. In such case, It is recommended to concatenate strings or bit strings, by using the **CONCAT** function.

```
<concat_operand1> + <concat_operand2>
<concat_operand1> || <concat_operand2>

<concat_operand1> ::=
    bit string |
    character string
    NULL

<concat_operand2> ::=
    bit string |
```

character string  
NULL

- <concat\_operand1>: Left string after concatenation. String or bit string can be specified.
- <concat\_operand2>: Right string after concatenation. String or bit string can be specified.

```
SELECT 'CUBRID' || ',' + '2008';
```

```
'CUBRID' || ',' + '2008'
=====
'CUBRID,2008'
```

```
SELECT 'cubrid' || ',' || B'0010' || B'0000' || B'0000' || B'1000';
```

```
'cubrid' || ',' || B'0010' || B'0000' || B'0000' || B'1000'
=====
'cubrid,2008'
```

```
SELECT ((EXTRACT(YEAR FROM SYS_TIMESTAMP)) || (EXTRACT(MONTH FROM
SYS_TIMESTAMP)));
```

```
(( extract(year from SYS_TIMESTAMP )) || ( extract(month from
SYS_TIMESTAMP )))
=====
'200812'
```

```
SELECT 'CUBRID' || ',' + NULL;
```

```
'CUBRID' || ',' + null
=====
NULL
```

## ASCII

### ASCII(str)

The **ASCII** function returns the ASCII code of the most left character in numeric value. If an input string is **NULL**, **NULL** is returned. This **ASCII** function supports single-byte character

sets only. If a numeric value is entered, it is converted into character string and then the ASCII code of the most left character is returned.

Parameters:

**str** – Input string

Return type:

STRING

```
SELECT ASCII('5');
```

```
53
```

```
SELECT ASCII('ab');
```

```
97
```

## BIN

### BIN(*n*)

The **BIN** function converts a **BIGINT** type number into binary string. If an input string is **NULL**, **NULL** is returned. When you input the string which cannot be transformed into **BIGINT**, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**n** – A **BIGINT** type number

Return type:

STRING

```
SELECT BIN(12);
```

```
'1100'
```

## BIT\_LENGTH

### BIT\_LENGTH(*string*)

The **BIT\_LENGTH** function returns the length (bits) of a character string or bit string as an integer value. The return value of the **BIT\_LENGTH** function may depend on the character set, because for the character string, the number of bytes taken up by a single character is different depending on the character set of the data input environment (e.g., UTF-8 Korean characters: one Korean character is 3\*8 bits). For details about character sets supported by CUBRID, see [Character Strings](#). When you input the invalid value, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**string** – Specifies the character string or bit string whose number of bits is to be calculated. If this value is **NULL**, **NULL** is returned.

#### Return type:

INT

```
SELECT BIT_LENGTH('');
```

```
bit_length('')
=====
0
```

```
SELECT BIT_LENGTH('CUBRID');
```

```
bit_length('CUBRID')
=====
48
```

```
-- UTF-8 Korean character
SELECT BIT_LENGTH('큐브리드');
```

```
      bit_length('큐브리드')
=====
                        96
```

```
SELECT BIT_LENGTH(B'010101010');
```

```
      bit_length(B'010101010')
=====
                        9
```

```
CREATE TABLE bit_length_tbl (char_1 CHAR, char_2 CHAR(5), varchar_1
VARCHAR, bit_var_1 BIT VARYING);
INSERT INTO bit_length_tbl VALUES(' ', ' ', ' ', B''); --Length of
empty string
INSERT INTO bit_length_tbl VALUES('a', 'a', 'a', B'010101010'); --
English character
INSERT INTO bit_length_tbl VALUES(NULL, '큐', '큐', B'010101010'); --
UTF-8 Korean character and NULL
INSERT INTO bit_length_tbl VALUES(' ', ' 큐', ' 큐', B'010101010'); --
UTF-8 Korean character and space

SELECT BIT_LENGTH(char_1), BIT_LENGTH(char_2),
BIT_LENGTH(varchar_1), BIT_LENGTH(bit_var_1) FROM bit_length_tbl;
```

```
bit_length(char_1)  bit_length(char_2)      bit_length(varchar_1)
bit_length(bit_var_1)

9
```

## CHAR\_LENGTH, CHARACTER\_LENGTH, LENGTHB, LENGTH

CHAR\_LENGTH(*string*)

CHARACTER\_LENGTH(*string*)

LENGTHB(*string*)

LENGTH(*string*)

**CHAR\_LENGTH**, **CHARACTER\_LENGTH**, **LENGTHB**, and **LENGTH** are used interchangeably. The number of characters is returned as an integer. For details on character set supported by CUBRID, see [An Overview of Globalization](#).

### Parameters:

**string** – Specifies the string whose length will be calculated according to the number of characters. If the character string is **NULL**, **NULL** is returned.

### Return type:

INT

### Note

- In versions lower than CUBRID 9.0, the multibyte string returns the number of bytes in the string. Therefore, the length of one character is calculated as 2- or 3-bytes according to the charset.
- The length of each space character that is included in a character string is one byte.
- The length of empty quotes (") to represent a space character is 0. Note that in a **CHAR (n)** type, the length of a space character is *n*, and it is specified as 1 if *n* is omitted.

```
--character set is UTF-8 for Korean characters
SELECT LENGTH('');
```

```
char length('')
=====
0
```

```
SELECT LENGTH('CUBRID');
```

```
char length('CUBRID')
=====
6
```

```
SELECT LENGTH('큐브리드');
```

```
char length('큐브리드')
=====
4
```

```
CREATE TABLE length_tbl (char_1 CHAR, char_2 CHAR(5), varchar_1
VARCHAR, varchar_2 VARCHAR);
INSERT INTO length_tbl VALUES(' ', ' ', ' ', ' '); --Length of empty
string
INSERT INTO length_tbl VALUES('a', 'a', 'a', 'a'); --English
character
INSERT INTO length_tbl VALUES(NULL, '큐', '큐', '큐'); --Korean
character and NULL
INSERT INTO length_tbl VALUES(' ', ' 큐', ' 큐', ' 큐'); --Korean
character and space

SELECT LENGTH(char_1), LENGTH(char_2), LENGTH(varchar_1),
LENGTH(varchar_2) FROM length_tbl;
```

```
char_length(char_1) char_length(char_2) char_length(varchar_1)
char_length(varchar_2)
=====
=====
1                5                0                0
1                5                1                1
NULL             5                1                1
1                5                2                2
```

## CHR

CHR(*number\_operand* [*USING charset\_name*])

The **CHR** function returns a character that corresponds to the return value of the expression specified as an argument. When you input the code value within invalid ranges, it returns

an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

- **number\_operand** – Specifies an expression that returns a numeric value.
- **charset\_name** – Characterset name. It supports utf8 and iso88591.

#### Return type:

STRING

```
SELECT CHR(68) || CHR(68-2);
```

```
chr(68)|| chr(68-2)
=====
'DB'
```

If you want to get a multibyte character with the **CHR** function, input a number with the valid range of the charset.

```
SELECT CHR(14909886 USING utf8);
-- Below query's result is the same as above.
SET NAMES utf8;
SELECT CHR(14909886);
```

```
chr(14909886 using utf8)
=====
'ま'
```

If you want to get the hexadecimal string from a character, use **HEX** function.

```
SET NAMES utf8;
SELECT HEX('ま');
```

```
hex(_utf8'ま')
=====
'E381BE'
```

If you want to get the decimal string from a hexadecimal string, use **CONV** function.

```
SET NAMES utf8;
SELECT CONV('E381BE',16,10);
```

```
conv(_utf8'E381BE', 16, 10)
=====
'14909886'
```

## CONCAT

**CONCAT**(*string1, string2 [,string3 [, ... [, stringN]...]]*)

The **CONCAT** function has at least one argument specified for it and returns a string as a result of concatenating all argument values. The number of parameters that can be specified is unlimited. Automatic type casting takes place if a non-string type is specified as the argument. If any of the arguments is specified as **NULL**, **NULL** is returned.

If you want to insert separators between strings specified as arguments for concatenation, use the **CONCAT\_WS()** Function.

Parameters:

**strings** – character string

Return type:

STRING

```
SELECT CONCAT('CUBRID', '2008' , 'R3.0');
```

```
concat('CUBRID', '2008', 'R3.0')
=====
'CUBRID2008R3.0'
```

```
--it returns null when null is specified for one of parameters
SELECT CONCAT('CUBRID', '2008' , 'R3.0', NULL);
```

```
concat('CUBRID', '2008', 'R3.0', null)
=====
NULL
```

```
--it converts number types and then returns concatenated strings
SELECT CONCAT(2008, 3.0);
```

```
concat(2008, 3.0)
=====
'20083.0'
```

## CONCAT\_WS

CONCAT\_WS(*string1*, *string2* [, *string3* [, ... [, *stringN*]...]])

The **CONCAT\_WS** function has at least two arguments specified for it. The function uses the first argument value as the separator and returns the result.

Parameters:

**strings** – character string

Return type:

STRING

```
SELECT CONCAT_WS(' ', 'CUBRID', '2008' , 'R3.0');
```

```
concat_ws(' ', 'CUBRID', '2008', 'R3.0')
=====
'CUBRID 2008 R3.0'
```

```
--it returns strings even if null is specified for one of parameters
SELECT CONCAT_WS(' ', 'CUBRID', '2008', NULL, 'R3.0');
```

```
concat_ws(' ', 'CUBRID', '2008', null, 'R3.0')
=====
'CUBRID 2008 R3.0'
```

```
--it converts number types and then returns concatenated strings
with separator
SELECT CONCAT_WS(' ',2008, 3.0);
```

```
concat_ws(' ', 2008, 3.0)
=====
'2008 3.0'
```

## ELT

ELT(*N*, *string1*, *string2*, ...)

If *N* is 1, the **ELT** function returns *string1* and if *N* is 2, it returns *string2*. The return value is a **VARCHAR** type. You can add conditional expressions as needed.

The maximum byte length of the character string is 33,554,432 and if this length is exceeded, **NULL** will be returned.

If *N* is 0 or a negative number, an empty string will be returned. If *N* is greater than the number of this input character string, **NULL** will be returned as it is out of range. If *N* is a type that cannot be converted to an integer, an error will be returned.

### Parameters:

- **N** – A position of a string to return among the list of strings
- **strings** – The list of strings

### Return type:

STRING

```
SELECT ELT(3,'string1','string2','string3');
```

```
elt(3, 'string1', 'string2', 'string3')
=====
'string3'
```

```
SELECT ELT('3','1/1/1','23:00:00','2001-03-04');
```

```
elt('3', '1/1/1', '23:00:00', '2001-03-04')
=====
'2001-03-04'
```

```
SELECT ELT(-1, 'string1','string2','string3');
```

```
elt(-1, 'string1','string2','string3')
=====
NULL
```

```
SELECT ELT(4,'string1','string2','string3');
```

```
elt(4, 'string1', 'string2', 'string3')
=====
NULL
```

```
SELECT ELT(3.2,'string1','string2','string3');
```

```
elt(3.2, 'string1', 'string2', 'string3')
=====
'string3'
```

```
SELECT ELT('a','string1','string2','string3');
```

```
ERROR: Cannot coerce 'a' to type bigint.
```

## FIELD

FIELD(*search\_string*, *string1* [,*string2* [, ... [, *stringN*...]]])

The **FIELD** function returns the location index value (position) of a string of *string1*, *string2*. The function returns 0 if it does not have a parameter value which is the same as *search\_string*. It returns 0 if *search\_string* is **NULL** because it cannot perform the comparison operation with the other arguments.

If all arguments specified for **FIELD** function are of string type, string comparison operation is performed: if all of them are of number type, numeric comparison operation is performed. If the type of one argument is different from that of another, a comparison operation is performed by casting each argument to the type of the first argument. If type casting fails during the comparison operation with each argument, the function considers the result of the comparison operation as **FALSE** and resumes the other operations.

#### Parameters:

- **search\_string** – A string pattern to search
- **strings** – The list of strings to be searched

#### Return type:

INT

```
SELECT FIELD('abc', 'a', 'ab', 'abc', 'abcd', 'abcde');
```

```
field('abc', 'a', 'ab', 'abc', 'abcd', 'abcde')
=====
3
```

```
--it returns 0 when no same string is found in the list
SELECT FIELD('abc', 'a', 'ab', NULL);
```

```
field('abc', 'a', 'ab', null)
=====
0
```

```
--it returns 0 when null is specified in the first parameter
SELECT FIELD(NULL, 'a', 'ab', NULL);
```

```
field(null, 'a', 'ab', null)
=====
0
```

```
SELECT FIELD('123', 1, 12, 123.0, 1234, 12345);
```

```
field('123', 1, 12, 123.0, 1234, 12345)
=====
0
```

```
SELECT FIELD(123, 1, 12, '123.0', 1234, 12345);
```

```
field(123, 1, 12, '123.0', 1234, 12345)
=====
3
```

## FIND\_IN\_SET

### FIND\_IN\_SET(*str*, *strlist*)

The **FIND\_IN\_SET** function looks for the string *str* in the string list *strlist* and returns a position of *str* if it exists. A string list is a string composed of substrings separated by a comma (.). If *str* is not in *strlist* or *strlist* is an empty string, 0 is returned. If either argument is **NULL**, **NULL** is returned. This function does not work properly if *str* contains a comma (.).

#### Parameters:

- **str** – A string to be searched
- **strlist** – A group of strings separated by a comma

#### Return type:

INT

```
SELECT FIND_IN_SET('b', 'a,b,c,d');
```

2

## FROM\_BASE64

### FROM\_BASE64(*str*)

**FROM\_BASE64** function returns the the decoded result as binary string from the input string encoded as base-64 rule, which is used in **TO\_BASE64** function. If the input value is **NULL**, it returns **NULL**. **When you input the invalid base-64 string, it returns an error if the value of `**return_null_on_function_errors` in `cubrid.conf` is no(the default); NULL if this value is yes.** See [TO\\_BASE64\(\)](#) for more details on base-64 encoding rules.

Parameters:

**str** – Input string

Return type:

STRING

```
SELECT TO_BASE64('abcd'), FROM_BASE64(TO_BASE64('abcd'));
```

```
to_base64('abcd') from_base64( to_base64('abcd'))
=====
'YWJjZA==' 'abcd'
```

### ! See also

[TO\\_BASE64\(\)](#)

## INSERT

### INSERT(*str, pos, len, string*)

The **INSERT** function inserts a partial character string as long as the length from the specific location of the input character string. The return value is a **VARCHAR** type. The maximum length of the character string is 33,554,432 and if this length is exceeded, **NULL** will be returned.

Parameters:

• **str** – Input character string

- **pos** – *str* location. Starts from 1. If *pos* is smaller than 1 or greater than the length of *string* + 1, the *string* will not be inserted and the *str* will be returned instead.
- **len** – Length of *string* to insert *pos* of *str*. If *len* exceeds the length of the partial character string, insert as many values as *string* in the *pos* of the *str*. If *len* is a negative number, *str* will be the end of the character string.
- **string** – Partial character string to insert to *str*

Return type:

STRING

```
SELECT INSERT('cubrid',2,2,'dbsql');
```

```
insert('cubrid', 2, 2, 'dbsql')
=====
'cdbsqlrid'
```

```
SELECT INSERT('cubrid',0,3,'db');
```

```
insert('cubrid', 0, 3, 'db')
=====
'cubrid'
```

```
SELECT INSERT('cubrid',-3,3,'db');
```

```
insert('cubrid', -3, 3, 'db')
=====
'cubrid'
```

```
SELECT INSERT('cubrid',3,100,'db');
```

```
insert('cubrid', 3, 100, 'db')
=====
'cudb'
```

```
SELECT INSERT('cubrid',7,100,'db');
```

```
insert('cubrid', 7, 100, 'db')
=====
'cubriddb'
```

```
SELECT INSERT('cubrid',3,-1,'db');
```

```
insert('cubrid', 3, -1, 'db')
=====
'cudb'
```

## INSTR

INSTR(*string*, *substring*[, *position*])

The **INSTR** function, similarly to the **POSITION**, returns the position of a *substring* within *string*; the position. For the **INSTR** function, you can specify the starting position of the search for *substring* to make it possible to search for duplicate *substring*.

Parameters:

- **string** – Specifies the input character string.
- **substring** – Specifies the character string whose position is to be returned.
- **position** – Optional. Represents the position of a *string* where the search begins in character unit. If omitted, the default value 1 is applied. The first position of the *string* is specified as 1. If the value is negative, the system counts backward from the end of the *string*.

Return type:

INT

**Note**

In the earlier versions of CUBRID 9.0, position value is returned in byte unit, not character unit. When a multi-byte character set is used, the number of bytes representing one character is different; so the return value may not the same.

```
--character set is UTF-8 for Korean characters
--it returns position of the first 'b'
SELECT INSTR ('12345abcdeabcde','b');
```

```
instr('12345abcdeabcde', 'b', 1)
=====
7
```

```
-- it returns position of the first '나' on UTF-8 Korean charset
SELECT INSTR ('12345가나다라마가나다라마', '나' );
```

```
instr('12345가나다라마가나다라마', '나', 1)
=====
7
```

```
-- it returns position of the second '나' on UTF-8 Korean charset
SELECT INSTR ('12345가나다라마가나다라마', '나', 11 );
```

```
instr('12345가나다라마가나다라마', '나', 11)
=====
12
```

```
--it returns position of the 'b' searching from the 8th position
SELECT INSTR ('12345abcdeabcde','b', 8);
```

```
instr('12345abcdeabcde', 'b', 8)
=====
12
```

```
--it returns position of the 'b' searching backwardly from the end
SELECT INSTR ('12345abcdeabcde','b', -1);
```

```
instr('12345abcdeabcde', 'b', -1)
=====
12
```

```
--it returns position of the 'b' searching backwardly from a
specified position
SELECT INSTR ('12345abcdeabcde','b', -8);
```

```
instr('12345abcdeabcde', 'b', -8)
=====
7
```

## LCASE, LOWER

LCASE(*string*)

LOWER(*string*)

The functions **LCASE** and **LOWER** are used interchangeably. They convert uppercase characters included in string to lowercase characters.

Parameters:

**string** – Specifies the string in which uppercase characters are to be converted to lowercase. If the value is **NULL**, **NULL** is returned.

Return type:

STRING

```
SELECT LOWER('');
```

```
lower('')
=====
''
```

```
SELECT LOWER(NULL);
```

```
lower(null)
=====
NULL
```

```
SELECT LOWER('Cubrid');
```

```
lower('Cubrid')
=====
'cubrid'
```

Note that the **LOWER** function may not work properly by specified collation. For example, when you try to change character Ă used in Romanian as lower character, this function works as follows by collation.

If collation is utf8\_bin, this character is not changed.

```
SET NAMES utf8 COLLATE utf8_bin;
SELECT LOWER('Ă');

lower(_utf8'Ă')
=====
'Ă'
```

If collation is utf8\_ro\_RO, 'Ă' can be changed.

```
SET NAMES utf8 COLLATE utf8_ro_cs;
SELECT LOWER('Ă');

lower(_utf8'Ă' COLLATE utf8_ro_cs)
=====
'ă'
```

For supporting collations in CUBRID, see [CUBRID Collation](#).

## LEFT

LEFT(*string*, *length*)

The **LEFT** function returns a length number of characters from the leftmost *string*. If any of the arguments is **NULL**, **NULL** is returned. If a value greater than the *length* of the *string* or

a negative number is specified for a length, the entire string is returned. To extract a length number of characters from the rightmost string, use the `RIGHT()`.

#### Parameters:

- **string** – Input string
- **length** – The length of a string to be returned

#### Return type:

STRING

```
SELECT LEFT('CUBRID', 3);
```

```
left('CUBRID', 3)
=====
'CUB'
```

```
SELECT LEFT('CUBRID', 10);
```

```
left('CUBRID', 10)
=====
'CUBRID'
```

## LOCATE

`LOCATE(substring, string [, position])`

The **LOCATE** function returns the location index value of a *substring* within a character string. The third argument *position* can be omitted. If this argument is specified, the function searches for *substring* from the given position and returns the location index value of the first occurrence. If the *substring* cannot be found within the string, 0 is returned. The **LOCATE** function behaves like the `POSITION()`, but you cannot use **LOCATE** for bit strings.

#### Parameters:

- **substring** – A string pattern to search
- **string** – A whole string to be searched

- **position** – Starting position of a whole string to be searched

Return type:

INT

```
--it returns 1 when substring is empty space  
SELECT LOCATE ('', '12345abcdeabcde');
```

```
locate('', '12345abcdeabcde')  
=====1
```

```
--it returns position of the first 'abc'  
SELECT LOCATE ('abc', '12345abcdeabcde');
```

```
locate('abc', '12345abcdeabcde')  
=====6
```

```
--it returns position of the second 'abc'  
SELECT LOCATE ('abc', '12345abcdeabcde', 8);
```

```
locate('abc', '12345abcdeabcde', 8)  
=====11
```

```
--it returns 0 when no substring found in the string  
SELECT LOCATE ('ABC', '12345abcdeabcde');
```

```
locate('ABC', '12345abcdeabcde')  
=====0
```

## LPAD

### LPAD(*char1*, *n* [, *char2*])

The **LPAD** function pads the left side of a string until the string length reaches the specified value.

#### Parameters:

- **char1** – Specifies the string to pad characters to. If *n* is smaller than the length of *char1*, padding is not performed, and *char1* is truncated to length *n* and then returned. If the value is **NULL**, **NULL** is returned.
- **n** – Specifies the total length of *char1* in bytes. If the value is **NULL**, **NULL** is returned.
- **char2** – Specifies the string to pad to the left until the length of *char1* reaches *n*. If it is not specified, empty characters (' ') are used as a default. If the value is **NULL**, **NULL** is returned.

#### Return type:

STRING

#### Note

In versions lower than CUBRID 9.0, a single character is processed as 2 or 3 bytes in a multi-byte character set environment. If *n* is truncated up to the first byte representing a character according to a value of *char1*, the last byte is removed and a space character (1 byte) is added to the left because the last character cannot be represented normally. When the value is **NULL**, **NULL** is returned as its result.

```
--character set is UTF-8 for Korean characters
--it returns only 3 characters if not enough length is specified
SELECT LPAD ('CUBRID', 3, '?');
```

```
lpad('CUBRID', 3, '?')
=====
'CUB'
```

```
SELECT LPAD ('큐브리드', 3, '?');
```

```
lpad('큐브리드', 3, '?')
=====
'큐브리'
```

```
--padding spaces on the left till char_length is 10
SELECT LPAD ('CUBRID', 10);
```

```
lpad('CUBRID', 10)
=====
'      CUBRID'
```

```
--padding specific characters on the left till char_length is 10
SELECT LPAD ('CUBRID', 10, '?');
```

```
lpad('CUBRID', 10, '?')
=====
'????CUBRID'
```

```
--padding specific characters on the left till char_length is 10
SELECT LPAD ('큐브리드', 10, '?');
```

```
lpad('큐브리드', 10, '?')
=====
'??????큐브리드'
```

```
--padding 4 characters on the left
SELECT LPAD ('큐브리드', LENGTH('큐브리드')+4, '?');
```

```
lpad('큐브리드', char_length('큐브리드')+4, '?')
=====
'????큐브리드'
```

## LTRIM

### LTRIM(*string*[, *trim\_string*])

The **LTRIM** function removes all specified characters from the left-hand side of a string.

Parameters:

- **string** – Enters a string or string-type column to trim. If this value is **NULL**, **NULL** is returned.
- **trim\_string** – You can specify a specific string to be removed in the left side of *string*. If it is not specified, empty characters (' ') is automatically specified so that the empty characters in the left side are removed.

Return type:

STRING

```
--trimming spaces on the left
SELECT LTRIM ('    Olympic    ');
```

```
ltrim('    Olympic    ')
=====
'Olympic    '
```

```
--If NULL is specified, it returns NULL
SELECT LTRIM ('iiiiOlympiciiii', NULL);
```

```
ltrim('iiiiOlympiciiii', null)
=====
NULL
```

```
-- trimming specific strings on the left
SELECT LTRIM ('iiiiOlympiciiii', 'i');
```

```
ltrim('iiiiOlympiciiii', 'i')
=====
'Olympiciiii'
```

## MID

### MID(*string*, *position*, *substring\_length*)

The **MID** function extracts a string with the length of *substring\_length* from a *position* within the *string* and then returns it. If a negative number is specified as a *position* value, the *position* is calculated in a reverse direction from the end of the *string*. **substring\_length** cannot be omitted. If a negative value is specified, the function considers this as 0 and returns an empty string.

The **MID** function is working like the **SUBSTR()**, but there are differences in that it cannot be used for bit strings, that the *substring\_length* argument must be specified, and that it returns an empty string if a negative number is specified for *substring\_length*.

#### Parameters:

- **string** – Specifies an input character string. If this value is **NULL**, **NULL** is returned.
- **position** – Specifies the starting position from which the string is to be extracted. The position of the first character is 1. It is considered to be 1 even if it is specified as 0. If the input value is **NULL**, **NULL** is returned.
- **substring\_length** – Specifies the length of the string to be extracted. If 0 or a negative number is specified, an empty string is returned; if **NULL** is specified, **NULL** is returned.

#### Return type:

STRING

```
CREATE TABLE mid_tbl(a VARCHAR);
INSERT INTO mid_tbl VALUES('12345abcdeabcde');

--it returns empty string when substring_length is 0
SELECT MID(a, 6, 0), SUBSTR(a, 6, 0), SUBSTRING(a, 6, 0) FROM
mid_tbl;
```

| mid(a, 6, 0) | substr(a, 6, 0) | substring(a from 6 for 0) |
|--------------|-----------------|---------------------------|
| =====        | =====           | =====                     |
| ' '          | ' '             | ' '                       |

```
--it returns 4-length substrings counting from the 6th position
SELECT MID(a, 6, 4), SUBSTR(a, 6, 4), SUBSTRING(a, 6, 4) FROM
mid_tbl;
```

| mid(a, 6, 4) | substr(a, 6, 4) | substring(a from 6 for 4) |
|--------------|-----------------|---------------------------|
| 'abcd'       | 'abcd'          | 'abcd'                    |

```
--it returns an empty string when substring_length < 0
SELECT MID(a, 6, -4), SUBSTR(a, 6, -4), SUBSTRING(a, 6, -4) FROM
mid_tbl;
```

| mid(a, 6, -4) | substr(a, 6, -4) | substring(a from 6 for -4) |
|---------------|------------------|----------------------------|
| ' '           | NULL             | 'abcdeabcde'               |

```
--it returns 4-length substrings at 6th position counting backward
from the end
SELECT MID(a, -6, 4), SUBSTR(a, -6, 4), SUBSTRING(a, -6, 4) FROM
mid_tbl;
```

| mid(a, -6, 4) | substr(a, -6, 4) | substring(a from -6 for 4) |
|---------------|------------------|----------------------------|
| 'eabc'        | 'eabc'           | '1234'                     |

## OCTET\_LENGTH

### OCTET\_LENGTH(string)

The **OCTET\_LENGTH** function returns the length (byte) of a character string or bit string as an integer. Therefore, it returns 1 (byte) if the length of the bit string is 8 bits, but 2 (bytes) if the length is 9 bits.

Parameters:

**string** – Specifies the character or bit string whose length is to be returned in bytes. If the value is **NULL**, **NULL** is returned.

Return type:

INT

```
--character set is UTF-8 for Korean characters
```

```
SELECT OCTET_LENGTH('');
```

```
octet_length('')
=====
0
```

```
SELECT OCTET_LENGTH('CUBRID');
```

```
octet_length('CUBRID')
=====
6
```

```
SELECT OCTET_LENGTH('큐브리드');
```

```
octet_length('큐브리드')
=====
12
```

```
SELECT OCTET_LENGTH(B'010101010');
```

```
octet_length(B'010101010')
=====
2
```

```
CREATE TABLE octet_length_tbl (char_1 CHAR, char_2 CHAR(5),
varchar_1 VARCHAR, bit_var_1 BIT VARYING);
INSERT INTO octet_length_tbl VALUES(' ', ' ', ' ', B' '); --Length of
```

```

empty string
INSERT INTO octet_length_tbl VALUES('a', 'a', 'a', B'010101010'); --
English character
INSERT INTO octet_length_tbl VALUES(NULL, '큐', '큐', B'010101010');
--Korean character and NULL
INSERT INTO octet_length_tbl VALUES(' ', ' 큐', ' 큐', B'010101010');
--Korean character and space

SELECT OCTET_LENGTH(char_1), OCTET_LENGTH(char_2),
OCTET_LENGTH(varchar_1), OCTET_LENGTH(bit_var_1) FROM
octet_length_tbl;

```

```

octet_length(char_1) octet_length(char_2) octet_length(varchar_1)
octet_length(bit_var_1)
=====
=====
1                5
0                0
1                5
1                2
NULL            7
3                2
1                7
4                2

```

## POSITION

### POSITION(*substring IN string*)

The **POSITION** function returns the position of a character string corresponding to *substring* within a character string corresponding to *string*.

An expression that returns a character string or a bit string can be specified as an argument of this function. The return value is an integer greater than or equal to 0. This function returns the position value in character unit for a character string, and in bits for a bit string.

The **POSITION** function is occasionally used in combination with other functions. For example, if you want to extract a certain string from another string, you can use the result of the **POSITION** function as an input to the **SUBSTRING** function.

#### Note

The location is returned in the unit of byte, not the character, in version lower than CUBRID 9.0. The multi-byte charset uses different numbers of bytes to express one character, so the result value may differ.

#### Parameters:

**substring** – Specifies the character string whose position is to be returned. If the value is an empty character, 1 is returned. If the value is **NULL**, **NULL** is returned.

#### Return type:

INT

```
--character set is UTF-8 for Korean characters
--it returns 1 when substring is empty space
SELECT POSITION ('' IN '12345abcdeabcde');
```

```
position('' in '12345abcdeabcde')
=====
1
```

```
--it returns position of the first 'b'
SELECT POSITION ('b' IN '12345abcdeabcde');
```

```
position('b' in '12345abcdeabcde')
=====
7
```

```
-- it returns position of the first '나'
SELECT POSITION ('나' IN '12345가나다라마가나다라마');
```

```
position('나' in '12345가나다라마가나다라마')
=====
7
```

```
--it returns 0 when no substring found in the string
SELECT POSITION ('f' IN '12345abcdeabcde');
```

```
position('f' in '12345abcdeabcde')
=====
0
```

```
SELECT POSITION (B'1' IN B'000011110000');
```

```
position(B'1' in B'000011110000')
=====
5
```

## REPEAT

### REPEAT(*string*, *count*)

The **REPEAT** function returns the character string with a length equal to the number of repeated input character strings. The return value is a **VARCHAR** type. The maximum length of the character string is 33,554,432 and if it this length is exceeded, **NULL** will be returned. If one of the parameters is **NULL**, **NULL** will be returned.

Parameters:

- **substring** – Character string
- **count** – Repeat count. If you enter 0 or a negative number, an empty string will be returned and if you enter a non-numeric data type, an error will be returned.

Return type:

STRING

```
SELECT REPEAT('cubrid',3);
```

```
repeat('cubrid', 3)
=====
'cubridcubridcubrid'
```

```
SELECT REPEAT('cubrid',32000000);
```

```
repeat('cubrid', 32000000)
=====
NULL
```

```
SELECT REPEAT('cubrid',-1);
```

```
repeat('cubrid', -1)
=====
''
```

```
SELECT REPEAT('cubrid','a');
```

```
ERROR: Cannot coerce 'a' to type integer.
```

## REPLACE

REPLACE(*string*, *search\_string*[, *replacement\_string*])

The **REPLACE** function searches for a character string, *search\_string*, within a given character string, *string*, and replaces it with a character string, *replacement\_string*. If the string to be replaced, *replacement\_string* is omitted, all *search\_strings* retrieved from *string* are removed. If **NULL** is specified as an argument, **NULL** is returned.

Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **search\_string** – Specifies the string to be searched. If the value is **NULL**, **NULL** is returned
- **replacement\_string** – Specifies the string to replace the *search\_string*. If this value is omitted, *string* is returned with the *search\_string* removed. If the value is **NULL**, **NULL** is returned.

Return type:

## STRING

```
--it returns NULL when an argument is specified with NULL value
SELECT REPLACE('12345abcdeabcde','abcde',NULL);
```

```
replace('12345abcdeabcde', 'abcde', null)
=====
NULL
```

```
--not only the first substring but all substrings into 'ABCDE' are
replaced
SELECT REPLACE('12345abcdeabcde','abcde','ABCDE');
```

```
replace('12345abcdeabcde', 'abcde', 'ABCDE')
=====
'12345ABCDEABCDE'
```

```
--it removes all of substrings when replace_string is omitted
SELECT REPLACE('12345abcdeabcde','abcde');
```

```
replace('12345abcdeabcde', 'abcde')
=====
'12345'
```

The following shows how to print out the newline as “\n”.

```
-- no_backslash_escapes=yes (default)

CREATE TABLE tbl (cmt_no INT PRIMARY KEY, cmt VARCHAR(1024));
INSERT INTO tbl VALUES (1234,
'This is a test for
new line.');
```

```
SELECT REPLACE(cmt, CHR(10), '\n')
FROM tbl
WHERE cmt_no=1234;
```

```
This is a test for\n\n new line.
```

## REVERSE

### REVERSE(*string*)

The **REVERSE** function returns *string* converted in the reverse order.

#### Parameters:

**string** – Specifies an input character string. If the value is an empty string, empty value is returned. If the value is NULL, NULL is returned.

#### Return type:

STRING

```
SELECT REVERSE( 'CUBRID' );
```

```
reverse( 'CUBRID' )
=====
'DIRBUC'
```

## RIGHT

### RIGHT(*string*, *length*)

The **RIGHT** function returns a *length* number of characters from the rightmost *string*. If any of the arguments is **NULL**, **NULL** is returned. If a value greater than the length of the *string* or a negative number is specified for a *length*, the entire string is returned. To extract a length number of characters from the leftmost string, use the **LEFT()**.

#### Parameters:

- **string** – Input string
- **length** – The length of a string to be returned

#### Return type:

STRING

```
SELECT RIGHT('CUBRID', 3);
```

```
right('CUBRID', 3)
=====
'RID'
```

```
SELECT RIGHT ('CUBRID', 10);
```

```
right('CUBRID', 10)
=====
'CUBRID'
```

## RPAD

RPAD(*char1*, *n* [, *char2*])

The **RPAD** function pads the right side of a string until the string length reaches the specified value.

Parameters:

- **char1** – Specifies the string to pad characters to. If *n* is smaller than the length of *char1*, padding is not performed, and *char1* is truncated to length *n* and then returned. If the value is **NULL**, **NULL** is specified.
- **n** – Specifies the total length of *char1*. If the value is **NULL**, **NULL** is specified.
- **char2** – Specifies the string to pad to the right until the length of *char1* reaches *n*. If it is not specified, empty characters ( ' ') are used as a default. If the value is **NULL**, **NULL** is returned.

Return type:

STRING

### Note

In versions lower than CUBRID 9.0, a single character is processed as 2 or 3 bytes in a multi-byte character set environment. If *n* is truncated up to the first byte representing a character according to a value of *char1*, the last byte is removed and a space character (1 byte) is added to the right because the last character cannot be represented normally. When the value is **NULL**, **NULL** is returned as its result.

```
--character set is UTF-8 for Korean characters

--it returns only 3 characters if not enough length is specified
SELECT RPAD ('CUBRID', 3, '?');
```

```
rpad('CUBRID', 3, '?')
=====
'CUB '
```

```
--on multi-byte charset, it returns the first character only with a
right-padded space
SELECT RPAD ('큐브리드', 3, '?');
```

```
rpad('큐브리드', 3, '?')
=====
'큐브리 '
```

```
--padding spaces on the right till char_length is 10
SELECT RPAD ('CUBRID', 10);
```

```
rpad('CUBRID', 10)
=====
'CUBRID      '
```

```
--padding specific characters on the right till char_length is 10
SELECT RPAD ('CUBRID', 10, '?');
```

```
rpad('CUBRID', 10, '?')
=====
'CUBRID????'
```

```
--padding specific characters on the right till char_length is 10
SELECT RPAD ('큐브리드', 10, '?');
```

```
rpad('큐브리드', 10, '?')
=====
'큐브리드??????'
```

```
--padding 4 characters on the right
SELECT RPAD ('큐브리드', LENGTH('큐브리드')+4, '?');
```

```
rpad('', char_length('')+4, '?')
=====
'큐브리드????'
```

## RTRIM

RTRIM(*string* [, *trim\_string*])

The **RTRIM** function removes specified characters from the right-hand side of a string.

Parameters:

- **string** – Enters a string or string-type column to trim. If this value is **NULL**, **NULL** is returned.
- **trim\_string** – You can specify a specific string to be removed in the right side of *string*. If it is not specified, empty characters (' ') is automatically specified so that the empty characters in the right side are removed.

Return type:

STRING

```
SELECT RTRIM ('      Olympic     ');
```

```
rtrim('      Olympic      ')
=====
'      Olympic'
```

```
--If NULL is specified, it returns NULL
SELECT RTRIM ('iiiiOlympiciiii', NULL);
```

```
rtrim('iiiiOlympiciiii', null)
=====
NULL
```

```
-- trimming specific strings on the right
SELECT RTRIM ('iiiiOlympiciiii', 'i');
```

```
rtrim('iiiiOlympiciiii', 'i')
=====
'iiiiOlympic'
```

## SPACE

### SPACE(*N*)

The **SPACE** function returns as many empty strings as the number specified. The return value is a **VARCHAR** type.

#### Parameters:

**N** – Space count. It cannot be greater than the value specified in the system parameter, **string\_max\_size\_bytes** (default 1048576). If it exceeds the specified value, **NULL** will be returned. The maximum value is 33,554,432; if this length is exceeded, **NULL** will be returned. If you enter 0 or a negative number, an empty string will be returned; if you enter a type that can't be converted to a numeric value, an error will be returned.

#### Return type:

STRING

```
SELECT SPACE(8);
```

```
space(8)
=====
      '      '
```

```
SELECT LENGTH(space(1048576));
```

```
char_length( space(1048576))
=====
                    1048576
```

```
SELECT LENGTH(space(1048577));
```

```
char_length( space(1048577))
=====
                    NULL
```

```
-- string_max_size_bytes=33554432
SELECT LENGTH(space('33554432'));
```

```
char_length( space('33554432'))
=====
                    33554432
```

```
SELECT SPACE('aaa');
```

```
ERROR: Cannot coerce 'aaa' to type bigint.
```

## STRCMP

### STRCMP(*string1*, *string2*)

The **STRCMP** function compares two strings, *string1* and *string2*, and returns 0 if they are identical, 1 if *string1* is greater, or -1 if *string1* is smaller. If any of the parameters is **NULL**, **NULL** is returned.

**Parameters:**

- **string1** – A string to be compared
- **string2** – A string to be compared

**Return type:**

INT

```
SELECT STRCMP('abc', 'abc');
```

```
0
```

```
SELECT STRCMP ('acc', 'abc');
```

```
1
```

**Note**

Until the previous version of 9.0, STRCMP did not distinguish an uppercase and a lowercase. From 9.0, it compares the strings case-sensitively. To make STRCMP case-insensitive, you should use case-insensitive collation(e.g.: utf8\_en\_ci).

```
-- In previous version of 9.0 STRCMP works case-insensitively  
SELECT STRCMP ('ABC', 'abc');
```

```
0
```

```
-- From 9.0 version, STRCMP distinguish the uppercase and the  
lowercase when the collation is case-sensitive.  
-- charset is en_US.iso88591
```

```
SELECT STRCMP ('ABC', 'abc');
```

```
-1
```

```
-- If the collation is case-insensitive, it does not distinguish  
the uppercase and the lowercase.  
-- charset is en_US.iso88591
```

```
SELECT STRCMP ('ABC' COLLATE utf8_en_ci , 'abc' COLLATE utf8_en_ci);
```

```
0
```

## SUBSTR

SUBSTR(*string*, *position*[, *substring\_length*])

The **SUBSTR** function extracts a character string with the length of *substring\_length* from a position, *position*, within character string, *string*, and then returns it.

### Note

In the previous versions of CUBRID 9.0, the starting position and string length are calculated in byte unit, not in character unit; therefore, in a multi-byte character set, you must specify the parameter in consideration of the number of bytes representing a single character.

## Parameters:

- **string** – Specifies the input character string. If the input value is **NULL**, **NULL** is returned.
- **position** – Specifies the position from where the string is to be extracted in bytes. Even though the position of the first character is specified as 1 or a negative number, it is considered as 1. If a value greater than the string length or **NULL** is specified, **NULL** is returned.
- **substring\_length** – Specifies the length of the string to be extracted in bytes. If this argument is omitted, character strings between the given position, *position*, and the end of them are extracted. **NULL** cannot be specified as an argument value of this function. If 0 is specified, an empty string is returned; if a negative value is specified, **NULL** is returned.

## Return type:

STRING

```
--character set is UTF-8 for Korean characters
--it returns empty string when substring_length is 0
SELECT SUBSTR('12345abcdeabcde',6, 0);
```

```
substr('12345abcdeabcde', 6, 0)
=====
''
```

```
--it returns 4-length substrings counting from the position
SELECT SUBSTR('12345abcdeabcde', 6, 4), SUBSTR('12345abcdeabcde',
-6, 4);
```

```
substr('12345abcdeabcde', 6, 4)    substr('12345abcdeabcde', -6, 4)
=====
'abcd'                            'eabc'
```

```
--it returns substrings counting from the position to the end
SELECT SUBSTR('12345abcdeabcde', 6), SUBSTR('12345abcdeabcde', -6);
```

```
substr('12345abcdeabcde', 6)    substr('12345abcdeabcde', -6)
=====
'abcdeabcde'                  'eabcde'
```

```
-- it returns 4-length substrings counting from 11th position
SELECT SUBSTR ('12345가나다라마가나다라마', 11 , 4);
```

```
substr('12345가나다라마가나다라마', 11 , 4)
=====
'가나다라'
```

## SUBSTRING

SUBSTRING ( string, position [, substring\_length]),

SUBSTRING(*string FROM position [FOR substring\_length]*)

The **SUBSTRING** function, operating like **SUBSTR**, extracts a character string having the length of *substring\_length* from a position, *position*, within character string, *string*, and returns it. If a negative number is specified as the *position* value, the **SUBSTRING** function calculates the position from the beginning of the string. And **SUBSTR** function calculates the position from the end of the string. If a negative number is specified as the *substring\_length* value, the **SUBSTRING** function handles the argument is omitted, but the **SUBSTR** function returns **NULL**.

Parameters:

- **string** – Specifies the input character string. If the input value is **NULL**, **NULL** is returned.
- **position** – Specifies the position from where the string is to be extracted. If the position of the first character is specified as 0 or a negative number, it is considered as 1. If a value greater than the string length is specified, an empty string is returned. If **NULL**, **NULL** is returned.
- **substring\_length** – Specifies the length of the string to be extracted. If this argument is omitted, character strings between the given position, *position*, and the end of them

are extracted. **NULL** cannot be specified as an argument value of this function. If 0 is specified, an empty string is returned; if a negative value is specified, **NULL** is returned.

Return type:

STRING

```
SELECT SUBSTRING('12345abcdeabcde', -6 ,4),
SUBSTR('12345abcdeabcde', -6 ,4);
```

```
substring('12345abcdeabcde' from -6 for 4)
substr('12345abcdeabcde', -6, 4)
=====
'1234'                                'eabc'
```

```
SELECT SUBSTRING('12345abcdeabcde', 16), SUBSTR('12345abcdeabcde',
16);
```

```
substring('12345abcdeabcde' from 16)    substr('12345abcdeabcde',
16)
=====
' '                                NULL
```

```
SELECT SUBSTRING('12345abcdeabcde', 6, -4),
SUBSTR('12345abcdeabcde', 6, -4);
```

```
substring('12345abcdeabcde' from 6 for -4)
substr('12345abcdeabcde', 6, -4)
=====
'abcdeabcde'                        NULL
```

## SUBSTRING\_INDEX

SUBSTRING\_INDEX(*string*, *delim*, *count*)

The **SUBSTRING\_INDEX** function counts the separators included in the partial character string and will return the partial character string before the *count*-th separator. The return value is a **VARCHAR** type.

**Parameters:**

- **string** – Input character string. The maximum length is 33,554,432 and if this length is exceeded, **NULL** will be returned.
- **delim** – Delimiter. It is case-sensitive.
- **count** – Delimiter occurrence count. If you enter a positive number, it counts the character string from the left and if you enter a negative number, it counts it from the right. If it is 0, an empty string will be returned. If the type cannot be converted, an error will be returned.

**Return type:**

STRING

```
SELECT SUBSTRING_INDEX('www.cubrid.org','.', '2');
```

```
substring_index('www.cubrid.org', '.', '2')
=====
'www.cubrid'
```

```
SELECT SUBSTRING_INDEX('www.cubrid.org','.', '2.3');
```

```
substring_index('www.cubrid.org', '.', '2.3')
=====
'www.cubrid'
```

```
SELECT SUBSTRING_INDEX('www.cubrid.org', ':', '2.3');
```

```
substring_index('www.cubrid.org', ':', '2.3')
=====
'www.cubrid.org'
```

```
SELECT SUBSTRING_INDEX('www.cubrid.org', 'cubrid', 1);
```

```
substring_index('www.cubrid.org', 'cubrid', 1)
=====
'www.'
```

```
SELECT SUBSTRING_INDEX('www.cubrid.org','.',100);
```

```
substring_index('www.cubrid.org', '.', 100)
=====
'www.cubrid.org'
```

## TO\_BASE64

### TO\_BASE64(*str*)

Returns the result as the transformed base-64 string. If the input argument is not a string, it is changed into a string before it is transformed. If the input argument is **NULL**, it returns **NULL**. The base-64 encoded string can be decoded with `FROM_BASE64()` function.

#### Parameters:

**str** – Input string

#### Return type:

STRING

```
SELECT TO_BASE64('abcd'), FROM_BASE64(TO_BASE64('abcd'));
```

```
to_base64('abcd') from_base64( to_base64('abcd'))
=====
'YWJjZA==' 'abcd'
```

The following is rules for `TO_BASE64()` function and `FROM_BASE64()`.

- The encoded character for the alphabet value 62 is '+'.
- The encoded character for the alphabet value 63 is '/'.
- The encoded result consists of character groups, and each group has 4 characters which can be printed out. The 3 bytes of the input data are encoded into 4 bytes. If the last group are not filled with 4 characters, '=' character is padded into that group and 4 characters are made.

- To divide the long output into the several lines, a newline is added into each 76 encoded output characters.
- Decoding process indicates newline, carriage return, tab, and space and ignore them.

### ! See also

`FROM_BASE64()`

## TRANSLATE

### TRANSLATE(*string*, *from\_substring*, *to\_substring*)

The **TRANSLATE** function replaces a character into the character specified in *to\_substring* if the character exists in the specified *string*. Correspondence relationship is determined based on the order of characters specified in *from\_substring* and *to\_substring*. Any characters in *from\_substring* that do not have one on one relationship to *to\_substring* are all removed. This function is working like the `REPLACE()` but the argument of *to\_substring* cannot be omitted in this function.

#### Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **from\_substring** – Specifies the string to be retrieved. If the value is **NULL**, **NULL** is returned.
- **to\_substring** – Specifies the character string in the *from\_substring* to be replaced. It cannot be omitted. If the value is **NULL**, **NULL** is returned.

#### Return type:

STRING

```
--it returns NULL when an argument is specified with NULL value
SELECT TRANSLATE('12345abcdeabcde', 'abcde', NULL);
```

```

translate('12345abcdeabcde', 'abcde', null)
=====
NULL

```

```

--it translates 'a','b','c','d','e' into '1', '2', '3', '4', '5'
respectively
SELECT TRANSLATE('12345abcdeabcde', 'abcde', '12345');

```

```

translate('12345abcdeabcde', 'abcde', '12345')
=====
'123451234512345'

```

```

--it translates 'a','b','c' into '1', '2', '3' respectively and
removes 'd's and 'e's
SELECT TRANSLATE('12345abcdeabcde','abcde', '123');

```

```

translate('12345abcdeabcde', 'abcde', '123')
=====
'12345123123'

```

```

--it removes 'a's,'b's,'c's,'d's, and 'e's in the string
SELECT TRANSLATE('12345abcdeabcde','abcde', '');

```

```

translate('12345abcdeabcde', 'abcde', '')
=====
'12345'

```

```

--it only translates 'a','b','c' into '3', '4', '5' respectively
SELECT TRANSLATE('12345abcdeabcde','ABabc', '12345');

```

```

translate('12345abcdeabcde', 'ABabc', '12345')
=====
'12345345de345de'

```

## TRIM

**TRIM**([ [ *LEADING* | *TRAILING* | *BOTH* ] [ *trim\_string* ] *FROM* ] *string* )

The **TRIM** function removes specific characters which are located before and after the string.

#### Parameters:

- **trim\_string** – Specifies a specific string to be removed that is in front of or at the back of the target string. If it is not specified, an empty character ( ' ') is automatically specified so that spaces in front of or at the back of the target string are removed.
- **string** – Enters a string or string-type column to trim. If this value is **NULL**, **NULL** is returned.

#### Return type:

STRING

- **[LEADING|TRAILING|BOTH]** : You can specify an option to trim a specified string that is in a certain position of the target string. If it is **LEADING**, trimming is performed in front of a character string if it is **TRAILING**, trimming is performed at the back of a character string if it is **BOTH**, trimming is performed in front and at the back of a character string. If the option is not specified, **BOTH** is specified by default.
- The character string of *trim\_string* and *string* should have the same character set.

```
--trimming NULL returns NULL
SELECT TRIM (NULL);
```

```
trim(both from null)
=====
NULL
```

```
--trimming spaces on both leading and trailing parts
SELECT TRIM ('    Olympic   ');
```

```
trim(both from '    Olympic    ')
=====
'Olympic'
```

```
--trimming specific strings on both leading and trailing parts
SELECT TRIM ('i' FROM 'iiiiOlympiciiii');
```

```
trim(both 'i' from 'iiiiOlympiciiii')
=====
'Olympic'
```

```
--trimming specific strings on the leading part
SELECT TRIM (LEADING 'i' FROM 'iiiiOlympiciiii');
```

```
trim(leading 'i' from 'iiiiOlympiciiii')
=====
'Olympiciiii'
```

```
--trimming specific strings on the trailing part
SELECT TRIM (TRAILING 'i' FROM 'iiiiOlympiciiii');
```

```
trim(trailing 'i' from 'iiiiOlympiciiii')
=====
'iiiiOlympic'
```

## UCASE, UPPER

UCASE(*string*)

UPPER(*string*)

The function **UCASE** or **UPPER** converts lowercase characters that are included in a character string to uppercase characters.

Parameters:

**string** – Specifies the string in which lowercase characters are to be converted to uppercase. If the value is **NULL**, **NULL** is returned.

Return type:

STRING

```
SELECT UPPER('');
```

```
upper('')
=====
''
```

```
SELECT UPPER(NULL);
```

```
upper(null)
=====
NULL
```

```
SELECT UPPER('Cubrid');
```

```
upper('Cubrid')
=====
'CUBRID'
```

Note that the **UPPER** function may not work properly by specified collation. For example, when you try to change character 'ă' used in Romanian as upper character, this function works as follows by collation.

If collation is utf8\_bin, it is not changed.

```
SET NAMES utf8 COLLATE utf8_bin;
SELECT UPPER('ă');
```

```
upper(_utf8'ă')
=====
'ă'
```

If collation is utf8\_ro\_RO, this can be changed.

```
SET NAMES utf8 COLLATE utf8_ro_cs;
SELECT UPPER('ă');
```

```
upper(_utf8'ă' COLLATE utf8_ro_cs)
=====
'Ă'
```

Regarding collations which CUBRID supports, see [CUBRID Collation](#).

## Regular Expressions Functions and Operators

A regular expression is a powerful way to specify a pattern for a complex search. The functions and operators described in this section performs regular expression matching on a string.

## Regular Expressions Pattern Syntax

To implement regular expressions, CUBRID uses the Google RE2 library and the C++ `<regex>` standard library. You can select the regular expression library to use by setting the **regex\_engine** system parameter, and the Google RE2 library is used as a default.

The following sub-sections describes supported regular expression grammars with several examples.

### Note

#### Compatibility Considerations

- In the prior version of CUBRID 11, CUBRID used Henry Spencer's implementation of regular expressions.
  - From the CUBRID 11.0, CUBRID removes the Henry Spencer library and uses C++ `<regex>` standard library to support regular expression functions and operators.
  - From the CUBRID 11.2, CUBRID has added the Google RE2 library. Either C++ `<regex>` or Google RE2 can be used by setting the system parameter.
1. The Henry Spencer's implementation of regular expressions operates in byte-wise fashion. So the REGEXP and RLIKE were not multibyte safe, they only worked as ASCII encoding without considering the collation of operands.
  2. The Spencer library supports the POSIX *collating sequence* expressions (`[.character.]`). But it does not support anymore. Also, *character equivalents* (`[=word=]`) does not support. CUBRID occurs an error when these collating element syntax is given.
  3. The Spencer library matches line-terminator characters for the dot operator (`.`). But it does not.
  4. The word-beginning and word-end boundary (`[[<:]]` and `[[>:]]`) doesn't support anymore. Instead, the word boundary notation (`\b`) can be used.

 **Warning****C++ <regex> library caveats**

There is an issue with the C++ <regex> library that can cause excessive recursive calls when the input string is long or the regular expression pattern is complex. Therefore, it is recommended to use Google RE2 instead of C++ <regex>. C++ <regex> is reserved for backwards compatibility and has been deprecated.

 **Note****Multibyte Character Comparison Considerations**

C++ <regex> performs multibyte comparison by C++ <locale> standard dependent on system-supplied locales. Therefore, system locale should be installed on your system for locale-sensitive functions.

## Special Pattern Characters

Special pattern characters are characters (or sequences of characters) that have a special meaning when they appear in a regular expression pattern, either to represent a character that is difficult to express in a string, or to represent a category of characters. Each of these special pattern characters is matched in a string against a single character (unless a quantifier specifies otherwise).

| Characters | Description                                             |
|------------|---------------------------------------------------------|
| .          | Any character except line terminators (LF, CR, LS, PS). |
| \t         | A horizontal tab character (same as \u0009).            |
| \n         | A newline (line feed) character (same as \u000A).       |

| Characters              | Description                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\v</code>         | A vertical tab character (same as <code>\u000B</code> ).                                                                                     |
| <code>\f</code>         | A form feed character (same as <code>\u000C</code> ).                                                                                        |
| <code>\r</code>         | A carriage return character (same as <code>\u000D</code> ).                                                                                  |
| <code>\cletter</code>   | A control code character whose code unit value is the same as the remainder of dividing the code unit value of <i>letter</i> by 32.          |
| <code>\xhh</code>       | A character whose code unit value has a hex value equivalent to the two hex digits <i>hh</i> .                                               |
| <code>\uhhhh</code>     | A character whose code unit value has a hex value equivalent to the four hex digits <i>hhhh</i> . <i>Only supported in C++ &lt;regex&gt;</i> |
| <code>\x{digits}</code> | A hex character code corresponds to the value of <i>digits</i> . <i>Only supported in Google RE2</i>                                         |
| <code>\0</code>         | A null character (same as <code>\u0000</code> ). <i>Only supported in C++ &lt;regex&gt;</i>                                                  |
| <code>\num</code>       | The result of the submatch whose opening parenthesis is the <i>num</i> -th. See groups below for more info.                                  |
| <code>\d</code>         | A decimal digit character (same as <code>[[:digit:]]</code> ).                                                                               |
| <code>\D</code>         | Any character that is not a decimal digit character (same as <code>[^[:digit:]]</code> ).                                                    |

| Characters              | Description                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\s</code>         | A whitespace character (same as <code>[[:space:]]</code> ).                                                                                                                                                                                                                                |
| <code>\S</code>         | Any character that is not a whitespace character (same as <code>[^[:space:]]</code> ).                                                                                                                                                                                                     |
| <code>\w</code>         | An alphanumeric or underscore character (same as <code>[_[:alnum:]]</code> ).                                                                                                                                                                                                              |
| <code>\W</code>         | Any character that is not an alphanumeric or underscore character (same as <code>[^_[:alnum:]]</code> ).                                                                                                                                                                                   |
| <code>\character</code> | <p>The <i>character</i> character as it is, without interpreting its special meaning within a regex expression.</p> <p>Any character can be escaped except those which form any of the special character sequences above.</p> <p>Needed for: <code>^ \$ \ . * + ? ( ) [ ] { }  </code></p> |
| <code>[class]</code>    | A string is part of the <i>class</i> . see <a href="#">POSIX-based character classes</a> .                                                                                                                                                                                                 |
| <code>[^class]</code>   | A string is not part of the <i>class</i> . see <a href="#">POSIX-based character classes</a> .                                                                                                                                                                                             |
| <code>\p{class}</code>  | A string is range of Unicode range of <i>class</i> . see <a href="#">Unicode Character Class</a> .                                                                                                                                                                                         |

```
-- .: match any character
SELECT ('cubrid dbms' REGEXP '^c.*$');
```

```
('cubrid dbms' regexp '^c.*$')
=====
1
```

To match special characters such as “\n”, “\t”, “\r”, and “\\”, some must be escaped with the backslash (\) by specifying the value of **no\_backslash\_escapes** (default: yes) to **no**. For details on **no\_backslash\_escapes**, see [Escape Special Characters](#).

```
-- \n : match a special character, when no_backslash_escapes=yes
(default)
SELECT ('new\nline' REGEXP 'new\\nline');
```

```
('new\nline' REGEXP 'new\\nline');
=====
1
```

```
-- \n : match a special character, when no_backslash_escapes=no
SELECT ('new\nline' REGEXP 'new
line');
```

```
('new
line' regexp 'new
line')
=====
0
```

## Quantifiers

Quantifiers follow a character or a special pattern character. They can modify the amount of times that character is repeated in the match:

| Characters | Description                               |
|------------|-------------------------------------------|
| *          | The preceding is matched 0 or more times. |
| +          | The preceding is matched 1 or more times. |
| ?          |                                           |

| Characters             | Description                                                                        |
|------------------------|------------------------------------------------------------------------------------|
|                        | The preceding is optional (matched either 0 times or once).                        |
| <code>{num}</code>     | The preceding is matched exactly <i>num</i> times.                                 |
| <code>{num,}</code>    | The preceding is matched <i>num</i> or more times.                                 |
| <code>{min,max}</code> | The preceding is matched at least <i>min</i> times, but not more than <i>max</i> . |

```
-- a+ : match any sequence of one or more a characters. case
insensitive.
SELECT ('Aaaapricot' REGEXP '^A+pricot');
```

```
('Aaaapricot' regexp '^A+pricot')
=====
1
```

```
-- a? : match either zero or one a character.
SELECT ('Apricot' REGEXP '^Aa?pricot');
```

```
('Apricot' regexp '^Aa?pricot')
=====
1
```

```
SELECT ('Aapricot' REGEXP '^Aa?pricot');
```

```
('Aapricot' regexp '^Aa?pricot')
=====
1
```

```
SELECT ('Aaapricot' REGEXP '^Aa?pricot');
```

```
('Aapricot' regexp '^Aa?pricot')
=====
0
```

```
-- (cub)* : match zero or more instances of the sequence abc.
SELECT ('cubcub' REGEXP '^ (cub)*$');
```

```
('cubcub' regexp '^ (cub)*$')
=====
1
```

By default, all these quantifiers perform in a *greedy* way which takes as many characters that meet the condition as possible. And this behavior can be overridden to *non-greedy* by adding a question mark (?) after the quantifier.

```
-- (a+), (a+?) : match with quantifiers performs greedy and ungreedy
respectively.
SELECT REGEXP_SUBSTR ('aardvark', '(a+)'), REGEXP_SUBSTR
('aardvark', '(a+?');
```

```
regexp_substr('aardvark', '(a+)')  regexp_substr('aardvark', '(a+?')
=====
'aa'                                'a'
```

## Groups

Groups allow to apply quantifiers to a sequence of characters (instead of a single character). There are two kinds of groups:

### Warning

a backreference syntax using \$int is supported only in C++ <regex>.

### Characters

### Description

(subpattern)

Group which creates a backreference.

| Characters     | Description                                          |
|----------------|------------------------------------------------------|
| (?:subpattern) | Passive group which does not create a backreference. |

```
-- The captured group can be referenced with $int
SELECT REGEXP_REPLACE ('hello cubrid','([[:alnum:]]+'),' $1!');
```

```
regexp_replace('hello cubrid','([[:alnum:]]+'),' $1!')
=====
'hello! cubrid!'
```

When a group creates a backreference, the characters that represent the subpattern in a string are stored as a submatch. Each submatch is numbered after the order of appearance of their opening parenthesis (the first submatch is number 1, the second is number 2, and so on...). These submatches can be used in the regular expression itself to specify that the entire subpattern should appear again somewhere else (see int in the special characters list). They can also be used in the replacement string in the REGEXP\_REPLACE function.

```
-- performs regexp_substr without groups. the following is the case
that fully matched.
SELECT REGEXP_SUBSTR ('abckabcjabc', '[a-c]{3}k[a-c]{3}j[a-c]{3}');

-- ([a-c]{3}) creates a backreference, \1
SELECT REGEXP_SUBSTR ('abckabcjabc', '([a-c]{3})k\1j\1');
```

```
regexp_substr('abckabcjabc', '[a-c]{3}k[a-c]{3}j[a-c]{3}')
=====
'abckabcjabc'

regexp_substr('abckabcjabc', '([a-c]{3})k\1j\1')
=====
'abckabcjabc'
```

## Assertions

Assertions are conditions that do not consume characters in a string: they do not describe a character, but a condition that must be fulfilled before or after a character.

| Characters | Description                                             |
|------------|---------------------------------------------------------|
| ^          | The beginning of a string, or follows a line terminator |
| \$         | The end of a string, or precedes a line terminator      |

**Note**

The following syntax is supported only in C++ <regex>.

| Characters     | Description                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| \b             | The previous character is a word character and the next is a non-word character (or vice-versa).                      |
| \B             | The previous and next characters are both word characters or both are non-word characters.                            |
| (?=subpattern) | Positive lookahead. The characters following the character must match subpattern, but no characters are consumed.     |
| (?!subpattern) | Negative lookahead. The characters following the assertion must not match subpattern, but no characters are consumed. |

```
-- ^ : match the beginning of a string
SELECT ('cubrid dbms' REGEXP '^cub');
```

```
('cubrid dbms' regexp '^cub')
=====
1
```

```
-- $ : match the end of a string
SELECT ('this is cubrid dbms' REGEXP 'dbms$');
```

```
('this is cubrid dbms' regexp 'dbms$')
=====
1
```

```
-- (?=subpattern): positive lookahead
SELECT REGEXP_REPLACE ('cubrid dbms cubrid sql cubrid rdbms',
'cubrid(?= sql)', 'CUBRID');

-- (?!subpattern): negative lookahead
SELECT REGEXP_REPLACE ('cubrid dbms cubrid sql cubrid rdbms',
'cubrid(?! sql)', 'CUBRID');
```

```
regexp_replace('cubrid dbms cubrid sql cubrid rdbms', 'cubrid(?=
sql)', 'CUBRID')
=====
'cubrid dbms CUBRID sql cubrid rdbms'

regexp_replace('cubrid dbms cubrid sql cubrid rdbms', 'cubrid(?!
sql)', 'CUBRID')
=====
'CUBRID dbms cubrid sql CUBRID rdbms'
```

## Alternatives

A pattern can include different alternatives:

| Characters | Description                                        |
|------------|----------------------------------------------------|
|            | Separates two alternative patterns or subpatterns. |

```
-- a|b : matches any character that is either a or b.
SELECT ('a' REGEXP 'a|b');
SELECT ('d' REGEXP 'a|b');
```

```
('a' regexp 'a|b')
=====
1

('d' regexp 'a|b')
=====
0
```

A regular expression can contain multiple alternative patterns simply by separating them with the separator operator (|): The regular expression will match if any of the alternatives match, and as soon as one does. Subpatterns (in groups or assertions) can also use the separator operator to separate different alternatives.

```
-- a|b|c : matches any character that is either a, b or c.
SELECT ('a' REGEXP 'a|b|c');
SELECT ('d' REGEXP 'a|b|c');
```

```
('a' regexp 'a|b|c')
=====
1

('d' regexp 'a|b|c')
=====
0
```

## Character classes

Character classes syntax matches one of characters or a category of characters within square brackets.

## Individual characters

Any character specified is considered part of the class (except the characters \, [, ]).

```
-- [abc] : matches any character that is either a, b or c.
SELECT ('a' REGEXP '[abc]');
SELECT ('d' REGEXP '[abc]');
```

```

('a' regexp '[abc]')
=====
1

('d' regexp '[abc]')
=====
0

```

## Ranges

To represent a range of characters, use the dash character (-) between two valid characters. For example, “[a-z]” matches any alphabet letter whereas “[0-9]” matches any single number.

```

SELECT ('adf' REGEXP '[a-f]');
SELECT ('adf' REGEXP '[g-z]');

```

```

('adf' regexp '[a-f]')
=====
1

('adf' regexp '[g-z]')
=====
0

```

```

-- [0-9]+: matches number sequence in a string
SELECT REGEXP_SUBSTR ('aas200gjb', '[0-9]+');

```

```

regexp_substr('aas200gjb', '[0-9]+')
=====
'200'

```

```

SELECT ('strike' REGEXP '^[^a-dXYZ]+$');

```

```

('strike' regexp '^[^a-dXYZ]+$')
=====
1

```

## POSIX-based character classes

The POSIX-based character class (`[[:classname:]]`) defines categories of characters as shown below.

### Note

Google RE2 matches only ASCII characters, and C++ `<regex>` matches Unicode characters as well.

| Class                    | Description                             |
|--------------------------|-----------------------------------------|
| <code>[[:alnum:]]</code> | Alpha-numerical character               |
| <code>[[:alpha:]]</code> | Alphabetic character                    |
| <code>[[:blank:]]</code> | Blank character                         |
| <code>[[:cntrl:]]</code> | Control character                       |
| <code>[[:digit:]]</code> | Decimal digit character                 |
| <code>[[:graph:]]</code> | Character with graphical representation |
| <code>[[:lower:]]</code> | Lowercase letter                        |
| <code>[[:print:]]</code> | Printable character                     |
| <code>[[:punct:]]</code> | Punctuation mark character              |
| <code>[[:space:]]</code> | Whitespace character                    |
| <code>[[:upper:]]</code> | Uppercase letter                        |

| Class                   | Description                 |
|-------------------------|-----------------------------|
| <code>[:xdigit:]</code> | Hexadecimal digit character |

`[:d:]`, `[:w:]` and `[:s:]` are an extension to the ECMAScript grammar. Only available in C++ <regex>.

| Class              | Description                   |
|--------------------|-------------------------------|
| <code>[:d:]</code> | Decimal digit character (0-9) |
| <code>[:w:]</code> | Word character                |
| <code>[:s:]</code> | Whitespace character          |

```

```

## Unicode Character Class

Unicode character classes (`\p{classname}`) are only supported by Google RE2. The Unicode class name can be specified as shown in the table below. For example, to match Korean characters, you can use `\p{Hangul}`.

## REGEXP, RLIKE

The **REGEXP** and **RLIKE** are used interchangeably. It performs a regular expression matching of a string. In the below syntax, if *expression* matches *pattern*, 1 is returned; otherwise, 0 is returned. If either *expression* or *pattern* is **NULL**, **NULL** is returned. The second syntax has the same meaning as the third syntax, which both syntaxes are using **NOT**.

```
expression REGEXP | RLIKE [BINARY] pattern
expression NOT REGEXP | RLIKE pattern
NOT (expression REGEXP | RLIKE pattern)
```

- *expression* : Column or input expression
- *pattern* : Pattern used in regular expressions

The difference between **REGEXP** and **LIKE** are as follows:

- The **LIKE** operator succeeds only if the pattern matches the entire value.
- The **REGEXP** operator succeeds if the pattern matches anywhere in the value. To match the entire value, you should use “^” at the beginning and “\$” at the end.
- The **LIKE** operator is case sensitive, but patterns of regular expressions in **REGEXP** is not case sensitive. To enable case sensitive, you should use **REGEXP BINARY** statement.

```
-- [a-dX] : matches any character that is either a, b, c, d or X.
SELECT ('aXbc' REGEXP '[a-dX]');
```

```
('aXbc' regexp '[a-dX]')
=====
1
```

```
-- When REGEXP is used in SELECT list, enclosing this with
parentheses is required.
-- But used in WHERE clause, no need parentheses.
-- case insensitive, except when used with BINARY.
SELECT name FROM public.athlete where name REGEXP '^[a-d]';
```

```
name
=====
'Dziouba Irina'
'Dzieciol Iwona'
'Dzamalutdinov Kamil'
'Crucq Maurits'
'Crosta Daniele'
'Bukovec Brigita'
'Bukic Perica'
'AbduLLayev Namik'
```

## REGEXP\_COUNT

REGEXP\_COUNT(*string*, *pattern\_string*[, *position*[, *match\_type*]])

The **REGEXP\_COUNT** function returns the number of occurrences of the regular expression pattern, *pattern\_string*, within a given character string, *string*. If **NULL** is specified as an argument, **NULL** is returned.

## Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **pattern\_string** – Specifies the regular expression pattern string to be searched. If the value is **NULL**, **NULL** is returned.
- **position** – Specifies the position of the *string* to start the search. If the value is omitted, the default value 1 is applied. If the value is negative or zero, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **match\_type** – Specifies the string to change default matching behavior of the function. If the value is omitted, the default value 'i' is applied. If the value is other than 'c' or 'i', an error will be returned. If the value is **NULL**, **NULL** is returned.

## Return type:

INT

```
-- it returns NULL when an argument is specified with NULL value
SELECT REGEXP_COUNT('ab123ab111a','[a-d]+',NULL);
```

```
regexp_count('ab123ab111a','[a-d]+',NULL)
=====
NULL
```

```
-- an empty string pattern doesn't match with any string
SELECT REGEXP_COUNT('ab123ab111a','');
```

```
regexp_count('ab123ab111a','')
=====
0
```

```
SELECT REGEXP_COUNT('ab123Ab111aAA','[a-d]', 3);
```

```
regexp_count('ab123Ab111aAA', '[a-d]', 3)
=====
5
```

```
-- case insensitive ('i') is the default value
SELECT REGEXP_COUNT('ab123Ab111aAA', '[a-d]', 3, 'i');

-- If case sensitive ('c') is specified as match_type, A is not
matched.
SELECT REGEXP_COUNT('ab123Ab111aAA', '[a-d]', 3, 'c');
```

```
regexp_count('ab123Ab111aAA', '[a-d]', 3, 'i')
=====
5

regexp_count('ab123Ab111aAA', '[a-d]', 3, 'c')
=====
2
```

```

```

```
regexp_count('가나123abc가다abc가가' collate utf8_ko_cs, '[가-나]+'
collate utf8_ko_cs)
=====
=====
3
```

## REGEXP\_INSTR

REGEXP\_INSTR(*string*, *pattern\_string*[, *position*[, *occurrence*[, *return\_option*[, *match\_type*]]])

The **REGEXP\_INSTR** function returns the beginning or ending position by searching for a regular expression pattern, *pattern\_string*, within a given character string, *string*. If **NULL** is specified as an argument, **NULL** is returned.

Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.

- **pattern\_string** – Specifies the regular expression pattern string to be searched. If the value is **NULL**, **NULL** is returned.
- **position** – Specifies the position of the *string* to start the search. If the value is omitted, the default value 1 is applied. If the value is negative or zero, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **occurrence** – Specifies the occurrence of the match to use. If the value is omitted, the default value 1 is applied. If the value is negative, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **return\_option** – Specifies whether to return the position of the start or end of the matched string. If the value is 0, the position of the first character of the match is returned. If the value is 1, the starting position of the matched string is returned. If the value is 2, the end position of the matched string is returned. If the value is other than 0 or 1, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **match\_type** – Specifies the string to change default matching behavior of the function. If the value is omitted, the default value 'i' is applied. If the value is other than 'c' or 'i', an error will be returned. If the value is **NULL**, **NULL** is returned.

Return type:

INT

```
-- it returns NULL when an argument is specified with NULL value
SELECT REGEXP_INSTR('12345abcdeabcde','[abc]',NULL);
```

```
regexp_instr('12345abcdeabcde', '[abc]', null)
=====
NULL
```

```
-- an empty string pattern doesn't match with any string
SELECT REGEXP_INSTR('12345abcdeabcde','');
```

```
regexp_instr('12345abcdeabcde', '')
=====
0
```

```
-- it returns the position of the first character of the match.
SELECT REGEXP_INSTR('12354abc5', '[:alpha:]+', 1, 1, 0);
```

```
regexp_instr('12354abc5', '[:alpha:]+', 1, 1, 0);
=====
6
```

```
-- it returns the position of the character following the match.
SELECT REGEXP_INSTR('12354abc5', '[:alpha:]+', 1, 1, 1);
```

```
regexp_instr('12354abc5', '[:alpha:]+', 1, 1, 1);
=====
7
```

```
SET NAMES utf8 COLLATE utf8_ko_cs;
SELECT REGEXP_INSTR('12345가나다라마가나다라마바', '[가-다]+');
```

```
regexp_instr('12345가나다라마가나다라마바' collate utf8_ko_cs, '[가-다]+'
collate utf8_ko_cs)
=====
=====
6
```

## REGEXP\_LIKE

**REGEXP\_LIKE**(*string*, *pattern\_string* [, *match\_type*])

The **REGEXP\_LIKE** function searches for a regular expression pattern, *pattern\_string*, within a given character string, *string*. If the pattern matched anywhere in the *string*, 1 is returned. Otherwise, 0 is returned. If **NULL** is specified as an argument, **NULL** is returned.

## Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **pattern\_string** – Specifies the regular expression pattern string to be searched. If the value is **NULL**, **NULL** is returned.
- **match\_type** – Specifies the string to change default matching behavior of the function. If the value is omitted, the default value 'i' is applied. If the value is other than 'c' or 'i', an error will be returned. If the value is **NULL**, **NULL** is returned.

## Return type:

INT

```
SELECT REGEXP_LIKE('abbbbc','ab+c');
```

```
regexp_like('abbbbc','ab+c');
=====
1
```

```
-- an empty string pattern doesn't match with any string
SELECT REGEXP_LIKE('abbbbc','');
```

```
regexp_like('abbbbc','');
=====
0
```

```
SELECT REGEXP_LIKE('abbbbc','AB+C','c');
```

```
regexp_like('abbbbc','AB+C');
=====
0
```

```
SET NAMES utf8 COLLATE utf8_ko_cs;
SELECT REGEXP_LIKE('가나다', '가나?다');
SELECT REGEXP_LIKE('가나라다', '가나?다');
```

```
regexp_like('가나다' collate utf8_ko_cs, '가나?다' collate utf8_ko_cs)
=====
=====
1

regexp_like('가나라다' collate utf8_ko_cs, '가나?다' collate utf8_ko_cs)
=====
=====
0
```

## REGEXP\_REPLACE

REGEXP\_REPLACE(*string*, *pattern\_string*, *replacement\_string*[, *position*[, *occurrence*[, *match\_type*]]])

The **REGEXP\_REPLACE** function searches for a regular expression pattern, *pattern\_string*, within a given character string, *string*, and replaces it with a character string, *replacement\_string*. If **NULL** is specified as an argument, **NULL** is returned.

Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **pattern\_string** – Specifies the regular expression pattern string to be searched. If the value is **NULL**, **NULL** is returned.
- **replacement\_string** – Specifies the string to replace the matched string by *pattern\_string*. If the value is **NULL**, **NULL** is returned.
- **position** – Specifies the position of the *string* to start the search. If the value is omitted, the default value 1 is applied. If the value is negative or zero, an error will be returned. If the value is **NULL**, **NULL** is returned.

- **occurrence** – Specifies the occurrence of the pattern to use. If the value is omitted, the default value 0 is applied. If the value is negative, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **match\_type** – Specifies the string to change default matching behavior of the function. If the value is omitted, the default value 'i' is applied. If the value is other than 'c' or 'i', an error will be returned. If the value is **NULL**, **NULL** is returned.

Return type:

STRING

```
-- it returns NULL when an argument is specified with NULL value
SELECT REGEXP_REPLACE('12345abcdeabcde','[a-d]',NULL);
```

```
regexp_replace('12345abcdeabcde', '[a-d]', null)
=====
NULL
```

```
-- an empty string pattern doesn't match with any string
SELECT REGEXP_REPLACE('12345abcdeabcde','', '#');
```

```
regexp_replace('12345abcdeabcde', '', '#')
=====
'12345abcdeabcde'
```

```
SELECT REGEXP_REPLACE('12345abDEKBcde','[a-d]', '#');
```

```
regexp_replace('12345abDEKBcde', '[a-d]', '#')
=====

```

```
-- case insensitive ('i') is the default value
SELECT REGEXP_REPLACE('12345abDEKBcde','[a-d]', '#', 1, 0, 'i');

-- match_type is specified as case sensitive ('c'). 'B' and 'D' are
```

```
not matched.
SELECT REGEXP_REPLACE('12345abDEKBcde','[a-d]','#', 1, 0, 'c');
```

```
regexp_replace('12345abDEKBcde', '[a-d]', '#', 1, 0, 'i')
=====
'12345###EK###e'

regexp_replace('12345abDEKBcde', '[a-d]', '#', 1, 0, 'c')
=====
'12345##DEKB##e'
```

```
SET NAMES utf8 COLLATE utf8_ko_cs;
SELECT REGEXP_REPLACE('a1가b2나다라','[가-다]','#',6);
```

```
regexp_replace('a1가b2나다라' collate utf8_ko_cs, '[가-다]' collate
utf8_ko_cs, '#' collate utf8_ko_cs, 6)
=====
'a1가b2##라'
```

## REGEXP\_SUBSTR

REGEXP\_SUBSTR(*string*, *pattern\_string*[, *position*[, *occurrence*[, *match\_type*]]])

The **REGEXP\_SUBSTR** function extracts a character string matched for a regular expression pattern, *pattern\_string*, within a given character string, *string*. If **NULL** is specified as an argument, **NULL** is returned.

Parameters:

- **string** – Specifies the original string. If the value is **NULL**, **NULL** is returned.
- **pattern\_string** – Specifies the regular expression pattern string to be searched. If the value is **NULL**, **NULL** is returned.
- **position** – Specifies the position of the *string* to start the search. If the value is omitted, the default value 1 is applied. If the value is negative or zero, an error will be returned. If the value is **NULL**, **NULL** is returned.

- **occurrence** – Specifies the occurrence of the pattern to use. If the value is omitted, the default value 0 is applied. If the value is negative, an error will be returned. If the value is **NULL**, **NULL** is returned.
- **match\_type** – Specifies the string to change default matching behavior of the function. If the value is omitted, the default value 'i' is applied. If the value is other than 'c' or 'i', an error will be returned. If the value is **NULL**, **NULL** is returned.

Return type:

STRING

```
-- if pattern is not matched, null is returned
SELECT REGEXP_SUBSTR('12345abcdeabcde','[k-z]+');
```

```
regexp_substr('12345abcdeabcde','[k-z]+');
=====
NULL
```

```
-- an empty string pattern doesn't match with any string
SELECT REGEXP_SUBSTR('12345abcdeabcde','');
```

```
regexp_substr('12345abcdeabcde','')
=====
NULL
```

```

## ABS

### ABS(*number\_expr*)

The **ABS** function returns the absolute value of a given number. The data type of the return value is the same as that of the argument. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**number\_expr** – An operator which returns a numeric value

Return type:

same as that of the argument

```
--it returns the absolute value of the argument
SELECT ABS(12.3), ABS(-12.3), ABS(-12.3000), ABS(0.0);
```

| abs(12.3) | abs(-12.3) | abs(-12.3000) | abs(0.0) |
|-----------|------------|---------------|----------|
| =====     | =====      | =====         | =====    |
| 12.3      | 12.3       | 12.3000       | 0        |

## ACOS

### ACOS(x)

The **ACOS** function returns an arc cosine value of the argument. That is, it returns a value whose cosine is x in radian. The return value is a **DOUBLE** type. x must be a value between -1 and 1, inclusive. Otherwise, **NULL** is returned. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT ACOS(1), ACOS(0), ACOS(-1);
```

| acos(1) | acos(0) | acos(-1) |
|---------|---------|----------|
| =====   | =====   | =====    |

```
=====
0.0000000000000000e+00      1.570796326794897e+00
3.141592653589793e+00
```

## ASIN

### ASIN(x)

The **ASIN** function returns an arc sine value of the argument. That is, it returns a value whose sine is x in radian. The return value is a **DOUBLE** type. x must be a value between -1 and 1, inclusive. Otherwise, **NULL** is returned. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**x** – An expression that returns a numeric value

#### Return type:

DOUBLE

```
SELECT ASIN(1), ASIN(0), ASIN(-1);
```

```
asin(1)              asin(0)              asin(-1)

-1.570796326794897e+00
```

## ATAN

### ATAN([y, ]x)

The **ATAN** function returns a value whose tangent is x in radian. The argument y can be omitted. If y is specified, the function calculates the arc tangent value of y/x. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**x,y** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT ATAN(1), ATAN(-1), ATAN(1,-1);
```

```

              atan(1)              atan(-1)
atan2(1, -1)

## ATAN2

ATAN2(y, x)

The **ATAN2** function returns the arc tangent value of y/x in radian. This function is working like the **ATAN()**. Arguments x and y must be specified. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x,y** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT ATAN2(1,1), ATAN2(-1,-1), ATAN2(Pi(),0);
```

```

              atan2(-1, -1)              atan2( pi(), 0)
atan2(1, 1)

1.570796326794897e+00
```

## CEIL

### CEIL(*number\_operand*)

The **CEIL** function returns the smallest integer that is not less than its argument. The return value is determined based on the valid number of digits that are specified as the *number\_operand* argument. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**number\_operand** – An expression that returns a numeric value

Return type:

INT

```
SELECT CEIL(34567.34567), CEIL(-34567.34567);
```

```

ceil(34567.34567)      ceil(-34567.34567)
=====
34568.00000           -34567.00000

SELECT CEIL(34567.1), CEIL(-34567.1);
```

```

ceil(34567.1)          ceil(-34567.1)
=====
34568.0                -34567.0
```

## CONV

### CONV(*number, from\_base, to\_base*)

The **CONV** function converts numbers between different number bases. This function returns a string representation of a converted number. The minimum value is 2 and the maximum value is 36. If *to\_base* (representing the base to be returned) is negative, *number* is regarded as a signed number. Otherwise, it regarded as a unsigned number. When you input the string which cannot be transformed into the number to *from\_base* or *to\_base*, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

- **number** – An input number
- **from\_base** – The base of an input number
- **to\_base** – The base of an returned value

Return type:

STRING

```
SELECT CONV('f',16,2);
```

```
'1111'
```

```
SELECT CONV('6H',20,8);
```

```
'211'
```

```
SELECT CONV(-30,10,-20);
```

```
'-1A'
```

## COS

### COS(x)

The **COS** function returns a cosine value of the argument. The argument *x* must be a radian value. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT COS(pi()/6), COS(pi()/3), COS(pi());
```

```
cos( pi()/6)          cos( pi()/3)          cos( pi())
=====
=====
8.660254037844387e-01  5.0000000000000001e-01
-1.0000000000000000e+00
```

## COT

COT(*x*)

The **COT** function returns the cotangent value of the argument *x*. That is, it returns a value whose tangent is *x* in radian. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT COT(1), COT(-1), COT(0);
```

```
cot(1)          cot(-1)  cot(0)
=====
=====
6.420926159343306e-01  -6.420926159343306e-01  NULL
```

## CRC32

CRC32(*string*)

The **CRC32** function returns a cyclic redundancy check value as 32-bit integer. When NULL is given as input, it returns NULL.

Parameters:

**string** – An expression that returns a string value

Return type:

INTEGER

```
SELECT CRC32('cubrid');
```

```
crc32('cubrid')
=====
          908740081
```

## DEGREES

### DEGREES(x)

The **DEGREES** function returns the argument *x* specified in radian converted to a degree value. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT DEGREES(pi()/6), DEGREES(pi()/3), DEGREES (pi());
```

```
degrees( pi()/6)          degrees( pi()/3)          degrees(
pi())
=====
=====

1.8000000000000000e+02
```

## DRANDOM, DRAND

DRANDOM([*seed*])

DRAND([*seed*])

The function **DRANDOM** or **DRAND** returns a random double-precision floating point value in the range of between 0.0 and 1.0. A *seed* argument that is **INTEGER** type can be specified. It rounds up real numbers and an error is returned when it exceeds the range of **INTEGER**.

When *seed* value is not given, the **DRAND** function performs the operation only once to produce only one random number regardless of the number of rows where the operation is output, but the **DRANDOM** function performs the operation every time the statement is repeated to produce a different random value for each row. Therefore, to output rows in a random order, you must use the **DRANDOM** function in the **ORDER BY** clause. To obtain a random integer value, use the `RANDOM()`.

Parameters:

**seed** – seed value

Return type:

DOUBLE

```
SELECT DRAND(), DRAND(1), DRAND(1.4);
```

```

                                drand()                                drand(1)

## EXP

### EXP(x)

The **EXP** function returns  $e^x$  (the base of natural logarithm) raised to a power. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**x** – An operator which returns a numeric value

#### Return type:

DOUBLE

```
SELECT EXP(1), EXP(0);
```

```

exp(1)                exp(0)
=====
2.718281828459045e+000 1.0000000000000000e+000

3.678794411714423e-001 7.389056098930650e+000

```

## FLOOR

### FLOOR(number\_operand)

The **FLOOR** function returns the largest integer that is not greater than its argument. The data type of the return value is the same as that of the argument. When you input the

string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**number\_operand** – An operator which returns a numeric value

Return type:

same as that of the argument

```
--it returns the largest integer less than or equal to the arguments
SELECT FLOOR(34567.34567), FLOOR(-34567.34567);
```

```
floor(34567.34567)    floor(-34567.34567)

```

```
floor(34567)    floor(-34567)
=====
34567          -34567
```

## HEX

### HEX(*n*)

The **HEX** function returns a hexadecimal string about the string which is specified as an argument; it returns a hexadecimal string of the number if a number is specified as an argument. If a number is specified as an argument, it returns a value like CONV(num, 10, 16).

Parameters:

**n** – A string or a number

Return type:

STRING

```
SELECT HEX('ab'), HEX(128), CONV(HEX(128), 16, 10);
```

| hex('ab') | hex(128) | conv(hex(128), 16, 10) |
|-----------|----------|------------------------|
| '6162'    | '80'     | '128'                  |

## LN

### LN(x)

The **LN** function returns the natural log value (base = e) of an antilogarithm x. The return value is a **DOUBLE** type. If the antilogarithm is 0 or a negative number, an error is returned. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**x** – An expression that returns a positive number

#### Return type:

DOUBLE

```
SELECT ln(1), ln(2.72);
```

| ln(1)                  | ln(2.72)              |
|------------------------|-----------------------|
| 0.0000000000000000e+00 | 1.000631880307906e+00 |

## LOG

### LOG(x, y)

The **LOG** function returns the logarithm of x with base y, and its return type is **DOUBLE**. If either x or y is 0 or a negative number, the function returns an error. When a non-numeric string is provided as input, the function's behavior depends on the value of the **return\_null\_on\_function\_errors** parameter in **cubrid.conf**.

**Parameters:**

- **x** – The base of the logarithm; it must be an expression that evaluates to a positive value other than 1.
- **y** – The antilogarithm of the logarithm expression; it must be an expression that evaluates to a positive value.

**Return type:**

DOUBLE

```
SELECT log(2,1), log(2,8), log(10,1), log(10,1000);
```

```

log(2,1)          log(2,8)          log(10,
1)               log(10, 1000)
=====

0.000000000000000e+00    3.000000000000000e+00

```

**LOG2****LOG2(x)**

The **LOG2** function returns a log value whose antilogarithm is x and base is 2. The return value is a **DOUBLE** type. If the antilogarithm is 0 or a negative number, an error is returned. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

**Parameters:**

- x** – An expression that returns a positive number

**Return type:**

DOUBLE

```
SELECT log2(1), log2(8);
```

```

log2(1)                                log2(8)
=====
0.0000000000000000e+00                3.0000000000000000e+00

```

## LOG10

### LOG10(x)

The **LOG10** function returns the common log value of an antilogarithm  $x$ . The return value is a **DOUBLE** type. If the antilogarithm is 0 or a negative number, an error is returned. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

**x** – An expression that returns a positive number

#### Return type:

DOUBLE

```
SELECT log10(1), log10(1000);
```

```

log10(1)                                log10(1000)
=====
0.0000000000000000e+00                3.0000000000000000e+00

```

## MOD

### MOD(m, n)

The **MOD** function returns the remainder of the first parameter  $m$  divided by the second parameter  $n$ . If  $n$  is 0 or greater than  $m$ ,  $m$  is returned without the division operation being performed. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Note that if the dividend, the parameter  $m$  of the **MOD** function, is a negative number, the function operates differently from a typical operation (classical modulus) method.

#### Result of MOD

| <b>m</b> | <b>n</b> | <b>MOD(m, n)</b> | <b>Classical Modulus<br/>m-n*FLOOR(m/n)</b> |
|----------|----------|------------------|---------------------------------------------|
| 11       | 4        | 3                | 3                                           |
| 11       | -4       | 3                | -1                                          |
| -11      | 4        | -3               | 1                                           |
| -11      | -4       | -3               | -3                                          |
| 11       | 0        | 11               | Divided by 0 error                          |

#### Parameters:

- **m** – Represents a dividend. It is an expression that returns a numeric value.
- **n** – Represents a divisor. It is an expression that returns a numeric value.

#### Return type:

Result type of m/n

```
--it returns the reminder of m divided by n
SELECT MOD(11, 4), MOD(11, -4), MOD(-11, 4), MOD(-11, -4), MOD(11,0);

## POW, POWER

### POW(x, y)

### POWER(x, y)

The **POW** function returns x to the power of y. The functions **POW** and **POWER** are used interchangeably. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

- **x** – It represents the base. It is an expression that returns a numeric value. An expression that returns a numeric value.

- **y** – It represents the exponent. An expression that returns a numeric value. If the base is a negative number, an integer must specified as the exponent.

Return type:

DOUBLE

```
SELECT POWER(2, 5), POWER(-2, 5), POWER(0, 0), POWER(1,0);
```

```

power(2, 5)           power(-2, 5)           power(0,

exponent
```

```
SELECT POWER(-2, -5.1), POWER(-2, -5.1);
```

```
ERROR: Argument of power() is out of range.
```

## RADIANS

### RADIANS(x)

The **RADIANS** function returns the argument *x* specified in degrees converted to a radian value. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT RADIANS(90), RADIANS(180), RADIANS(360);
```

| radians(90)           | radians(180)          | radians(360)          |
|-----------------------|-----------------------|-----------------------|
| 1.570796326794897e+00 | 3.141592653589793e+00 | 6.283185307179586e+00 |

## RANDOM, RAND

RANDOM([*seed*])

RAND([*seed*])

The function **RANDOM** or **RAND** returns any integer value, which is greater than or equal to 0 and less than  $2^{31}$ , and a *seed* argument that is **INTEGER** type can be specified. It rounds up real numbers and an error is returned when it exceeds the range of **INTEGER**.

When *seed* value is not given, the **RAND** function performs the operation only once to produce only one random number regardless of the number of rows where the operation is output, but the **RANDOM** function performs the operation every time the statement is repeated to produce a different random value for each row. Therefore, to output rows in a random order, you must use the **RANDOM** function.

To obtain a random real number, use the **DRANDOM()**.

Parameters:

**seed**

Return type:

INT

```
SELECT RAND(), RAND(1), RAND(1.4);
```

| rand()     | rand(1)  | rand(1.4) |
|------------|----------|-----------|
| 1526981144 | 89400484 | 89400484  |

## ROUND

### ROUND(*number\_operand*, *integer*)

The **ROUND** function returns the specified argument, *number\_operand*, rounded to the number of places after the decimal point specified by the *integer*. If the *integer* argument is a negative number, it rounds to a place before the decimal point, that is, at the integer part. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

- **number\_operand** – An expression that returns a numeric value
- **integer** – Specifies the place to round to. If a positive integer *n* is specified, the number is represented to the *n*th place after the decimal point; if a negative integer *n* is specified, the number is rounded to the *n*th place before the decimal point.

#### Return type:

same type as the *number\_operand*

```
--it rounds a number to one decimal point when the second argument
is omitted
SELECT ROUND(34567.34567), ROUND(-34567.34567);
```

```
round(34567.34567, 0)    round(-34567.34567, 0)
=====
34567.00000             -34567.00000
```

```
--it rounds a number to three decimal point
SELECT ROUND(34567.34567, 3), ROUND(-34567.34567, 3) FROM db_root;
```

```
round(34567.34567, 3)    round(-34567.34567, 3)
=====
34567.34600            -34567.34600
```

```
--it rounds a number three digit to the left of the decimal point
SELECT ROUND(34567.34567, -3), ROUND(-34567.34567, -3);
```

```
round(34567.34567, -3)    round(-34567.34567, -3)
=====
35000.00000              -35000.00000
```

## SIGN

### SIGN(*number\_operand*)

The **SIGN** function returns the sign of a given number. It returns 1 for a positive value, -1 for a negative value, and 0 for zero. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**number\_operand** – An operator which returns a numeric value

Return type:

INT

```
--it returns the sign of the argument
SELECT SIGN(12.3), SIGN(-12.3), SIGN(0);
```

```
sign(12.3)    sign(-12.3)    sign(0)
=====
1            -1            0
```

## SIN

### SIN(*x*)

The **SIN** function returns a sine value of the parameter. The argument *x* must be a radian value. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT SIN(pi()/6), SIN(pi()/3), SIN(pi());
```

| sin( pi()/6)          | sin( pi()/3)          | sin( pi()) |
|-----------------------|-----------------------|------------|
| =====                 | =====                 | =====      |
| =====                 | =====                 | =====      |
| 4.999999999999999e-01 | 8.660254037844386e-01 |            |
| 1.224646799147353e-16 |                       |            |

## SQRT

### SQRT(*x*)

The **SQRT** function returns the square root of *x* as a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value. An error is returned if this value is a negative number.

Return type:

DOUBLE

```
SELECT SQRT(4), SQRT(16.0);
```

```

      sqrt(4)                                sqrt(16.0)
=====
2.0000000000000000e+00    4.0000000000000000e+00

```

## TAN

### TAN(*x*)

The **TAN** function returns a tangent value of the argument. The argument *x* must be a radian value. The return value is a **DOUBLE** type. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

Parameters:

**x** – An expression that returns a numeric value

Return type:

DOUBLE

```
SELECT TAN(pi()/6), TAN(pi()/3), TAN(pi()/4);
```

```

      tan( pi()/6)                                tan( pi()/3)                                tan( pi()/4)

9.999999999999999e-01

```

## TRUNC, TRUNCATE

### TRUNC(*x*, *dec*)

### TRUNCATE(*x*, *dec*)

The function **TRUNC** or **TRUNCATE** truncates the numbers of the specified argument *x* to the right of the *dec* position. If the *dec* argument is a negative number, it displays 0s to the *dec*-th position left to the decimal point. Note that the *dec* argument of the **TRUNC** function can be omitted, but that of the **TRUNCATE** function cannot be omitted. If the *dec* argument is a negative number, it displays 0s to the *dec* -th position left to the decimal point. The number of digits of the return value to be represented follows the argument *x*. When you input the string which cannot be transformed into the number, it returns an error if the

value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

#### Parameters:

- **x** – An expression that returns a numeric value
- **dec** – The place to be truncated is specified. If a positive integer *n* is specified, the number is represented to the *n*-th place after the decimal point; if a negative integer *n* is specified, the number is truncated to the *n*-th place before the decimal point. It truncates to the first place after the decimal point if the *dec* argument is 0 or omitted. Note that the *dec* argument cannot be omitted in the **TRUNCATE** function.

#### Return type:

same type as the x

```
--it returns a number truncated to 0 places
SELECT TRUNC(34567.34567), TRUNCATE(34567.34567, 0);
```

```
trunc(34567.34567, 0)    trunc(34567.34567, 0)
=====
34567.00000            34567.00000
```

```
--it returns a number truncated to three decimal places
SELECT TRUNC(34567.34567, 3), TRUNC(-34567.34567, 3);
```

```
trunc(34567.34567, 3)    trunc(-34567.34567, 3)
=====
34567.34500             -34567.34500
```

```
--it returns a number truncated to three digits left of the decimal
point
SELECT TRUNC(34567.34567, -3), TRUNC(-34567.34567, -3);
```

```
trunc(34567.34567, -3)   trunc(-34567.34567, -3)
=====
34000.00000             -34000.00000
```

## WIDTH\_BUCKET

**WIDTH\_BUCKET**(*expression*, *from*, *to*, *num\_buckets*)

**WIDTH\_BUCKET** distributes the rows in an ordered partition into a specified number of buckets. The buckets are numbered, starting from one. That is, **WIDTH\_BUCKET** function creates an equi-width histogram. The return value is an integer. When you input the string which cannot be transformed into the number, it returns an error if the value of **return\_null\_on\_function\_errors** in **cubrid.conf** is no(the default), or returns NULL if it is yes.

This function equally divides the range by the given number of buckets and assigns the bucket number to each bucket. That is, every interval (bucket) has the identical size.

Note that **NTILE()** function equally divides the number of rows by the given number of buckets and assigns the bucket number to each bucket. That is, every bucket has the same number of rows.

### Parameters:

- **expression** – an input value to assign the bucket number. It specifies a certain expression which returns the number.
- **from** – a start value of the range, which is given to *expression*. It is included in the entire range.
- **to** – an end value of the range, which is given to *expression*. It is not included in the entire range.
- **num\_buckets** – the number of buckets. The #0 bucket and the #(num\_buckets + 1) bucket are created to include the contents beyond the range.

### Return type:

INT

*expression* is an input value to assign the bucket number. *from* and *to* should be numeric values, date/time values, or the string which can be converted to date/time value. *from* is included in the acceptable range, but *to* is beyond the range.

For example, `WIDTH_BUCKET (score, 80, 50, 3)` returns

- 0 when the score is larger than 80,
- 1 for [80, 70),
- 2 for [70, 60),
- 3 for [60, 50),
- and 4 when the score is 50 or smaller.

The following example divides the range equal to 80 or smaller and larger than 50 into the score range that has the identical score range from 1 to 3. If any score is beyond the range, 0 is given for the score larger than 80 and 4 is given for the score of 50 or smaller than 50.

```
CREATE TABLE t_score (name VARCHAR(10), score INT);
INSERT INTO t_score VALUES
  ('Amie', 60),
  ('Jane', 80),
  ('Lora', 60),
  ('James', 75),
  ('Peter', 70),
  ('Tom', 50),
  ('Ralph', 99),
  ('David', 55);

SELECT name, score, WIDTH_BUCKET (score, 80, 50, 3) grade
FROM t_score
ORDER BY grade ASC, score DESC;
```

| name    | score | grade |
|---------|-------|-------|
| 'Ralph' | 99    | 0     |
| 'Jane'  | 80    | 1     |
| 'James' | 75    | 1     |
| 'Peter' | 70    | 2     |
| 'Amie'  | 60    | 3     |
| 'Lora'  | 60    | 3     |
| 'David' | 55    | 3     |
| 'Tom'   | 50    | 4     |

In the following example, **WIDTH\_BUCKET** function evenly divides the birthdate range into buckets and assigns the bucket number based on the range. It divides the range of eight customers from '1950-01-01' to '1999-12-31' into five buckets based on their dates of birth. If the birthdate value is beyond the range, 0 or 6 (*num\_buckets* + 1) is returned.

```

CREATE TABLE t_customer (name VARCHAR(10), birthdate DATE);
INSERT INTO t_customer VALUES
    ('Amie', date'1978-03-18'),
    ('Jane', date'1983-05-12'),
    ('Lora', date'1987-03-26'),
    ('James', date'1948-12-28'),
    ('Peter', date'1988-10-25'),
    ('Tom', date'1980-07-28'),
    ('Ralph', date'1995-03-17'),
    ('David', date'1986-07-28');

SELECT name, birthdate, WIDTH_BUCKET (birthdate, date'1950-01-01',
date'2000-1-1', 5) age_group
FROM t_customer
ORDER BY birthdate;

```

| name    | birthdate  | age_group |
|---------|------------|-----------|
| 'James' | 12/28/1948 | 0         |
| 'Amie'  | 03/18/1978 | 4         |
| 'Tom'   | 07/28/1980 | 4         |
| 'Jane'  | 05/12/1983 | 5         |
| 'David' | 07/28/1986 | 5         |
| 'Lora'  | 03/26/1987 | 5         |
| 'Peter' | 10/25/1988 | 5         |
| 'Ralph' | 03/17/1995 | 6         |

## ADDDATE, DATE\_ADD

ADDDATE(*date*, *INTERVAL expr unit*)

ADDDATE(*date*, *days*)

DATE\_ADD(*date*, *INTERVAL expr unit*)

The **ADDDATE** function performs an addition or subtraction operation on a specific **DATE** value; **ADDDATE** and **DATE\_ADD** are used interchangeably. The return value is a **DATE** or **DATETIME** type. The **DATETIME** type is returned in the following cases.

- The first argument is a **DATETIME** or **TIMESTAMP** type
- The first argument is a **DATE** type and the unit of **INTERVAL** value specified is less than the unit of day

Therefore, to return value of **DATETIME** type, you should convert the value of first argument by using the **CAST** function. Even though the date resulting from the operation exceeds the last day of the month, the function returns a valid **DATE** value considering the last date of the month.

If every input argument value of date and time is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

If the calculated value is between '0000-00-00 00:00:00' and '0001-01-01 00:00:00', a value having 0 for all arguments is returned in **DATE** or **DATETIME** type. Note that operation in JDBC program is determined by the configuration of zeroDateTimeBehavior, connection URL property. For more information about JDBC connection URL, please see [Configuration Connection](#).

### Parameters:

- **date** – It is a **DATE**, **TIMETIME**, or **TIMESTAMP** expression that represents the start date. If an invalid **DATE** value such as '2006-07-00' is specified, an error is returned.
- **expr** – It represents the interval value to be added to the start date. If a negative number is specified next to the **INTERVAL** keyword, the interval value is subtracted from the start date.
- **unit** – It represents the unit of the interval value specified in the *expr* expression. See the following table to specify the format for the interpretation of the interval value. If the value of *expr* unit is less than the number requested in the *unit*, it is specified from the smallest unit. For

example, if it is HOUR\_SECOND, three values such as 'HOURS:MINUTES:SECONDS' are required. In the case, if only two values such as "1:1" are given, it is regarded as 'MINUTES:SECONDS'.

Return type:

**DATE** or **DATETIME**

#### Format of expr for unit

| unit Value  | expr Format  | Example                                       |
|-------------|--------------|-----------------------------------------------|
| MILLISECOND | MILLISECONDS | ADDDATE(SYSDATE,<br>INTERVAL 123 MILLISECOND) |
| SECOND      | SECONDS      | ADDDATE(SYSDATE,<br>INTERVAL 123 SECOND)      |
| MINUTE      | MINUTES      | ADDDATE(SYSDATE,<br>INTERVAL 123 MINUTE)      |
| HOUR        | HOURS        | ADDDATE(SYSDATE, INTERVAL<br>123 HOUR)        |
| DAY         | DAYS         | ADDDATE(SYSDATE,<br>INTERVAL 123 DAY)         |
| WEEK        | WEEKS        | ADDDATE(SYSDATE, INTERVAL<br>123 WEEK)        |
| MONTH       | MONTHS       | ADDDATE(SYSDATE, INTERVAL<br>12 MONTH)        |
| QUARTER     | QUARTERS     | ADDDATE(SYSDATE,<br>INTERVAL 12 QUARTER)      |

| unit Value         | expr Format                                      | Example                                                            |
|--------------------|--------------------------------------------------|--------------------------------------------------------------------|
| YEAR               | YEARS                                            | ADDDATE(SYSDATE,<br>INTERVAL 12 YEAR)                              |
| SECOND_MILLISECOND | 'SECONDS.MILLISECONDS'                           | ADDDATE(SYSDATE,<br>INTERVAL '12.123'<br>SECOND_MILLISECOND)       |
| MINUTE_MILLISECOND | 'MINUTES:SECONDS.MILLISEC<br>ONDS'               | ADDDATE(SYSDATE,<br>INTERVAL '12:12.123'<br>MINUTE_MILLISECOND)    |

ERROR: Conversion error in date format.
```

```
SELECT ADDDATE('0001-01-01 00:00:00', -1);
```

```
'12:00:00.000 AM 00/00/0000'
```

## ADDTIME

ADDTIME(*expr1*, *expr2*)

The **ADDTIME** function adds or subtracts a value of specific time. The first argument is **DATE**, **DATETIME**, **TIMESTAMP**, or **TIME** type and the second argument is **TIME**, **DATETIME**, or **TIMESTAMP** type. Time should be included in the second argument, and the date of the second argument is ignored. The return type for each argument type is follows:

| First Type       | Argument | Second Type                              | Argument | Return Type | Note                                                     |
|------------------|----------|------------------------------------------|----------|-------------|----------------------------------------------------------|
| TIME             |          | TIME, DATETIME, TIMESTAMP                |          | TIME        | The result value must be equal to or less than 24 hours. |
| DATE             |          | TIME, DATETIME, TIMESTAMP                |          | DATETIME    |                                                          |
| DATETIME         |          | TIME, DATETIME, TIMESTAMP                |          | DATETIME    |                                                          |
| date/time string |          | TIME, DATETIME, TIMESTAMP or time string |          | VARCHAR     | The result string includes time.                         |

Parameters:

- **expr1** – **DATE**, **DATETIME**, **TIME** or **TIMESTAMP** type
- **expr2** – **DATETIME**, **TIMESTAMP**, **TIME** type or date/time string

```
SELECT ADDTIME(datetime'2007-12-31 23:59:59', time'1:1:2');
```

```
01:01:01.000 AM 01/01/2008
```

```
SELECT ADDTIME(time'01:00:00', time'02:00:01');
```

```
03:00:01 AM
```

## ADD\_MONTHS

**ADD\_MONTHS**(*date\_argument*, *month*)

The **ADD\_MONTHS** function adds a *month* value to the expression *date\_argument* of **DATE** type, and it returns a **DATE** type value. If the day (*dd*) of the value specified as an argument exists within the month of the result value of the operation, it returns the given day (*dd*); otherwise returns the last day of the given month (*dd*). If the result value of the operation exceeds the expression range of the **DATE** type, it returns an error.

Parameters:

- **date\_argument** – Specifies an expression of **DATE** type. To specify a **TIMESTAMP** or **DATETIME** value, an explicit casting to **DATE** type is required. If the value is **NULL**, **NULL** is returned.
- **month** – Specifies the number of the months to be added to the *date\_argument*. Both positive and negative values can be specified. If the given value is not an integer type, conversion to an integer type by an implicit casting (rounding to the first place after the decimal point) is performed. If the value is **NULL**, **NULL** is returned.

```
--it returns DATE type value by adding month to the first argument
SELECT ADD_MONTHS(DATE '2008-12-25', 5), ADD_MONTHS(DATE
'2008-12-25', -5);
```

```
05/25/2009
```

```
07/25/2008
```

```
SELECT ADD_MONTHS(DATE '2008-12-31', 5.5), ADD_MONTHS(DATE
'2008-12-31', -5.5);
```

```
06/30/2009
```

```
06/30/2008
```

```
SELECT ADD_MONTHS(CAST (SYS_DATETIME AS DATE), 5), ADD_MONTHS(CAST
(SYS_TIMESTAMP AS DATE), 5);
```

```
07/03/2010
```

```
07/03/2010
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT ADD_MONTHS (datetimeeltz'2001-10-11 10:11:12', 1);
```

```
11/11/2001
```

```
SELECT ADD_MONTHS (datetimeetz'2001-10-11 10:11:12 Europe/Paris', 1);
```

```
11/11/2001
```

```
SELECT ADD_MONTHS (timestamppltz'2001-10-11 10:11:12', 1);
```

```
11/11/2001
```

```
SELECT ADD_MONTHS (timestampptz'2001-10-11 10:11:12 Europe/Paris', 1);
```

```
11/11/2001
```

## CURDATE, CURRENT\_DATE

CURDATE()

CURRENT\_DATE()

### CURRENT\_DATE

**CURDATE** (), **CURRENT\_DATE** and **CURRENT\_DATE** () are used interchangeably and they return the current date of session as the **DATE** type (MM/DD/YYYY or YYYY-MM-DD). The unit is day. When the time zone of the current session is same as that of server, these functions are same as **SYS\_DATE** , **SYSDATE** . Please refer **SYS\_DATE** , **SYSDATE** and the following examples to find a difference and **DBTIMEZONE()** , **SESSIONTIMEZONE()** for details of the functions.

If input every argument value of year, month, and day is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Return type:

DATE

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone           sessiontimezone
=====
'Asia/Seoul'         'Asia/Seoul'
```

```
-- it returns the current date in DATE type
```

```
SELECT CURDATE(), CURRENT_DATE(), CURRENT_DATE, SYS_DATE, SYSDATE;
```

```

    CURRENT_DATE    CURRENT_DATE    CURRENT_DATE    SYS_DATE
SYS_DATE
=====
===
    02/05/2016      02/05/2016      02/05/2016      02/05/2016  02/05/
2016
```

```
-- it returns the date 60 days added to the current date
```

```
SELECT CURDATE()+60;
```

```

CURRENT_DATE +60
=====
04/05/2016

```

```

-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'

SET TIME_ZONE 'America/Los_Angeles';

SELECT DBTIMEZONE(), SESSIONTIMEZONE();

    dbtimezone          sessiontimezone
=====
    'Asia/Seoul'        'America/Los_Angeles'

-- Note that CURDATE() and SYS_DATE returns different results

SELECT CURDATE(), CURRENT_DATE(), CURRENT_DATE, SYS_DATE, SYSDATE;

    CURRENT_DATE    CURRENT_DATE    CURRENT_DATE    SYS_DATE
SYS_DATE
=====
===
    02/04/2016      02/04/2016      02/04/2016      02/05/2016  02/05/
2016

```

### ⚠ Warning

As 10.0, **CURDATE ()**, **CURRENT\_DATE**, **CURRENT\_DATE ()** are different from **SYS\_DATE** and **SYSDATE**. They are synonym for 9.x and lower.

## CURRENT\_DATETIME, NOW

### CURRENT\_DATETIME()

### CURRENT\_DATETIME

### NOW()

**CURRENT\_DATETIME**, **CURRENT\_DATETIME ()** and **NOW ()** are used interchangeably, and they return the current date and time of session in **DATETIME** type. The unit is millisecond. When the time zone of the current session is same as that of server, these functions are same as **SYS\_DATETIME**, **SYSDATETIME**. Please also refer **SYS\_DATETIME**, **SYSDATETIME** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

Return type:

DATETIME

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'
```

```
-- it returns the current date and time in DATETIME type
```

```
SELECT NOW(), SYS_DATETIME;
```

```

CURRENT_DATETIME          SYS_DATETIME
=====
04:05:09.292 PM 02/05/2016  04:05:09.292 PM 02/05/2016
```

```
-- it returns the timestamp value 1 hour added to the current
sys_datetime value
```

```
SELECT TO_CHAR(SYSDATETIME+3600*1000, 'YYYY-MM-DD HH24:MI');
```

```

to_char( SYS_DATETIME +3600*1000, 'YYYY-MM-DD HH24:MI')
=====
'2016-02-05 17:05'
```

```
-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'
```

```
set time zone 'America/Los_Angeles';
```

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'America/Los_Angeles'
```

```
-- Note that NOW() and SYS_DATETIME return different results
```

```
SELECT NOW(), SYS_DATETIME;
```

```

CURRENT_DATETIME          SYS_DATETIME
=====
11:08:57.041 PM 02/04/2016  04:08:57.041 PM 02/05/2016
```

**Warning**

As 10.0, **CURRENT\_DATETIME** (), **NOW** () are different from **SYS\_DATEIME**, **SYSDATETIME**. They are synonym for 9.x and lower.

**CURTIME, CURRENT\_TIME****CURTIME()****CURRENT\_TIME****CURRENT\_TIME()**

**CURTIME** (), **CURRENT\_TIME** and **CURRENT\_TIME** () are used interchangeably and they return the current time of session as **TIME** type (HH:MM:SS). The unit is second. When the time zone of the current session is same as that of server, these functions are same as **SYS\_TIME**, **SYSTIME**. Please also refer **SYS\_TIME**, **SYSTIME** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

Return type:

TIME

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'

-- it returns the current time in TIME type

SELECT CURTIME(), CURRENT_TIME(), CURRENT_TIME, SYS_TIME, SYSTIME;

      CURRENT_TIME      CURRENT_TIME      CURRENT_TIME      SYS_TIME
SYS_TIME
=====
=====
04:22:54 PM      04:22:54 PM      04:22:54 PM      04:22:54 PM      04:22:
54 PM
```

```
-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'

SET TIME ZONE 'AMERICA/LOS_ANGELES';
```

```

SELECT DBTIMEZONE(), SESSIONTIMEZONE();

      dbtimezone              sessiontimezone
=====
'Asia/Seoul'                'America/Los_Angeles'

-- Note that CURTIME() and SYS_TIME return different results

SELECT CURTIME(), CURRENT_TIME(), CURRENT_TIME, SYS_TIME, SYSTIME;

16 PM

```

### Warning

As 10.0, **CURTIME** (), **CURRENT\_TIME** () are different from **SYS\_TIME**, **SYSTIME**. They are synonym for 9.x and lower.

## CURRENT\_TIMESTAMP, LOCALTIME, LOCALTIMESTAMP

### CURRENT\_TIMESTAMP

CURRENT\_TIMESTAMP()

### LOCALTIME

LOCALTIME()

### LOCALTIMESTAMP

LOCALTIMESTAMP()

**CURRENT\_TIMESTAMP**, **CURRENT\_TIMESTAMP** (), **LOCALTIME**, **LOCALTIME** (), **LOCALTIMESTAMP** and **LOCALTIMESTAMP** () are used interchangeably and they return the current date and time of session as **TIMESTAMP** type. The unit is second. When the time zone of the current session is same as that of server, these functions are same as **SYS\_TIMESTAMP**, **SYSTIMESTAMP**. Please also refer **SYS\_TIMESTAMP**, **SYSTIMESTAMP** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

Return type:

## TIMESTAMP

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone           sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'
```

-- it returns the current date and time in TIMESTAMP type of session and server timezones.

```
SELECT LOCALTIME, SYS_TIMESTAMP;
```

```

CURRENT_TIMESTAMP    SYS_TIMESTAMP
=====
04:34:16 PM 02/05/2016  04:34:16 PM 02/05/2016
```

-- change session time from 'Asia/Seoul' to 'America/Los\_Angeles'

```
SET TIME ZONE 'America/Los_Angeles';
```

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone           sessiontimezone
=====
'Asia/Seoul'        'America/Los_Angeles'
```

-- Note that LOCALTIME() and SYS\_TIMESTAMP return different results

```
SELECT LOCALTIME, SYS_TIMESTAMP;
```

```

CURRENT_TIMESTAMP    SYS_TIMESTAMP
=====
11:34:37 PM 02/04/2016  04:34:37 PM 02/05/2016
```

### Warning

As 10.0, **CURRENT\_TIMESTAMP**, **CURRENT\_TIMESTAMP** (), **LOCALTIME**, **LOCALTIME** (), **LOCALTIMESTAMP** and **LOCALTIMESTAMP** () are different from **SYS\_TIMESTAMP** (), **SYSTIMESTAMP**. They are synonym for 9.x and lower.

## DATE

### DATE(*date*)

The **DATE** function extracts the date part from specified argument, and returns it as 'MM/DD/YYYY' format string. Arguments that can be specified are **DATE**, **TIMESTAMP** and **DATETIME** types. The return value is a **VARCHAR** type.

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to date and time, string where 0 is specified for year, month, and day is returned.

Parameters:

**date** – **DATE**, **TIMESTAMP** or **DATETIME** can be specified.

Return type:

STRING

```
SELECT DATE('2010-02-27 15:10:23');
```

```
'02/27/2010'
```

```
SELECT DATE(NOW());
```

```
'04/01/2010'
```

```
SELECT DATE('0000-00-00 00:00:00');
```

```
'00/00/0000'
```

## DATEDIFF

### DATEDIFF(*date1*, *date2*)

The **DATEDIFF** function returns the difference between two arguments as an integer representing the number of days. Arguments that can be specified are **DATE**, **TIMESTAMP** and **DATETIME** types and its return value is only **INTEGER** type.

If every input argument value of date and time is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Parameters:

**date1,date2** – Specifies the types that include date (**DATE**, **TIMESTAMP** or **DATETIME**) type or string that represents the value of corresponding type. If invalid string is specified, an error is returned.

Return type:

INT

```
SELECT DATEDIFF('2010-2-28 23:59:59','2010-03-02');
```

```
-2
```

```
SELECT DATEDIFF('0000-00-00 00:00:00', '2010-2-28 23:59:59');
```

```
ERROR: Conversion error in date format.
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT IF(DATEDIFF('2002-03-03 12:00:00 AM','1990-01-01 11:59:59 PM') = DATEDIFF(timestamptz'2002-03-03 12:00:00 AM',timestamptz'1990-01-01 11:59:59 PM'),'ok','nok');
```

```
'ok'
```

## DATE\_SUB, SUBDATE

DATE\_SUB(*date*, *INTERVAL expr unit*)

SUBDATE(*date*, *INTERVAL expr unit*)

## SUBDATE(*date*, *days*)

The functions **DATE\_SUB** and **SUBDATE** () are used interchangeably and they perform an addition or subtraction operation on a specific **DATE** value. The value is returned in **DATE** or **DATETIME** type. If the date resulting from the operation exceeds the last day of the month, the function returns a valid **DATE** value considering the last date of the month.

If every input argument value of date and time is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

If the calculated value is between '0000-00-00 00:00:00' and '0001-01-01 00:00:00', a value having 0 for all arguments is returned in **DATE** or **DATETIME** type. Note that operation in JDBC program is determined by the configuration of `zeroDateTimeBehavior`, connection URL property (see [Configuration Connection](#) for details).

### param date:

It is a **DATE** or **TIMESTAMP** expression that represents the start date. If an invalid **DATE** value such as '2006-07-00' is specified, **NULL** is returned.

### param expr:

It represents the interval value to be subtracted from the start date. If a negative number is specified next to the **INTERVAL** keyword, the interval value is added to the start date.

### param unit:

It represents the unit of the interval value specified in the *expr* expression. To check the *expr* argument for the unit value, see the table of [ADDDATE\(\)](#).

### rtype:

DATE or DATETIME

```
SELECT SYSDATE, SUBDATE(SYSDATE,INTERVAL 24 HOUR), SUBDATE(SYSDATE,
1);
```

```
03/30/2010 12:00:00.000 AM 03/29/2010 03/29/2010
```

```
--it adds days when argument < 0
SELECT SYSDATE, SUBDATE(SYSDATE,INTERVAL -24 HOUR), SUBDATE(SYSDATE,
-1);
```

```
03/30/2010 12:00:00.000 AM 03/31/2010 03/31/2010
```

```
SELECT SUBDATE('0000-00-00 00:00:00', -50);
```

```
ERROR: Conversion error in date format.
```

```
SELECT SUBDATE('0001-01-01 00:00:00', 10);
```

```
'12:00:00.000 AM 00/00/0000'
```

## DAY, DAYOFMONTH

DAY(*date*)

DAYOFMONTH(*date*)

The function **DAY** or **DAYOFMONTH** returns day in the range of 1 to 31 from the specified parameter. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to year, month, and day, 0 is returned as an exception.

Parameters:

**date** – Date

Return type:

INT

```
SELECT DAYOFMONTH('2010-09-09');
```

9

```
SELECT DAY('2010-09-09 19:49:29');
```

9

```
SELECT DAYOFMONTH('0000-00-00 00:00:00');
```

0

## DAYOFWEEK

### DAYOFWEEK(*date*)

The **DAYOFWEEK** function returns a day in the range of 1 to 7 (1: Sunday, 2: Monday, ..., 7: Saturday) from the specified parameters. The day index is same as the ODBC standards. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

If every input argument value of year, month, and day is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Parameters:

**date** – Date

Return type:

INT

```
SELECT DAYOFWEEK( '2010-09-09' );
```

```
5
```

```
SELECT DAYOFWEEK( '2010-09-09 19:49:29' );
```

```
5
```

```
SELECT DAYOFWEEK( '0000-00-00' );
```

```
ERROR: Conversion error in date format.
```

## DAYOFYEAR

### DAYOFYEAR(*date*)

The **DAYOFYEAR** function returns the day of a year in the range of 1 to 366. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** types; the value is returned in **INTEGER** type.

If every input argument value of year, month, and day is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Parameters:

**date** – Date

Return type:

INT

```
SELECT DAYOFYEAR( '2010-09-09' );
```

```
252
```

```
SELECT DAYOFYEAR('2010-09-09 19:49:29');
```

252

```
SELECT DAYOFYEAR('0000-00-00');
```

```
ERROR: Conversion error in date format.
```

## EXTRACT

EXTRACT(*field FROM date-time\_argument*)

The **EXTRACT** operator extracts the values from *date-time\_argument* and then converts the value type into **INTEGER**.

0 is not allowed in the input argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to date and time, 0 is returned as an exception.

### Parameters:

- **field** – Specifies a value to be extracted from date-time expression.
- **date-time\_argument** – An expression that returns a value of date-time. This expression must be one of **TIME**, **DATE**, **TIMESTAMP**, or **DATETIME** types. If the value is **NULL**, **NULL** is returned.

### Return type:

INT

```
SELECT EXTRACT(MONTH FROM DATETIME '2008-12-25 10:30:20.123');
```

12

```
SELECT EXTRACT(HOUR FROM DATETIME '2008-12-25 10:30:20.123' );
```

```
10
```

```
SELECT EXTRACT(MILLISECOND FROM DATETIME '2008-12-25 10:30:20.123' );
```

```
123
```

```
SELECT EXTRACT(MONTH FROM '0000-00-00 00:00:00');
```

```
0
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT EXTRACT (MONTH FROM datetimetz'10/15/1986 5:45:15.135 am  
Europe/Bucharest');
```

```
10
```

```
SELECT EXTRACT (MONTH FROM datetimeltz'10/15/1986 5:45:15.135 am  
Europe/Bucharest');
```

```
10
```

```
SELECT EXTRACT (MONTH FROM timestamptz'10/15/1986 5:45:15 am Europe/  
Bucharest');
```

```
10
```

```
SELECT EXTRACT (MONTH FROM timestamptz'10/15/1986 5:45:15 am Europe/  
Bucharest');
```

## FROM\_DAYS

### FROM\_DAYS(*N*)

The **FROM\_DAYS** function returns a date value in **DATE** type if **INTEGER** type is inputted as an argument.

It is not recommended to use the **FROM\_DAYS** function for dates prior to the year 1582 because the function does not take dates prior to the introduction of the Gregorian Calendar into account.

If a value in the range of 0 to 3,652,424 can be inputted as an argument. If a value in the range of 0 to 365 is inputted, 0 is returned. 3,652,424, which is the maximum value, means the last day of year 9999.

#### Parameters:

**N** – Integer in the range of 0 to 3,652,424

#### Return type:

DATE

```
SELECT FROM_DAYS(719528);
```

```
01/01/1970
```

```
SELECT FROM_DAYS('366');
```

```
01/03/0001
```

```
SELECT FROM_DAYS(3652424);
```

```
12/31/9999
```

```
SELECT FROM_DAYS(0);
```

```
00/00/0000
```

## FROM\_TZ

### FROM\_TZ(*datetime*, *timezone\_string*)

Converts date/time type without timezone as date/time type with timezone by adding timezone to DATETIME typed value. Input value's type is DATETIME, and the result value's type is DATETIMEZ.

Parameters:

- **datetime** – DATETIME
- **timezone\_string** – String representing a timezone name or and offset '+05:00', 'Asia/Seoul'.

Return type:

DATETIMEZ

```
SELECT FROM_TZ(datetime '10/10/2014 00:00:00 AM', 'Europe/Vienna');
```

```
12:00:00.000 AM 10/10/2014 Europe/Vienna CEST
```

```
SELECT FROM_TZ(datetime '10/10/2014 23:59:59 PM', '+03:25:25');
```

```
11:59:59.000 PM 10/10/2014 +03:25:25
```

For timezone related description, see [Date/Time Types with Timezone](#).

### See also

DBTIMEZONE(), SESSIONTIMEZONE(), NEW\_TIME(), TZ\_OFFSET()

## FROM\_UNIXTIME

### FROM\_UNIXTIME(*unix\_timestamp*[, *format*])

The **FROM\_UNIXTIME** function returns the string of the specified format in **VARCHAR** type if the argument *format* is specified; if the argument *format* is omitted, it returns a value of **TIMESTAMP** type. Specify the argument *unix\_timestamp* as an **INTEGER** type that corresponds to the UNIX timestamp. The returned value is displayed in the current time zone.

It displays the result according to the format that you specified, and the date/time format, *format* follows the Date/Time Format 2 table of [DATE\\_FORMAT\(\)](#).

The relation is not one of one-to-one correspondence between **TIMESTAMP** and UNIX timestamp so if you use [UNIX\\_TIMESTAMP\(\)](#) or **FROM\_UNIXTIME** function, partial value could be lost. For details, see [UNIX\\_TIMESTAMP\(\)](#).

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to date and time, string where 0 is specified for every date and time value is returned. Note that operation in JDBC program is determined by the configuration of zeroDateTimeBehavior, connection URL property (see [Configuration Connection](#) for details).

#### Parameters:

- **unix\_timestamp** – Positive integer
- **format** – Time format. Follows the date/time format of the [DATE\\_FORMAT\(\)](#).

#### Return type:

STRING, INT

```
SELECT FROM_UNIXTIME(1234567890);
```

```
01:31:30 AM 02/14/2009
```

```
SELECT FROM_UNIXTIME('1000000000');
```

```
04:46:40 AM 09/09/2001
```

```
SELECT FROM_UNIXTIME(1234567890,'%M %Y %W');
```

```
'February 2009 Saturday'
```

```
SELECT FROM_UNIXTIME('1234567890','%M %Y %W');
```

```
'February 2009 Saturday'
```

```
SELECT FROM_UNIXTIME(0);
```

```
12:00:00 AM 00/00/0000
```

## hour

### hour(*time*)

The **hour** function extracts the hour from the specified parameter and then returns the value in integer. The type **TIME**, **TIMESTAMP** or **DATETIME** can be specified and a value is returned in the **INTEGER** type.

Parameters:

**time** – Time

Return type:

INT

```
SELECT HOUR('12:34:56');
```

```
12
```

```
SELECT HOUR('2010-01-01 12:34:56');
```

12

```
SELECT HOUR(datetime'2010-01-01 12:34:56');
```

12

## LAST\_DAY

### LAST\_DAY(*date\_argument*)

The **LAST\_DAY** function returns the last day of the given month as **DATE** type.

If every input argument value of year, month, and day is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Parameters:

**date\_argument** – Specifies an expression of **DATE** type. To specify a **TIMESTAMP** or **DATETIME** value, explicit casting to **DATE** is required. If the value is **NULL**, **NULL** is returned.

Return type:

DATE

```
--it returns last day of the month in DATE type
SELECT LAST_DAY(DATE '1980-02-01'), LAST_DAY(DATE '2010-02-01');
```

02/28/1980

02/28/2010

```
--it returns last day of the month when explicitly casted to DATE
type
SELECT LAST_DAY(CAST (SYS_TIMESTAMP AS DATE)), LAST_DAY(CAST
(SYS_DATETIME AS DATE));
```

02/28/2010

02/28/2010

```
SELECT LAST_DAY('0000-00-00');
```

```
ERROR: Conversion error in date format.
```

## MAKEDATE

### MAKEDATE(*year*, *dayofyear*)

The **MAKEDATE** function returns a date from the specified parameter. You can specify an **INTEGER** type corresponding to the day of the year in the range of 1 to 9999 as an argument; the value in the range of 1/1/1 to 12/31/9999 is returned in **DATE** type. If the day of the year has passed the corresponding year, it will become the next year. For example, **MAKEDATE**(1999, 366) will return 2000-01-01. However, if you input a value in the range of 0 to 69 as the year, it will be processed as the year 2000-2069, if it is a value in the range of 70 to 99, it will be processed as the year 1970-1999.

If every value specified in *year* and *dayofyear* is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

#### Parameters:

- **year** – Year in the range of 1 to 9999
- **dayofyear** – If you input a value in the range of 0 to 99 in the argument, it is handled as an exception; *dayofyear* must be equal to or less than 3,615,902 and the return value of **MAKEDATE**(100, 3615902) is 9999/12/31.

#### Return type:

DATE

```
SELECT MAKEDATE(2010,277);
```

```
10/04/2010
```

```
SELECT MAKEDATE(10,277);
```

```
10/04/2010
```

```
SELECT MAKEDATE(70,277);
```

```
10/04/1970
```

```
SELECT MAKEDATE(100,3615902);
```

```
12/31/9999
```

```
SELECT MAKEDATE(9999,365);
```

```
12/31/9999
```

```
SELECT MAKEDATE(0,0);
```

```
ERROR: Conversion error in date format.
```

## MAKETIME

**MAKETIME**(*hour*, *min*, *sec*)

The **MAKETIME** function returns the hour from specified argument in the AM/PM format. You can specify the **INTEGER** types corresponding hours, minutes and seconds as arguments; the value is returned in **DATETIME**.

### Parameters:

- **hour** – An integer representing the hours in the range of 0 to 23
- **min** – An integer representing the minutes in the range of 0 to 59
- **sec** – An integer representing the minutes in the range of 0 to 59

Return type:

DATETIME

```
SELECT MAKETIME(13,34,4);
```

```
01:34:04 PM
```

```
SELECT MAKETIME('1','34','4');
```

```
01:34:04 AM
```

```
SELECT MAKETIME(24,0,0);
```

```
ERROR: Conversion error in time format.
```

## MINUTE

### MINUTE(*time*)

The **MINUTE** function returns the minutes in the range of 0 to 59 from specified argument. You can specify the **TIME**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

Parameters:

**time** – Time

Return type:

INT

```
SELECT MINUTE('12:34:56');
```

```
34
```

```
SELECT MINUTE('2010-01-01 12:34:56');
```

```
34
```

```
SELECT MINUTE('2010-01-01 12:34:56.7890');
```

```
34
```

## MONTH

### MONTH(*date*)

The **MONTH** function returns the month in the range of 1 to 12 from specified argument. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to date, 0 is returned as an exception.

Parameters:

**date** – Date

Return type:

INT

```
SELECT MONTH('2010-01-02');
```

```
1
```

```
SELECT MONTH('2010-01-02 12:34:56');
```

```
1
```

```
SELECT MONTH('2010-01-02 12:34:56.7890');
```

1

```
SELECT MONTH('0000-00-00');
```

0

## MONTHS\_BETWEEN

MONTHS\_BETWEEN(*date\_argument*, *date\_argument*)

The **MONTHS\_BETWEEN** function returns the difference between the given **DATE** value. The return value is **DOUBLE** type. An integer value is returned if the two dates specified as arguments are identical or are the last day of the given month; otherwise, a value obtained by dividing the day difference by 31 is returned.

Parameters:

**date\_argument** – Specifies an expression of **DATE** type. **TIMESTAMP** or **DATETIME** value also can be used. If the value is **NULL**, **NULL** is returned.

Return type:

DOUBLE

```
--it returns the negative months when the first argument is the
previous date
SELECT MONTHS_BETWEEN(DATE '2008-12-31', DATE '2010-6-30');
```

```
-1.8000000000000000e+001
```

```
--it returns integer values when each date is the last date of the
month
SELECT MONTHS_BETWEEN(DATE '2010-6-30', DATE '2008-12-31');
```

```
1.8000000000000000e+001
```

```
--it returns months between two arguments when explicitly casted to
DATE type
SELECT MONTHS_BETWEEN(CAST (SYS_TIMESTAMP AS DATE), DATE
'2008-12-25');
```

```
1.332258064516129e+001
```

```
--it returns months between two arguments when explicitly casted to
DATE type
SELECT MONTHS_BETWEEN(CAST (SYS_DATETIME AS DATE), DATE
'2008-12-25');
```

```
1.332258064516129e+001
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT MONTHS_BETWEEN(datetimetz'2001-10-11 10:11:12 +02:00',
datetimetz'2001-05-11 10:11:12 +03:00');
```

```
5.0000000000000000e+00
```

## NEW\_TIME

### NEW\_TIME(*src\_datetime*, *src\_timezone*, *dst\_timezone*)

Moves a date value from a timezone to the other timezone. The type of *src\_datetime* is DATETIME or TIME, and the return value's type is the same with the *src\_datetime*'s value.

Parameters:

- **src\_datetime** – input value of DATETIME or TIME
- **src\_timezone** – a region name of a source timezone
- **dst\_timezone** – a region name of a target timezone

Return type:

the same type with a *src\_datetimes* type

```
SELECT NEW_TIME(datetime '10/10/2014 10:10:10 AM', 'Europe/Vienna',  
'Europe/Bucharest');
```

```
11:10:10.000 AM 10/10/2014
```

TIME type only accept an offset timezone as an input argument; a region name is not allowed.

```
SELECT NEW_TIME(time '10:10:10 PM', '+03:00', '+10:00');
```

```
05:10:10 AM
```

To see the timezone related description, see [Date/Time Types with Timezone](#).

### See also

`DBTIMEZONE()` , `SESSIONTIMEZONE()` , `FROM_TZ()` , `TZ_OFFSET()`

## QUARTER

### QUARTER(*date*)

The **QUARTER** function returns the quarter in the range of 1 to 4 from specified argument. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

Parameters:

**date** – Date

Return type:

INT

```
SELECT QUARTER('2010-05-05');
```

```
2
```

```
SELECT QUARTER('2010-05-05 12:34:56');
```

2

```
SELECT QUARTER('2010-05-05 12:34:56.7890');
```

2

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT QUARTER('2008-04-01 01:02:03 Asia/Seoul');
```

2

```
SELECT QUARTER(datetimetz'2003-12-31 01:02:03.1234 Europe/Paris');
```

4

## ROUND

ROUND(*date*, *fmt*)

This function rounds date to the unit specified by the format string, *fmt*. It returns a value of DATE type.

param date:

The value of **DATE**, **TIMESTAMP** or **DATETIME**

param fmt:

Specifies the format for the truncating unit. If omitted, “dd” is default.

rtype:

DATE

The format and its unit and the return value are as follows:

| Format          | Unit    | Return value                                                                                    |
|-----------------|---------|-------------------------------------------------------------------------------------------------|
| 'yyyy' or 'yy'  | year    | a value rounded to year                                                                         |
| 'mm' or 'month' | month   | a value rounded to month                                                                        |
| 'q'             | quarter | a value rounded to quarter, one of 1/1, 4/1, 7/1, 10/1                                          |
| 'day'           | week    | a value rounded to week, this Sunday of <i>date</i> week or the next Sunday of <i>date</i> week |
| 'dd'            | day     | a value rounded to day                                                                          |
| 'hh'            | hour    | a value rounded to hour                                                                         |
| 'mi'            | minute  | a value rounded to minute                                                                       |
| 'ss'            | second  | a value rounded to second                                                                       |

```
SELECT ROUND(date'2012-10-26', 'yyyy');
```

```
01/01/2013
```

```
SELECT ROUND(timestamp'2012-10-26 12:10:10', 'mm');
```

```
11/01/2012
```

```
SELECT ROUND(datetime'2012-12-26 12:10:10', 'dd');
```

```
12/27/2012
```

```
SELECT ROUND(datetime'2012-12-26 12:10:10', 'day');
```

```
12/30/2012
```

```
SELECT ROUND(datetime'2012-08-26 12:10:10', 'q');
```

```
10/01/2012
```

```
SELECT TRUNC(datetime'2012-08-26 12:10:10', 'q');
```

```
07/01/2012
```

```
SELECT ROUND(datetime'2012-02-28 23:10:00', 'hh');
```

```
02/28/2012
```

```
SELECT ROUND(datetime'2012-02-28 23:58:59', 'hh');
```

```
02/29/2012
```

```
SELECT ROUND(datetime'2012-02-28 23:59:59', 'mi');
```

```
02/29/2012
```

```
SELECT ROUND(datetime'2012-02-28 23:59:59.500', 'ss');
```

```
02/29/2012
```

In order to truncate date instead of rounding, please see [TRUNC\(date, fmt\)](#).

## SEC\_TO\_TIME

### SEC\_TO\_TIME(*second*)

The **SEC\_TO\_TIME** function returns the time including hours, minutes and seconds from specified argument. You can specify the **INTEGER** type in the range of 0 to 86,399; the value is returned in **TIME** type.

Parameters:

**second** – Seconds in the range of 0 to 86,399

Return type:

TIME

```
SELECT SEC_TO_TIME(82800);
```

```
sec_to_time(82800)
=====
11:00:00 PM
```

```
SELECT SEC_TO_TIME('82800.3');
```

```
sec_to_time('82800.3')
=====
11:00:00 PM
```

```
SELECT SEC_TO_TIME(86399);
```

```
sec_to_time(86399)
=====
11:59:59 PM
```

## SECOND

### SECOND(*time*)

The **SECOND** function returns the seconds in the range of 0 to 59 from specified argument. You can specify the **TIME**, **TIMESTAMP** or **DATETIME**; the value is returned in **INTEGER** type.

Parameters:

**time** – Time

Return type:

INT

```
SELECT SECOND('12:34:56');
```

```
second('12:34:56')
=====
56
```

```
SELECT SECOND('2010-01-01 12:34:56');
```

```
second('2010-01-01 12:34:56')
=====
56
```

```
SELECT SECOND('2010-01-01 12:34:56.7890');
```

```
second('2010-01-01 12:34:56.7890')
=====
56
```

## SYS\_DATE, SYSDATE

### SYS\_DATE

### SYSDATE

**SYS\_DATE** and **SYSDATE** are used interchangeably and they return the current date of server as the **DATE** type (MM/DD/YYYY or YYYY-MM-DD). The unit is day. When the time zone of the current session is same as that of server, these functions are same as **CURDATE()**, **CURRENT\_DATE()** and **CURRENT\_DATE**. Please also refer **CURDATE()**, **CURRENT\_DATE()** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

If input every argument value of year, month, and day is 0, the return value is determined by the **return\_null\_on\_function\_errors** system parameter; if it is set to yes, then **NULL** is returned; if it is set to no, an error is returned. The default value is **no**.

Return type:

DATE

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```
dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'
```

```
-- it returns the current date in DATE type
```

```
SELECT CURDATE(), CURRENT_DATE(), CURRENT_DATE, SYS_DATE, SYSDATE;
```

```

CURRENT_DATE    CURRENT_DATE    CURRENT_DATE    SYS_DATE
SYS_DATE
=====
===
02/05/2016      02/05/2016      02/05/2016      02/05/2016  02/05/
2016
```

```
-- it returns the date 60 days added to the current date
```

```
SELECT CURDATE()+60;
```

```

    CURRENT_DATE +60
=====
04/05/2016

```

```
-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'
```

```
SET TIME_ZONE 'America/Los_Angeles';
```

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

    dbtimezone          sessiontimezone
=====
'Asia/Seoul'          'America/Los_Angeles'

```

```
-- Note that CURDATE() and SYS_DATE returns different results
```

```
SELECT CURDATE(), CURRENT_DATE(), CURRENT_DATE, SYS_DATE, SYSDATE;
```

```

    CURRENT_DATE    CURRENT_DATE    CURRENT_DATE    SYS_DATE
SYS_DATE
=====
02/04/2016        02/04/2016        02/04/2016        02/05/2016  02/05/
2016

```

### Warning

As 10.0, **SYS\_DATE** and **SYSDATE** are different from **CURDATE** (), **CURRENT\_DATE**, **CURRENT\_DATE** (). They are synonym for 9.x and lower.

## SYS\_DATETIME, SYSDATETIME

### SYS\_DATETIME

### SYSDATETIME

**SYS\_DATETIME** and **SYSDATETIME** are used interchangeably, and they return the current date and time of server in **DATETIME** type. The unit is millisecond. When the time zone of the current session is same as that of server, these functions are same as `CURRENT_DATETIME()`,

`CURRENT_DATETIME`, `NOW()`. Please also refer `CURRENT_DATETIME()`, `NOW()` to find a difference and `DBTIMEZONE()`, `SESSIONTIMEZONE()` for details of the functions.

Return type:

DATETIME

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'
```

-- it returns the current date and time in DATETIME type

```
SELECT NOW(), SYS_DATETIME;
```

```

CURRENT_DATETIME    SYS_DATETIME
=====
04:05:09.292 PM 02/05/2016    04:05:09.292 PM 02/05/2016
```

-- it returns the timestamp value 1 hour added to the current sys\_datetime value

```
SELECT TO_CHAR(SYSDATETIME+3600*1000, 'YYYY-MM-DD HH24:MI');
```

```

to_char( SYS_DATETIME +3600*1000, 'YYYY-MM-DD HH24:MI')
=====
'2016-02-05 17:05'
```

-- change session time from 'Asia/Seoul' to 'America/Los\_Angeles'

```
SET TIME_ZONE 'America/Los_Angeles';
```

```
SELECT DBTIMEZONE(), SESSIONTIMEZONE();
```

```

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'America/Los_Angeles'
```

-- Note that NOW() and SYS\_DATETIME return different results

```
SELECT NOW(), SYS_DATETIME;
```

```

CURRENT_DATETIME    SYS_DATETIME
```

```
=====
11:08:57.041 PM 02/04/2016      04:08:57.041 PM 02/05/2016
```

### Warning

As 10.0, **SYS\_DATEIME**, **SYSDATETIME** are different from **CURRENT\_DATETIME** (), **NOW** (). They are synonym for 9.x and lower.

## SYS\_TIME, SYSTIME

### SYS\_TIME

### SYSTIME

**SYS\_TIME** and **SYSTIME** are used interchangeably and they return the current time of server as **TIME** type (HH:MI:SS). The unit is second. When the time zone of the current session is same as that of server, these functions are same as **CURTIME()**, **CURRENT\_TIME**, **CURRENT\_TIME()**. Please also refer **CURTIME()**, **CURRENT\_TIME()** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

Return type:

TIME

```
select dbtimezone(), sessiontimezone();

dbtimezone          sessiontimezone
=====
'Asia/Seoul'        'Asia/Seoul'

-- it returns the current time in TIME type

SELECT CURTIME(), CURRENT_TIME(), CURRENT_TIME, SYS_TIME, SYSTIME;

CURRENT_TIME    CURRENT_TIME    CURRENT_TIME    SYS_TIME
SYS_TIME
=====
=====
04:22:54 PM      04:22:54 PM      04:22:54 PM      04:22:54 PM  04:22:
54 PM
```

```
-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'
```

```

SET TIME_ZONE 'America/Los_Angeles';

select dbtimezone(), sessiontimezone();

    dbtimezone          sessiontimezone
=====
    'Asia/Seoul'        'America/Los_Angeles'

-- Note that CURTIME() and SYS_TIME return different results

SELECT CURTIME(), CURRENT_TIME(), CURRENT_TIME, SYS_TIME, SYSTIME;

    CURRENT_TIME    CURRENT_TIME    CURRENT_TIME    SYS_TIME
SYS_TIME
=====
=====
    11:23:16 PM    11:23:16 PM    11:23:16 PM    04:23:16 PM    04:23:
16 PM

```

### ⚠ Warning

As 10.0, **SYS\_TIME**, **SYSTIME** are different from **CURTIME** (), **CURRENT\_TIME** (). They are synonym for 9.x and lower.

## SYS\_TIMESTAMP, SYSTIMESTAMP

### SYS\_TIMESTAMP

### SYSTIMESTAMP

**SYS\_TIMESTAMP** and **SYSTIMESTAMP** are used interchangeably and they return the current date and time of server as **TIMESTAMP** type. The unit is second. When the time zone of the current session is same as that of server, these functions are same as **CURRENT\_TIMESTAMP**, **CURRENT\_TIMESTAMP()**, **LOCALTIME**, **LOCALTIME()**, **LOCALTIMESTAMP**, **LOCALTIMESTAMP()**. Please also refer **CURRENT\_TIMESTAMP**, **CURRENT\_TIMESTAMP()**, **LOCALTIME**, **LOCALTIME()**, **LOCALTIMESTAMP**, **LOCALTIMESTAMP()** to find a difference and **DBTIMEZONE()**, **SESSIONTIMEZONE()** for details of the functions.

Return type:

TIMESTAMP

```

SELECT DBTIMEZONE(), SESSIONTIMEZONE();

    dbtimezone          sessiontimezone

```

```
=====
'Asia/Seoul'          'Asia/Seoul'

-- it returns the current date and time in TIMESTAMP type of session
and server timezones.

SELECT LOCALTIME, SYS_TIMESTAMP;

CURRENT_TIMESTAMP      SYS_TIMESTAMP
=====
04:34:16 PM 02/05/2016    04:34:16 PM 02/05/2016
```

```
-- change session time from 'Asia/Seoul' to 'America/Los_Angeles'

SET TIME_ZONE 'America/Los_Angeles';

SELECT DBTIMEZONE(), SESSIONTIMEZONE();

dbtimezone      sessiontimezone
=====
'Asia/Seoul'    'America/Los_Angeles'

-- Note that LOCALTIME() and SYS_TIMESTAMP return different results

SELECT LOCALTIME, SYS_TIMESTAMP;

CURRENT_TIMESTAMP      SYS_TIMESTAMP
=====
11:34:37 PM 02/04/2016    04:34:37 PM 02/05/2016
```

### Warning

As 10.0, **SYS\_TIMESTAMP** (), **SYSTIMESTAMP** are different from **CURRENT\_TIMESTAMP**, **CURRENT\_TIMESTAMP** (), **LOCALTIME**, **LOCALTIME** (), **LOCALTIMESTAMP** and **LOCALTIMESTAMP** (). They are synonym for 9.x and lower.

## TIME

### TIME(*time*)

The **TIME** function extracts the time part from specified argument and returns the **VARCHAR** type string in the 'HH:MI:SS' format. You can specify the **TIME**, **TIMESTAMP** and **DATETIME** types.

Parameters:

**time** – Time

Return type:

STRING

```
SELECT TIME('12:34:56');
```

```
time('12:34:56')
=====
'12:34:56'
```

```
SELECT TIME('2010-01-01 12:34:56');
```

```
time('2010-01-01 12:34:56')
=====
'12:34:56'
```

```
SELECT TIME(datetime'2010-01-01 12:34:56');
```

```
time(datetime '2010-01-01 12:34:56')
=====
'12:34:56'
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT TIME(datetimetz'1996-02-03 02:03:04 AM America/Lima PET');
```

```
'02:03:04'
```

```
SELECT TIME(datetimeltz'1996-02-03 02:03:04 AM America/Lima PET');
```

```
'16:03:04'
```

```
SELECT TIME(datetimeltz'2000-12-31 17:34:23.1234 -05:00');
```

```
'07:34:23.123'
```

```
SELECT TIME(datetimetz'2000-12-31 17:34:23.1234 -05:00');
```

```
'17:34:23.123'
```

## TIME\_TO\_SEC

### TIME\_TO\_SEC(*time*)

The **TIME\_TO\_SEC** function returns the seconds in the range of 0 to 86,399 from specified argument. You can specify the **TIME**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

Parameters:

**time** – Time

Return type:

INT

```
SELECT TIME_TO_SEC('23:00:00');
```

```
82800
```

```
SELECT TIME_TO_SEC('2010-10-04 23:00:00');
```

```
82800
```

```
SELECT TIME_TO_SEC('2010-10-04 23:00:00.1234');
```

```
82800
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT TIME_TO_SEC(datetimeltz'1996-02-03 02:03:04 AM America/Lima  
PET');
```

```
57784
```

```
SELECT TIME_TO_SEC(datetimetz'1996-02-03 02:03:04 AM America/Lima  
PET');
```

```
7384
```

## TIMEDIFF

### TIMEDIFF(*expr1*, *expr2*)

The **TIMEDIFF** function returns the time difference between the two specified time arguments. You can enter a date/time type, the **TIME**, **DATE**, **TIMESTAMP** or **DATETIME** type and the data types of the two arguments must be identical. The **TIME** will be returned and the time difference between the two arguments must be in the range of 00:00:00 -23:59:59. If it exceeds the range, an error will be returned.

#### Parameters:

**expr2** (*expr1*,) – Time. The data types of the two arguments must be identical.

#### Return type:

TIME

```
SELECT TIMEDIFF(time '17:18:19', time '12:05:52');
```

```
05:12:27 AM
```

```
SELECT TIMEDIFF('17:18:19','12:05:52');
```

```
05:12:27 AM
```

```
SELECT TIMEDIFF('2010-01-01 06:53:45', '2010-01-01 03:04:05');
```

```
03:49:40 AM
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT TIMEDIFF (datetimeltz'2013-10-28 03:11:12 AM Asia/Seoul',
datetimeltz'2013-10-27 04:11:12 AM Asia/Seoul');
```

```
11:00:00 PM
```

## TIMESTAMP

### TIMESTAMP(*date* [, *time*])

The **TIMESTAMP** function converts a **DATE** or **TIMESTAMP** type expression to **DATETIME** type.

If the **DATE** format string ('YYYY-MM-DD' or 'MM/DD/YYYY') or **TIMESTAMP** format string ('YYYY-MM-DD HH:MI:SS' or 'HH:MI:SS MM/DD/ YYYY') is specified as the first argument, the function returns it as **DATETIME**.

If the **TIME** format string ('HH:MI:SS.\*FF\*') is specified as the second, the function adds it to the first argument and returns the result as a **DATETIME** type. If the second argument is not specified, **12:00:00.000 AM** is specified by default.

#### Parameters:

- **date** – The format strings can be specified as follows:  
'YYYY-MM-DD', 'MM/DD/YYYY', 'YYYY-MM-DD HH:MI:SS.\*FF\*',  
'HH:MI:SS.\*FF\* MM/DD/YYYY'.
- **time** – The format string can be specified as follows:  
'HH:MI:SS\*[\*FF]'

Return type:

DATETIME

```
SELECT TIMESTAMP('2009-12-31'), TIMESTAMP('2009-12-31','12:00:00');
```

```
12:00:00.000 AM 12/31/2009      12:00:00.000 PM 12/31/2009
```

```
SELECT TIMESTAMP('2010-12-31 12:00:00','12:00:00');
```

```
12:00:00.000 AM 01/01/2011
```

```
SELECT TIMESTAMP('13:10:30 12/25/2008');
```

```
01:10:30.000 PM 12/25/2008
```

The following are examples of using timezone type values. For timezone related description, see [Date/Time Types with Timezone](#).

```
SELECT TIMESTAMP(datetimetz'2010-12-31 12:00:00 America/New_York',  
'03:00');
```

```
03:00:00.000 PM 12/31/2010
```

```
SELECT TIMESTAMP(datetimeltz'2010-12-31 12:00:00 America/New_York',  
'03:00');
```

```
05:00:00.000 AM 01/01/2011
```

## TO\_DAYS

### TO\_DAYS(*date*)

The **TO\_DAYS** function returns the number of days after year 0 in the range of 366 to 3652424 from specified argument. You can specify **DATE** type; the value is returned in **INTEGER** type.

It is not recommended to use the **TO\_DAYS** function for dates prior to the year 1582, as the function does not take dates prior to the introduction of the Gregorian Calendar into account.

Parameters:

**date** – Date

Return type:

INT

```
SELECT TO_DAYS('2010-10-04');
```

```
to_days('2010-10-04')
=====
734414
```

```
SELECT TO_DAYS('2010-10-04 12:34:56');
```

```
to_days('2010-10-04 12:34:56')
=====
734414
```

```
SELECT TO_DAYS('2010-10-04 12:34:56.7890');
```

```
to_days('2010-10-04 12:34:56.7890')
=====
734414
```

```
SELECT TO_DAYS('1-1-1');
```

```
to_days('1-1-1')
=====
366
```

```
SELECT TO_DAYS('9999-12-31');
```

```
to_days('9999-12-31')
=====
3652424
```

## TRUNC

TRUNC(*date*[, *fmt*])

This function truncates date to the unit specified by the format string, *fmt*. It returns a value of DATE type.

param date:

The value of **DATE**, **TIMESTAMP** or **DATETIME**

param fmt:

Specifies the format for the truncating unit. If omitted, “dd” is default.

rtype:

DATE

The format and its unit and the return value are as follows:

| Format          | Unit    | Return value                |
|-----------------|---------|-----------------------------|
| 'yyyy' or 'yy'  | year    | the same year with Jan. 1st |
| 'mm' or 'month' | month   | the same month with 1st     |
| 'q'             | quarter |                             |

| Format | Unit | Return value                                                        |
|--------|------|---------------------------------------------------------------------|
|        |      | the same quarter with one of Jan. 1st, Apr. 1st, Jul. 1st, Oct. 1st |
| 'day'  | week | Sunday of the same week(starting date of the week including date)   |
| 'dd'   | day  | the same date with date                                             |

```
SELECT TRUNC(date'2012-12-26', 'yyyy');
```

```
01/01/2012
```

```
SELECT TRUNC(timestamp'2012-12-26 12:10:10', 'mm');
```

```
12/01/2012
```

```
SELECT TRUNC(datetime'2012-12-26 12:10:10', 'q');
```

```
10/01/2012
```

```
SELECT TRUNC(datetime'2012-12-26 12:10:10', 'dd');
```

```
12/26/2012
```

```
-- It returns the date of Sunday of the week which includes
date'2012-12-26'
SELECT TRUNC(datetime'2012-12-26 12:10:10', 'day');
```

```
12/23/2012
```

In order to round date instead of truncation, please see [ROUND\(date, fmt\)](#).

## TZ\_OFFSET

### TZ\_OFFSET(*timezone\_string*)

This returns a timezone offset from a timezone offset or timezone region name (e.g. '-05:00', or 'Europe/Vienna').

Parameters:

**timezone\_string** – timezone offset of timezone region name.

Return type:

STRING

```
SELECT TZ_OFFSET( '+05:00' );
```

```
'+05:00'
```

```
SELECT TZ_OFFSET( 'Asia/Seoul' );
```

```
'+09:00'
```

For timezone related description, see [Date/Time Types with Timezone](#).

### ! See also

[DBTIMEZONE\(\)](#) , [SESSIONTIMEZONE\(\)](#) , [FROM\\_TZ\(\)](#) , [NEW\\_TIME\(\)](#)

## UNIX\_TIMESTAMP

UNIX\_TIMESTAMP(*[date]*)

The argument of the **UNIX\_TIMESTAMP** function can be omitted. If it is omitted, the function returns the interval between '1970-01-01 00:00:00' UTC and the current system date/time in seconds as **INTEGER** type. If the date argument is specified, the function returns the interval between '1970-01-01 00:00:00' UTC and the specified date/time in seconds.

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is given in every argument value corresponding to date and time, 0 is returned as an exception.

Argument of DATETIME type is considered in session timezone.

#### Parameters:

**date** – **DATE** type, **TIMESTAMP** type, **TIMESTAMPPTZ** type, **TIMESTAMPLTZ** type, **DATETIME** type, **DATETIMEZ** type, **DATETIMELTZ** type, **DATE** format string ('YYYY-MM-DD' or 'MM/DD/YYYY'), **TIMESTAMP** format string ('YYYY-MM-DD HH:MI:SS', 'HH:MI:SS MM/DD/YYYY') or 'YYYYMMDD' format string can be specified.

#### Return type:

INT

```
SELECT UNIX_TIMESTAMP('1970-01-02'), UNIX_TIMESTAMP();
```

```
unix_timestamp('1970-01-02')    unix_timestamp()
=====
                        54000                1270196737
```

```
SELECT UNIX_TIMESTAMP ('0000-00-00 00:00:00');
```

```
unix_timestamp('0000-00-00 00:00:00')
=====
                        0
```

```
-- when used without argument, it returns the exact value at the
moment of execution of each occurrence
```

```
SELECT UNIX_TIMESTAMP(), SLEEP(1), UNIX_TIMESTAMP();
```

```
unix_timestamp()    sleep(1)    unix_timestamp()
```

```
=====
1454661297      0      1454661298
```

## UTC\_DATE

### UTC\_DATE()

The **UTC\_DATE** function returns the UTC date in 'YYYY-MM-DD' format.

Return type:

STRING

```
SELECT UTC_DATE();
```

```
utc_date()
=====
01/12/2011
```

## UTC\_TIME

### UTC\_TIME()

The **UTC\_TIME** function returns the UTC time in 'HH:MI:SS' format.

Return type:

STRING

```
SELECT UTC_TIME();
```

```
utc_time()
=====
10:35:52 AM
```

## WEEK

WEEK(*date*[, *mode*])

The **WEEK** function returns the week in the range of 0 to 53 from specified argument. You can specify the **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

**Parameters:**

- **date** – Date
- **mode** – Value in the range of 0 to 7

**Return type:**

INT

You can omit the second argument, *mode* and must input a value in the range of 0 to 7. You can set that a week starts from Sunday or Monday and the range of the return value is from 0 to 53 or 1 to 53 with this value. If you omit the *mode*, the system parameter, **default\_week\_format** value(default: 0) will be used. The *mode* value means as follows:

| mode | Start Day of the Week | Range | The First Week of the Year                                        |
|------|-----------------------|-------|-------------------------------------------------------------------|
| 0    | Sunday                | 0~53  | The first week that Sunday is included in the year                |
| 1    | Monday                | 0~53  | The first week that more than three days are included in the year |
| 2    | Sunday                | 1~53  | The first week in the year that includes a Sunday                 |
| 3    | Monday                | 1~53  | The first week in the year that includes more than three days     |

| mode | Start Day of the Week | Range | The First Week of the Year                                    |
|------|-----------------------|-------|---------------------------------------------------------------|
| 4    | Sunday                | 0~53  | The first week in the year that includes more than three days |
| 5    | Monday                | 0~53  | The first week in the year that includes Monday               |
| 6    | Sunday                | 1~53  | The first week in the year that includes more than three days |
| 7    | Monday                | 1~53  | The first week in the year that includes Monday               |

If the *mode* value is one of 0, 1, 4 or 5, and the date corresponds to the last week of the previous year, the **WEEK** function will return 0. The purpose is to see what nth of the year the week is so it returns 0 for the 52th week of the year 1999.

```
SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
```

```

year('2000-01-01')  week('2000-01-01', 0)
=====
2000                0

```

To see what n-th the week is based on the year including the start day of the week, use 0, 2, 5 or 7 as the *mode* value.

```
SELECT WEEK('2000-01-01',2);
```

```
week('2000-01-01', 2)
=====
52
```

```
SELECT WEEK('2010-04-05');
```

```
week('2010-04-05', 0)
=====
14
```

```
SELECT WEEK('2010-04-05 12:34:56',2);
```

```
week('2010-04-05 12:34:56',2)
=====
14
```

```
SELECT WEEK('2010-04-05 12:34:56.7890',4);
```

```
week('2010-04-05 12:34:56.7890',4)
=====
14
```

## WEEKDAY

### WEEKDAY(*date*)

The **WEEKDAY** function returns the day of week in the range of 0 to 6 (0: Monday, 1: Tuesday, ..., 6: Sunday) from the specified parameter. You can specify **DATE**, **TIMESTAMP**, **DATETIME** types as parameters and an **INTEGER** type will be returned.

Parameters:

**date** – Date

Return type:

INT

```
SELECT WEEKDAY('2010-09-09');
```

```
weekday('2010-09-09')
=====
3
```

```
SELECT WEEKDAY('2010-09-09 13:16:00');
```

```
weekday('2010-09-09 13:16:00')
=====
3
```

## YEAR

### YEAR(*date*)

The **YEAR** function returns the year in the range of 1 to 9,999 from the specified parameter. You can specify **DATE**, **TIMESTAMP** or **DATETIME** type; the value is returned in **INTEGER** type.

Parameters:

**date** – Date

Return type:

INT

```
SELECT YEAR('2010-10-04');
```

```
year('2010-10-04')
=====
2010
```

```
SELECT YEAR('2010-10-04 12:34:56');
```

```
year('2010-10-04 12:34:56')
=====
2010
```

```
SELECT YEAR('2010-10-04 12:34:56.7890');
```

```
year('2010-10-04 12:34:56.7890')
=====
2010
```

## JSON functions

### Introduction to JSON functions

The functions described in this section perform operations on JSON data. All supported JSON functions can be found in next table:

|                   |                    |                         |              |
|-------------------|--------------------|-------------------------|--------------|
| ->                | JSON_CONTAINS_PATH | JSON_MERGE_PATCH        | JSON_REPLACE |
| ->>               | JSON_DEPTH         | JSON_MERGE_PRESE<br>RVE | JSON_SEARCH  |
| JSON_ARRAY        | JSON_EXTRACT       | JSON_OBJECT             | JSON_SET     |
| JSON_ARRAYAGG     | JSON_INSERT        | JSON_OBJECTAGG          | JSON_TABLE   |
| JSON_ARRAY_APPEND | JSON_KEYS          | JSON_PRETTY             | JSON_TYPE    |
| JSON_ARRAY_INSERT | JSON_LENGTH        | JSON_QUOTE              | JSON_UNQUOTE |
| JSON_CONTAINS     | JSON_MERGE         | JSON_REMOVE             | JSON_VALID   |

They have in common several types of input arguments:

- *json\_doc*: a JSON or string that is parsed as JSON
- *val*: a JSON or a value that can be interpreted as one of supported JSON scalar types
- *json key*: a string as key name
- *json path/pointer*: a string that follows the rules explained in [JSON Paths](#) and [JSON Pointers](#).

#### Note

UTF8 is expected to be the codeset of JSON functions string arguments. Inputs with different codesets are implicitly converted to UTF8. One consequence is that searching a case insensitive collation string with a codeset other than UTF8 may not provide expected results.

The next table shows the differences between *json\_doc* and *val* when accepting input arguments:

| Input type             | <i>json_doc</i>                 | <i>val</i>                         |
|------------------------|---------------------------------|------------------------------------|
| JSON                   | Input is unchanged              | Input is unchanged                 |
| String                 | JSON value is parsed from input | Input is converted to JSON STRING  |
| Short, Integer         | Conversion error                | Input is converted to JSON INTEGER |
| Bigint                 | Conversion error                | Input is converted to JSON BIGINT  |
| Float, Double, Numeric | Conversion error                | Input is converted to JSON DOUBLE  |
| NULL                   | NULL                            | Input is converted to JSON_NULL    |

| Input type | <i>json_doc</i>  | <i>val</i>       |
|------------|------------------|------------------|
| Other      | Conversion error | Conversion error |

## JSON\_ARRAY

### JSON\_ARRAY(*[val1 [ , val2] ...]*)

The **JSON\_ARRAY** function returns a json array containing the given list (possibly empty) of values.

```
SELECT JSON_ARRAY();
```

```
json_array()  
=====  
[]
```

```
SELECT JSON_ARRAY(1, '1', json '{"a":4}', json '[1,2,3]');
```

```
json_array(1, '1', json '{"a":4}', json '[1,2,3]')  
=====  
[1,"1",{"a":4},[1,2,3]]
```

## JSON\_OBJECT

### JSON\_OBJECT(*[key1, val1 [ , key2, val2] ...]*)

The **JSON\_OBJECT** function returns a json object containing the given list (possibly empty) of key-value pairs.

```
SELECT JSON_OBJECT();
```

```
json_object()  
=====  
{}
```

```
SELECT JSON_OBJECT('a', 1, 'b', '1', 'c', json '{"a":4}', 'd', json
'[1,2,3]');
```

```
      json_object('a', 1, 'b', '1', 'c', json '{"a":4}', 'd', json
'[1,2,3]')
=====
      {"a":1,"b":"1","c":{"a":4},"d":[1,2,3]}
```

## JSON\_KEYS

**JSON\_KEYS**(*json\_doc* [, *json path*])

The **JSON\_KEYS** function returns a json array of all the object keys of the json object at the given path. Json null is returned if the path addresses a json element that is not a json object. If json path argument is missing, the keys are gathered from json root element. An error occurs if *json path* does not exist. Returns **NULL** if *json\_doc* argument is **NULL**.

```
SELECT JSON_KEYS('{}');
```

```
      json_keys('{}')
=====
      []
```

```
SELECT JSON_KEYS('"non-object"');
```

```
      json_keys('"non-object"')
=====
      null
```

```
SELECT JSON_KEYS('{"a":1, "b":2, "c":{"d":1}}');
```

```
      json_keys('{"a":1, "b":2, "c":{"d":1}}')
=====
      ["a","b","c"]
```

## JSON\_DEPTH

JSON\_DEPTH(*json\_doc*)

The **JSON\_DEPTH** function returns the maximum depth of the json. Depth count starts at 1. The depth level is increased by one by non-empty json arrays or by non-empty json objects. Returns **NULL** if argument is **NULL**.

```
SELECT JSON_DEPTH('"scalar"');
```

```
json_depth('"scalar"')
=====
1
```

```
SELECT JSON_DEPTH('[{"a":4}, 2]');
```

```
json_depth('[{"a":4}, 2]')
=====
3
```

Example of a deeper json:

```
SELECT JSON_DEPTH('[{"a":[1,2,3,{"k":[4,5]}]},2,3,4,5,6,7]');
```

```
json_depth('[{"a":[1,2,3,{"k":[4,5]}]},2,3,4,5,6,7]')
=====
6
```

## JSON\_LENGTH

JSON\_LENGTH(*json\_doc* [, *json path*])

The **JSON\_LENGTH** function returns the length of the json element at the given path. If no path argument is given, the returned value is the length of the root json element. Returns **NULL** if any argument is **NULL** or if no element exists at the given path.

```
SELECT JSON_LENGTH('"scalar"');
```

```
json_length('"scalar"')
=====
1
```

```
SELECT JSON_LENGTH(['{"a":4}, 2'], '$.a');
```

```
json_length(['{"a":4}, 2'], '$.a')
=====
NULL
```

```
SELECT JSON_LENGTH('[2, {"a":4, "b":4, "c":4}]', '$[1]');
```

```
json_length('[2, {"a":4, "b":4, "c":4}]', '$[1]')
=====
3
```

```
SELECT JSON_LENGTH(['{"a":[1,2,3,{"k":[4,5,6,7,8]}}],2]');
```

```
json_length(['{"a":[1,2,3,{"k":[4,5,6,7,8]}}],2]')
=====
2
```

## JSON\_VALID

### JSON\_VALID(*val*)

The **JSON\_VALID** function returns 1 if the given *val* argument is a valid json\_doc, 0 otherwise. Returns **NULL** if argument is **NULL**.

```
SELECT JSON_VALID(['{"a":4}, 2']);
1
SELECT JSON_VALID('{"wrong json object":}');
0
```

## JSON\_TYPE

JSON\_TYPE(*json\_doc*)

The **JSON\_TYPE** function returns the type of the *json\_doc* argument as a string.

```
SELECT JSON_TYPE ( '["a":4], 2]');
'JSON_ARRAY'
SELECT JSON_TYPE ( '{"a":4}');
'JSON_OBJECT'
SELECT JSON_TYPE ( '"aaa"');
'String'
```

## JSON\_QUOTE

JSON\_QUOTE(*str*)

Escapes quotes and special characters and surrounds the resulting string in quotes. Returns result as a json\_string. Returns **NULL** if *str* argument is **NULL**.

```
SELECT JSON_QUOTE ('simple');
```

```
json_unquote('simple')
=====
'"simple"'
```

```
SELECT JSON_QUOTE ('');
```

```
json_unquote('')
=====
'"\\"'
```

## JSON\_UNQUOTE

JSON\_UNQUOTE(*json\_doc*)

Unquotes a json\_value's json string and returns the resulting string. Returns **NULL** if *json\_doc* argument is **NULL**.

```
SELECT JSON_UNQUOTE ( '"\\u0032"');
```

```
json_unquote('"\u0032"')
=====
'2'
```

```
SELECT JSON_UNQUOTE ('"\\""');
```

```
json_unquote('"\\"')
=====
''
```

## JSON\_PRETTY

### JSON\_PRETTY(*json\_doc*)

Returns a string containing the *json\_doc* pretty-printed. Returns **NULL** if *json\_doc* argument is **NULL**.

```
SELECT JSON_PRETTY('["a": "val1", "b": "val2", "c": [1, "elem2", 3, 4, {"key": "val"}]]');
```

```
json_pretty('["a": "val1", "b": "val2", "c": [1, "elem2", 3, 4, {"key": "val"}]]')
=====
'[
{
  "a": "val1",
  "b": "val2",
  "c": [
    1,
    "elem2",
    3,
    4,
    {
      "key": "val"
    }
  ]
}
]'
```

## JSON\_SEARCH

**JSON\_SEARCH**(*json\_doc*, *one/all*, *search\_str* [, *escape\_char* [, *json path*] ...)

Returns a json array of json paths or a single json path which contain json strings matching the given *search\_str*. The matching is performed by applying the **LIKE** operator on internal json strings and *search\_str*. Same rules apply for the *escape\_char* and *search\_str* of **JSON\_SEARCH** as for their counter-parts from the **LIKE** operator. For further description of **LIKE**-related arguments rules refer to **LIKE**.

Using 'one' as one/all argument will cause the **JSON\_SEARCH** to stop after the first match is found. On the other hand, 'all' will force **JSON\_SEARCH** to gather all paths matching the given *search\_str*.

The given json paths determine filters on the returned paths, the resulting json paths's prefixes need to match at least one given json path argument. If no json path argument is given, **JSON\_SEARCH** will execute the search starting from the root element.

```
SELECT JSON_SEARCH('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'one', 'a');
```

```
json_search('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'one', 'a')
=====
"$ .a[0]"
```

```
SELECT JSON_SEARCH('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'all', 'a');
```

```
json_search('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'all', 'a')
=====
["$ .a[0]", "$ .b", "$ .c"]
```

```
SELECT JSON_SEARCH('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'all', 'a',
NULL, '$.a', '$.b');
```

```
json_search('{ "a": ["a", "b"], "b": "a", "c": "a" }', 'all', 'a', null,
'$.a', '$.b')
=====
["$ .a[0]", "$ .b"]
```

Wildcards can be used to define path filters as more general formats. Accepting only json paths that start with object key identifier:

```
SELECT JSON_SEARCH('{ "a":["a","b"],"b":"a","c":"a"}', 'all', 'a',
NULL, '$.*');
```

```
json_search('{ "a":["a","b"],"b":"a","c":"a"}', 'all', 'a', null,
'$.*')
=====
["$a[0]","$.b","$.c"]
```

Accepting only json paths that start with object key identifier and follow immediately with a json array index will filter out '\$.b', '\$.d.e[0]' matches:

```
SELECT JSON_SEARCH('{ "a":["a","b"],"b":"a","c":["a"], "d":{"e":
["a"]}}', 'all', 'a', NULL, '$.*[*]');
```

```
json_search('{ "a":["a","b"],"b":"a","c":["a"], "d":{"e":["a"]}}',
'all', 'a', null, '$.*[*]')
=====
["$a[0]","$.c[0]"]
```

Accepting any paths that contain json array indexes will filter out '\$.b'

```
SELECT JSON_SEARCH('{ "a":["a","b"],"b":"a","c":["a"], "d":{"e":
["a"]}}', 'all', 'a', NULL, '$**[*]');
```

```
json_search('{ "a":["a","b"],"b":"a","c":["a"], "d":{"e":["a"]}}',
'all', 'a', null, '$**[*]')
=====
["$a[0]","$.c[0]","$.d.e[0]"]
```

## JSON\_EXTRACT

**JSON\_EXTRACT**(*json\_doc*, *json path* [, *json path*] ...)

Returns json elements from the *json\_doc*, that are addressed by the given paths. If json path arguments contain wildcards, all elements that are addressed by a path compatible with the wildcards-containing json path are gathered in a resulting json array. A single json element is returned if no wildcards are used in the given json paths and a single element is found, otherwise the json elements found are wrapped in a json array. Raises an error if a json path is **NULL** or invalid or if *json\_doc* argument is invalid. Returns **NULL** if no elements are found or if *json\_doc* is **NULL**.

```
SELECT JSON_EXTRACT('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}', '$.a');
```

```
json_extract('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}',
'$.a')
=====
"[a","b]" -- at '$.a' we have the json array ["a","b"]
```

```
SELECT JSON_EXTRACT('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}', '$.a[*]');
```

```
json_extract('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}',
'$.a[*]')
=====
"[a","b]" -- '$.a[0]' and '$.a[1]' wrapped in a json array,
forming ["a","b"]
```

Changing 'a' from previous query with '\*' wildcards will also match '\$.c[0]'. This will match any json path that is exactly an object key identifier followed by an array index.

```
SELECT JSON_EXTRACT('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}', '$.*[*]');
```

```
json_extract('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}',
'$.**[*]')
=====
"[a","b","a"]"
```

The following json path will match all json paths that end with a json array index (matches all previous matched paths and, in addition, '\$.d.e[0]'):

```
SELECT JSON_EXTRACT('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}', '$.**[*]');
```

```
json_extract('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}',
'$.**[*]')
=====
"[a","b","a","a"]"
```

```
SELECT JSON_EXTRACT('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}', '$.d**[*]');
```

```
json_extract('{ "a":["a","b"], "b":"a", "c":["a"], "d":{"e":["a"]}}',
'$d**[*]')
=====
"[a]" -- '$.d.e[0]' is the only path matching the given argument
path family - paths that start with '.d' and end with an array index
```

->

json\_doc -> json path

Alias operator for **JSON\_EXTRACT** with two arguments, having the *json\_doc* argument constrained to be a column. Raises an error if the json path is **NULL** or invalid. Returns **NULL** if it is applied on a **NULL** *json\_doc* argument.

```
CREATE TABLE tj (a json);
INSERT INTO tj values ('{"a":1}'), ('{"a":2}'), ('{"a":3}'), (NULL);

SELECT a->'$.a' from tj;
```

```
json_extract(a, '$.a')
=====
1
2
3
NULL
```

->>

json\_doc ->> json path

Alias for **JSON\_UNQUOTE** (json\_doc->json path). Operator can be applied only on *json\_doc* arguments that are columns. Raises an error if the json path is **NULL** or invalid. Returns **NULL** if it is applied on a **NULL** *json\_doc* argument.

```
CREATE TABLE tj (a json);
INSERT INTO tj values ('{"a":1}'), ('{"a":2}'), ('{"a":3}'), (NULL);

SELECT a->>'$.a' from tj;
```

```

json_unquote(json_extract(a, '$.a'))
=====
'1'
'2'
'3'
NULL

```

## JSON\_CONTAINS\_PATH

### JSON\_CONTAINS\_PATH(*json\_doc*, *one/all*, *json path* [, *json path*] ...)

The **JSON\_CONTAINS\_PATH** function verifies whether the given paths exist inside the *json\_doc*.

When one/all argument is 'all', all given paths must exist to return 1. Returns 0 otherwise.

When one/all argument is 'one', it returns 1 if any given path exists. Returns 0 otherwise.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

```

SELECT JSON_CONTAINS_PATH ('[{"0":0},1,"2",{"three":3}]', 'all',
'$[0]', '$[0].0"', '$[1]', '$[2]', '$[3]');

```

```

json_contains_path('[{"0":0},1,"2",{"three":3}]', 'all', '$[0]',
'$[0].0"', '$[1]', '$[2]', '$[3]')
=====
=====

```

1

```

SELECT JSON_CONTAINS_PATH ('[{"0":0},1,"2",{"three":3}]', 'all',
'$[0]', '$[0].0"', '$[1]', '$[2]', '$[3]', '$.inexistent');

```

```

json_contains_path('[{"0":0},1,"2",{"three":3}]', 'all', '$[0]',
'$[0].0"', '$[1]', '$[2]', '$[3]', '$.inexistent')
=====
=====

```

0

The **JSON\_CONTAINS\_PATH** function supports wildcards inside json paths.

```
SELECT JSON_CONTAINS_PATH ('[{"0":0},1,"2",{"three":3}]', 'one',
'$.$inexistent', '$[*].three');
```

```
json_contains_path('["0":0},1,"2",{"three":3}]', 'one',
'$.$inexistent', '$[*].three')
=====
=====
1
```

## JSON\_CONTAINS

**JSON\_CONTAINS**(*json\_doc doc1*, *json\_doc doc2*[, *json path*])

The **JSON\_CONTAINS** function verifies whether the *doc2* is contained inside the *doc1* at the optionally specified path. A json element contains another json element if the following recursive rules are satisfied:

- A json scalar contains another json scalar if they have the same type (their **JSON\_TYPE** () are equal) and are equal. As an exception, json integer can be compared and equal to json double (even if their **JSON\_TYPE** () evaluation are different).
- A json array contains a json scalar or a json object if any of json array's elements contains the json\_nonarray.
- A json array contains another json array if all the second json array's elements are contained in the first json array.
- A json object contains another json object if, for every (*key2*, *value2*) pair in the second object, there exists a (*key1*, *value1*) pair in the first object with *key1* = *key2* and *value2* contained in *value1*.
- Otherwise the json element is not contained.

Returns whether *doc2* is contained in root json element of *doc1* if no json path argument is given. Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

```
SELECT JSON_CONTAINS ('"simple"', '"simple"');
```

```
json_contains('"simple"', '"simple"')
=====
1
```

```
SELECT JSON_CONTAINS ('["a", "b"]', '"b"');
```

```
json_contains(['a", "b"], 'b')
=====
1
```

```
SELECT JSON_CONTAINS ('["a", "b1", ["a", "b2"]]', '["b1", "b2"]');
```

```
json_contains(['a", "b1", ["a", "b2"]], '["b1", "b2"]')
=====
1
```

```
SELECT JSON_CONTAINS ('{"k1":["a", "b1"], "k2": ["a", "b2"]}', '{"k1":"b1", "k2":"b2"}');
```

```
json_contains('{"k1":["a", "b1"], "k2": ["a", "b2"]}', '{"k1":"b1", "k2":"b2"}')
=====
=====
1
```

Note that json objects do not check containment the same way json arrays do. It is impossible to have a json element that is not a descendent of a json object contained in a sub-element of a json object.

```
SELECT JSON_CONTAINS ('["a", "b1", ["a", {"k":"b2"}]]', '["b1", "b2"]');
```

```
json_contains(['a", "b1", ["a", {"k":"b2"}]]', '["b1", "b2"]')
=====
0
```

```
SELECT JSON_CONTAINS ('["a", "b1", ["a", {"k":["b2"]}]]', '["b1", {"k":"b2"}]');
```

```
json_contains(['a", "b1", ["a", {"k":["b2"]}]]', '["b1", {"k":"b2"}]')
```

```
=====
===
1
```

## JSON\_MERGE\_PATCH

**JSON\_MERGE\_PATCH**(*json\_doc*, *json\_doc* [, *json\_doc*] ...)

The **JSON\_MERGE\_PATCH** function merges two or more json docs and returns the resulting merged json. **JSON\_MERGE\_PATCH** differs from **JSON\_MERGE\_PRESERVE** in that it will take the second argument when encountering merging conflicts. **JSON\_MERGE\_PATCH** is compliant with [RFC 7396](#).

The merging of two json documents is performed with the following rules, recursively:

- when two non-object jsons are merged, the result of the merge is the second value.
- when a non-object json is merged with a json object, the result is the merge of an empty object with the second merging argument.
- when two objects are merged, the resulting object consists of the following members:
  - All members from the first object that have no corresponding member with the same key in the second object.
  - All members from the second object that have no corresponding members with equal keys in the first object, having values not null. Members with null values from second object are ignored.
  - One member for each member in the first object that has a corresponding non-null valued member in the second object with the same key. Same key members that appear in both objects and the second object's member value is null, are ignored. The values of these pairs become the results of merging operations performed on the values of the members from the first and second object.

Merge operations are executed serially when there are more than two arguments: the result of merging first two arguments is merged with third, this result is then merged with fourth and so on.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is not valid.

```
SELECT JSON_MERGE_PATCH ( '["a","b","c"]', '"scalar"' );
```

```
json_merge_patch(['a","b","c"], 'scalar')
=====
"scalar"
```

The exception to the merge-patching, when the first argument is non-object and the second is an object. A merge operation is performed between an empty object and the second object argument.

```
SELECT JSON_MERGE_PATCH ('a'], {'a':null});
```

```
json_merge_patch(['a'], {'a':null})
=====
{}
```

Objects merging example, exemplifying the described object merging rules:

```
SELECT JSON_MERGE_PATCH ('{"a":null,"c":["elem"]}','{"b":null,"c":
{"k":null},"d":"elem"}');
```

```
json_merge_patch('{"a":null,"c":["elem"]}', '{"b":null,"c":
{"k":null},"d":"elem"}')
=====
{"a":null,"c":{"k":null},"d":"elem"}
```

## JSON\_MERGE\_PRESERVE

### JSON\_MERGE\_PRESERVE(*json\_doc*, *json\_doc* [, *json\_doc*] ...)

The **JSON\_MERGE\_PRESERVE** function merges two or more json docs and returns the resulting merged json. **JSON\_MERGE\_PRESERVE** differs from **JSON\_MERGE\_PATCH** in that it preserves both json elements on merging conflicts.

The merging of two json documents is performed after the following rules, recursively:

- when two json arrays are merged, they are concatenated.
- when two non-array (scalar/object) json elements are merged and at most one of them is a json object, the result is an array containing the two json elements.
- when a non-array json element is merged with a json array, the non-array is wrapped as a single element json array and then merged with the json array according to json array merging rules.

- when two json objects are merged, all pairs that do not have a corresponding pair in the other json object are preserved. For matching keys, the values are always merged by applying the rules recursively.

Merge operations are executed serially when there are more than two arguments: the result of merging first two arguments is merged with third, this result is then merged with fourth and so on.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is not valid.

```
SELECT JSON_MERGE_PRESERVE ('"a"', '"b"');
```

```
json_merge('"a"', '"b"')
=====
["a","b"]
```

```
SELECT JSON_MERGE_PRESERVE ('["a","b","c"]', '"scalar"');
```

```
json_merge('["a","b","c"]', '"scalar"')
=====
["a","b","c","scalar"]
```

**JSON\_MERGE\_PRESERVE**, as opposed to **JSON\_MERGE\_PATCH**, will not drop and patch first argument's elements during merges and will gather them together.

```
SELECT JSON_MERGE_PRESERVE ('{"a":null,"c":["elem"]}','{"b":null,"c":{"k":null},"d":"elem"}');
```

```
json_merge('{"a":null,"c":["elem"]}','{"b":null,"c":{"k":null},"d":"elem"}')
=====
{"a":null,"c":["elem",{"k":null}], "b":null, "d":"elem"}
```

## JSON\_MERGE

**JSON\_MERGE**(*json\_doc*, *json\_doc* [, *json\_doc*] ...)

**JSON\_MERGE** is an alias for **JSON\_MERGE\_PRESERVE**.

## JSON\_ARRAY\_APPEND

JSON\_ARRAY\_APPEND(*json\_doc*, *json path*, *json\_val* [, *json path*, *json\_val*] ...)

The **JSON\_ARRAY\_APPEND** function returns a modified copy of the first argument. For each given <*json path*, *json\_val*> pair, the function appends the value to the json array addressed by the corresponding path.

The (*json path*, *json\_val*) pairs are evaluated one by one, from left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

If the json path points to a json array inside the *json\_doc*, the *json\_val* is appended at the end of the array. If the json path points to a non-array json element, the non-array gets wrapped as a single element json array containing the referred non-array element followed by the appending of the given *json\_val*.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

```
SELECT JSON_ARRAY_APPEND ('{"a":[1,2]}', '$.a', 'b');
```

```
json_array_append('{"a":[1,2]}', '$.a', 'b')
=====

json_array_append('{"a":[1,2]}', '$.a[0]', '1')
=====
{"a":[[1,"1"],2]}
```

## JSON\_ARRAY\_INSERT

JSON\_ARRAY\_INSERT(*json\_doc*, *json path*, *json\_val* [, *json path*, *json\_val*] ...)

The **JSON\_ARRAY\_INSERT** function returns a modified copy of the first argument. For each given *<json\_path, json\_val>* pair, the function inserts the value in the json array addressed by the corresponding path.

The (*json\_path, json\_val*) pairs are evaluated one by one, from left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

The rules of the **JSON\_ARRAY\_INSERT** operation are the following:

- if a json path addresses an element of a json\_array, the given *json\_val* is inserted at the specified index, shifting any following elements to the right.
- if the json path points to an array index after the end of an array, the array is filled with nulls after end of the array until the specified index and the *json\_val* is inserted at the specified index.
- if the json path does not exist inside the *json\_doc*, the last token of the json path is an array index and the json path without the last array index token would have pointed to an element inside the *json\_doc*, the element found by the stripped json path is replaced with single element json array and the **JSON\_ARRAY\_INSERT** operation is performed with the original json path.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid or if a *json\_path* does not address a cell of an array inside the *json\_doc*.

```
SELECT JSON_ARRAY_INSERT ('[0,1,2]', '$[0]', '1');
```

```
json_array_insert('[0,1,2]', '$[0]', '1')
=====
["1",0,1,2]
```

```
SELECT JSON_ARRAY_INSERT ('[0,1,2]', '$[5]', '1');
```

```
json_array_insert('[0,1,2]', '$[5]', '1')
=====
[0,1,2,null,null,"1"]
```

Examples for **JSON\_ARRAY\_INSERT**'s third rule.

```
SELECT JSON_ARRAY_INSERT ('{"a":4}', '$[5]', '1');
```

```
json_array_insert('{"a":4}', '$[5]', '1')
=====
[{"a":4},null,null,null,null,"1"]
```

```
SELECT JSON_ARRAY_INSERT ('"a"', '$[5]', '1');
```

```
json_array_insert('"a"', '$[5]', '1')
=====
["a",null,null,null,null,"1"]
```

## JSON\_INSERT

**JSON\_INSERT**(*json\_doc*, *json path*, *json\_val* [, *json path*, *json\_val*] ...)

The **JSON\_INSERT** function returns a modified copy of the first argument. For each given *<json path, json\_val>* pair, the function inserts the value if no other value exists at the corresponding path.

The insertion rules for **JSON\_INSERT** are the following:

The *json\_val* is inserted if the json path addresses one of the following json values inside the *json\_doc*:

- An inexistent object member of an existing json object. A (*key, value*) pair is added to the json object with the key being json path's last element and the value being the *json\_val*.
- An array index past of an existing json array's end. The array is filled with nulls after the initial end of the array and the *json\_val* is inserted at the specified index.

The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

Paths to existing elements inside the *json\_doc* are ignored:

```
SELECT JSON_INSERT ('{"a":1}', '$.a', 'b');
```

```
json_insert('{"a":1}', '$.a', 'b')
=====
{"a":1}
```

```
SELECT JSON_INSERT ('{"a":1}','$.b','1');
```

```
json_insert('{"a":1}', '$.b', '1')
=====
{"a":1,"b":"1"}
```

```
SELECT JSON_INSERT ('[0,1,2]','$[4]','1');
```

```
json_insert('[0,1,2]', '$[4]', '1')
=====
[0,1,2,null,"1"]
```

## JSON\_SET

**JSON\_SET**(*json\_doc*, *json path*, *json\_val* [, *json path*, *json\_val*] ...)

The **JSON\_SET** function returns a modified copy of the first argument. For each given <*json path*, *json\_val*> pair, the function inserts or replaces the value at the corresponding path. Otherwise, the *json\_val* is inserted if the json path addresses one of the following json values inside the *json\_doc*:

- An inexistent object member of an existing json object. A (*key*, *value*) pair is added to the json object with the key deduced from the json path and the value being the *json\_val*.
- An array index past of an existing json array's end. The array is filled with nulls after the initial end of the array and the *json\_val* is inserted at the specified index.

The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

```
SELECT JSON_SET ('{"a":1}','$.a','b');
```

```
json_set('{"a":1}', '$.a', 'b')
=====
{"a":"b"}
```

```
SELECT JSON_SET ('{"a":1}','$.b','1');
```

```
json_set('{"a":1}', '$.b', '1')
=====
{"a":1,"b":"1"}
```

```
SELECT JSON_SET ('[0,1,2]', '$[4]', '1');
```

```
json_set('[0,1,2]', '$[4]', '1')
=====
[0,1,2,null,"1"]
```

## JSON\_REPLACE

**JSON\_REPLACE**(*json\_doc*, *json\_path*, *json\_val* [, *json\_path*, *json\_val*] ...)

The **JSON\_REPLACE** function returns a modified copy of the first argument. For each given *<json\_path, json\_val>* pair, the function replaces the value only if another value is found at the corresponding path.

If the *json\_path* does not exist inside the *json\_doc*, the (*json\_path*, *json\_val*) pair is ignored and has no effect.

The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid.

```
SELECT JSON_REPLACE ('{"a":1}', '$.a', 'b');
```

```
json_replace('{"a":1}', '$.a', 'b')
=====
{"a":"b"}
```

No replacement is done if the *json\_path*\*` does not exist inside the *\*json\_doc*.

```
SELECT JSON_REPLACE ('{"a":1}', '$.b', '1');
```

```
json_replace('{"a":1}', '$.b', '1')
=====
{"a":1}
```

```
SELECT JSON_REPLACE ('[0,1,2]','$[4]','1');
```

```
json_replace('[0,1,2]', '$[4]', '1')
=====
[0,1,2]
```

## JSON\_REMOVE

**JSON\_REMOVE**(*json\_doc*, *json path* [, *json path*] ...)

The **JSON\_REMOVE** function returns a modified copy of the first argument, by removing values from all given paths.

The json path arguments are evaluated one by one, from left to right. The result produced by evaluating a json path becomes the value against which the next json path is evaluated.

Returns **NULL** if any argument is **NULL**. An error occurs if any argument is invalid or if a path points to the root or if a path does not exist.

```
SELECT JSON_REMOVE ('[0,1,2]','$[1]');
```

```
json_remove('[0,1,2]', '$[1]')
=====
[0,2]
```

```
SELECT JSON_REMOVE ('{"a":1,"b":2}','$.a');
```

```
json_remove('{"a":1,"b":2}','$.a')
=====
{"b":2}
```

## JSON\_TABLE

**JSON\_TABLE** function facilitates transforming jsons into a table-like structures that can be queried similarly as regular tables. The transformation generates a single row or multiple rows, by expanding for example the elements of a JSON\_ARRAY.

The full syntax of **JSON\_TABLE**:

```

JSON_TABLE(
    expr,
    path COLUMNS (column_list)
) [AS] alias

<column_list>::=
    <column> [, <column>] ...

<column>::=
    name FOR ORDINALITY
    | name type PATH string_path <on_empty> <on_error>
    | name type EXISTS PATH string_path
    | NESTED [PATH] string_path COLUMNS <column_list>

<on_empty>::=
    NULL | ERROR | DEFAULT value ON EMPTY

<on_error>::=
    NULL | ERROR | DEFAULT value ON ERROR

```

The *json\_doc* expr must be an expression that results in a json\_doc. This can be a constant json, a table's column or the result of a function or operator. The *json path* must be a valid path and is used to extract json data to be evaluated in the **COLUMNS** clause. The **COLUMNS** clause defines output column types and operations performed to get the output. The **[AS] alias** clause is required.

**JSON\_TABLE** supports four types of columns:

- *name* **FOR ORDINALITY**: this type keeps track of a row's number inside a **COLUMNS** clause. The column's type is **INTEGER**.
- *name type* **PATH json path [on empty] [on error]**: Columns of this type are used to extract json\_values from the specified json paths. The extracted json data is then coerced to the specified type. If the path does not exist, json value triggers the **on empty** clause. The **on error** clause is triggered if the extracted json value is not coercible to the target type.
  - **on empty** determines the behavior of **JSON\_TABLE** in case the path does not exist. **on empty** can have one of the following values:
    - **NULL ON EMPTY**: the column is set to **NULL**. This is the default behavior.
    - **ERROR ON EMPTY**: an error is thrown
    - **DEFAULT value ON EMPTY**: *value* will be used instead of the missing value.

◦ **on error** can have one of the following values:

- **NULL ON ERROR:** the column is set to **NULL**. This is the default behavior.
- **ERROR ON ERROR:** an error is thrown.
- **DEFAULT value ON ERROR:** *value* will be used instead of the array/object/json scalar that failed coercion to desired column type.

- *name type* **EXISTS PATH json path:** this returns 1 if any data is present at the json path location, 0 otherwise.
- **NESTED [PATH] json path COLUMNS (column list)** generates from json data found at path a separate subset of rows and columns that are combined with the results of parent. Results are combined similarly as “for each” loops. The json path is relative to the parent’s path. Same rules for **COLUMNS** clause are applied recursively.

```
SELECT * FROM JSON_TABLE (
    '{"a":[1,[2,3]]}',
    '$.a[*]' COLUMNS ( col INT PATH '$')
) AS jt;
```

```
col
=====
1 -- first value found at '$.a[*]' is 1 json
scalar, which is coercible to 1
NULL -- second value found at '$.a[*]' is [2,3]
json array which cannot be coerced to int, triggering NULL ON ERROR
default behavior
```

Overriding the default on\_error behavior, results in a different output from previous example:

```
SELECT * FROM JSON_TABLE (
    '{"a":[1,[2,3]]}',
    '$.a[*]' COLUMNS ( col INT PATH '$' DEFAULT '-1' ON ERROR)
) AS jt;
```

```
col
=====
1 -- first value found at '$.a[*]' is '1' json
scalar, which is coercible to 1
-1 -- second value found at '$.a[*]' is '[2,3]'
json array which cannot be coerced to int, triggering ON ERROR
```

**ON EMPTY** example:

```

SELECT * FROM JSON_TABLE (
    '{"a":1}',
    '$' COLUMNS ( col1 INT PATH '$.a',
                  col2 INT PATH '$.b',
                  col3 INT PATH '$.c' DEFAULT '0' ON EMPTY)
) AS jt;

```

| col1  | col2  | col3  |
|-------|-------|-------|
| ===== | ===== | ===== |
| 1     | NULL  | 0     |

In the example below, '\$.\*' path will be used to make the parent columns receive root json object's member values one by one. Column a shows what is processed. Each member's value of the root object will then be processed further by the **NESTED [PATH]** clause. **NESTED PATH** uses path '\$[\*]' take each element of the array to be further processed by its columns. **FOR ORDINALITY** columns track the count of the current processed element. In the example's result we can see that for each new element in a column, the *ord* column's value also gets incremented. **FOR ORDINALITY** *nested\_ord* column also acts as a counter of the number of elements processed by sibling columns. The nested **FOR ORDINALITY** column gets reset after finishing each processing batch. The third member's value, 6 cannot be treated as an array and therefore cannot be processed by the nested columns. Nested columns will yield **NULL** values.

```

SELECT * FROM JSON_TABLE (
    '{"a":[1,2],"b":[3,4,5],"d":6,"c":[7]}',
    '$.*' COLUMNS ( ord FOR ORDINALITY,
                    col JSON PATH '$',
                    NESTED PATH '$[*]' COLUMNS ( nested_ord FOR
ORDINALITY,
                                                    nested_col JSON
PATH '$'))
) AS jt;

```

| ord   | col     | nested_ord | nested_col |
|-------|---------|------------|------------|
| ===== | =====   | =====      | =====      |
| 1     | [1,2]   | 1          | 1          |
| 1     | [1,2]   | 2          | 2          |
| 2     | [3,4,5] | 1          | 3          |
| 2     | [3,4,5] | 2          | 4          |
| 2     | [3,4,5] | 3          | 5          |
| 3     | 6       | NULL       | NULL       |
| 4     | [7]     | 1          | 7          |

The following example showcases how multiple same-level **NESTED [PATH]** clauses are treated by the **JSON\_TABLE**. The value to be processed gets passed once, one by one and in order, to each of

the **NESTED [PATH]** clauses. During processing of a value by a **NESTED [PATH]** clause, any sibling **NESTED [PATH]** clauses will fill their column with **NULL** values.

```
SELECT * FROM JSON_TABLE (
    '{"a":{"key1":[1,2], "key2":[3,4,5]}, "b":{"key1":6, "key2":
    [7]}}',
    '$.*' COLUMNS ( ord FOR ORDINALITY,
                     col JSON PATH '$',
                     NESTED PATH '$.key1[*]' COLUMNS (
nested_ord1 FOR ORDINALITY,
nested_col1 JSON PATH '$'),
                     NESTED PATH '$.key2[*]' COLUMNS (
nested_ord2 FOR ORDINALITY,
nested_col2 JSON PATH '$'))
    ) AS jt;
```

|             | ord | col                            | nested_ord1 |
|-------------|-----|--------------------------------|-------------|
| nested_col1 |     | nested_ord2                    | nested_col2 |
| =====       |     |                                |             |
|             |     |                                |             |
|             | 1   | {"key1":[1,2], "key2":[3,4,5]} | 1           |
| 1           |     | NULL NULL                      |             |
|             | 1   | {"key1":[1,2], "key2":[3,4,5]} | 2           |
| 2           |     | NULL NULL                      |             |
|             | 1   | {"key1":[1,2], "key2":[3,4,5]} | NULL        |
| NULL        |     | 1 3                            |             |
|             | 1   | {"key1":[1,2], "key2":[3,4,5]} | NULL        |
| NULL        |     | 2 4                            |             |
|             | 1   | {"key1":[1,2], "key2":[3,4,5]} | NULL        |
| NULL        |     | 3 5                            |             |
|             | 2   | {"key1":6, "key2":[7]}         | NULL        |
| NULL        |     | 1 7                            |             |

An example for multiple layers **NESTED [PATH]** clauses:

```
SELECT * FROM JSON_TABLE (
    '{"a":{"key1":[1,2], "key2":[3,4,5]}, "b":{"key1":6, "key2":
    [7]}}',
    '$.*' COLUMNS ( ord FOR ORDINALITY,
                     col JSON PATH '$',
                     NESTED PATH '$.*' COLUMNS ( nested_ord1 FOR
ORDINALITY,
nested_col1 JSON
PATH '$',
NESTED PATH '$
[*]' COLUMNS ( nested_ord11 FOR ORDINALITY,
```

```

        nested_col11 JSON PATH '$')),
        NESTED PATH '$.key2[*]' COLUMNS (
nested_ord2 FOR ORDINALITY,
nested_col2 JSON PATH '$'))
) AS jt;

```

|             | ord | col                           | nested_ord11 | nested_col11 | nested_ord1 |
|-------------|-----|-------------------------------|--------------|--------------|-------------|
| nested_col1 |     |                               | nested_ord11 | nested_col11 |             |
| nested_ord2 |     | nested_col2                   |              |              |             |
| =====       |     |                               |              |              |             |
| =====       |     |                               |              |              |             |
| =====       |     |                               |              |              |             |
| 2]          | 1   | {"key1":[1,2],"key2":[3,4,5]} | 1 1          | [1,          | 1 [1,       |
| NULL        |     |                               |              | NULL         | NULL        |
| 2]          | 1   | {"key1":[1,2],"key2":[3,4,5]} | 2 2          | [1,          | 1 [1,       |
| NULL        |     |                               |              | NULL         | NULL        |
| 5]          | 1   | {"key1":[1,2],"key2":[3,4,5]} | 1 3          | [3,4,        | 2 [3,4,     |
| NULL        |     |                               |              | NULL         | NULL        |
| 5]          | 1   | {"key1":[1,2],"key2":[3,4,5]} | 2 4          | [3,4,        | 2 [3,4,     |
| NULL        |     |                               |              | NULL         | NULL        |
| 5]          | 1   | {"key1":[1,2],"key2":[3,4,5]} | 3 5          | [3,4,        | 2 [3,4,     |
| NULL        |     |                               |              | NULL         | NULL        |
| NULL        | 1   | {"key1":[1,2],"key2":[3,4,5]} | NULL NULL    |              | NULL        |
| 1 3         |     |                               |              |              |             |
| NULL        | 1   | {"key1":[1,2],"key2":[3,4,5]} | NULL NULL    |              | NULL        |
| 2 4         |     |                               |              |              |             |
| NULL        | 1   | {"key1":[1,2],"key2":[3,4,5]} | NULL NULL    |              | NULL        |
| 3 5         |     |                               |              |              |             |
| 6           | 2   | {"key1":6,"key2":[7]}         | NULL NULL    |              | 1           |
| NULL NULL   |     |                               |              |              |             |
| [7]         | 2   | {"key1":6,"key2":[7]}         | 1 7          |              | 2           |
| NULL NULL   |     |                               |              |              |             |
| NULL        | 2   | {"key1":6,"key2":[7]}         | NULL NULL    |              | NULL        |
| 1 7         |     |                               |              |              |             |

| ● CLOB_TO_CHAR       | 585        |

## BIT\_TO\_BLOB

### BIT\_TO\_BLOB(*blob\_type\_column\_or\_value*)

This function converts **BIT** or **VARYING BIT** type into **BLOB** type.

#### Parameters:

**blob\_type\_column\_or\_value** – Target column or value to convert

#### Return type:

BLOB

## BLOB\_FROM\_FILE

### BLOB\_FROM\_FILE(*file\_pathname*)

This function read the contents from the file with **VARCHAR** type data and returns **BLOB** type data.

Parameters:

**file\_pathname** – the path on the server which DB clients like CAS or CSQL are started

Return type:

BLOB

```
SELECT CAST(BLOB_FROM_FILE('local:/home/cubrid/demo/lob/ces_622/
image_t.00001352246696287352_4131')
AS BIT VARYING) result;

SELECT CAST(BLOB_FROM_FILE('file:/home/cubrid/demo/lob/ces_622/
image_t.00001352246696287352_4131')
AS BIT VARYING) result;
```

## BLOB\_LENGTH

### BLOB\_LENGTH(*blob\_column*)

The length of **LOB** data stored in **BLOB** file is returned.

Parameters:

**blob\_column** – The column to get the length of **BLOB**

Return type:

INT

## BLOB\_TO\_BIT

### BLOB\_TO\_BIT(*blob\_type\_column*)

This function converts **BLOB** type to **VARYING BIT** type.

Parameters:

**blob\_type\_column** – Target column to convert

Return type:

VARYING BIT

## CHAR\_TO\_BLOB

CHAR\_TO\_BLOB(*char\_type\_column\_or\_value*)

This function converts **CHAR** or **VARCHAR** type into **BLOB** type.

Parameters:

**char\_type\_column\_or\_value** – Target column or value to convert

Return type:

BLOB

## CHAR\_TO\_CLOB

CHAR\_TO\_CLOB(*char\_type\_column\_or\_value*)

This function converts **CHAR** or **VARCHAR** type into **CLOB** type.

Parameters:

**char\_type\_column\_or\_value** – Target column or value to convert

Return type:

CLOB

## CLOB\_FROM\_FILE

CLOB\_FROM\_FILE(*file\_pathname*)

This function read the contents from the file with **VARCHAR** type data and returns **CLOB** type data.

Parameters:

**file\_pathname** – the path on the server which DB clients like CAS or CSQL are started

Return type:

CLOB

If you specify the *file\_pathname* as the relative path, the parent path will be the current working directory.

For the statement including this function, the query plan is not cached.

```
SELECT CAST(CLOB_FROM_FILE('local:/home/cubrid/demo/lob/ces_622/
image_t.00001352246696287352_4131')
AS VARCHAR) result;

SELECT CAST(CLOB_FROM_FILE('file:/home/cubrid/demo/lob/ces_622/
image_t.00001352246696287352_4131')
AS VARCHAR) result;
```

## CLOB\_LENGTH

CLOB\_LENGTH(*clob\_column*)

The length of **LOB** data stored in **CLOB** file is returned.

Parameters:

**clob\_column** – The column to get the length of **CLOB**

Return type:

INT

## CLOB\_TO\_CHAR

CLOB\_TO\_CHAR(*clob\_type\_column* [USING charset] )

This function converts **CLOB** type into **VARCHAR** type.

**Parameters:**

- **clob\_type\_column** – Target column to convert
- **charset** – The character set of string to convert. It can be utf8, euckr or iso88591.

**Return type:**

STRING

## Data Type Casting Functions and Operators

| ● | TO_TIMESTAMP_TZ | 632 |

## CAST

CAST(*cast\_operand AS cast\_target*)

The **CAST** operator can be used to explicitly cast one data type to another in the **SELECT** statement. A query list or a value expression in the **WHERE** clause can be cast to another data type.

### Parameters:

- **cast\_operand** – Declares the value to cast to a different data type.
- **cast\_target** – Specifies the type to cast to.

Return type:

cast\_target

Depending on the situation, data type can be automatically converted without using the **CAST** operator. For details, see [Implicit Type Conversion](#).

See **CASTing a String to Date/Time Type** regarding to convert the string of date/time type into date/time type.

The following table shows a summary of explicit type conversions (casts) using the **CAST** operator in CUBRID.

|           | E | A | V | F | V      | F      | E           | B           | C           | D      | T      | U | U      | D      | D      | S      | M      | S      |

[illegible][illegible][illegible]

(\*): The **CAST** operation is allowed only when the value expression and the data type to be cast have the same character set.

#### • Data Type Key

- **EN**: Exact numeric data type (**INTEGER**, **SMALLINT**, **BIGINT**, **NUMERIC**, **DECIMAL**)
- **AN**: Approximate numeric data type (**FLOAT/REAL**, **DOUBLE**)
- **VC**: Variable-length character string (**VARCHAR** (*n*))
- **FC**: Fixed-length character string (**CHAR** (*n*))
- **VB**: Variable-length bit string (**BIT VARYING** (*n*))
- **FB**: Fixed-length bit string (**BIT** (*n*))
- **ENUM**: **ENUM** type
- **BLOB**: Binary data that is stored outside DB
- **CLOB**: String data that is stored inside DB
- **D**: **DATE**
- **T**: **TIME**
- **DT**: **DATETIME**
- **DTZ**: **DATETIME WITH TIME ZONE** and **DATETIME WITH LOCAL TIME ZONE** data types
- **UT**: **TIMESTAMP**
- **UTZ**: **TIMESTAMP WITH TIME ZONE** and **TIMESTAMP WITH LOCAL TIME ZONE** data types
- **S**: **SET**
- **MS**: **MULTISET**
- **SQ**: **LIST** (= **SEQUENCE**)

```

```
Cannot coerce timestamp '09:00:01 AM 01/01/1970' to type integer.
```

#### Note

- **CAST** is allowed only between data types having the same character set.
- If you cast an approximate data type(FLOAT, DOUBLE) to integer type, the number is rounded to zero decimal places.
- If you cast an exact numeric data type(NUMERIC) to integer type, the number is rounded to zero decimal places.
- If you cast a numeric data type to string character type, it should be longer than the length of significant figures + decimal point. An error occurs otherwise.

- If you cast a character string type *A* to a character string type *B*, *B* should be longer than the *A*. The end of character string is truncated otherwise.
- If you cast a character string type *A* to a date-time date type *B*, it is converted only when literal of *A* and *B* type match one another. An error occurs otherwise.
- You must explicitly do type casting for numeric data stored in a character string so that an arithmetic operation can be performed.

## DATE\_FORMAT

### DATE\_FORMAT(*date*, *format*)

The **DATE\_FORMAT** function converts the value of date/time data type which include a date to specified date/time format and then return the value with the **VARCHAR** data type. For the format parameter to assign, refer to **Date/Time Format 2** table of the `DATE_FORMAT()`. The **Date/Time Format 2** table is used in `DATE_FORMAT()`, `TIME_FORMAT()`, and `STR_TO_DATE()` functions.

#### Parameters:

- **date** – A value of DATE, TIMESTAMP, DATETIME, DATETIME TZ, DATETIME LTZ, TIMESTAMPTZ, or TIMESTAMP.
- **format** – Specifies the output format. The format specifier starting with ‘%’ is used.

#### Return type:

STRING

When the *format* argument is assigned, the string is interpreted according to the specified language. At that time, the language specified as the **intl\_date\_lang** system parameter is applied. If the **intl\_date\_lang** value is not set, the language specified when creating DB is applied.

For example, when the language is “de\_DE” and the format is “%d %M %Y”, the string “3 Oktober 2009” is interpreted as the DATE type of “2009-10-03”. When the specified *format* argument does not correspond to the given string, an error is returned.

In the following **Date/Time Format 2** table, the month/day, date, and AM/PM in characters are different by language.

### Date/Time Format 2

| format Value | Meaning                                                                             |
|--------------|-------------------------------------------------------------------------------------|
| %a           | Weekday, English abbreviation (Sun, ... , Sat)                                      |
| %b           | Month, English abbreviation (Jan, ... , Dec)                                        |
| %c           | Month (1, ... , 12)                                                                 |
| %D           | Day of the month, English ordinal number (1st, 2nd, 3rd, ...)                       |
| %d           | Day of the month, two-digit number (01, ... , 31)                                   |
| %e           | Day of the month (1, ... , 31)                                                      |
| %f           | Microseconds, three-digit number (000, ... , 999)                                   |
| %H           | Hour, 24-hour based, number with at least two-digit (00, ... , 23, ... , 100, ... ) |
| %h           | Hour, 12-hour based two-digit number (01, ... , 12)                                 |
| %l           | Hour, 12-hour based two-digit number (01, ... , 12)                                 |
| %i           | Minutes, two-digit number (00, ... , 59)                                            |
| %j           | Day of year, three-digit number (001, ... , 366)                                    |
| %k           |                                                                                     |

| format Value | Meaning                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------|
|              | Hour, 24-hour based, number with at least one-digit (0, ... , 23, ... , 100, ... )                     |
| %l           | Hour, 12-hour based (1, ... , 12)                                                                      |
| %M           | Month, English string (January, ... , December)                                                        |
| %m           | Month, two-digit number (01, ... , 12)                                                                 |
| %p           | AM or PM                                                                                               |
| %r           | Time, 12-hour based, hour:minute:second (hh:mi:ss AM or hh:mi:ss PM)                                   |
| %S           | Seconds, two-digit number (00, ... , 59)                                                               |
| %s           | Seconds, two-digit number (00, ... , 59)                                                               |
| %T           | Time, 24-hour based, hour:minute:second (hh:mi:ss)                                                     |
| %U           | Week, two-digit number, week number of the year with Sunday being the first day<br>Week (00, ... , 53) |
| %u           | Week, two-digit number, week number of the year with Monday being the first day (00, ... , 53)         |
| %V           | Week, two-digit number, week number of the year with Sunday being the first day                        |

| format Value | Meaning                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | Week (00, ... , 53) (Available to use in combination with %X)                                                                                                  |
| %v           | Week, two-digit number, week number of the year with Monday being the first day (00, ... , 53) (Available to use in combination with %x)                       |
| %W           | Weekday, English string (Sunday, ... , Saturday)                                                                                                               |
| %w           | Day of the week, number index (0=Sunday, ... , 6=Saturday)                                                                                                     |
| %X           | Year, four-digit number calculated as the week number with Sunday being the first day of the week (0000, ... , 9999) (Available to use in combination with %V) |
| %x           | Year, four-digit number calculated as the week number with Monday being the first day of the week (0000, ... , 9999) (Available to use in combination with %v) |
| %Y           | Year, four-digit number (0001, ... , 9999)                                                                                                                     |
| %y           | Year, two-digit number (00, 01, ... , 99)                                                                                                                      |
| %%           | Output the special character “%” as a string                                                                                                                   |
| %x           | Output an arbitrary character x as a string out of English letters that are not used as format specifiers.                                                     |

| format Value | Meaning                                        |
|--------------|------------------------------------------------|
| %TZR         | Time zone region information. e.g. US/Pacific. |
| %TZD         | Daylight saving information. e.g. KST, KT, EET |
| %TZH         | Timezone hour offset. e.g. +09, -09            |
| %TzM         | Timezone minute offset. e.g. +00, +30          |

#### Note

%TZR, %TZD, %TZH, %TzM can be used only in timezone types.

#### Note

##### **A format specifying a number after TZD**

See [A format specifying a number after TZD](#).

The following example shows the case when the system parameter **intl\_date\_lang** is “en\_US”.

```
SELECT DATE_FORMAT(datetime'2009-10-04 22:23:00', '%W %M %Y');
```

```
'Sunday October 2009'
```

```
SELECT DATE_FORMAT(datetime'2007-10-04 22:23:00', '%H:%i:%s');
```

```
'22:23:00'
```

```
SELECT DATE_FORMAT(datetime'1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
```

```
'4th 00 Thu 04 10 Oct 277'
```

```
SELECT DATE_FORMAT(date'1999-01-01', '%X %V');
```

```
'1998 52'
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE";  
SELECT DATE_FORMAT(datetime'2009-10-04 22:23:00', '%W %M %Y');
```

```
'Sonntag Oktober 2009'
```

```
SELECT DATE_FORMAT(datetime'2007-10-04 22:23:00', '%H:%i:%s %p');
```

```
'22:23:00 Nachm.'
```

```
SELECT DATE_FORMAT(datetime'1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
```

```
'4 00 Do. 04 10 Okt 277'
```

#### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see **Note** in the `TO_CHAR()` .

The following example outputs the value of DATETIMETZ type which includes timezone information as the desired format.

```
SELECT DATE_FORMAT(datetimetz'2012-02-02 10:10:10 Europe/Zurich
CET', '%TZR %TZD %TZh %TZM');
```

::

'Europe/Zurich CET 01 00'

## FORMAT

### FORMAT(x, dec)

The **FORMAT** function displays the number *x* by using digit grouping symbol as a thousands separator, so that its format becomes `'#,###,###.#####'` and performs rounding after the decimal point symbol to express as many as *dec* digits after it. The return value is a **VARCHAR** type.

#### Parameters:

- **x** – An expression that returns a numeric value
- **dec** – the number of digits of fractional parts

#### Return type:

STRING

Thousands separator symbol and decimal point symbol is output in the format according to the specified language. The language is specified by the **intl\_number\_lang** system parameter. If the value of **intl\_number\_lang** is not set, the language specified when creating DB is applied.

For example, when the language is one of the European languages, such as "de\_DE" or "fr\_FR", "." is interpreted as the thousands separator and "," as the decimal point symbol (see [Default output of number by language](#) of the `TO_CHAR()`).

The following example shows command execution by setting the value of the **intl\_number\_lang system** parameter to "en\_US".

```
SET SYSTEM PARAMETERS 'intl_number_lang="en_US"';
SELECT FORMAT(12000.123456,3), FORMAT(12000.123456,0);
```

'12,000.123'

'12,000'

The following example shows command execution on the database by setting the value of the **intl\_number\_lang** system parameter to “de\_DE”. In the number output format of most European countries, such as Germany and France, “.” is the cipher identifier and “,” is the decimal point symbol.

```
SET SYSTEM PARAMETERS 'intl_number_lang="de_DE";
SELECT FORMAT(12000.123456,3), FORMAT(12000.123456,0);
```

```
'12.000,123'          '12.000'
```

## STR\_TO\_DATE

### STR\_TO\_DATE(*string*, *format*)

The **STR\_TO\_DATE** function converts the given character string to a date/time value by interpreting it according to the specified format and operates in the opposite way to the **DATE\_FORMAT()** function. The return value is determined by the date/time part included in the character string.

#### Parameters:

- **string** – String.
- **format** – Specifies the format to interpret the character string. You should use character strings including % for the format specifiers. See [Date/Time Format 2](#) table of **DATE\_FORMAT()** function.

#### Return type:

DATETIME, DATE, TIME, DATETIME TZ

For the *format* argument to assign, see [Date/Time Format 2](#) table of the **DATE\_FORMAT()**.

If *string* is invalid date/time value or *format* is invalid, it returns an error.

When the *format* argument is assigned, the *string* is interpreted according to the specified language. At that time, the language specified as the **intl\_date\_lang** system parameter is applied. If the **intl\_date\_lang** value is not set, the language specified when creating DB is applied.

For example, when the language is “de\_DE” and the *format* is “%d %M %Y”, the string “3 Oktober 2009” is interpreted as the **DATE** type of “2009-10-03”. If the *format* argument does not correspond to the given *string*, an error is returned.

0 is not allowed in the argument value corresponding to year, month, and day; however, if 0 is inputted in every argument value corresponding to date and time, the value of **DATE** or **DATETIME** type that has 0 for every date and time value is returned as an exception. Note that operation in JDBC program is determined by the configuration of `zeroDateTimeBehavior`, connection URL property. For more information about `zeroDateTimeBehavior`, please see [Configuration Connection](#).

The following example shows the case when the system parameter **intl\_date\_lang** is “en\_US”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="en_US";  
SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
```

```
05/01/2013
```

```
SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
```

```
05/01/2013
```

```
SELECT STR_TO_DATE('13:30:17','%H:%i');
```

```
01:30:00 PM
```

```
SELECT STR_TO_DATE('09:30:17 PM','%r');
```

```
09:30:17 PM
```

```
SELECT STR_TO_DATE('0,0,0000','%d,%m,%Y');
```

```
00/00/0000
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”. The German Oktober is interpreted to 10.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE";  
SELECT STR_TO_DATE('3 Oktober 2009','%d %M %Y');
```

10/03/2009

#### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see **Note** in the **TO\_CHAR()** ).

The following example shows which converts a date/time string with timezone information into DATETIME TZ type value.

```
SELECT STR_TO_DATE('2001-10-11 02:03:04 AM Europe/Bucharest EEST',
'%Y-%m-%d %h:%i:%s %p %TZR %TZD');
```

```
02:03:04.000 AM 10/11/2001 Europe/Bucharest EEST
```

## TIME\_FORMAT

### TIME\_FORMAT(*time*, *format*)

The **TIME\_FORMAT** function converts the date/time data type value including time value into a string of specified date/time format, and returns the value with the **VARCHAR** data type.

#### Parameters:

- **time** – A value of a type with time. (TIME, TIMESTAMP, DATETIME, TIMESTAMPTZ or DATETIME TZ)
- **format** – Specifies the output format. Use a string that contains ‘%’ as a specifier. See the table **Date/Time Format 2** of **DATE\_FORMAT()** function.

#### Return type:

STRING

When the *format* argument is assigned, the time is output according to the specified language. At this time, the language specified as the **intl\_date\_lang** system parameter is applied. If **intl\_date\_lang** system parameter is not set, the language specified when creating DB is applied.

For example, when the language is set to “de\_DE” and the format is “%h:%i:%s %p”, “08:46:53 PM” is output as “08:46:53 Nachm.”. When the *format* argument specified does not correspond to the given string, an error is returned.

The following example shows the case when the system parameter **intl\_date\_lang** is “en\_US”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="en_US";  
SELECT TIME_FORMAT(time'22:23:00', '%H %i %s');
```

```
'22 23 00'
```

```
SELECT TIME_FORMAT(time'23:59:00', '%H %h %i %s %f');
```

```
'23 11 59 00 000'
```

```
SELECT SYSTIME, TIME_FORMAT(SYSTIME, '%p');
```

```
08:46:53 PM 'PM'
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE";  
SELECT SYSTIME, TIME_FORMAT(SYSTIME, '%p');
```

```
08:46:53 PM 'Nachm.'
```

#### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see **Note** in the `TO_CHAR()` ).

The following outputs the value with a timezone information into a specified format string.

```
SELECT TIME_FORMAT(datetimetz'2001-10-11 02:03:04 AM Europe/
Bucharest EEST', '%h:%i:%s %p %TZR %TZD');
```

```
'02:03:04 AM Europe/Bucharest EEST'
```

## TO\_CHAR(date\_time)

TO\_CHAR(*date\_time*[, *format*[, *date\_lang\_string\_literal*]])

The **TO\_CHAR** (*date\_time*) function converts the value of date/time types (**TIME**, **DATE**, **TIMESTAMP**, **DATETIME**) to a string depending on the table **Date/Time Format 1** and then returns the value. The type of the return value is **VARCHAR**.

**param date\_time:**

A value of date/time type. (TIME, DATE, TIMESTAMP, DATETIME, DATETIMETZ, DATETIMELTZ, TIMESTAMPTZ, TIMESTAMPLTZ)

**param format:**

A format of return value.

**param**

**date\_lang\_string\_literal:**

Specifies a language applied to a return value.

**rtype:**

STRING

When the *format* argument is specified, the *date\_time* is output according to the specified language (see the **Date/Time Format 1** table). A language is defined by the *date\_lang\_string\_literal*. If *date\_lang\_string\_literal* is omitted, the language specified by the *intl\_date\_lang* parameter is applied; if the value of *intl\_date\_lang* is not specified, the language specified when creating DB is applied.

For example, when the language is set to “de\_DE” and the format is “HH:MI:SS:AM”, “08:46:53 PM” is output as “08:46:53 Nachm.”. When the *format* argument specified does not correspond to the given *string*, an error is returned.

When the *format* argument is omitted, the *date\_time* is output as a string according to the default output format of the “en\_US”(see the following table [Default Date/Time Output Format for Each Language](#)).

### Note

The **CUBRID\_DATE\_LANG** environment used in earlier version of CUBRID 9.0 is no longer supported.

### Default Date/Time Output Format for Each Language

| LANG  | DATE          | TIME           | TIMESTAMP                  | DATETIME                      | TIMESTAMP WITH TIME ZONE       | DATETIME WITH TIME ZONE           |
|-------|---------------|----------------|----------------------------|-------------------------------|--------------------------------|-----------------------------------|
| en_US | 'MM/DD/YYYY'  | 'HH:MI:SS AM'  | 'HH:MI:SS AM MM/DD/YYYY'   | 'HH:MI:SS.FF AM MM/DD/YYYY'   | 'HH:MI:SS AM MM/DD/YYYY TZR'   | 'HH:MI:SS.FF AM MM/DD/YYYY TZR'   |
| de_DE | 'DD.MM.YY YY' | 'HH24:MI:SS S' | 'HH24:MI:SS S DD.MM.YY YY' | 'HH24:MI:SS S.FF DD.MM.YY YY' | 'HH24:MI:SS S DD.MM.YY YY TZR' | 'HH24:MI:SS S.FF DD.MM.YY YY TZR' |
| es_ES | 'DD.MM.YY YY' | 'HH24:MI:SS S' | 'HH24:MI:SS S DD.MM.YY YY' | 'HH24:MI:SS S.FF DD.MM.YY YY' | 'HH24:MI:SS S DD/MM/YYYY TZR'  | 'HH24:MI:SS S.FF DD/MM/YYYY TZR'  |
| fr_FR | 'DD.MM.YY YY' | 'HH24:MI:SS S' | 'HH24:MI:SS S              | 'HH24:MI:SS S.FF              | 'HH24:MI:SS S DD/MM/YYYY TZR'  | 'HH24:MI:SS S.FF DD/              |

| LANG  | DATE             | TIME             | TIMESTAMP                          | DATETIME                              | TIMESTAMP WITH TIME ZONE               | DATETIME WITH TIME ZONE                   |

Date/Time Format 1

| Format Element | Description                                                                |
|----------------|----------------------------------------------------------------------------|
| CC             | Century                                                                    |
| YYYY , YY      | Year with 4 numbers, Year with 2 numbers                                   |
| Q              | Quarter (1, 2, 3, 4; January - March = 1)                                  |
| MM             | Month (01-12; January = 01) <i>Note: MI represents the minute of hour.</i> |
| MONTH          | Month in characters                                                        |
| MON            | Abbreviated month name                                                     |
| DD             | Day (1 - 31)                                                               |

| Format Element            | Description                                                               |
|---------------------------|---------------------------------------------------------------------------|
| <b>DAY</b>                | Day of the week in characters                                             |
| <b>DY</b>                 | Abbreviated day of the week                                               |
| <b>D or d</b>             | Day of the week in numbers (1 - 7)                                        |
| <b>AM or PM</b>           | AM/PM                                                                     |
| <b>A.M. or P.M.</b>       | AM/PM with periods                                                        |
| <b>HH or HH12</b>         | Hour (1 -12)                                                              |
| <b>HH24</b>               | Hour (0 - 23)                                                             |
| <b>MI</b>                 | Minute (0 - 59)                                                           |
| <b>SS</b>                 | Second (0 - 59)                                                           |
| <b>FF</b>                 | Millisecond (0-999)                                                       |
| <b>- / , . ; : "text"</b> | Punctuation and quotation marks are represented as they are in the result |
| <b>TZD</b>                | Daylight saving information. e.g. KST, KT, EET                            |
| <b>TZH</b>                | Timezone hour offset. e.g. +09, -09                                       |
| <b>TZM</b>                | Timezone minute offset. e.g. +00, +30                                     |

**Note**

TZR, TZD, TZH, TZM can be used only in timezone types.

**Note**

**A format to specify a number after “TZD”**

A number can be added after “TZD”. This format is from TZD2 to TZD11; When you use a general character as a separator of a string, this format can be used.

```
SELECT STR_TO_DATE('09:30:17 20140307XEESTXEurope/
Bucharest', '%h:%i:%s %Y%d%mX%TZD4X%TZR');
```

```
09:30:17.000 AM 07/03/2014 Europe/Bucharest EEST
```

When you use a general character, ‘X’, as a separator to separate each value, TZD value’s string length is variable; therefore, it is confused to separate TZD value and a separator. In this case, TZD values’ length should be specified.

**Example of date\_lang\_string\_literal**

| Format Element | date_lang_string_literal |         |
|----------------|--------------------------|---------|
|                | ‘en_US’                  | ‘ko_KR’ |
| MONTH          | JANUARY                  | 1월      |
| MON            | JAN                      | 1       |
| DAY            | MONDAY                   | 월요일     |
| DY             | MON                      | 월       |

| Format Element | date_lang_string_literal |         |
|----------------|--------------------------|---------|
|                | 'en_US'                  | 'ko_KR' |
| Month          | January                  | 1월      |
| Mon            | Jan                      | 1       |
| Day            | Monday                   | 월요일     |
| Dy             | Mon                      | 월       |
| month          | january                  | 1월      |
| mon            | jan                      | 1       |
| day            | monday                   | 월요일     |
| Dy             | mon                      | 월       |
| AM             | AM                       | 오전      |
| Am             | Am                       | 오전      |
| am             | am                       | 오전      |
| A.M.           | A.M.                     | 오후      |
| A.m.           | A.m.                     | 오전      |
| a.m.           | a.m.                     | 오전      |

| Format Element | date_lang_string_literal |         |
|----------------|--------------------------|---------|
|                | 'en_US'                  | 'ko_KR' |
| <b>PM</b>      | PM                       | 오후      |
| <b>Pm</b>      | Pm                       | 오후      |
| <b>pm</b>      | pm                       | 오후      |
| <b>P.M.</b>    | P.M.                     | 오후      |
| <b>P.m.</b>    | P.m.                     | 오후      |
| <b>p.m.</b>    | p.m.                     | 오후      |

#### Example of Format Digits of Return Value

| Format Element              | en_US Digits   ko_KR Digits |                        |
|-----------------------------|-----------------------------|------------------------|
| <b>MONTH</b> (Month, month) | 9                           | 4                      |
| <b>MON</b> (Mon, mon)       | 3                           | 2                      |
| <b>DAY</b> (Day, day)       | 9                           | 6                      |
| <b>DY</b> (Dy, dy)          | 3                           | 2                      |
| <b>HH12, HH24</b>           | 2                           | 2                      |
| "text"                      | The length of the text      | The length of the text |

| Format Element | en_US Digits   ko_KR Digits |  |
|----------------|-----------------------------|--|
|----------------|-----------------------------|--|

|               |                                  |                                  |
|---------------|----------------------------------|----------------------------------|
| Other formats | Same as the length of the format | Same as the length of the format |
|---------------|----------------------------------|----------------------------------|

The following example shows the query executed by setting the language and charset to “en\_US.iso88591”.

```
-- create database testdb en_US.iso88591

--creating a table having date/time type columns
CREATE TABLE datetime_tbl(a TIME, b DATE, c TIMESTAMP, d DATETIME);
INSERT INTO datetime_tbl VALUES(SYSTIME, SYSDATE, SYSTIMESTAMP,
SYSDATETIME);

--selecting a VARCHAR type string from the data in the specified
format
SELECT TO_CHAR(b, 'DD, DY , MON, YYYY') FROM datetime_tbl;
```

```
'20, TUE , AUG, 2013'
```

```
SELECT TO_CHAR(c, 'HH24:MI, DD, MONTH, YYYY') FROM datetime_tbl;
```

```
'17:00, 20, AUGUST , 2013'
```

```
SELECT TO_CHAR(d, 'HH12:MI:SS:FF pm, YYYY-MM-DD-DAY') FROM
datetime_tbl;
```

```
'05:00:58:358 pm, 2013-08-20-TUESDAY '
```

```
SELECT TO_CHAR(TIMESTAMP'2009-10-04 22:23:00', 'Day Month yyyy');
```

```
'Sunday October 2009'
```

The following example shows an additional language parameter given to the **TO\_CHAR** function in the database created above. When the charset is ISO-8859-1, setting the language parameter of

the **TO\_CHAR** function to “tr\_TR” or “ko\_KR” is allowed, but the other languages are not allowed. To use all languages by setting the language parameter of **TO\_CHAR**, the charset when creating DB should be UTF-8.

```
SELECT TO_CHAR(TIMESTAMP'2009-10-04 22:23:00', 'Day Month
yyyy', 'ko_KR');
```

```
'Iryoil      10wol 2009'
```

```
SELECT TO_CHAR(TIMESTAMP'2009-10-04 22:23:00', 'Day Month
yyyy', 'tr_TR');
```

```
'Pazar      Ekim      2009'
```

#### Note

- In the function that interprets the month/day in characters and AM/PM differently by language, if the charset is ISO-8859-1, the language can be changed to “ko\_KR” or “tr\_TR” only by using the **intl\_date\_lang** except “en\_US” (see the above example). If the charset is UTF-8, the language can be changed to any language supported by CUBRID. By setting the **intl\_date\_lang** system parameter or by specifying the language parameter of the **TO\_CHAR** function, the language can be changed to one of all the languages supported by CUBRID (see *date\_lang\_string\_literal* of “Syntax” above). For a list of functions that interpret the date/time differently by language, see the description of the **intl\_date\_lang** system parameter.

```
-- change date locale as "de_DE" and run the below query.
-- This case is failed because database locale, en_US's charset
is ISO-8859-1
-- and 'de_DE' only supports UTF-8 charset.
```

```
SELECT TO_CHAR(TIMESTAMP'2009-10-04 22:23:00', 'Day Month
yyyy', 'de_DE');
```

```
ERROR: before ' , 'Day Month yyyy', 'de_DE'); '
Locales for language 'de_DE' are not available with charset
'iso8859-1'.
```

The following example shows how to set the language parameter of the **TO\_CHAR** function to “de\_DE” when you created DB with the locale “en\_US.utf8”.

```
SELECT TO_CHAR(TIMESTAMP'2009-10-04 22:23:00', 'Day Month
yyyy', 'de_DE');
```

```
'Sonntag   Oktober 2009'
```

- If the first argument is zerodate and the second argument has a literal like ‘Month’, ‘Day’, then TO\_CHAR function returns NULL.

```
SELECT TO_CHAR(timestamp '0000-00-00 00:00:00', 'Month Day
YYYY');
```

```
NULL
```

The following is an example to output date/time type with timezone in TO\_CHAR function.

If you don’t define a format, it outputs as the following format

```
SELECT TO_CHAR(datetimetz'2001-10-11 02:03:04 AM Europe/Bucharest
EEST');
```

```
'02:03:04.000 AM 10/11/2001 Europe/Bucharest EEST'
```

If you define a format, it outputs as the defined format.

```
SELECT TO_CHAR(datetimetz'2001-10-11 02:03:04 AM Europe/Bucharest
EEST', 'MM/DD/YYYY HH24:MI TZR TZD TZH TZM');
```

```
'10/11/2001 02:03 Europe/Bucharest EEST +03 +00'
```

**TO\_CHAR(number)**

**TO\_CHAR(number[, format[, number\_lang\_string\_literal]])**

The **TO\_CHAR** function converts a numeric data type to a character string according to **Number Format** and returns it. The type of the return value is **VARCHAR**.

#### Parameters:

- **number** – Specifies an expression that returns numeric data type string. If the input value is **NULL**, **NULL** is returned. If the input value is character type, the character itself is returned.
- **format** – Specifies a format of return value. If format is not specified, all significant figures are returned as character string by default. If the value is **NULL**, **NULL** is returned.
- **number\_lang\_string\_literal** – Specifies the language to be applied to the input value.

#### Return type:

STRING

If *format* argument is specified, *number* is converted into a character string according to a specified language. At this time, the language is defined by the *number\_lang\_string\_literal* argument. If *number\_lang\_string\_literal* is omitted, the language specified by **intl\_number\_lang** system parameter is applied; if **intl\_number\_lang** is not set, the language specified when creating DB is applied.

For example, if the language is one of the European languages, such as “de\_DE” or “fr\_FR”, “.” is printed out as a thousands separator and “,” is printed out as a decimal point. If the *format* argument does not correspond to the given string, the function returns an error.

If *format* argument is omitted, *number* is converted into a character string according to the default format of a specified language(see the table **Default Output of Number for Each Language**).

#### Number Format

| Format Element | Example | Description                                                          |
|----------------|---------|----------------------------------------------------------------------|
| 9              | 9999    | The number of 9's represents the number of significant figures to be |

| Format Element   | Example | Description                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |         | returned. If the number of significant figures specified in the format is not sufficient, only the decimal part is rounded. If it is less than the number of digits in an integer, # is outputted. If the number of significant figures specified in the format is sufficient, the part preceding the integer part is filled with space characters and the decimal part is filled with 0. |
| <b>0</b>         | 0999    | If the number of significant figures specified in the format is sufficient, the part preceding the integer part is filled with 0, not space characters before the value is returned.                                                                                                                                                                                                      |
| <b>S</b>         | S9999   | Outputs the negative/positive sign in the specified position. These signs can be used only at the beginning of character string.                                                                                                                                                                                                                                                          |
| <b>C</b>         | C9999   | Returns the ISO currency code at the specified position.                                                                                                                                                                                                                                                                                                                                  |
| <b>, (comma)</b> | 9,999   | Returns a comma (",") at the specified position. Multiple                                                                                                                                                                                                                                                                                                                                 |

| Format Element    | Example  | Description                                                                                                                                                                                                                      |
|-------------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |          | commas are allowed in the format.                                                                                                                                                                                                |
| . (decimal point) | 9.999    | Returns a decimal point (".") which distinguishes between a decimal and an at the specified position. Only one decimal point is allowed in the format. see the table, <a href="#">Default Output of Number for Each Language</a> |
| EEEE              | 9.99EEEE | Returns a scientific notation number.                                                                                                                                                                                            |

Default Output of Number for Each Language

| Language | Locale | Number Digits | of Decimal Symbol | Example of Number Usage |
|----------|--------|---------------|-------------------|-------------------------|
| English  | en_US  | ,(comma)      | .(period)         | 123,456,789.012         |
| German   | de_DE  | .(period)     | ,(comma)          | 123.456.789,012         |
| Spanish  | es_ES  | .(period)     | ,(comma)          | 123.456.789,012         |
| French   | fr_FR  | .(period)     | ,(comma)          | 123.456.789,012         |
| Italian  | it_IT  | .(period)     | ,(comma)          |                         |

| Language   | Locale | Number<br>Digits | of<br>Decimal Symbol | Example of<br>Number<br>Usage |
|------------|--------|------------------|----------------------|-------------------------------|
|            |        |                  |                      | 123.456.789,0<br>12           |
| Japanese   | ja_JP  | ,(comma)         | .(period)            | 123,456,789.0<br>12           |
| Cambodian  | km_KH  | .(period)        | ,(comma)             | 123.456.789,0<br>12           |
| Korean     | ko_KR  | ,(comma)         | .(period)            | 123,456,789.0<br>12           |
| Turkish    | tr_TR  | .(period)        | ,(comma)             | 123.456.789,0<br>12           |
| Vietnamese | vi_VN  | .(period)        | ,(comma)             | 123.456.789,0<br>12           |
| Chinese    | zh_CN  | ,(comma)         | .(period)            | 123,456,789.0<br>12           |
| Romanian   | ro_RO  | .(period)        | ,(comma)             | 123.456.789,0<br>12           |

The following example shows execution of the database by the locale specified when creating DB to “en\_US.utf8”.

```
--selecting a string casted from a number in the specified format
SELECT TO_CHAR(12345,'S999999'), TO_CHAR(12345,'S099999');
```

```
' +12345 '
```

```
' +012345 '
```

```
SELECT TO_CHAR(1234567,'9,999,999,999');
```

```
'      1,234,567'
```

```
SELECT TO_CHAR(1234567,'9.999.999.999');
```

```
'#####'
```

```
SELECT TO_CHAR(123.4567,'99'), TO_CHAR(123.4567,'999.99999'),  
TO_CHAR(123.4567,'99999.999');
```

```
'##'                '123.45670'                '  123.457'
```

The following example shows command execution by setting the value of the **intl\_number\_lang** system parameter to “de\_DE”. In the number output format of most European countries such as Germany and France, “.” is the cipher identifier and “,” is the decimal point symbol.

```
SET SYSTEM PARAMETERS 'intl_number_lang="de_DE";
```

```
--selecting a string casted from a number in the specified format  
SELECT TO_CHAR(12345,'S999999'), TO_CHAR(12345,'S099999');
```

```
' +12345'                '+012345'
```

```
SELECT TO_CHAR(1234567,'9,999,999,999');
```

```
'#####'
```

```
SELECT TO_CHAR(1234567,'9.999.999.999');
```

```
'      1.234.567'
```

```
SELECT TO_CHAR(123.4567,'99'), TO_CHAR(123.4567,'999,99999'),
TO_CHAR(123.4567,'99999,999');
```

```
'##'                '123,45670'                ' 123,457'
```

```
SELECT TO_CHAR(123.4567,'99','en_US'), TO_CHAR(123.
4567,'999.99999','en_US'), TO_CHAR(123.4567,'99999.999','en_US');
```

```
'##'                '123.45670'                ' 123.457'
```

```
SELECT TO_CHAR(1.234567,'99.999EEEE','en_US'), TO_CHAR(1.
234567,'99,999EEEE','de_DE'), to_char(123.4567);
```

```
'1.235E+00'          '1,235E+00'          '123,4567'
```

## TO\_DATE

**TO\_DATE**(*string*[, *format*[, *date\_lang\_string\_literal*]])

The **TO\_DATE** function interprets a character string based on the date format given as an argument, converts it to a **DATE** type value, and returns it. For the format, see [Date/Time Format 1](#).

Parameters:

- **string** – A character string
- **format** – Specifies a format of return value to be converted as **DATE** type. See [Date/Time Format 1](#). If the value is **NULL**, **NULL** is returned.
- **date\_lang\_string\_literal** – Specifies the language for the input value to be applied.

Return type:

DATE

When the *format* argument is specified, the *string* is interpreted according to the specified language. At this time, the language is set by *date\_lang\_string\_literal* argument. If *date\_lang\_string\_literal* argument is not set, the language is specified by the **intl\_date\_lang** system parameter; if the value of **intl\_date\_lang** is not set, the language is applied by the language specified when creating DB.

For example, when a language is “de\_DE” and *string* is “12.mai.2012”, and *format* is “DD.mon.YYYY”, it is interpreted as May 12th, 2012. When the *format* parameter specified does not correspond to the given *string*, an error is returned.

When the *format* argument is omitted, *string* is interpreted as the CUBRID default format (refer to [Recommended Format for Strings in Date/Time Type](#)) and if it fails, *string* is interpreted as the language format (see the table [Default Output Format of Language](#) in the `TO_CHAR()` by **intl\_date\_lang**. If the value of **intl\_date\_lang** is not set, the language is applied by the language specified when creating DB.

For example, when a language is “de\_DE”, the acceptable strings for **DATE** type are “MM/DD/YYYY”, CUBRID default format and “DD.MM.YYYY”, “de\_DE” default format.

The following example shows the query executed by the locale specified when creating DB to “en\_US.utf8”.

```
--selecting a date type value casted from a string in the specified format
```

```
SELECT TO_DATE('12/25/2008');
```

```
12/25/2008
```

```
SELECT TO_DATE('25/12/2008', 'DD/MM/YYYY');
```

```
12/25/2008
```

```
SELECT TO_DATE('081225', 'YYMMDD');
```

```
12/25/2008
```

```
SELECT TO_DATE('2008-12-25', 'YYYY-MM-DD');
```

```
12/25/2008
```

The following example shows the query executed when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE"';
SELECT TO_DATE('25.12.2012');
```

```
12/25/2012
```

```
SELECT TO_DATE('12/mai/2012','dd/mon/yyyy','de_DE');
```

```
05/12/2012
```

#### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see [Note](#) in the [TO\\_CHAR\(\)](#) .

## TO\_DATETIME

**TO\_DATETIME**(*string*[, *format*[, *date\_lang\_string\_literal*]])

The **TO\_DATETIME** function interprets a character string based on the date-time format given as an argument, converts it to a **DATETIME** type value, and returns it. For the format, see [Date/Time Format 1](#).

Parameters:

- **string** – A character string
- **format** – Specifies a format of return value to be converted as **DATETIME** type. See the table, [Date/Time Format 1](#). If the value is **NULL**, **NULL** is returned.
- **date\_lang\_string\_literal** – Specifies the language for the input value to be applied.

**Return type:**

DATETIME

When the *format* argument is specified, the *string* is interpreted according to the specified language.

For example, when a language is “de\_DE” and *string* is “12/mai/2012 12:10:00 Nachm.” and *format* is “DD/MON/YYYY HH:MI:SS AM”, it is interpreted as May 12th, 2012 12:10:00 PM. At this time, the language is set by *date\_lang\_string\_literal* argument. If *date\_lang\_string\_literal* argument is not set, the language is specified by the **intl\_date\_lang** system parameter; if the value of **intl\_date\_lang** is not set, the language is specified by the language specified when creating DB. When the *format* parameter specified does not correspond to the given *string*, an error is returned.

When the *format* argument is omitted, *string* is interpreted as the CUBRID default format (refer to [Recommended Format for Strings in Date/Time Type](#)) and if it fails, *string* is interpreted as the language format (see the table [Default Output Format of Language](#) in the [TO\\_CHAR\(\)](#) by **intl\_date\_lang**. If the value of **intl\_date\_lang** is not set, the language is applied by the language specified when creating DB.

For example, when a language is “de\_DE”, the acceptable strings for **DATETIME** type are “HH:MI:SS.FF AM MM/DD/YYYY”, CUBRID default format and “HH24:MI:SS.FF DD.MM.YYYY”, “de\_DE” default format.

**Note**

The **CUBRID\_DATE\_LANG** environment used in earlier version of CUBRID 9.0 is no longer supported.

The following example shows execution of the database by setting the environment variable **CUBRID\_CHARSET** to “en\_US”.

```
--selecting a datetime type value casted from a string in the  
specified format
```

```
SELECT TO_DATETIME('13:10:30 12/25/2008');
```

```
01:10:30.000 PM 12/25/2008
```

```
SELECT TO_DATETIME('08-Dec-25 13:10:30.999', 'YY-Mon-DD
HH24:MI:SS.FF');
```

```
01:10:30.999 PM 12/25/2008
```

```
SELECT TO_DATETIME('DATE: 12-25-2008 TIME: 13:10:30.999', '"DATE:"
MM-DD-YYYY "TIME:" HH24:MI:SS.FF');
```

```
01:10:30.999 PM 12/25/2008
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE"';
SELECT TO_DATETIME('13:10:30.999 25.12.2012');
```

```
01:10:30.999 PM 12/25/2012
```

```
SELECT TO_DATETIME('12/mai/2012 12:10:00 Nachm.', 'DD/MON/YYYY
HH:MI:SS AM', 'de_DE');
```

```
12:10:00.000 PM 05/12/2012
```

#### Note

When the charset is ISO-8859-1, the language that can be changed in **TO\_DATETIME** function is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see **Note** in the [TO\\_CHAR\(\)](#).

## TO\_DATETIME\_TZ

**TO\_DATETIME\_TZ**(*string*[, *format*[, *date\_lang\_string\_literal*]])

**TO\_DATETIME\_TZ** function is the same as [TO\\_DATETIME\(\)](#) function except that this function can include a timezone information on this input string.

Return type:

DATETIME

```
SELECT TO_DATETIME_TZ('13:10:30 Asia/Seoul 12/25/2008', 'HH24:MI:SS  
TZR MM/DD/YYYY');
```

```
01:10:30.000 PM 12/25/2008 Asia/Seoul
```

## TO\_NUMBER

**TO\_NUMBER**(*string* [, *format*])

The **TO\_NUMBER** function interprets a character string based on the number format given as an argument, converts it to a **NUMERIC** type value, and returns it.

Parameters:

- **string** – Specifies an expression that returns character string. If the value is **NULL**, **NULL** is returned.
- **format** – Specifies a format of return value to be converted as **NUMBER** type. See [Number Format](#). If it is omitted, **NUMERIC(38,0)** value is returned.

Return type:

NUMERIC

When the *format* argument is assigned, the string is interpreted according to the specified language. At this time, the language is specified by the **intl\_number\_lang** system parameter. If the value of **intl\_number\_lang** is not set, the language specified when creating DB is applied.

For example, when the language is one of the European languages, such as “de\_DE” and “fr\_FR”, “.” is interpreted as the cipher identifier and “,” as the decimal point symbol. When the format parameter specified does not correspond to the given string, an error is returned.

If the *format* argument is omitted, string is interpreted according to the default output format set by **intl\_number\_lang** (see [Default Output of Number for Each Language](#)). When the **intl\_number\_lang** is not set, the language specified when creating DB is applied.

The following example shows execution of the database by setting the value of system parameter **intl\_number\_lang** as “en\_US”.

```
SET SYSTEM PARAMETERS 'intl_number_lang="en_US";  
  
--selecting a number casted from a string in the specified format  
SELECT TO_NUMBER('-1234');
```

```
-1234
```

```
SELECT TO_NUMBER('12345','999999');
```

```
12345
```

```
SELECT TO_NUMBER('12,345.67','99,999.999');
```

```
12345.670
```

```
SELECT TO_NUMBER('12345.67','99999.999');
```

```
12345.670
```

The following example shows command execution on the database by setting the value of the **intl\_number\_lang** system parameter to “de\_DE”. In the number output format of most European countries, such as Germany and France, “.” is the cipher identifier and “,” is the decimal point symbol.

```
SET SYSTEM PARAMETERS 'intl_number_lang="de_DE";  
SELECT TO_NUMBER('12.345,67','99.999,999');
```

```
12345.670
```

## TO\_TIME

`TO_TIME(string[, format[, date_lang_string_literal]])`

The **TO\_TIME** function interprets a character string based on the time format given as an argument, converts it to a **TIME** type value, and returns it. For the format, see [Date/Time Format 1](#).

**Parameters:**

- **string** – Specifies an expression that returns character string. If the value is **NULL**, **NULL** is returned.
- **format** – Specifies a format of return value to be converted as **TIME** type. See [Date/Time Format 1](#). If the value is **NULL**, **NULL** is returned.
- **date\_lang\_string\_literal** – Specifies the language for the input value to be applied.

**Return type:**

TIME

When the *format* argument is specified, the *string* is interpreted according to the specified language. At this time, the language is set by *date\_lang\_string\_literal* argument. If *date\_lang\_string\_literal* argument is not set, the language is specified by the **intl\_date\_lang** system parameter; if the value of **intl\_date\_lang** is not set, the language specified when creating DB is applied. When the *format* parameter does not correspond to the given *string*, an error is returned.

For example, when a language is “de\_DE” and *string* is “10:23:00 Nachm.”, and *format* is “HH/MI/SS/AM”, it is interpreted as 10:23:00 PM.

When the *format* argument is omitted, *string* is interpreted as the CUBRID default format (refer to [Recommended Format for Strings in Date/Time Type](#)) and if it fails, *string* is interpreted as the language format (see the table [Default Output Format of Language](#) in the [TO\\_CHAR\(\)](#) by **intl\_date\_lang**. If the value of **intl\_date\_lang** is not set, the language is applied by the language specified when creating DB.

For example, when a language is “de\_DE”, the acceptable strings for **TIME** type are “HH:MI:SS AM”, CUBRID default format and “HH24:MI:SS”, “de\_DE” default format.

**Note**

The **CUBRID\_DATE\_LANG** environment used in earlier version of CUBRID 9.0 is no longer supported.

The following example shows execution of the database by setting the value of system parameter **intl\_date\_lang** as “en\_US”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="en_US";
```

```
--selecting a time type value casted from a string in the specified  
format
```

```
SELECT TO_TIME ('13:10:30');
```

```
01:10:30 PM
```

```
SELECT TO_TIME('HOUR: 13 MINUTE: 10 SECOND: 30', '"HOUR:" HH24  
"MINUTE:" MI "SECOND:" SS');
```

```
01:10:30 PM
```

```
SELECT TO_TIME ('13:10:30', 'HH24:MI:SS');
```

```
01:10:30 PM
```

```
SELECT TO_TIME ('13:10:30', 'HH12:MI:SS');
```

```
ERROR: Conversion error in date format.
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE";
```

```
SELECT TO_TIME('13:10:30');
```

```
01:10:30 PM
```

```
SELECT TO_TIME('10:23:00 Nachm.', 'HH:MI:SS AM');
```

```
10:23:00 PM
```

### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see [Note](#) in the [TO\\_CHAR\(\)](#) .

## TO\_TIMESTAMP

**TO\_TIMESTAMP**(*string*[, *format*[, *date\_lang\_string\_literal*]])

The **TO\_TIMESTAMP** function interprets a character string based on the time format given as an argument, converts it to a **TIMESTAMP** type value, and returns it. For the format, see [Date/Time Format 1](#).

### Parameters:

- **string** – Specifies an expression that returns character string. If the value is **NULL**, **NULL** is returned.
- **format** – Specifies a format of return value to be converted as **TIMESTAMP** type. See [Date/Time Format 1](#). If the value is **NULL**, **NULL** is returned.
- **date\_lang\_string\_literal** – Specifies the language for the input value to be applied.

### Return type:

TIMESTAMP

When the *format* argument is specified, the *string* is interpreted according to the specified language. The language is set by *date\_lang\_string\_literal* argument. If *date\_lang\_string\_literal* argument is not set, the language is specified by the **intl\_date\_lang** system parameter; if the value of **intl\_date\_lang** is not set, the language specified when creating DB is applied.

For example, when a language is “de\_DE” and *string* is “12/mai/2012 12:10:00 Nachm.”, and *format* is “DD/MON/YYYY HH:MI:SS AM”, it is interpreted as May 12th, 2012, 12:10:00 AM. When the *format* parameter specified does not correspond to the given string, an error is returned.

When the *format* argument is omitted, *string* is interpreted as the CUBRID default format(refer to [Recommended Format for Strings in Date/Time Type](#)) and if it fails, *string* is interpreted as the language format (see the table [Default Output Format of Language](#) in the [TO\\_CHAR\(\)](#) by **intl\_date\_lang**. If the value of **intl\_date\_lang** is not set, the language is applied by the language specified when creating DB.

For example, when a language is “de\_DE”, the acceptable strings for **TIMESTAMP** type are “HH:MI:SS AM MM/DD/YYYY”, CUBRID default format and “HH24:MI:SS DD.MM.YYYY”, “de\_DE” default format.

The following example shows execution of the database by setting the value of system parameter **intl\_date\_lang** as “en\_US”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="en_US";
```

```
--selecting a timestamp type value casted from a string in the  
specified format
```

```
SELECT TO_TIMESTAMP('13:10:30 12/25/2008');
```

```
01:10:30 PM 12/25/2008
```

```
SELECT TO_TIMESTAMP('08-Dec-25 13:10:30', 'YY-Mon-DD HH24:MI:SS');
```

```
01:10:30 PM 12/25/2008
```

```
SELECT TO_TIMESTAMP('YEAR: 2008 DATE: 12-25 TIME: 13:10:30',  
'"YEAR:" YYYY "DATE:" MM-DD "TIME:" HH24:MI:SS');
```

```
01:10:30 PM 12/25/2008
```

The following example shows the case when the system parameter **intl\_date\_lang** is “de\_DE”.

```
SET SYSTEM PARAMETERS 'intl_date_lang="de_DE";  
SELECT TO_TIMESTAMP('13:10:30 25.12.2008');
```

```
01:10:30 PM 12/25/2008
```

```
SELECT TO_TIMESTAMP('10:23:00 Nachm.', 'HH12:MI:SS AM');
```

```
10:23:00 PM 08/01/2012
```

### Note

When the charset is ISO-8859-1, the language that can be changed by the system parameter **intl\_date\_lang** is “ko\_KR” and “tr\_TR” except “en\_US”. If the charset is UTF-8, it can be changed to any language supported by CUBRID. For details, see **Note** in the **TO\_CHAR()** .

## TO\_TIMESTAMP\_TZ

**TO\_TIMESTAMP\_TZ**(*string*[, *format*[, *date\_lang\_string\_literal*]])

**TO\_TIMESTAMP\_TZ** function is the same as **TO\_TIMESTAMP()** function except that this function can include a timezone information on this input string.

rtype:

TIMESTAMPTZ

```
SELECT TO_TIMESTAMP_TZ('13:10:30 Asia/Seoul 12/25/2008',
'HH24:MI:SS TZR MM/DD/YYYY');
```

```
01:10:30 PM 12/25/2008 Asia/Seoul
```

## Overview

Aggregate/Analytic function is used when you want to analyze data and extract some results.

- Aggregate function returns the grouped results and it returns only the columns which are grouped.
- Analytic function returns the grouped results, but it includes the ungrouped columns, so it can return multiple rows for one group.

For examples, aggregate/analytic function can be used to get the answers as follows.

1. What is the total sales amount per year?
2. How can you display the sales amount from the highest one's month by grouping each year?
3. How can you display the accumulated sales amount as annual and monthly order by grouping each year?

You can answer for No. 1 with aggregate function. for No. 2 and No. 3, you can answer with analytic function. Above questions can be written as following SQL statements.

Below is the table which stores the sales amounts per month of each year.

```
CREATE TABLE sales_mon_tbl (
  yyyy INT,
  mm INT,
```

```

        sales_sum INT
    );

INSERT INTO sales_mon_tbl VALUES
    (2000, 1, 1000), (2000, 2, 770), (2000, 3, 630), (2000, 4, 890),
    (2000, 5, 500), (2000, 6, 900), (2000, 7, 1300), (2000, 8, 1800),
    (2000, 9, 2100), (2000, 10, 1300), (2000, 11, 1500), (2000, 12,
1610),
    (2001, 1, 1010), (2001, 2, 700), (2001, 3, 600), (2001, 4, 900),
    (2001, 5, 1200), (2001, 6, 1400), (2001, 7, 1700), (2001, 8,
1110),
    (2001, 9, 970), (2001, 10, 690), (2001, 11, 710), (2001, 12,
880),
    (2002, 1, 980), (2002, 2, 750), (2002, 3, 730), (2002, 4, 980),
    (2002, 5, 1110), (2002, 6, 570), (2002, 7, 1630), (2002, 8,
1890),
    (2002, 9, 2120), (2002, 10, 970), (2002, 11, 420), (2002, 12,
1300);

```

1. What is the total sales amount per year?

```

SELECT yyyy, sum(sales_sum)
FROM sales_mon_tbl
GROUP BY yyyy;

```

| yyyy | sum(sales_sum) |
|------|----------------|
| 2000 | 14300          |
| 2001 | 11870          |
| 2002 | 13450          |

1. How can you display the sales amount from the highest one's month by grouping each year?

```

SELECT yyyy, mm, sales_sum, RANK() OVER (PARTITION BY yyyy ORDER BY
sales_sum DESC) AS rnk
FROM sales_mon_tbl;

```

| yyyy | mm | sales_sum | rnk |
|------|----|-----------|-----|
| 2000 | 9  | 2100      | 1   |
| 2000 | 8  | 1800      | 2   |
| 2000 | 12 | 1610      | 3   |
| 2000 | 11 | 1500      | 4   |
| 2000 | 7  | 1300      | 5   |
| 2000 | 10 | 1300      | 5   |
| 2000 | 1  | 1000      | 7   |

|      |    |      |    |
|------|----|------|----|
| 2000 | 6  | 900  | 8  |
| 2000 | 4  | 890  | 9  |
| 2000 | 2  | 770  | 10 |
| 2000 | 3  | 630  | 11 |
| 2000 | 5  | 500  | 12 |
| 2001 | 7  | 1700 | 1  |
| 2001 | 6  | 1400 | 2  |
| 2001 | 5  | 1200 | 3  |
| 2001 | 8  | 1110 | 4  |
| 2001 | 1  | 1010 | 5  |
| 2001 | 9  | 970  | 6  |
| 2001 | 4  | 900  | 7  |
| 2001 | 12 | 880  | 8  |
| 2001 | 11 | 710  | 9  |
| 2001 | 2  | 700  | 10 |
| 2001 | 10 | 690  | 11 |
| 2001 | 3  | 600  | 12 |
| 2002 | 9  | 2120 | 1  |
| 2002 | 8  | 1890 | 2  |
| 2002 | 7  | 1630 | 3  |
| 2002 | 12 | 1300 | 4  |
| 2002 | 5  | 1110 | 5  |
| 2002 | 1  | 980  | 6  |
| 2002 | 4  | 980  | 6  |
| 2002 | 10 | 970  | 8  |
| 2002 | 2  | 750  | 9  |
| 2002 | 3  | 730  | 10 |
| 2002 | 6  | 570  | 11 |
| 2002 | 11 | 420  | 12 |

1. How can you display the accumulated sales amount as annual and monthly order by grouping each year?

```
SELECT yyyy, mm, sales_sum, SUM(sales_sum) OVER (PARTITION BY yyyy
ORDER BY yyyy, mm) AS a_sum
FROM sales_mon_tbl;
```

| yyyy  | mm | sales_sum | a_sum |
|-------|----|-----------|-------|
| ===== |    |           |       |
| 2000  | 1  | 1000      | 1000  |
| 2000  | 2  | 770       | 1770  |
| 2000  | 3  | 630       | 2400  |
| 2000  | 4  | 890       | 3290  |
| 2000  | 5  | 500       | 3790  |
| 2000  | 6  | 900       | 4690  |
| 2000  | 7  | 1300      | 5990  |
| 2000  | 8  | 1800      | 7790  |
| 2000  | 9  | 2100      | 9890  |
| 2000  | 10 | 1300      | 11190 |

|      |    |      |       |
|------|----|------|-------|
| 2000 | 11 | 1500 | 12690 |
| 2000 | 12 | 1610 | 14300 |

| 2002 | 10 | 970  | 11730 |
| 2002 | 11 | 420  | 12150 |
| 2002 | 12 | 1300 | 13450 |

### Aggregate vs. Analytic

**Aggregate function** returns one result based on the group of rows. When the **GROUP BY** clause is included, a one-row aggregate result per group is returned. When the **GROUP BY** clause is omitted, a one-row aggregate result for all rows is returned. The **HAVING** clause is used to add a condition to the query which contains the **GROUP BY** clause.

Most aggregate functions can use **DISTINCT**, **UNIQUE** constraints. For the **GROUP BY ... HAVING** clause, see [GROUP BY ... HAVING Clause](#).

**Analytic function** calculates the aggregate value based on the result of rows. The analytic function is different from the aggregate function since it can return one or more rows based on the groups specified by the *<partition\_by\_clause>* after the **OVER** clause (when this clause is omitted, all rows are regarded as a group).

The analytic function is used along with a new analytic clause, **OVER**, for the existing aggregate functions to allow a variety of statistics for a group of specific rows.

```
function_name ([<argument_list>]) OVER (<analytic_clause>)

<analytic_clause>::=
```

```

[<partition_by_clause>] [<order_by_clause>]

<partition_by_clause>::=
    PARTITION BY value_expr[, value_expr]...

<order_by_clause>::=
    ORDER BY { expression | position | column_alias } [ ASC | DESC ]
             [, { expression | position | column_alias } [ ASC |
DESC ] ] ...

```

- *<partition\_by\_clause>*: Groups based on one or more *value\_expr*. It uses the **PARTITION BY** clause to partition the query result.
- *<order\_by\_clause>*: defines the data sorting method in the partition made by *<partition\_by\_clause>*. The result can be sorted with several keys. When *<partition\_by\_clause>* is omitted, the data is sorted within the overall result sets. Based on the sorting order, the function is applied to the column values of accumulated records, including the previous values.

The behavior of a query with the expression of ORDER BY/PARTITION BY clause which is used together after the OVER clause is as follows.

- ORDER BY/PARTITION BY *<expression with non-constant>* (ex: i, sin(i+1)): The expression is used to do ordering/partitioning.
- ORDER BY/PARTITION BY *<constant>* (ex: 1): Constant is considered as the column position of SELECT list.
- ORDER BY/PARTITION BY *<constant expression>* (ex: 1+0): Constant is ignored and it is not used to do ordering/partitioning.

### Analytic functions which “ORDER BY” clause must be specified in OVER function

The below functions require ordering; therefore, “ORDER BY” clause must be specified inside OVER function. In the case of omitting “ORDER BY” clause, please note that an error occurs or proper ordering is not guaranteed.

- CUME\_DIST()
- DENSE\_RANK()
- LAG()
- LEAD()
- NTILE()
- PERCENT\_RANK()

- `RANK()`
- `ROW_NUMBER()`

## AVG

`AVG([ DISTINCT | DISTINCTROW | UNIQUE | ALL ] expression)`

`AVG([ DISTINCT | DISTINCTROW | UNIQUE | ALL ] expression) OVER (<analytic_clause>)`

The **AVG** function is used as an aggregate function or an analytic function. It calculates the arithmetic average of the value of an expression representing all rows. Only one *expression* is specified as a parameter. You can get the average without duplicates by using the **DISTINCT** or **UNIQUE** keyword in front of the expression or the average of all values by omitting the keyword or by using **ALL**.

### param expression:

Specifies an expression that returns a numeric value. An expression that returns a collection-type data is not allowed.

### param ALL:

Calculates an average value for all data (default).

### param

**DISTINCT**,**DISTINCTROW**,**UNIQUE**:

Calculates an average value without duplicates.

### rtype:

DOUBLE

The following example shows how to retrieve the average number of gold medals that Korea won in Olympics in the *demodb* database.

```
SELECT AVG(gold)
FROM participant
WHERE nation_code = 'KOR';
```

```

                                avg(gold)
=====
          9.600000000000000e+00

```

The following example shows how to output the number of gold medals by year and the average number of accumulated gold medals in history, acquired whose nation\_code starts with 'AU'.

```

SELECT host_year, nation_code, gold,
       AVG(gold) OVER (PARTITION BY nation_code ORDER BY host_year)
  avg_gold
FROM participant WHERE nation_code like 'AU%';

```

| host_year | nation_code | gold | avg_gold              |
|-----------|-------------|------|-----------------------|
| =====     |             |      |                       |
| ==        |             |      |                       |
| 1988      | 'AUS'       | 3    | 3.000000000000000e+00 |
| 1992      | 'AUS'       | 7    | 5.000000000000000e+00 |
| 1996      | 'AUS'       | 9    | 6.333333333333333e+00 |
| 2000      | 'AUS'       | 16   | 8.750000000000000e+00 |

The following example is removing the "ORDER BY host\_year" clause under the **OVER** analysis clause from the above example. The avg\_gold value is the average of gold medals for all years, so the value is identical for every year by nation\_code.

```

SELECT host_year, nation_code, gold, AVG(gold) OVER (PARTITION BY
  nation_code) avg_gold
FROM participant WHERE nation_code LIKE 'AU%';

```

```

      host_year  nation_code      gold
avg_gold

## COUNT

COUNT(\*)

COUNT(\*) OVER (<analytic\_clause>)

COUNT([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression)

COUNT([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression) OVER (<analytic\_clause>)

The **COUNT** function is used as an aggregate function or an analytic function. It returns the number of rows returned by a query. If an asterisk (\*) is specified, the number of all rows satisfying the condition (including the rows with the **NULL** value) is returned. If the **DISTINCT** or **UNIQUE** keyword is specified in front of the expression, only the number of rows that have a unique value (excluding the rows with the **NULL** value) is returned after duplicates have been removed. Therefore, the value returned is always a big integer and **NULL** is never returned.

param expression:

Specifies an expression.

**param ALL:**

Gets the number of rows given in the *expression* (default).

**param**

**DISTINCT,DISTINCTROW,UNIQUE:**

Gets the number of rows without duplicates.

**rtype:**

BIGINT

A column that has collection type and object domain (user-defined class) can also be specified in the *expression*.

The following example shows how to retrieve the number of Olympic Games that have a mascot in the *demodb* database.

```
SELECT COUNT(*)
FROM olympic
WHERE mascot IS NOT NULL;
```

```
count(*)
=====
9
```

The following example shows how to output the number of players whose *nation\_code* is 'AUT' in *demodb* by accumulating the number of events when the event is changed. The last row shows the number of all players.

```
SELECT nation_code, event, name, COUNT(*) OVER (ORDER BY event) co
FROM athlete WHERE nation_code='AUT';
```

```
nation_code      event
name
=====
=====
'AUT'            'Athletics'      'Kiesl'
```

## CUME\_DIST

**CUME\_DIST**(*expression*[, *expression*] ...) *WITHIN GROUP* (<*order\_by\_clause*>)

**CUME\_DIST**() *OVER* ([<*partition\_by\_clause*>] <*order\_by\_clause*>)

**CUME\_DIST** function is used as an aggregate function or an analytic function. It returns the value of cumulated distribution about the specified value within the group. The range of a return value by **CUME\_DIST** is 0 < and 1 ≤. The return value of **CUME\_DIST** about the same input argument is evaluated as the same cumulated distribution value.

**param expression:**

an expression which returns the number or string.  
This should not be a column.

**param order\_by\_clause:**

column names followed by ORDER BY clause should  
be matched to the number of expressions

**rtype:**

DOUBLE

**See also**

[PERCENT\\_RANK\(\)](#) , [CUME\\_DIST](#) vs. [PERCENT\\_RANK](#)

If it is used as an aggregate function, **CUME\_DIST** sorts the data by the order specified in **ORDER BY** clause; then it returns the relative position of a hypothetical row in the rows of aggregate group. At this time, the position is calculated as if a hypothetical row is newly inserted. That is, **CUME\_DIST** returns (“cumulated RANK of a hypothetical row” + 1)/ (“the number of total rows in an aggregate group”).

If it is used as an analytic function, **CUME\_DIST** returns the relative position of a value in the group after sorting each row (**ORDER BY**) within each partitioned group (**PARTITION BY**). The relative position is calculated by dividing the number of rows with values less than or equal to the input argument by the total number of rows in the group (rows grouped by the partition\_by\_clause or all rows if no partition is specified). That is, it returns (cumulative rank of a certain row)/(number of rows within the group). For example, if the number of rows with RANK 1 is 2, the **CUME\_DIST** values of the first and second rows will be “2/10 = 0.2”.

The following is a schema and data to use in the example of this function.

```
CREATE TABLE scores(id INT PRIMARY KEY AUTO_INCREMENT, math INT,
english INT, pe CHAR, grade INT);
```

```
INSERT INTO scores(math, english, pe, grade)
VALUES(60, 70, 'A', 1),
(60, 70, 'A', 1),
(60, 80, 'A', 1),
(60, 70, 'B', 1),
(70, 60, 'A', 1) ,
```

```

(70, 70, 'A', 1) ,
(80, 70, 'C', 1) ,
(70, 80, 'C', 1),
(85, 60, 'C', 1),
(75, 90, 'B', 1);
INSERT INTO scores(math, english, pe, grade)
VALUES(95, 90, 'A', 2),
(85, 95, 'B', 2),
(95, 90, 'A', 2),
(85, 95, 'B', 2),
(75, 80, 'D', 2),
(75, 85, 'D', 2),
(75, 70, 'C', 2),
(65, 95, 'A', 2),
(65, 95, 'A', 2),
(65, 95, 'A', 2);

```

The following is an example to be used as an aggregate function; it returns the result that the sum of each cumulated distribution about each column - *math*, *english* and *pe* - is divided by 3.

```

SELECT CUME_DIST(60, 70, 'D')
WITHIN GROUP(ORDER BY math, english, pe) AS cume
FROM scores;

```

```
1.904761904761905e-01
```

The following is an example to be used as an analytic function; it returns the cumulated distributions of each row about the 3 columns - *math*, *english* and *pe*.

```

SELECT id, math, english, pe, grade, CUME_DIST() OVER(ORDER BY math,
english, pe) AS cume_dist
FROM scores
ORDER BY cume_dist;

```

| grade | id | math | english | pe | cume_dist |
|-------|----|------|---------|----|-----------|

2      1.0000000000000000e+00
13     95      90      'A'
2      1.0000000000000000e+00

```

In the above result, the row that *id* is 1, is located at the first and the second on the total 10 rows, and the value of CUME\_DIST is 2/10, that is, 0.2.

The row that *id* is 5, is located at the fifth on the total 10 rows, and the value of **CUME\_DIST** is 5/10, that is, 0.5.

## DENSE\_RANK

**DENSE\_RANK()** *OVER* ([<partition\_by\_clause>] <order\_by\_clause>)

**DENSE\_RANK** function is used as an analytic function only. The rank of the value in the column value group made by the **PARTITION BY** clause is calculated and output as **INTEGER**.

Even when there is the same rank, 1 is added to the next rank value. For example, when there are three rows of Rank 13, the next rank is 14, not 16. On the contrary, the `RANK()` function calculates the next rank by adding the number of same ranks.

#### Return type:

INT

The following example shows output of the number of Olympic gold medals of each country and the rank of the countries by year: The number of the same rank is ignored and the next rank is calculated by adding 1 to the rank.

```
SELECT host_year, nation_code, gold,
DENSE_RANK() OVER (PARTITION BY host_year ORDER BY gold DESC) AS
d_rank
FROM participant;
```

| host_year | nation_code | gold  | d_rank |
|-----------|-------------|-------|--------|

## FIRST\_VALUE

**FIRST\_VALUE**(*expression*) [{*RESPECT*|*IGNORE*} *NULLS*] *OVER* (<*analytic\_clause*>)

**FIRST\_VALUE** function is used as an analytic function only. It returns **NULL** if the first value in the set is null. But, if you specify **IGNORE NULLS**, the first value will be returned as excluding null or **NULL** will be returned if all values are null.

### Parameters:

**expression** – a column or an expression which returns a number or a string. **FIRST\_VALUE** function or other analytic function cannot be included.

### Return type:

a type of an expression

### See also

`LAST_VALUE()` , `NTH_VALUE()`

The following is schema and data to run the example.

```

CREATE TABLE test_tbl(groupid int,itemno int);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,1);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,2);
INSERT INTO test_tbl VALUES(1,3);
INSERT INTO test_tbl VALUES(1,4);
INSERT INTO test_tbl VALUES(1,5);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,6);
INSERT INTO test_tbl VALUES(2,7);

```

The following is a query and a result to run **FIRST\_VALUE** function.

```

SELECT groupid, itemno, FIRST_VALUE(itemno) OVER(PARTITION BY
groupid ORDER BY itemno) AS ret_val
FROM test_tbl;

```

| groupid | itemno | ret_val |
|---------|--------|---------|
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | 1      | NULL    |
| 1       | 2      | NULL    |
| 1       | 3      | NULL    |
| 1       | 4      | NULL    |
| 1       | 5      | NULL    |
| 2       | NULL   | NULL    |
| 2       | NULL   | NULL    |
| 2       | NULL   | NULL    |
| 2       | 6      | NULL    |
| 2       | 7      | NULL    |

#### Note

CUBRID sorts **NULL** value as first order than other values. The below SQL1 is interpreted as SQL2 which includes **NULLS FIRST** in ORDER BY clause.

```

SQL1: FIRST_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY
itemno) AS ret_val

```

```
SQL2: FIRST_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY
itemno NULLS FIRST) AS ret_val
```

The following is an example to specify **IGNORE NULLS**.

```
SELECT groupid, itemno, FIRST_VALUE(itemno) IGNORE NULLS
OVER(PARTITION BY groupid ORDER BY itemno) AS ret_val
FROM test_tbl;
```

| groupid | itemno | ret_val |
|---------|--------|---------|
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | 1      | 1       |
| 1       | 2      | 1       |
| 1       | 3      | 1       |
| 1       | 4      | 1       |
| 1       | 5      | 1       |
| 2       | NULL   | NULL    |
| 2       | NULL   | NULL    |
| 2       | NULL   | NULL    |
| 2       | 6      | 6       |
| 2       | 7      | 6       |

## GROUP\_CONCAT

**GROUP\_CONCAT**(*[DISTINCT] expression [ORDER BY {column | unsigned\_int} [ASC | DESC]]*  
*[SEPARATOR str\_val]*)

The **GROUP\_CONCAT** function is used as an aggregate function only. It connects the values that are not **NULL** in the group and returns the character string in the **VARCHAR** type. If there are no rows of query result or there are only **NULL** values, **NULL** will be returned.

Parameters:

- **expression** – Column or expression returning numerical values or character strings
- **str\_val** – Character string to use as a separator
- **DISTINCT** – Removes duplicate values from the result.
- **ORDERBY** – Specifies the order of result values.

- **SEPARATOR** – Specifies the separator to divide the result values. If it is omitted, the default character, comma (,) will be used as a separator.

**Return type:**

STRING

The maximum size of the return value follows the configuration of the system parameter, **group\_concat\_max\_len**. The default is **1024** bytes, the minimum value is 4 bytes and the maximum value is IN\_MAX(about 2G) bytes.

This function is affected by **string\_max\_size\_bytes** parameter; if the value of **group\_concat\_max\_len** is larger than the value **string\_max\_size\_bytes** and the result size of **GROUP\_CONCAT** exceeds the value of **string\_max\_size\_bytes**, an error occurs.

To remove the duplicate values, use the **DISTINCT** clause. The default separator for the group result values is comma (,). To represent the separator explicitly, add the character string to use as a separator in the **SEPARATOR** clause and after that. If you want to remove separators, enter empty strings after the **SEPARATOR** clause.

If the non-character string type is passed to the result character string, an error will be returned.

To use the **GROUP\_CONCAT** function, you must meet the following conditions.

- Only one expression (or a column) is allowed for an input parameter.
- Sorting with **ORDER BY** is available only in the expression used as a parameter.
- The character string used as a separator allows not only character string type but also allows other types.

```
SELECT GROUP_CONCAT(s_name) FROM code;
```

```
group_concat(s_name)
=====
'X,W,M,B,S,G'
```

```
SELECT GROUP_CONCAT(s_name ORDER BY s_name SEPARATOR ':') FROM code;
```

```
group_concat(s_name order by s_name separator ':')
=====
'B:G:M:S:W:X'
```

```
CREATE TABLE t(i int);
INSERT INTO t VALUES (4),(2),(3),(6),(1),(5);

SELECT GROUP_CONCAT(i*2+1 ORDER BY 1 SEPARATOR '') FROM t;
```

```
group_concat(i*2+1 order by 1 separator '')
=====
'35791113'
```

### Note

**GROUP\_CONCAT** performance for processing large numbers of rows has been improved starting from CUBRID 11.3 through optimization of internal string operations.

## LAG

**LAG**(*expression*[, *offset*[, *default*]]) OVER ([<partition\_by\_clause>] <order\_by\_clause>)

**LAG** is an analytic function that returns the *expression* value from a previous row, before *offset* that comes before the current row. It can be used to access several rows simultaneously without making any self join.

Parameters:

- **expression** – a column or an expression that returns a number or a string
- **offset** – an integer which indicates the offset position. If not specified, the default is 1
- **default** – a value to return when an *expression* value before *offset* is NULL. If a default value is not specified, NULL is returned

Return type:

## NUMBER or STRING

The following example shows how to sort employee numbers and output the previous employee number on the same row:

```
CREATE TABLE t_emp (name VARCHAR(10), empno INT);
INSERT INTO t_emp VALUES
  ('Amie', 11011),
  ('Jane', 13077),
  ('Lora', 12045),
  ('James', 12006),
  ('Peter', 14006),
  ('Tom', 12786),
  ('Ralph', 23518),
  ('David', 55);

SELECT name, empno, LAG (empno, 1) OVER (ORDER BY empno) prev_empno
FROM t_emp;
```

| name    | empno | prev_empno |
|---------|-------|------------|
| 'David' | 55    | NULL       |
| 'Amie'  | 11011 | 55         |
| 'James' | 12006 | 11011      |
| 'Lora'  | 12045 | 12006      |
| 'Tom'   | 12786 | 12045      |
| 'Jane'  | 13077 | 12786      |
| 'Peter' | 14006 | 13077      |
| 'Ralph' | 23518 | 14006      |

On the contrary, `LEAD()` function returns the expression value from a subsequent row, after *offset* that follows the current row.

## LAST\_VALUE

`LAST_VALUE(expression) [{RESPECT|IGNORE} NULLS] OVER (<analytic_clause>)`

**LAST\_VALUE** function is used as an analytic function only. It returns **NULL** if the last value in the set is null. But, if you specify **IGNORE NULLS**, the last value will be returned as excluding null or **NULL** will be returned if all values are null.

Parameters:

**expression** – a column or an expression which returns a number or a string. **LAST\_VALUE** function or other analytic function cannot be included.

Return type:

a type of an *expression*

#### See also

[FIRST\\_VALUE\(\)](#) , [NTH\\_VALUE\(\)](#)

The following is schema and data to run the example.

```
CREATE TABLE test_tbl(groupid int,itemno int);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,1);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,2);
INSERT INTO test_tbl VALUES(1,3);
INSERT INTO test_tbl VALUES(1,4);
INSERT INTO test_tbl VALUES(1,5);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,6);
INSERT INTO test_tbl VALUES(2,7);
```

The following is a query and a result to run **LAST\_VALUE** function.

```
SELECT groupid, itemno, LAST_VALUE(itemno) OVER(PARTITION BY groupid
ORDER BY itemno) AS ret_val
FROM test_tbl;
```

| groupid | itemno | ret_val |
|---------|--------|---------|
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | 1      | 1       |
| 1       | 2      | 2       |
| 1       | 3      | 3       |

|   |      |      |
|---|------|------|
| 1 | 4    | 4    |
| 1 | 5    | 5    |
| 2 | NULL | NULL |
| 2 | NULL | NULL |
| 2 | NULL | NULL |
| 2 | 6    | 6    |
| 2 | 7    | 7    |

**LAST\_VALUE** function is calculated by the current row. That is, values which are not binded are not included on the calculation. For example, on the above result, the value of **LAST\_VALUE** is 1 when “(groupid, itemno) = (1, 1)”; 2 when “(groupid, itemno) = (1, 2)”

#### Note

CUBRID sorts **NULL** value as first order than other values. The below SQL1 is interpreted as SQL2 which includes **NULLS FIRST** in **ORDER BY** clause.

```
SQL1: LAST_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY
itemno) AS ret_val
SQL2: LAST_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY itemno
NULLS FIRST) AS ret_val
```

## LEAD

**LEAD**(*expression*, *offset*[, *default*]) **OVER** ([<*partition\_by\_clause*>] <*order\_by\_clause*>)

**LEAD** is an analytic function that returns the *expression* value from a subsequent row, after *offset* that follows the current row. It can be used to access several rows simultaneously without making any self join.

Parameters:

- **expression** – a column or an expression which returns a number or a string.
- **offset** – the number which indicates the offset location. If it's omitted, the default is 1.
- **default** – the output value when the *expression* value located before *offset* is **NULL**. The default is **NULL**.

Return type:

## NUMBER or STRING

The following example shows how to sort employee numbers and output the next employee number on the same row:

```
CREATE TABLE t_emp (name VARCHAR(10), empno INT);
INSERT INTO t_emp VALUES
('Amie', 11011), ('Jane', 13077), ('Lora', 12045), ('James', 12006),
('Peter', 14006), ('Tom', 12786), ('Ralph', 23518), ('David', 55);

SELECT name, empno, LEAD (empno, 1) OVER (ORDER BY empno) next_empno
FROM t_emp;
```

| name    | empno | next_empno |
|---------|-------|------------|
| 'David' | 55    | 11011      |
| 'Amie'  | 11011 | 12006      |
| 'James' | 12006 | 12045      |
| 'Lora'  | 12045 | 12786      |
| 'Tom'   | 12786 | 13077      |
| 'Jane'  | 13077 | 14006      |
| 'Peter' | 14006 | 23518      |
| 'Ralph' | 23518 | NULL       |

The following example shows how to output the title of the previous row and the title of the next row along with the title of the current row on the tbl\_board table:

```
CREATE TABLE tbl_board (num INT, title VARCHAR(50));
INSERT INTO tbl_board VALUES
(1, 'title 1'), (2, 'title 2'), (3, 'title 3'), (4, 'title 4'), (5,
'title 5'), (6, 'title 6'), (7, 'title 7');

SELECT num, title,
       LEAD (title,1,'no next page') OVER (ORDER BY num) next_title,
       LAG (title,1,'no previous page') OVER (ORDER BY num) prev_title
FROM tbl_board;
```

| num | title     | next_title | prev_title |
|-----|-----------|------------|------------|
| 1   | 'title 1' | 'title 2'  | NULL       |
| 2   | 'title 2' | 'title 3'  | 'title 1'  |
| 3   | 'title 3' | 'title 4'  | 'title 2'  |
| 4   | 'title 4' | 'title 5'  | 'title 3'  |
| 5   | 'title 5' | 'title 6'  | 'title 4'  |

|   |           |           |           |
|---|-----------|-----------|-----------|
| 6 | 'title 6' | 'title 7' | 'title 5' |
| 7 | 'title 7' | NULL      | 'title 6' |

The following example shows how to output the title of the previous row and the title of the next row along with the title of a specified row on the `tbl_board` table. If a `WHERE` condition is enclosed in parentheses, the values of `next_title` and `prev_title` are **NULL** as only one row is selected but the previous row and the subsequent row.

```
SELECT * FROM
(
  SELECT num, title,
         LEAD(title,1,'no next page') OVER (ORDER BY num) next_title,
         LAG(title,1,'no previous page') OVER (ORDER BY num)
prev_title
  FROM tbl_board
)
WHERE num=5;
```

| num   | title     | next_title | prev_title |
|-------|-----------|------------|------------|
| ===== | =====     | =====      | =====      |
| ===== | =====     | =====      | =====      |
| 5     | 'title 5' | 'title 6'  | 'title 4'  |

## MAX

`MAX([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression)`

`MAX([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression) OVER (<analytic_clause>)`

The **MAX** function is used as an aggregate function or an analytic function. It gets the greatest value of expressions of all rows. Only one *expression* is specified. For expressions that return character strings, the string that appears later in alphabetical order becomes the maximum value; for those that return numbers, the greatest value becomes the maximum value.

### param expression:

Specifies an expression that returns a numeric or string value. An expression that returns a collection-type data is not allowed.

### param ALL:

Gets the maximum value for all data (default).

param

DISTINCT,DISTINCTROW,UNIQUE:

Gets the maximum value without duplicates.

rtype:

same type as that the expression

The following example shows how to retrieve the maximum number of gold (*gold*) medals that Korea won in the Olympics in the *demodb* database.

```
SELECT MAX(gold) FROM participant WHERE nation_code = 'KOR';
```

```
max(gold)
=====
12
```

The following example shows how to output the number of gold medals by year and the maximum number of gold medals in history, acquired by the country whose nation\_code code starts with 'AU'.

```
SELECT host_year, nation_code, gold,
       MAX(gold) OVER (PARTITION BY nation_code) mx_gold
FROM participant
WHERE nation_code LIKE 'AU%'
ORDER BY nation_code, host_year;
```

| host_year | nation_code | gold  | mx_gold |
|-----------|-------------|-------|---------|
| =====     | =====       | ===== | =====   |
| 1988      | 'AUS'       | 3     | 17      |
| 1992      | 'AUS'       | 7     | 17      |
| 1996      | 'AUS'       | 9     | 17      |
| 2000      | 'AUS'       | 16    | 17      |
| 2004      | 'AUS'       | 17    | 17      |
| 1988      | 'AUT'       | 1     | 2       |
| 1992      | 'AUT'       | 0     | 2       |
| 1996      | 'AUT'       | 0     | 2       |
| 2000      | 'AUT'       | 2     | 2       |
| 2004      | 'AUT'       | 2     | 2       |

## MEDIAN

**MEDIAN**(*expression*)

**MEDIAN**(*expression*) **OVER** ([<*partition\_by\_clause*>])

**MEDIAN** function is used as an aggregate function or an analytic function. It returns the median value. The median value is the value which is located on the middle between the minimum value and the maximum value.

param expression:

column with value or expression which can be converted as number or date

rtype:

**DOUBLE** or **DATETIME**

The following is a schema and data to run examples.

```
CREATE TABLE tbl (col1 int, col2 double);
INSERT INTO tbl VALUES(1,2), (1,1.5), (1,1.7), (1,1.8), (2,3), (2,4), (3,5);
```

The following is an example to be used as an aggregate function. It returns the median values of aggregated col2 by each group of col1.

```
SELECT col1, MEDIAN(col2)
FROM tbl GROUP BY col1;
```

```
col1  median(col2)
=====
1     1.7500000000000000e+00
2     3.5000000000000000e+00
3     5.0000000000000000e+00
```

The following is an example to be used as an analytic function. It returns the median values of col2 by each group of col1.

```
SELECT col1, MEDIAN(col2) OVER (PARTITION BY col1)
FROM tbl;
```

```

col1  median(col2) over (partition by col1)
=====
1  1.7500000000000000e+00
1  1.7500000000000000e+00
1  1.7500000000000000e+00
1  1.7500000000000000e+00
2  3.5000000000000000e+00
2  3.5000000000000000e+00
3  5.0000000000000000e+00

```

## MIN

MIN(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*)

MIN(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*) OVER (<*analytic\_clause*>)

The **MIN** function is used as an aggregate function or an analytic function. It gets the smallest value of expressions of all rows. Only one *expression* is specified. For expressions that return character strings, the string that appears earlier in alphabetical order becomes the minimum value; for those that return numbers, the smallest value becomes the minimum value.

**param expression:**

Specifies an expression that returns a numeric or string value. A collection expression cannot be specified.

**param ALL:**

Gets the minimum value for all data (default).

**param**

**DISTINCT,DISTINCTROW,UNIQUE:**

Gets the maximum value without duplicates.

**rtype:**

same type as the *expression*

The following example shows how to retrieve the minimum number of gold (*gold*) medals that Korea won in the Olympics in the *demodb* database.

```
SELECT MIN(gold) FROM participant WHERE nation_code = 'KOR';
```

```
min(gold)
=====
7
```

The following example shows how to output the number of gold medals by year and the maximum number of gold medals in history, acquired by the country whose nation\_code code starts with 'AU'.

```
SELECT host_year, nation_code, gold,
MIN(gold) OVER (PARTITION BY nation_code) mn_gold
FROM participant WHERE nation_code like 'AU%' ORDER BY nation_code,
host_year;
```

| host_year | nation_code | gold | mn_gold |
|-----------|-------------|------|---------|
| 1988      | 'AUS'       | 3    | 3       |
| 1992      | 'AUS'       | 7    | 3       |
| 1996      | 'AUS'       | 9    | 3       |
| 2000      | 'AUS'       | 16   | 3       |
| 2004      | 'AUS'       | 17   | 3       |
| 1988      | 'AUT'       | 1    | 0       |
| 1992      | 'AUT'       | 0    | 0       |
| 1996      | 'AUT'       | 0    | 0       |
| 2000      | 'AUT'       | 2    | 0       |
| 2004      | 'AUT'       | 2    | 0       |

## NTH\_VALUE

**NTH\_VALUE(expression, N) [{RESPECT|IGNORE} NULLS] OVER (<analytic\_clause>)**

NTH\_VALUE is used as an analytic function only. It returns an *expression* value of *N*-th row in the set of sorted values.

Parameters:

- **expression** – a column or an expression which returns a number or a string
- **N** – a constant, a binding variable, a column or an expression which can be interpreted as a positive integer

Return type:

a type of an *expression*

#### ! See also

`FIRST_VALUE()` , `LAST_VALUE()`

**{RESPECT|IGNORE} NULLS** syntax decides if null value of *expression* is included in the calculation or not. The default is **RESPECT NULLS**.

The following is a schema and data to run examples.

```
CREATE TABLE test_tbl(groupid int,itemno int);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,1);
INSERT INTO test_tbl VALUES(1,null);
INSERT INTO test_tbl VALUES(1,2);
INSERT INTO test_tbl VALUES(1,3);
INSERT INTO test_tbl VALUES(1,4);
INSERT INTO test_tbl VALUES(1,5);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,null);
INSERT INTO test_tbl VALUES(2,6);
INSERT INTO test_tbl VALUES(2,7);
```

The following is a query and results to run **NTH\_VALUE** function by the value of N as 2.

```
SELECT groupid, itemno, NTH_VALUE(itemno, 2) IGNORE NULLS
OVER(PARTITION BY groupid ORDER BY itemno NULLS FIRST) AS ret_val
FROM test_tbl;
```

| groupid | itemno | ret_val |
|---------|--------|---------|
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | NULL   | NULL    |
| 1       | 1      | NULL    |
| 1       | 2      | 2       |
| 1       | 3      | 2       |
| 1       | 4      | 2       |
| 1       | 5      | 2       |

|   |      |      |
|---|------|------|
| 2 | NULL | NULL |
| 2 | NULL | NULL |
| 2 | NULL | NULL |
| 2 | 6    | NULL |
| 2 | 7    | 7    |

### Note

CUBRID sorts **NULL** value as first order than other values. The below SQL1 is interpreted as SQL2 which includes **NULLS FIRST** in **ORDER BY** clause.

```
SQL1: NTH_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY itemno)
      AS ret_val
SQL2: NTH_VALUE(itemno) OVER(PARTITION BY groupid ORDER BY itemno
      NULLS FIRST) AS ret_val
```

## NTILE

**NTILE**(*expression*) *OVER* ([<partition\_by\_clause>] <order\_by\_clause>)

**NTILE** is an analytic function. It divides an ordered data set into a number of buckets indicated by the input parameter value and assigns the appropriate bucket number from 1 to each row.

**Parameters:**

**expression** – the number of buckets. It specifies a certain expression which returns a number value.

**Return type:**

INT

**NTILE** function equally divides the number of rows by the given number of buckets and assigns the bucket number to each bucket. That is, **NTILE** function creates an equi-height histogram. The number of rows in the buckets can differ by at most 1. The remainder values (the remainder number of rows divided by buckets number) are distributed one for each bucket, starting with #1 Bucket.

On the contrary, **WIDTH\_BUCKET()** function equally divides the range by the given number of buckets and assigns the bucket number to each bucket. That is, every interval (bucket) has the identical size.

The following example divides rows into five buckets of eight customers based on their dates of birth. Because the total number of rows is not divisible by the number of buckets, the first three buckets have two rows and the remaining groups have one row each.

```
CREATE TABLE t_customer(name VARCHAR(10), birthdate DATE);
INSERT INTO t_customer VALUES
    ('Amie', date'1978-03-18'),
    ('Jane', date'1983-05-12'),
    ('Lora', date'1987-03-26'),
    ('James', date'1948-12-28'),
    ('Peter', date'1988-10-25'),
    ('Tom', date'1980-07-28'),
    ('Ralph', date'1995-03-17'),
    ('David', date'1986-07-28');

SELECT name, birthdate, NTILE(5) OVER (ORDER BY birthdate) age_group
FROM t_customer;
```

| name    | birthdate  | age_group |
|---------|------------|-----------|
| 'James' | 12/28/1948 | 1         |
| 'Amie'  | 03/18/1978 | 1         |
| 'Tom'   | 07/28/1980 | 2         |
| 'Jane'  | 05/12/1983 | 2         |
| 'David' | 07/28/1986 | 3         |
| 'Lora'  | 03/26/1987 | 3         |
| 'Peter' | 10/25/1988 | 4         |
| 'Ralph' | 03/17/1995 | 5         |

The following example divides eight students into five buckets that have the identical number of rows in the order of score and outputs in the order of the name. As the score column of the t\_score table has eight rows, the remaining three rows are assigned to buckets from #1 Bucket. The first three buckets have one more row than the remaining groups. The NTILE function equally divides the grade based on the number of rows, regardless the range of the score.

```
CREATE TABLE t_score(name VARCHAR(10), score INT);
INSERT INTO t_score VALUES
    ('Amie', 60),
    ('Jane', 80),
    ('Lora', 60),
    ('James', 75),
    ('Peter', 70),
    ('Tom', 30),
    ('Ralph', 99),
    ('David', 55);

SELECT name, score, NTILE(5) OVER (ORDER BY score DESC) grade
```

```
FROM t_score
ORDER BY name;
```

| name    | score | grade |
|---------|-------|-------|
| 'Ralph' | 99    | 1     |
| 'Jane'  | 80    | 1     |
| 'James' | 75    | 2     |
| 'Peter' | 70    | 2     |
| 'Amie'  | 60    | 3     |
| 'Lora'  | 60    | 3     |
| 'David' | 55    | 4     |
| 'Tom'   | 30    | 5     |

## PERCENT\_RANK

PERCENT\_RANK(*expression* [, *expression*] ...) WITHIN GROUP (<order\_by\_clause>)

PERCENT\_RANK() OVER ([<partition\_by\_clause>] <order\_by\_clause>)

**PERCENT\_RANK** function is used as an aggregate function or an analytic function. It returns the relative position of the row in the group as a ranking percent. It is similar to **CUME\_DIST** function (returns cumulated distribution value). The range of this function is from 0 to 1. The first value of **PERCENT\_RANK** is always 0.

param expression:

an expression which returns a number or a string. It should not be a column.

rtype:

**DOUBLE**

### ! See also

CUME\_DIST() , RANK()

If it is an aggregate function, it returns the value that the RANK minus 1 of a hypothetical row selected in the whole aggregated rows is divided by the number of rows in the aggregated group. That is, ("RANK of a hypothetical row" - 1)/(the number of rows in the aggregated group).

If it is an analytic function, it returns (“RANK per group” -1)/ (“the number of rows in the group” - 1) when each row with the group divided by **PARTITION BY** is sorted by the specified order by the **ORDER BY** clause. For example, if the number of rows appeared as the first rank(RANK=1) in the total 10 rows is 2, **PERCENT\_RANK** values of the first and second rows are  $(1-1)/(10-1)=0$ .

The following is a table which compares the return values of **CUME\_DIST** and **PERCENT\_RANK** which are used as aggregate functions when there are input arguments VAL.

| VAL | RANK() | DENSE_RANK() | CUME_DIST(VAL<br>)    | PERCENT_RANK<br>(VAL) |
|-----|--------|--------------|-----------------------|-----------------------|
| 100 | 1      | 1            | 0.33 => $(1+1)/(5+1)$ | 0 => $(1-1)/5$        |
| 200 | 2      | 2            | 0.67 => $(2+1)/(5+1)$ | 0.2 => $(2-1)/5$      |
| 200 | 2      | 2            | 0.67 => $(2+1)/(5+1)$ | 0.2 => $(2-1)/5$      |
| 300 | 4      | 3            | 0.83 => $(4+1)/(5+1)$ | 0.6 => $(4-1)/5$      |
| 400 | 5      | 4            | 1 => $(5+1)/(5+1)$    | 0.8 => $(5-1)/5$      |

The following is a table which compares the return values of **CUME\_DIST** and **PERCENT\_RANK** which are used as analytic functions when there are input arguments VAL.

| VAL | RANK() | DENSE_RANK() | CUME_DIST()  | PERCENT_RANK<br>( )   |
|-----|--------|--------------|--------------|-----------------------|
| 100 | 1      | 1            | 0.2 => $1/5$ | 0 => $(1-1)/(5-1)$    |
| 200 | 2      | 2            | 0.6 => $3/5$ | 0.25 => $(2-1)/(5-1)$ |

| VAL | RANK() | DENSE_RANK() | CUME_DIST() | PERCENT_RANK()      |
|-----|--------|--------------|-------------|---------------------|
| 200 | 2      | 2            | 0.6 => 3/5  | 0.25 => (2-1)/(5-1) |
| 300 | 4      | 3            | 0.8 => 4/5  | 0.75 => (4-1)/(5-1) |
| 400 | 5      | 4            | 1 => 5/5    | 1 => (5-1)/(5-1)    |

The following is a schema and examples of queries which are related to the above tables.

```
CREATE TABLE test_tbl(VAL INT);
INSERT INTO test_tbl VALUES (100), (200), (200), (300), (400);

SELECT CUME_DIST(100) WITHIN GROUP (ORDER BY val) AS cume FROM
test_tbl;
SELECT PERCENT_RANK(100) WITHIN GROUP (ORDER BY val) AS pct_rnk FROM
test_tbl;

SELECT CUME_DIST() OVER (ORDER BY val) AS cume FROM test_tbl;
SELECT PERCENT_RANK() OVER (ORDER BY val) AS pct_rnk FROM test_tbl;
```

The following is a schema and data which will be used in the below.

```
CREATE TABLE scores(id INT PRIMARY KEY AUTO_INCREMENT, math INT,
english INT, pe CHAR, grade INT);

INSERT INTO scores(math, english, pe, grade)
VALUES(60, 70, 'A', 1),
(60, 70, 'A', 1),
(60, 80, 'A', 1),
(60, 70, 'B', 1),
(70, 60, 'A', 1),
(70, 70, 'A', 1),
(80, 70, 'C', 1),
(70, 80, 'C', 1),
(85, 60, 'C', 1),
(75, 90, 'B', 1);
INSERT INTO scores(math, english, pe, grade)
VALUES(95, 90, 'A', 2),
```

```
(85, 95, 'B', 2),
(95, 90, 'A', 2),
(85, 95, 'B', 2),
(75, 80, 'D', 2),
(75, 85, 'D', 2),
(75, 70, 'C', 2),
(65, 95, 'A', 2),
(65, 95, 'A', 2),
(65, 95, 'A', 2);
```

The following is an example of aggregate function. It displays the result that each **PERCENT\_RANK** about three columns, *math*, *english* and *pe* are added and divided by 3.

```
SELECT PERCENT_RANK(60, 70, 'D')
WITHIN GROUP(ORDER BY math, english, pe) AS percent_rank
FROM scores;
```

```
1.5000000000000000e-01
```

The following is an example of analytic function. It returns the **PERCENT\_RANK** values of the entire rows based on three columns, *math*, *english* and *pe*.

```
SELECT id, math, english, pe, grade, PERCENT_RANK() OVER(ORDER BY
math, english, pe) AS percent_rank
FROM scores
ORDER BY percent_rank;
```

| grade | id | math | english | pe | percent_rank |
|-------|----|------|---------|----|--------------|
|       | 1  | 60   | 70      |    |              |
| 'A'   | 2  | 60   | 70      |    |              |
| 'A'   | 4  | 60   | 70      |    |              |
| 'B'   | 3  | 60   | 80      |    |              |
| 'A'   | 18 | 65   | 95      |    |              |
| 'A'   | 19 | 65   | 95      |    |              |
| 'A'   | 20 | 65   | 95      |    |              |
| 'A'   | 5  | 70   | 60      |    |              |

|     |    |    |   |                       |
|-----|----|----|---|-----------------------|
| 'A' |    |    | 1 | 3.684210526315789e-01 |
|     | 6  | 70 |   | 70                    |
| 'A' |    |    | 1 | 4.210526315789473e-01 |
|     | 8  | 70 |   | 80                    |
| 'C' |    |    | 1 | 4.736842105263158e-01 |
|     | 17 | 75 |   | 70                    |
| 'C' |    |    | 2 | 5.263157894736842e-01 |
|     | 15 | 75 |   | 80                    |
| 'D' |    |    | 2 | 5.789473684210527e-01 |
|     | 16 | 75 |   | 85                    |
| 'D' |    |    | 2 | 6.315789473684210e-01 |
|     | 10 | 75 |   | 90                    |
| 'B' |    |    | 1 | 6.842105263157895e-01 |
|     | 7  | 80 |   | 70                    |
| 'C' |    |    | 1 | 7.368421052631579e-01 |
|     | 9  | 85 |   | 60                    |
| 'C' |    |    | 1 | 7.894736842105263e-01 |
|     | 12 | 85 |   | 95                    |
| 'B' |    |    | 2 | 8.421052631578947e-01 |
|     | 14 | 85 |   | 95                    |
| 'B' |    |    | 2 | 8.421052631578947e-01 |
|     | 11 | 95 |   | 90                    |
| 'A' |    |    | 2 | 9.473684210526315e-01 |
|     | 13 | 95 |   | 90                    |
| 'A' |    |    | 2 | 9.473684210526315e-01 |

The following is an example of analytic function. It returns the **PERCENT\_RANK** values grouped by *grade* column, based on three columns, *math*, *english* and *pe*.

```
SELECT id, math, english, pe, grade, RANK(), PERCENT_RANK()
OVER(PARTITION BY grade ORDER BY math, english, pe) AS percent_rank
FROM scores
ORDER BY grade, percent_rank;
```

| grade | id | math | english | pe                     | percent_rank |
|-------|----|------|---------|------------------------|--------------|
|       | 1  | 60   | 70      |                        |              |
| 'A'   |    |      | 1       | 0.0000000000000000e+00 |              |
|       | 2  | 60   | 70      |                        |              |
| 'A'   |    |      | 1       | 0.0000000000000000e+00 |              |
|       | 4  | 60   | 70      |                        |              |
| 'B'   |    |      | 1       | 2.222222222222222e-01  |              |
|       | 3  | 60   | 80      |                        |              |
| 'A'   |    |      | 1       | 3.333333333333333e-01  |              |
|       | 5  | 70   | 60      |                        |              |
| 'A'   |    |      | 1       | 4.444444444444444e-01  |              |
|       | 6  | 70   | 70      |                        |              |

| 'B' |    |    | 2 | 6.666666666666666e-01 |
|     | 14 | 85 |   | 95                    |
| 'B' |    |    | 2 | 6.666666666666666e-01 |
|     | 11 | 95 |   | 90                    |
| 'A' |    |    | 2 | 8.888888888888888e-01 |
|     | 13 | 95 |   | 90                    |
| 'A' |    |    | 2 | 8.888888888888888e-01 |

In the above result, the rows with *id* 1 are located at the first and the second in the 10 rows whose *grade* is 1, and the values of **PERCENT\_RANK** will be  $(1-1)/(10-1)=0$ . A row whose *id* is 5 is located at the fifth in the 10 rows whose *grade* is 1, and the value of **PERCENT\_RANK** will be  $(5-1)/(10-1)=0.44$ .

## PERCENTILE\_CONT

**PERCENTILE\_CONT**(expression1) WITHIN GROUP (ORDER BY expression2 [ASC | DESC]) [OVER (<partition\_by\_clause>)]

**PERCENTILE\_CONT** is used as an aggregate or analytic function, and is a reverse distribution function to assume a continuous distribution model. This takes a percentile value and returns a interpolated value within a set of sorted values. NULLs are ignored when calculating.

This function's input value is a number or a string which can be converted into a number, and the type of returned value is DOUBLE.

**Parameters:**

- **expression1** – Percentile value. This must be between 0 and 1.
- **expression2** – The column names followed by an **ORDER BY** clause. The number of columns should be the same with the number of columns in *expression1*.

**Return type:****DOUBLE****See also**[Difference between PERCENTILE\\_DISC and PERCENTILE\\_CONT](#)

When this is an aggregate function, this sorts results by the order specified by the **ORDER BY** clause; then this returns an interpolation value belongs to the percentile value from the rows in the aggregate group.

When this is an analytic function, this sorts each row divided by **PARTITION BY** clause, by the order specified by the **ORDER BY** clause; then this returns an interpolation value belongs to the percentile value from the rows in the group.

**Note****Difference between PERCENTILE\_CONT and PERCENTILE\_DISC**

PERCENTILE\_CONT and PERCENTILE\_DISC can return different results.

PERCENTILE\_CONT operates continuous interpolation; then it returns the calculated result.

PERCENTILE\_DISC returns a value from the set of aggregated values.

In the below examples, when a percentile value is 0.5 and the group has even items, PERCENTILE\_CONT returns the average of the two values from the medium position; however, PERCENTILE\_DISC returns the first value between the two values from the medium position. If the group has odd items, both of them returns the value of a centered item.

In fact, the `MEDIAN` function is a particular case of `PERCENTILE_CONT` with the default of percentile value(0.5). Please also see [MEDIAN\(\)](#) for more details.

The below shows the schema and the data on the next examples.

```
CREATE TABLE scores([id] INT PRIMARY KEY AUTO_INCREMENT, [math] INT,
english INT, [class] CHAR);
```

```
INSERT INTO scores VALUES
```

```
(1, 30, 70, 'A'),
(2, 40, 70, 'A'),
(3, 60, 80, 'A'),
(4, 70, 70, 'A'),
(5, 72, 60, 'A'),
(6, 77, 70, 'A'),
(7, 80, 70, 'C'),
(8, 70, 80, 'C'),
(9, 85, 60, 'C'),
(10, 78, 90, 'B'),
(11, 95, 90, 'D'),
(12, 85, 95, 'B'),
(13, 95, 90, 'B'),
(14, 85, 95, 'B'),
(15, 75, 80, 'D'),
(16, 75, 85, 'D'),
(17, 75, 70, 'C'),
(18, 65, 95, 'C'),
(19, 65, 95, 'D'),
(20, 65, 95, 'D');
```

The below is an example of an aggregate function; it returns a median value for the *math* column.

```
SELECT PERCENTILE_CONT(0.5)
WITHIN GROUP(ORDER BY math) AS pcont
FROM scores;
```

```
pcont
=====
7.500000000000000e+01
```

The below is an example of an analytic function; it returns a median value for the *math* column within the set grouped by which the values of *class* column are the same.

```
SELECT math, [class], PERCENTILE_CONT(0.5)
WITHIN GROUP(ORDER BY math)
```

```
OVER (PARTITION BY [class]) AS pcont
FROM scores;
```

| math | class | pcont                 |
|------|-------|-----------------------|
| 30   | 'A'   | 6.500000000000000e+01 |
| 40   | 'A'   | 6.500000000000000e+01 |
| 60   | 'A'   | 6.500000000000000e+01 |
| 70   | 'A'   | 6.500000000000000e+01 |
| 72   | 'A'   | 6.500000000000000e+01 |
| 77   | 'A'   | 6.500000000000000e+01 |
| 78   | 'B'   | 8.500000000000000e+01 |
| 85   | 'B'   | 8.500000000000000e+01 |
| 85   | 'B'   | 8.500000000000000e+01 |
| 95   | 'B'   | 8.500000000000000e+01 |
| 65   | 'C'   | 7.500000000000000e+01 |
| 70   | 'C'   | 7.500000000000000e+01 |
| 75   | 'C'   | 7.500000000000000e+01 |
| 80   | 'C'   | 7.500000000000000e+01 |
| 85   | 'C'   | 7.500000000000000e+01 |
| 65   | 'D'   | 7.500000000000000e+01 |
| 65   | 'D'   | 7.500000000000000e+01 |
| 75   | 'D'   | 7.500000000000000e+01 |
| 75   | 'D'   | 7.500000000000000e+01 |
| 95   | 'D'   | 7.500000000000000e+01 |

In class 'A', the number of 'math' is totally 6; PERCENTILE\_CONT assumes that continuous values exist from the discrete values; therefore, the median value is 65, an average of the 3rd value (60) and the 4th value (70).

PERCENTILE\_CONT assumes the continuous value; therefore, it returns DOUBLE type value which can show the continuous representation.

## PERCENTILE\_DISC

PERCENTILE\_DISC(expression1) WITHIN GROUP (ORDER BY expression2 [ASC | DESC]) [OVER (<partition\_by\_clause>)]

**PERCENTILE\_DISC** is used as an aggregate or analytic function, and is a reverse distribution function to assume a discrete distribution model. This takes a percentile value and returns a discrete value within a set of sorted values. NULLs are ignored when calculating.

This function's input value is a number or a string which can be converted into a number, and the type of returned value is the same as the type of input value.

**Parameters:**

- **expression1** – Percentile value. This must be between 0 and 1.
- **expression2** – The column names followed by an **ORDER BY** clause. The number of columns should be the same with the number of columns in *expression1*.

**Return type:**

the same with the *expression2*'s type.

**See also**

[Difference between PERCENTILE\\_DISC and PERCENTILE\\_CONT](#)

When this is an aggregate function, this sorts results by the order specified by the **ORDER BY** clause; then this returns an interpolation value located to the percentile value from the rows in the aggregate group.

When this is an analytic function, this sorts each row divided by **PARTITION BY** clause, by the order specified by the **ORDER BY** clause; then this returns an interpolation value located to the percentile value from the rows in the group.

The schema and the data used in this function's example are the same with them in `PERCENTILE_CONT()`.

The below is an example of an aggregate function; it returns a median value for the *math* column.

```
SELECT PERCENTILE_DISC(0.5)
WITHIN GROUP(ORDER BY math) AS pdisc
FROM scores;
```

```
pdisc
=====
75
```

The below is an example of an analytic function; it returns a median value for the *math* column within the set grouped by which the values of *class* column are the same.

```
SELECT math, [class], PERCENTILE_DISC(0.5)
WITHIN GROUP(ORDER BY math)
OVER (PARTITION BY [class]) AS pdisc
FROM scores;
```

| math | class | pdisc |
|------|-------|-------|
| 30   | 'A'   | 60    |
| 40   | 'A'   | 60    |
| 60   | 'A'   | 60    |
| 70   | 'A'   | 60    |
| 72   | 'A'   | 60    |
| 77   | 'A'   | 60    |
| 78   | 'B'   | 85    |
| 85   | 'B'   | 85    |
| 85   | 'B'   | 85    |
| 95   | 'B'   | 85    |
| 65   | 'C'   | 75    |
| 70   | 'C'   | 75    |
| 75   | 'C'   | 75    |
| 80   | 'C'   | 75    |
| 85   | 'C'   | 75    |
| 65   | 'D'   | 75    |
| 65   | 'D'   | 75    |
| 75   | 'D'   | 75    |
| 75   | 'D'   | 75    |
| 95   | 'D'   | 75    |

In class 'A', the number of 'math' is totally 6; PERCENTILE\_DISC outputs the first one if the medium values are the two; therefore, the median value is 60, between the 3rd value (60) and the 4th value (70).

## RANK

**RANK()** *OVER ([<partition\_by\_clause>] <order\_by\_clause>)*

**RANK** function is used as an analytic function only. The rank of the value in the column value group made by the **PARTITION BY** clause is calculated and output as **INTEGER**. When there is another identical rank, the next rank is the number adding the number of the same ranks. For example, when there are three rows of Rank 13, the next rank is 16, not 14. On the contrary, the **DENSE\_RANK()** function calculates the next rank by adding 1 to the rank.

rtype:

INT

The following example shows output of the number of Olympic gold medals of each country and the rank of the countries by year. The next rank of the same rank is calculated by adding the number of the same ranks.

```
SELECT host_year, nation_code, gold,
RANK() OVER (PARTITION BY host_year ORDER BY gold DESC) AS g_rank
FROM participant;
```

| host_year | nation_code | gold  | g_rank |
|-----------|-------------|-------|--------|

2004 'PRK' 0 57

```

## ROW\_NUMBER

**ROW\_NUMBER()** *OVER* (*[<partition\_by\_clause>] <order\_by\_clause>*)

**ROW\_NUMBER** function is used as an analytic function only. The rank of a row is one plus the number of distinct ranks that come before the row in question by using the **PARTITION BY** clause and outputs as **INTEGER**.

Return type:

INT

The following example shows output of the serial number according to the number of Olympic gold medals of each country by year. If the number of gold medals is the same, the sorting follows the alphabetic order of the nation\_code.

```

SELECT host_year, nation_code, gold,
ROW_NUMBER() OVER (PARTITION BY host_year ORDER BY gold DESC) AS
r_num
FROM participant;

```

```

      host_year  nation_code      gold      r_num

## STDDEV, STDDEV\_POP

STDDEV(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*)

STDDEV\_POP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*)

STDDEV(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*) OVER (<*analytic\_clause*>)

STDDEV\_POP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*) OVER (<*analytic\_clause*>)

The functions **STDDEV** and **STDDEV\_POP** are used interchangeably and they are used as an aggregate function or an analytic function. They return a standard variance of the values calculated for all rows. The **STDDEV\_POP** function is a standard of the SQL:1999. Only one *expression* is specified as a parameter. If the **DISTINCT** or **UNIQUE** keyword is inserted before the expression, they calculate

the sample standard variance after deleting duplicates; if keyword is omitted or **ALL**, they it calculate the sample standard variance for all values.

**param expression:**

Specifies an expression that returns a numeric value.

**param ALL:**

Calculates the standard variance for all data (default).

**param**

**DISTINCT,DISTINCTROW,UNIQUE:**

Calculates the standard variance without duplicates.

**rtype:**

DOUBLE

The return value is the same with the square root of its variance (the return value of `VAR_POP()` and it is a **DOUBLE** type. If there are no rows that can be used for calculating a result, **NULL** is returned.

The following is a formula that is applied to the function.

$$\text{STDDEV}_{\text{POP}} = \left[ \left( \frac{1}{N} \right) * \text{SUM}(\{x_i - \text{AVG}(x)\}^2) \right]^{\frac{1}{2}}$$

**Note**

In CUBRID 2008 R3.1 or earlier, the **STDDEV** function worked the same as the `STDDEV_SAMP()`.

The following example shows how to output the population standard variance of all students for all subjects.

```
CREATE TABLE student (name VARCHAR(32), subjects_id INT, score
DOUBLE);
INSERT INTO student VALUES
('Jane',1, 78), ('Jane',2, 50), ('Jane',3, 60),
```

```
( 'Bruce', 1, 63), ( 'Bruce', 2, 50), ( 'Bruce', 3, 80),
( 'Lee', 1, 85), ( 'Lee', 2, 88), ( 'Lee', 3, 93),
( 'Wane', 1, 32), ( 'Wane', 2, 42), ( 'Wane', 3, 99),
( 'Sara', 1, 17), ( 'Sara', 2, 55), ( 'Sara', 3, 43);
```

```
SELECT STDDEV_POP (score) FROM student;
```

```
          stddev_pop(score)
=====
          2.329711474744362e+01
```

The following example shows how to output the score and population standard variance of all students by subject (subjects\_id).

```
SELECT subjects_id, name, score,
STDDEV_POP(score) OVER(PARTITION BY subjects_id) std_pop
FROM student
ORDER BY subjects_id, name;
```

```
  subjects_id  name
score          std_pop

## STDDEV\_SAMP

STDDEV\_SAMP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*)

STDDEV\_SAMP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*) OVER (<*analytic\_clause*>)

The **STDDEV\_SAMP** function is used as an aggregate function or an analytic function. It calculates the sample standard variance. Only one *expression* is specified as a parameter. If the **DISTINCT** or **UNIQUE** keyword is inserted before the expression, it calculates the sample standard variance after deleting duplicates; if a keyword is omitted or **ALL**, it calculates the sample standard variance for all values.

**param expression:**

An expression that returns a numeric value

**param ALL:**

Used to calculate the standard variance for all values. It is the default value.

**param**

**DISTINCT, DISTINCTROW, UNIQUE:**

Used to calculate the standard variance for the unique values without duplicates.

**rtype:**

DOUBLE

The return value is the same as the square root of its sample variance ( **VAR\_SAMP()** ) and it is a **DOUBLE** type. If there are no rows that can be used for calculating a result, **NULL** is returned.

The following are the formulas applied to the function.

$$\text{STDDEV}_{\text{SAMP}} = \left[ \left\{ \frac{1}{N-1} \right\} * \text{SUM}(\{x_i - \text{mean}(x)\}^2) \right]^{\frac{1}{2}}$$

The following example shows how to output the sample standard variance of all students for all subjects.

```
CREATE TABLE student (name VARCHAR(32), subjects_id INT, score
DOUBLE);
INSERT INTO student VALUES
('Jane',1, 78), ('Jane',2, 50), ('Jane',3, 60),
('Bruce', 1, 63), ('Bruce', 2, 50), ('Bruce', 3, 80),
('Lee', 1, 85), ('Lee', 2, 88), ('Lee', 3, 93),
('Wane', 1, 32), ('Wane', 2, 42), ('Wane', 3, 99),
('Sara', 1, 17), ('Sara', 2, 55), ('Sara', 3, 43);

SELECT STDDEV_SAMP (score) FROM student;
```

```
stddev_samp(score)

```

## SUM

`SUM([ DISTINCT / DISTINCTROW / UNIQUE / ALL ] expression )`

`SUM([ DISTINCT / DISTINCTROW / UNIQUE / ALL ] expression ) OVER (<analytic_clause>)`

The **SUM** function is used as an aggregate function or an analytic function. It returns the sum of expressions of all rows. Only one *expression* is specified as a parameter. You can get the sum without duplicates by inserting the **DISTINCT** or **UNIQUE** keyword in front of the expression, or get the sum of all values by omitting the keyword or by using **ALL**.

**param expression:**

Specifies an expression that returns a numeric value.

**param ALL:**

Gets the sum for all data (default).

**param**

**DISTINCT,DISTINCTROW,UNIQUE:**

Gets the sum of unique values without duplicates

**rtype:**

same type as that the expression

The following is an example that outputs the top 10 countries and the total number of gold medals based on the sum of gold medals won in the Olympic Games in *demodb*.

```
SELECT nation_code, SUM(gold)
FROM participant
GROUP BY nation_code
ORDER BY SUM(gold) DESC
LIMIT 10;
```

| nation_code | sum(gold) |
|-------------|-----------|
| 'USA'       | 190       |
| 'CHN'       | 97        |
| 'RUS'       | 85        |
| 'GER'       | 79        |
| 'URS'       | 55        |
| 'FRA'       | 53        |
| 'AUS'       | 52        |
| 'ITA'       | 48        |
| 'KOR'       | 48        |
| 'EUN'       | 45        |

The following example shows how to output the number of gold medals by year and the average sum of the accumulated gold medals to the year acquired by the country whose nation\_code code starts with 'AU' in *demodb*.

```
SELECT host_year, nation_code, gold,
       SUM(gold) OVER (PARTITION BY nation_code ORDER BY host_year)
       sum_gold
FROM participant
WHERE nation_code LIKE 'AU%';
```

| host_year | nation_code | gold | sum_gold |
|-----------|-------------|------|----------|
| 1988      | 'AUS'       | 3    | 3        |
| 1992      | 'AUS'       | 7    | 10       |
| 1996      | 'AUS'       | 9    | 19       |
| 2000      | 'AUS'       | 16   | 35       |
| 2004      | 'AUS'       | 17   | 52       |
| 1988      | 'AUT'       | 1    | 1        |
| 1992      | 'AUT'       | 0    | 1        |
| 1996      | 'AUT'       | 0    | 1        |

|      |       |   |   |
|------|-------|---|---|
| 2000 | 'AUT' | 2 | 3 |
| 2004 | 'AUT' | 2 | 5 |

The following example is removing the “ORDER BY host\_year” clause under the **OVER** analysis clause from the above example. The avg\_gold value is the average of gold medals for all years, so the value is identical for every year by nation\_code.

```
SELECT host_year, nation_code, gold, SUM(gold) OVER (PARTITION BY
nation_code) sum_gold
FROM participant
WHERE nation_code LIKE 'AU%';
```

| host_year | nation_code | gold  | sum_gold |
|-----------|-------------|-------|----------|
| =====     | =====       | ===== | =====    |
| 2004      | 'AUS'       | 17    | 52       |
| 2000      | 'AUS'       | 16    | 52       |
| 1996      | 'AUS'       | 9     | 52       |
| 1992      | 'AUS'       | 7     | 52       |
| 1988      | 'AUS'       | 3     | 52       |
| 2004      | 'AUT'       | 2     | 5        |
| 2000      | 'AUT'       | 2     | 5        |
| 1996      | 'AUT'       | 0     | 5        |
| 1992      | 'AUT'       | 0     | 5        |
| 1988      | 'AUT'       | 1     | 5        |

## VARIANCE, VAR\_POP

VARIANCE([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression)

VAR\_POP([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression)

VARIANCE([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression) OVER (<analytic\_clause>)

VAR\_POP([DISTINCT | DISTINCTROW | UNIQUE | ALL] expression) OVER (<analytic\_clause>)

The functions **VARPOP** and **VARIANCE** are used interchangeably and they are used as an aggregate function or an analytic function. They return a variance of expression values for all rows. Only one *expression* is specified as a parameter. If the **DISTINCT** or **UNIQUE** keyword is inserted before the expression, they calculate the population variance after deleting duplicates; if the keyword is omitted or **ALL**, they calculate the sample population variance for all values.

param expression:

Specifies an expression that returns a numeric value.

**param ALL:**

Gets the variance for all values (default).

**param**

**DISTINCT,DISTINCTROW,UNIQUE:**

Gets the variance of unique values without duplicates.

**rtype:**

DOUBLE

The return value is a **DOUBLE** type. If there are no rows that can be used for calculating a result, **NULL** will be returned.

The following is a formula that is applied to the function.

$$\text{VAR}_{\text{POP}} = \left( \frac{1}{N} \right) * \text{SUM}(\{x_i - \text{AVG}(x)\}^2)$$

#### Note

In CUBRID 2008 R3.1 or earlier, the **VARIANCE** function worked the same as the `VAR_SAMP()`.

The following example shows how to output the population variance of all students for all subjects

```
CREATE TABLE student (name VARCHAR(32), subjects_id INT, score
DOUBLE);
INSERT INTO student VALUES
('Jane',1, 78), ('Jane',2, 50), ('Jane',3, 60),
('Bruce', 1, 63), ('Bruce', 2, 50), ('Bruce', 3, 80),
('Lee', 1, 85), ('Lee', 2, 88), ('Lee', 3, 93),
('Wane', 1, 32), ('Wane', 2, 42), ('Wane', 3, 99),
('Sara', 1, 17), ('Sara', 2, 55), ('Sara', 3, 43);

SELECT VAR_POP(score) FROM student;
```

```

var_pop(score)
=====
5.42755555555550e+02

```

The following example shows how to output the score and population variance of all students by subject (subjects\_id).

```

## VAR\_SAMP

VAR\_SAMP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*)

VAR\_SAMP(*[DISTINCT | DISTINCTROW | UNIQUE | ALL] expression*) OVER (<*analytic\_clause*>)

The **VAR\_SAMP** function is used as an aggregate function or an analytic function. It returns the sample variance. The denominator is the number of all rows - 1. Only one *expression* is specified as a parameter. If the **DISTINCT** or **UNIQUE** keyword is inserted before the expression, it calculates the sample variance after deleting duplicates and if the keyword is omitted or **ALL**, it calculates the sample variance for all values.

**param expression:**

Specifies one expression to return the numeric.

**param ALL:**

Is used to calculate the sample variance of unique values without duplicates. It is the default value.

**param**

**DISTINCT, DISTINCTROW, UNIQUE:**

Is used to calculate the sample variance for the unique values without duplicates.

**rtype:**

DOUBLE

The return value is a **DOUBLE** type. If there are no rows that can be used for calculating a result, **NULL** is returned.

The following are the formulas applied to the function.

$$\text{VAR}_{\text{SAMP}} = \left\{ \frac{1}{N - 1} \right\} * \text{SUM}(\{x_i - \text{mean}(x)\}^2)$$

The following example shows how to output the sample variance of all students for all subjects.

```
CREATE TABLE student (name VARCHAR(32), subjects_id INT, score
DOUBLE);
```

```

INSERT INTO student VALUES
('Jane',1, 78), ('Jane',2, 50), ('Jane',3, 60),
('Bruce', 1, 63), ('Bruce', 2, 50), ('Bruce', 3, 80),
('Lee', 1, 85), ('Lee', 2, 88), ('Lee', 3, 93),
('Wane', 1, 32), ('Wane', 2, 42), ('Wane', 3, 99),
('Sara', 1, 17), ('Sara', 2, 55), ('Sara', 3, 43);

```

## JSON\_ARRAYAGG

JSON\_ARRAYAGG(*json\_val*)

Aggregate function that builds a json array out of the evaluated rows.

```

CREATE TABLE t_score(name VARCHAR(10), score INT);
INSERT INTO t_score VALUES
  ('Amie', 60),
  ('Jane', 80),
  ('Lora', 60),
  ('James', 75),
  ('Peter', 70),
  ('Tom', 30),
  ('Ralph', 99),
  ('David', 55),
  ('Amie', 65);

SELECT JSON_ARRAYAGG (name) AS test_takers from t_score;

```

```

test_takers
=====
["Amie","Jane","Lora","James","Peter","Tom","Ralph","David","Amie"]

```

## JSON\_OBJECTAGG

JSON\_OBJECTYAGG(*key*, *json\_val expr*)

Creates a json object out of the (key, json\_val) expressions gathered from each row evaluation.

```

CREATE TABLE t_score(name VARCHAR(10), score INT);
INSERT INTO t_score VALUES
  ('Amie', 60),
  ('Jane', 80),

```

```
( 'Lora', 60),
( 'James', 75),
( 'Peter', 70),
( 'Tom', 30),
( 'Ralph', 99),
( 'David', 55);
```

```
SELECT JSON_OBJECTAGG (name, score) AS test_scores from t_score;
```

```
test_scores
=====
{"Amie":60,"Jane":80,"Lora":60,"James":75,"Peter":70,"Tom":
30,"Ralph":99,"David":55}
```

#### INCR, DECR

INCR(*column\_name*)

DECR(*column\_name*)

The **INCR** function increases the column's value given as a parameter of the **SELECT** statement by 1. The **DECR** function decreases the value of the column by 1.

Parameters:

**column** – the name of column defined with SMALLINT, INT or BIGINT type

Return type:

SMALLINT, INT or BIGINT

The **INCR** and **DECR** functions are called “click counters” and can be effectively used to increase the number of post views for a Bulletin Board System (BBS) type of web service. In a scenario where you want to **SELECT** a post and immediately increase the number of views by 1 using an **UPDATE** statement, you can view the post and increment the number at once by using the **INCR** function in a single **SELECT** statement.

The **INCR** function increments the column value specified as an argument. Only integer type numbers can be used as arguments. If the value is **NULL**, the **INCR** function returns the **NULL**. That is, a value must be valid in order to be incremented by the **INCR** function. The **DECR** function decrements the column value specified as a parameter.

If an **INCR** function is specified in the **SELECT** statement, the **COUNTER** value is incremented by 1 and the query result is displayed with the values before the increment. Furthermore, the **INCR** function does not increment the value of the row(tuple) affected by the query process but rather the one affected by the final result.

If you want to increase or decrease the click counter without specifying **INCR** or **DECR** on the **SELECT** list, specify **WITH INCREMENT FOR column** or **WITH DECREMENT FOR column** after the **WHERE** clause.

```
CREATE TABLE board (id INT, cnt INT, content VARCHAR(8096));
SELECT content FROM board WHERE id=1 WITH INCREMENT FOR cnt;
```

#### Note

- The **INCR/DECR** functions execute independent of user-defined transactions and is applied automatically to the database by the top operation internally used in the system, apart from the transaction's **COMMIT/ROLLBACK**.
- When multiple **INCR/DECR** functions are specified in a single **SELECT** statement, the failure of any of the **INCR/DECR** functions leads to the failure of all of them.
- The **INCR/DECR** functions apply only to top-level **SELECT** statements. **SUB SELECT** statements such as **INSERT ... SELECT ...** statement and **UPDATE table SET col = SELECT ...** statement are not supported. The following example shows where the **INCR** function is not allowed.

```
SELECT b.content, INCR(b.read_count) FROM (SELECT * FROM board
WHERE id = 1) AS b
```

- If the **SELECT** statement with **INCR/DECR** functions returns more than one row as a result, it is treated as an error. The final result where only one row exists is valid.

- The **INCR/DECR** function can be used only in numerical type. Applicable domains are limited to integer data types such as **SMALLINT**, **INTEGER** and **BIGINT**. They cannot be used in other types.
- When the **INCR** function is called, the value to be returned will be the current value, while the value to be stored will be the current value + 1. Execute the following statement to select the value to be stored as a result :

```
SELECT content, INCR(read_count) + 1 FROM board WHERE id = 1;
```

- If the defined maximum value of the type is exceeded, the **INCR** function initializes the column value to 0. Likewise, the column value is also initialized to 0 when the **DECR** function applies to the minimum value.
- Data inconsistency can occur because the **INCR/DECR** functions are executed regardless of **UPDATE** trigger. The following example shows the database inconsistency in that situation.

```
CREATE TRIGGER event_tr BEFORE UPDATE ON event EXECUTE REJECT;
SELECT INCR(players) FROM event WHERE gender='M';
```

- The **INCR / DECR** functions returns an error in the write-protected broker mode such as slave mode of HA configuration, CSQL Interpreter (csql -r) of read-only, Read Only or Standby Only mode(ACCESS\_MODE=RO or SO in cubrid\_broker.conf).

## Example

Suppose that the following three rows of data are inserted into the 'board' table.

```
CREATE TABLE board (
  id INT,
  title VARCHAR(100),
  content VARCHAR(4000),
  read_count INT
);
INSERT INTO board VALUES (1, 'aaa', 'text...', 0);
INSERT INTO board VALUES (2, 'bbb', 'text...', 0);
INSERT INTO board VALUES (3, 'ccc', 'text...', 0);
```

The following example shows how to increment the value of the 'read\_count' column in data whose 'id' value is 1 by using the **INCR** function.

```
SELECT content, INCR(read_count) FROM board WHERE id = 1;
```

| content   | read_count |
|-----------|------------|
| 'text...' | 0          |

In the example, the column value becomes `read_count + 1` as a result of the **INCR** function in the **SELECT** statement. You can check the result using the following **SELECT** statement.

```
SELECT content, read_count FROM board WHERE id = 1;
```

| content   | read_count |
|-----------|------------|
| 'text...' | 1          |

## ROWNUM Functions

### ROWNUM, INST\_NUM

#### ROWNUM

##### INST\_NUM()

The **ROWNUM** function returns the number representing the order of the records that will be generated by the query result. The first result record is assigned 1, and the second result record is assigned 2.

Return type:

BIGINT

**ROWNUM** and **INST\_NUM()** can be used in the **SELECT** statement; **ORDERBY\_NUM()** can be used in the **SELECT** statement with **ORDER BY** clauses, and **GROUPBY\_NUM()** can be used in the **SELECT** statement with **GROUP BY** clauses. The **ROWNUM** function can be used to limit the number of result records of the query in several ways. For example, it can be used to search only the first 10 records or to return even or odd number records.

The **ROWNUM** function has a result value as a big integer, and can be used wherever an expression is valid such as the **SELECT** or **WHERE** clause. However, it is not allowed to compare the result of the **ROWNUM** function with the attribute or the correlated subquery.

#### Note

- The **ROWNUM** function specified in the **WHERE** clause works the same as the **INST\_NUM()** function.
- The **ROWNUM** function belongs to each **SELECT** statement. That is, if a **ROWNUM** function is used in a subquery, it returns the sequence of the subquery result while it is being executed. Internally, the result of the **ROWNUM** function is generated right before the searched record is written to the query result set. At this moment, the counter value that generates the serial number of the result set records increases.
- If you want to add a sequence on the **SELECT** result; use **ROWNUM** when there is no sorting process; use **ORDERBY\_NUM()** when there is an **ORDER BY** clause; use **GROUPBY\_NUM()** function when there is a **GROUP BY** clause.
- If an **ORDER BY** clause is included in the **SELECT** statement, the value of the **ORDERBY\_NUM()** function specified in the **WHERE** clause is generated after sorting for the **ORDER BY** clause.
- If a **GROUP BY** clause is included in the **SELECT** statement, the value of the **GROUPBY\_NUM()** function specified in the **HAVING** clause is calculated after the query results are grouped.
- For the purpose of limiting the sorted result rows, instead of **FOR ORDERBY\_NUM()** or **HAVING GROUPBY\_NUM()**, **LIMIT** clause can be used.
- The **ROWNUM** function can also be used in SQL statements such as **INSERT**, **DELETE** and **UPDATE** in addition to the **SELECT** statement. For example, as in the query **INSERT INTO table\_name SELECT ... FROM ... WHERE ...**, you can search for part of the row from one table and then insert it into another by using the **ROWNUM** function in the **WHERE** clause.

The following example shows how to retrieve country names ranked first to fourth based on the number of gold (*gold*) medals in the 1988 Olympics in the *demodb* database.

```
--Limiting 4 rows using ROWNUM in the WHERE condition
SELECT * FROM
(SELECT nation_code FROM participant WHERE host_year = 1988
```

```
ORDER BY gold DESC) AS T
WHERE ROWNUM <5;
```

```
nation_code
=====
'URS'
'GDR'
'USA'
'KOR'
```

LIMIT clause limits the sorted result rows; therefore, the below result is the same as the above.

```
--Limiting 4 rows using LIMIT
SELECT ROWNUM, nation_code FROM participant WHERE host_year = 1988
ORDER BY gold DESC
LIMIT 4;
```

```
rownum nation_code
=====
143 'URS'
51 'GDR'
145 'USA'
78 'KOR'
```

ROWNUM condition in the below limits before sorting; therefore, the result is different from the above.

```
--Unexpected results : ROWNUM operated before ORDER BY
SELECT ROWNUM, nation_code FROM participant
WHERE host_year = 1988 AND ROWNUM < 5
ORDER BY gold DESC;
```

```
rownum nation_code
=====
1 'AFG'
2 'AHO'
3 'AND'
4 'ANG'
```

ORDERBY\_NUM

ORDERBY\_NUM()

The **ORDERBY\_NUM()** function is used with the **ROWNUM()** or **INST\_NUM()** function to limit the number of result rows. The difference is that the **ORDERBY\_NUM()** function is combined after the **ORDER BY** clause to give order to a result that has been already sorted. That is, when retrieving only some of the result rows by using **ROWNUM** in a condition clause of the **SELECT** statement that includes the **ORDER BY** clause, **ROWNUM** is applied first and then group sorting by **ORDER BY** is performed. On the other hand, when retrieving only some of the result rows by using the **ORDER\_NUM()** function, **ROWNUM** is applied to the result of sorting by **ORDER BY**.

Return type:

BIGINT

The following example shows how to retrieve athlete names ranked 3rd to 5th and their records in the *history* table in the *demodb* database.

```
--Ordering first and then limiting rows using FOR ORDERBY_NUM()
SELECT ORDERBY_NUM(), athlete, score FROM history
ORDER BY score FOR ORDERBY_NUM() BETWEEN 3 AND 5;
```

| orderby_num() | athlete         | score     |
|---------------|-----------------|-----------|
| 3             | 'Luo Xuejuan'   | '01:07.0' |
| 4             | 'Rodal Vebjorn' | '01:43.0' |
| 5             | 'Thorpe Ian'    | '01:45.0' |

The following query using a **LIMIT** clause outputs the same result with the above query.

```
SELECT ORDERBY_NUM(), athlete, score FROM history
ORDER BY score LIMIT 2, 3;
```

The following query using **ROWNUM** limits the result rows before sorting; then **ORDER BY** sorting is operated.

```
--Limiting rows first and then Ordering using ROWNUM
SELECT athlete, score FROM history
WHERE ROWNUM BETWEEN 3 AND 5 ORDER BY score;
```

| athlete      | score     |
|--------------|-----------|
| 'Thorpe Ian' | '01:45.0' |

```
'Thorpe Ian'      '03:41.0'
'Hackett Grant'   '14:43.0'
```

## GROUPBY\_NUM

### GROUPBY\_NUM()

The **GROUPBY\_NUM()** function is used with the **ROWNUM** or **INST\_NUM()** function to limit the number of result rows. The difference is that the **GROUPBY\_NUM()** function is combined after the **GROUP BY ... HAVING** clause to give order to a result that has been already sorted. In addition, while the **INST\_NUM()** function is a scalar function, the **GROUPBY\_NUM()** function is kind of an aggregate function.

That is, when retrieving only some of the result rows by using **ROWNUM** in a condition clause of the **SELECT** statement that includes the **GROUP BY** clause, **ROWNUM** is applied first and then group sorting by **GROUP BY** is performed. On the other hand, when retrieving only some of the result rows by using the **GROUPBY\_NUM()** function, **ROWNUM** is applied to the result of group sorting by **GROUP BY**.

Return type:

BIGINT

The following example shows how to retrieve the fastest record in the previous five Olympic Games from the *history* table in the *demodb* database.

```
--Group-ordering first and then limiting rows using GROUPBY_NUM()
SELECT  GROUPBY_NUM(), host_year, MIN(score) FROM history
GROUP BY host_year HAVING GROUPBY_NUM() BETWEEN 1 AND 5;
```

| groupby_num() | host_year | min(score) |
|---------------|-----------|------------|
| 1             | 1968      | '8.9'      |
| 2             | 1980      | '01:53.0'  |
| 3             | 1984      | '13:06.0'  |
| 4             | 1988      | '01:58.0'  |
| 5             | 1992      | '02:07.0'  |

The following query using a **LIMIT** clause outputs the same result with the above query.

```
SELECT  GROUPBY_NUM(), host_year, MIN(score) FROM history
GROUP BY host_year LIMIT 5;
```

The following query using ROWNUM limits the result rows before grouping; then GROUP BY operation is performed.

```
--Limiting rows first and then Group-ordering using ROWNUM
SELECT host_year, MIN(score) FROM history
WHERE ROWNUM BETWEEN 1 AND 5 GROUP BY host_year;
```

```
host_year  min(score)
=====
2000      '03:41.0'
2004      '01:45.0'
```

## Information Functions

## CHARSET

### CHARSET(*expr*)

This function returns the character set of *expr*.

Parameters:

**expr** – Target expression to get the character set.

Return type:

STRING

```
SELECT CHARSET('abc');
```

```
'iso88591'
```

```
SELECT CHARSET(_utf8'abc');
```

```
'utf8'
```

```
SET NAMES utf8;  
SELECT CHARSET('abc');
```

```
'utf8'
```

## COERCIBILITY

### COERCIBILITY(*expr*)

This function returns the collation coercibility level of *expr*. The collation coercibility level determines which collation or charset should be used when each column(expression) has different collation or charset. For more details, please see [Collation Coercibility](#).

#### Parameters:

**expr** – Target expression to get the collation coercibility level.

#### Return type:

INT

```
SELECT COERCIBILITY(USER());
```

```
7
```

```
SELECT COERCIBILITY(_utf8'abc');
```

```
10
```

## COLLATION

### COLLATION(*expr*)

This function returns the collation of *expr*.

#### Parameters:

**expr** – Target expression to get the collation.

#### Return type:

## STRING

```
SELECT COLLATION('abc');
```

```
'iso88591_bin'
```

```
SELECT COLLATION(_utf8'abc');
```

```
'utf8_bin'
```

## CURRENT\_USER, USER

## CURRENT\_USER

## USER

**CURRENT\_USER** and **USER** are pseudo-columns and can be used interchangeably. They return the user name that is currently logged in to the database as a string.

Please note that `SYSTEM_USER()` and `USER()` functions return the user name with a host name where CSQL or CAS was executed.

Return type:

STRING

```
--selecting the current user on the session  
SELECT USER;
```

```
CURRENT_USER  
=====
```

|          |
|----------|
| 'PUBLIC' |
|----------|

```
SELECT USER(), CURRENT_USER;
```

```

user()                                CURRENT_USER
=====
'PUBLIC@cdfs006.cub'  'PUBLIC'

```

```

--selecting all users of the current database from the system table
SELECT name, id, password FROM db_user;

```

```

name                                id  password
=====
'DBA'                                NULL  NULL
'PUBLIC'                             NULL  NULL
'SELECT_ONLY_USER'                   NULL  db_password
'ALMOST_DBA_USER'                     NULL  db_password
'SELECT_ONLY_USER2'                   NULL  NULL

```

## DATABASE, SCHEMA

### DATABASE()

### SCHEMA()

The functions **DATABASE** and **SCHEMA** are used interchangeably. They return the name of currently-connected database as a **VARCHAR** type.

Return type:

STRING

```

SELECT DATABASE(), SCHEMA();

```

```

database()                            schema()
=====
'demodb'                              'demodb'

```

## DBTIMEZONE

### DBTIMEZONE()

Prints out a timezone of database server (offset or region name) as a string. (e.g. '-05:00', or 'Europe/Vienna').

```
SELECT DBTIMEZONE();
```

```
dbtimezone
=====
'Asia/Seoul'
```

### ! See also

SESSIONTIMEZONE(), FROM\_TZ(), NEW\_TIME(), TZ\_OFFSET()

## DEFAULT

DEFAULT(*column\_name*)

### DEFAULT

The **DEFAULT** and the **DEFAULT** function returns a default value defined for a column. If a default value is not specified for the column, **NULL** or an error is output. **DEFAULT** has no parameter, however, the **DEFAULT** function uses the column name as the input parameter. **DEFAULT** can be used for the input data of the **INSERT** statement and the **SET** clause of the **UPDATE** statement and the **DEFAULT** function can be used anywhere.

If any of constraints is not defined or the **UNIQUE** constraint is defined for the column where a default value is not defined, **NULL** is returned. If **NOT NULL** or **PRIMARY KEY** constraint is defined, an error is returned.

```
CREATE TABLE info_tbl(id INT DEFAULT 0, name VARCHAR);
INSERT INTO info_tbl VALUES (1,'a'),(2,'b'),(NULL,'c');

SELECT id, DEFAULT(id) FROM info_tbl;
```

```
      id  default(id)
=====
      1              0
      2              0
    NULL              0
```

```
UPDATE info_tbl SET id = DEFAULT WHERE id IS NULL;
DELETE FROM info_tbl WHERE id = DEFAULT(id);
INSERT INTO info_tbl VALUES (DEFAULT, 'd');
```

### **Note**

In version lower than CUBRID 9.0, the value at the time of CREATE TABLE has been saved when the value of the DATE, DATETIME, TIME, TIMESTAMP column has been specified as SYS\_DATE, SYS\_DATETIME, SYS\_TIME, SYS\_TIMESTAMP while creating a table. Therefore, to enter the value at the time of data INSERT in version lower than CUBRID 9.0, the function should be entered to the VALUES clause of the INSERT syntax.

## DISK\_SIZE

### DISK\_SIZE(*expr*)

This function returns the size in bytes required to store the value of *expr* after evaluation. Main usage is to get necessary size for storing values in database heap file.

#### Parameters:

**expr** – Target expression to get the size.

#### Return type:

INTEGER

```
SELECT DISK_SIZE('abc'), DISK_SIZE(1);
```

```
disk_size('abc')  disk_size(1)
=====
              7              4
```

The size depends on the actual content of value, **string compression** is also taken into account:

```
CREATE TABLE t1(s1 VARCHAR(10), s2 VARCHAR(300), c1 CHAR(10), c2
CHAR(300));
INSERT INTO t1 VALUES(REPEAT('a', 10), REPEAT('b', 300), REPEAT('c',
```

```
10), REPEAT('d', 300));
INSERT INTO t1 VALUES('a', 'b', 'c', 'd');
SELECT DISK_SIZE(s1), DISK_SIZE(s2), DISK_SIZE(c1), DISK_SIZE(c2)
FROM t1;
```

| disk_size(s1) | disk_size(s2) | disk_size(c1) | disk_size(c2) |
|---------------|---------------|---------------|---------------|
| 12            | 24            | 10            | 300           |
| 4             | 4             | 10            | 300           |

## INDEX\_CARDINALITY

### INDEX\_CARDINALITY(*table*, *index*, *key\_pos*)

The **INDEX\_CARDINALITY** function returns the index cardinality in a table. The index cardinality is the number of unique values defining the index. The index cardinality can be applied even to the partial key of the multiple column index and displays the number of the unique value for the partial key by specifying the column location with the third parameter. Note that this value is an approximate value.

If you want the updated result from this function, you should run **UPDATE STATISTICS** statement.

#### Parameters:

- **table** – Table name
- **index** – Index name that exists in the *table*
- **key\_pos** –

Partial key location. It *key\_pos* starts from 0 and has a range that is smaller than the number of columns consisting of keys; that is, the *key\_pos* of the first column is 0. For the single column index, it is 0. It can be one of the following types.

- Character string that can be converted to a numeric type.
- Numeric type that can be converted to an integer type. The **FLOAT** or the **DOUBLE** types will be the value converted by the **ROUND** function.

Return type:

INT

The return value is 0 or a positive integer and if any of the input parameters is **NULL**, **NULL** is returned. If tables or indexes that are input parameters are not found, or *key\_pos* is out of range, **NULL** is returned.

```
CREATE TABLE t1( i1 INTEGER ,
i2 INTEGER not null,
i3 INTEGER unique,
s1 VARCHAR(10),
s2 VARCHAR(10),
s3 VARCHAR(10) UNIQUE);

CREATE INDEX i_t1_i1 ON t1(i1 DESC);
CREATE INDEX i_t1_s1 ON t1(s1(7));
CREATE INDEX i_t1_i1_s1 on t1(i1,s1);
CREATE UNIQUE INDEX i_t1_i2_s2 ON t1(i2,s2);

INSERT INTO t1 VALUES (1,1,1,'abc','abc','abc');
INSERT INTO t1 VALUES (2,2,2,'zabc','zabc','zabc');
INSERT INTO t1 VALUES (2,3,3,'+abc','+abc','+abc');

UPDATE STATISTICS ON t1;
SELECT INDEX_CARDINALITY('t1','i_t1_i1_s1',0);
```

```
index_cardinality('t1', 'i_t1_i1_s1', 0)
=====
2
```

```
SELECT INDEX_CARDINALITY('t1','i_t1_i1_s1',1);
```

```
index_cardinality('t1', 'i_t1_i1_s1', 1)
=====
3
```

```
SELECT INDEX_CARDINALITY('t1','i_t1_i1_s1',2);
```

```
index_cardinality('t1', 'i_t1_i1_s1', 2)
=====
NULL
```

```
SELECT INDEX_CARDINALITY('t123','i_t1_i1_s1',1);
```

```
index_cardinality('t123', 'i_t1_i1_s1', 1)
=====
NULL
```

## INET\_ATON

### INET\_ATON(*ip\_string*)

The **INET\_ATON** function receives the string of an IPv4 address and returns a number. When an IP address string such as 'a.b.c.d' is entered, the function returns "a \* 256 ^ 3 + b \* 256 ^ 2 + c \* 256 + d". The return type is **BIGINT**.

Parameters:

**ip\_string** – IPv4 address string

Return type:

BIGINT

In the following example, 192.168.0.10 is calculated as "192 \* 256 ^ 3 + 168 \* 256 ^ 2 + 0 \* 256 + 10".

```
SELECT INET_ATON('192.168.0.10');
```

```
inet_aton('192.168.0.10')
=====
3232235530
```

## INET\_NTOA

### INET\_NTOA(*expr*)

The **INET\_NTOA** function receives a number and returns an IPv4 address string. The return type is VARCHAR.

Parameters:

**expr** – Numeric expression

Return type:

STRING

```
SELECT INET_NTOA(3232235530);
```

```
inet_ntoa(3232235530)
=====
'192.168.0.10'
```

## LAST\_INSERT\_ID

LAST\_INSERT\_ID()

The **LAST\_INSERT\_ID** function returns the value that has been most recently inserted to the **AUTO\_INCREMENT** column by a single **INSERT** statement.

Return type:

BIGINT

The value returned by the **LAST\_INSERT\_ID** function has the following characteristics.

- The latest **LAST\_INSERT\_ID** value which was INSERTed successfully will be maintained. If it fails to INSERT, there is no change for **LAST\_INSERT\_ID()** value, but **AUTO\_INCREMENT** value is internally increased. Therefore, **LAST\_INSERT\_ID()** value after the next **INSERT** statement's success reflects the internally increased **AUTO\_INCREMENT** value.

```
CREATE TABLE tbl(a INT PRIMARY KEY AUTO_INCREMENT, b INT UNIQUE);
INSERT INTO tbl VALUES (null, 1);
INSERT INTO tbl VALUES (null, 1);
```

```
ERROR: Operation would have caused one or more unique constraint
violations.
```

```
INSERT INTO tbl VALUES (null, 1);
```

ERROR: Operation would have caused one **or** more unique constraint violations.

```
SELECT LAST_INSERT_ID();
```

1

-- In 2008 R4.x **or** before, above value **is** 3.

```
INSERT INTO tbl VALUES (null, 2);  
SELECT LAST_INSERT_ID();
```

4

- In the Multiple-rows **INSERT** statement(**INSERT INTO tbl VALUES** (), (), ..., ()), **LAST\_INSERT\_ID()** returns the firstly inserted **AUTO\_INCREMENT** value. In other words, from the second row, there is no change on **LAST\_INSERT\_ID()** value even if the next rows are inserted.

```
INSERT INTO tbl VALUES (null, 11), (null, 12), (null, 13);  
SELECT LAST_INSERT_ID();
```

5

```
INSERT INTO tbl VALUES (null, 21);  
SELECT LAST_INSERT_ID();
```

8

- If **INSERT** statement succeeds to execute, **LAST\_INSERT\_ID** () value is not recovered to its previous value even if the transaction is rolled back.

```
-- csql> ;autocommit off  
CREATE TABLE tbl2(a INT PRIMARY KEY AUTO_INCREMENT, b INT UNIQUE);  
INSERT INTO tbl2 VALUES (null, 1);
```

```
COMMIT;

SELECT LAST_INSERT_ID();
```

1

```
INSERT INTO tbl2 VALUES (null, 2);
INSERT INTO tbl2 VALUES (null, 3);

ROLLBACK;

SELECT LAST_INSERT_ID();
```

3

- **LAST\_INSERT\_ID()** value used from the inside of a trigger cannot be identified from the outside of the trigger.
- **LAST\_INSERT\_ID** is independently kept by a session of each application.

```
CREATE TABLE ss (id INT AUTO_INCREMENT NOT NULL PRIMARY KEY, text
VARCHAR(32));
INSERT INTO ss VALUES (NULL, 'cubrid');
SELECT LAST_INSERT_ID ();
```

```
last_insert_id()
=====
1
```

```
INSERT INTO ss VALUES (NULL, 'database'), (NULL, 'manager');
SELECT LAST_INSERT_ID ();
```

```
last_insert_id()
=====
2
```

```
CREATE TABLE tbl (id INT AUTO_INCREMENT);
INSERT INTO tbl values (500), (NULL), (NULL);
SELECT LAST_INSERT_ID();
```

```
last_insert_id()
=====
1
```

```
INSERT INTO tbl VALUES (500), (NULL), (NULL);
SELECT LAST_INSERT_ID();
```

```
last_insert_id()
=====
3
```

```
SELECT * FROM tbl;
```

```
      id
=====
      500
       1
       2
      500
       3
       4
```

## LIST\_DBS

### LIST\_DBS()

The **LIST\_DBS** function outputs the list of all databases in the directory file(**\$CUBRID\_DATABASES/databases.txt**), separated by blanks.

Return type:

STRING

```
SELECT LIST_DBS();
```

```
list_dbs()
=====
'testdb demodb'
```

## ROW\_COUNT

### ROW\_COUNT()

The **ROW\_COUNT** function returns the number of rows updated (**UPDATE**, **INSERT**, **DELETE**, **REPLACE**) by the previous statement.

ROW\_COUNT returns 1 for each inserted row and 2 for each updated row for **INSERT ON DUPLICATE KEY UPDATE** statement. It returns the sum of number of deleted and inserted rows for **REPLACE** statement.

Statements triggered by trigger will not affect the ROW\_COUNT for the statement.

Return type:

INT

```
CREATE TABLE rc (i int);
INSERT INTO rc VALUES (1),(2),(3),(4),(5),(6),(7);
SELECT ROW_COUNT();
```

```
row_count()
=====
7
```

```
UPDATE rc SET i = 0 WHERE i > 3;
SELECT ROW_COUNT();
```

```
row_count()
=====
4
```

```
DELETE FROM rc WHERE i = 0;
SELECT ROW_COUNT();
```

```
row_count()
=====
4
```

## SESSIONTIMEZONE

### SESSIONTIMEZONE()

Prints out a timezone of session (offset or region name) as a string. (e.g. '-05:00', or 'Europe/Vienna').

```
SELECT SESSIONTIMEZONE();
```

```
sessiontimezone
=====
'Asia/Seoul'
```

#### ! See also

DBTIMEZONE(), FROM\_TZ(), NEW\_TIME(), TZ\_OFFSET()

## USER, SYSTEM\_USER

### USER()

### SYSTEM\_USER()

The functions **USER** and **SYSTEM\_USER** are identical and they return the user name together with the host name where CSQL or CAS was executed.

The `USER` and `CURRENT_USER` pseudo-columns return the user names who has logged on to the current database as character strings.

Return type:

STRING

```
--selecting the current user on the session
SELECT SYSTEM_USER ();
```

```
user()
=====
'PUBLIC@cubrid_host'
```

```
SELECT USER(), CURRENT_USER;
```

```

user()                CURRENT_USER
=====
'PUBLIC@cubrid_host'  'PUBLIC'

```

```
--selecting all users of the current database from the system table
SELECT name, id, password FROM db_user;
```

```

name                id  password
=====
'DBA'                NULL  NULL
'PUBLIC'             NULL  NULL
'SELECT_ONLY_USER'  NULL  db_password
'ALMOST_DBA_USER'   NULL  db_password
'SELECT_ONLY_USER2' NULL  NULL

```

## VERSION

### VERSION()

The **VERSION** function returns the version character string representing the CUBRID server version.

Return type:

STRING

```
SELECT VERSION();
```

```

version()
=====
'9.1.0.0203'

```

## Encryption Function

### Contents

|                            |            |
|----------------------------|------------|
| <b>Encryption Function</b> | <b>717</b> |
| ● MD5                      | 717        |
| ● SHA1                     | 718        |
| ● SHA2                     | 719        |

### MD5

#### MD5(*string*)

The **MD5** function returns the MD5 128-bit checksum for the input character string. The result value is displayed as a character string that is expressed in 32 hexadecimal, which you can use to create hash keys, for example.

#### Parameters:

**string** – Input string. If a value that is not a **VARCHAR** type is entered, it will be converted to **VARCHAR**.

#### Return type:

STRING

The return value is a **VARCHAR** (32) type and if an input parameter is **NULL**, **NULL** will be returned.

```
SELECT MD5('cubrid');
```

```
md5('cubrid')
=====
'685c62385ce717a04f909047d0a55a16'
```

```
SELECT MD5(255);
```

```
md5(255)
=====
'fe131d7f5a6b38b23cc967316c13dae2'
```

```
SELECT MD5('01/01/2010');
```

```
md5('01/01/2010')
=====
'4a2f373c30426a1b8e9cf002ef0d4a58'
```

```
SELECT MD5(CAST('2010-01-01' as DATE));
```

```
md5( cast('2010-01-01' as date))
=====
'4a2f373c30426a1b8e9cf002ef0d4a58'
```

## SHA1

### SHA1(*string*)

The **SHA1** function calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm).

Parameters:

**string** – target string to be encrypted

Return type:

STRING

The value is returned as a string of 40 hex digits, or NULL if the argument is NULL.

```
SELECT SHA1('cubrid');
```

```
sha1('cubrid')
=====
'0562A8E9C814E660F5FFEB0DAC739ABFBBB1CB69'
```

## SHA2

### SHA2(*string*, *hash\_length*)

The **SHA2** function calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the cleartext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256).

#### Parameters:

**string** – target string to be encrypted

#### Return type:

STRING

If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL. Otherwise, the function result is a hash value containing the desired number of bits.

```
SELECT SHA2('cubrid', 256);
```

```
sha2('cubrid', 256)
=====
'D14DA17F2C492114F4A57D9F7BED908FD3A351B40CD59F0F79413687E4CA85A5'
```

```
SELECT SHA2('cubrid', 224);
```

```
sha2('cubrid', 224)
=====
'8E5E18B5B47646C31CCEA98A87B19CBEF084036716FBD13D723AC9B2'
```

## Comparison Expression

### Simple Comparison Expression

A comparison expression is an expression that is included in the **WHERE** clause of the **SELECT**, **UPDATE** and **DELETE** statements, and in the **HAVING** clause of the **SELECT** statement. There are simple comparison, **ANY** / **SOME** / **ALL**, **BETWEEN**, **EXISTS**, **IN** / **NOT IN**, **LIKE** and **IS NULL** comparison expressions, depending on the kinds of the operators combined.

A simple comparison expression compares two comparable data values. Expressions or subqueries are specified as operands, and the comparison expression always returns **NULL** if one of the operands is **NULL**. The following table shows operators that can be used in the simple comparison expressions. For details, see [Comparison Operators](#).

### Comparison Operators

| Comparison Operator | Description                                                                | Comparison Expression | Return Value |
|---------------------|----------------------------------------------------------------------------|-----------------------|--------------|
| =                   | A value of left operand is the same as that of right operand.              | 1=2                   | 0            |
| <>, !=              | A value of left operand is not the same as that of right operand.          | 1<>2                  | 1            |
| >                   | A value of left operand is greater than that of right operand.             | 1>2                   | 0            |
| <                   | A value of left operand is less than that of right operand.                | 1<2                   | 1            |
| >=                  | A value of left operand is equal to or greater than that of right operand. | 1>=2                  | 0            |
| <=                  | A value of left operand is equal to                                        | 1<=2                  | 1            |

| Comparison Operator | Description                         | Comparison Expression | Return Value |
|---------------------|-------------------------------------|-----------------------|--------------|
|                     | or less than that of right operand. |                       |              |

### ANY/SOME/ALL quantifiers

A comparison expression that includes quantifiers such as **ANY/SOME/ALL** performs comparison operation on one data value and on some or all values included in the list. A comparison expression that includes **ANY** or **SOME** returns **TRUE** if the value of the data on the left satisfies simple comparison with at least one of the values in the list specified as an operand on the right. A comparison expression that includes **ALL** returns **TRUE** if the value of the data on the left satisfies simple comparison with all values in the list on the right.

When a comparison operation is performed on **NULL** in a comparison expression that includes **ANY** or **SOME**, **UNKNOWN** or **TRUE** is returned as a result; when a comparison operation is performed on **NULL** in a comparison expression that includes **ALL**, **UNKNOWN** or **FALSE** is returned.

```
expression comp_op SOME expression
expression comp_op ANY expression
expression comp_op ALL expression
```

- *comp\_op* : A comparison operator >, = or <= can be used.
- *expression* (left): A single-value column, path expression (ex.: *tbl\_name.col\_name*), constant value or arithmetic function that produces a single value can be used.
- *expression* (right): A column name, path expression, list (set) of constant values or subquery can be used. A list is a set represented within braces ({}). If a subquery is used, *expression* (left) and comparison operation on all results of the subquery execution is performed.

```
--creating a table
```

```
CREATE TABLE condition_tbl (id int primary key, name char(10),
dept_name VARCHAR, salary INT);
INSERT INTO condition_tbl VALUES(1, 'Kim', 'devel', 4000000);
INSERT INTO condition_tbl VALUES(2, 'Moy', 'sales', 3000000);
INSERT INTO condition_tbl VALUES(3, 'Jones', 'sales', 5400000);
INSERT INTO condition_tbl VALUES(4, 'Smith', 'devel', 5500000);
INSERT INTO condition_tbl VALUES(5, 'Kim', 'account', 3800000);
INSERT INTO condition_tbl VALUES(6, 'Smith', 'devel', 2400000);
```

```
INSERT INTO condition_tbl VALUES(7, 'Brown', 'account', NULL);

--selecting rows where department is sales or devel
SELECT * FROM condition_tbl WHERE dept_name = ANY{'devel','sales'};
```

| salary  | id | name    | dept_name |
|---------|----|---------|-----------|
| =====   |    |         |           |
| =       |    |         |           |
| 4000000 | 1  | 'Kim'   | 'devel'   |
| 3000000 | 2  | 'Moy'   | 'sales'   |
| 5400000 | 3  | 'Jones' | 'sales'   |
| 5500000 | 4  | 'Smith' | 'devel'   |
| 2400000 | 6  | 'Smith' | 'devel'   |

```
--selecting rows comparing NULL value in the ALL group conditions
SELECT * FROM condition_tbl WHERE salary > ALL{3000000, 4000000,
NULL};
```

There are no results.

```
--selecting rows comparing NULL value in the ANY group conditions
SELECT * FROM condition_tbl WHERE salary > ANY{3000000, 4000000,
NULL};
```

| salary  | id | name    | dept_name |
|---------|----|---------|-----------|
| =====   |    |         |           |
| =       |    |         |           |
| 4000000 | 1  | 'Kim'   | 'devel'   |
| 5400000 | 3  | 'Jones' | 'sales'   |
| 5500000 | 4  | 'Smith' | 'devel'   |
| 3800000 | 5  | 'Kim'   | 'account' |

```
--selecting rows where salary*0.9 is less than those salary in devel
department
SELECT * FROM condition_tbl WHERE (
  (0.9 * salary) < ALL (SELECT salary FROM condition_tbl
    WHERE dept_name = 'devel')
);
```

| salary  | id | name    | dept_name |
|---------|----|---------|-----------|
| =====   |    |         |           |
| =       |    |         |           |
|         | 6  | 'Smith' | 'devel'   |
| 2400000 |    |         |           |

## BETWEEN

The **BETWEEN** makes a comparison to determine whether the data value on the left exists between two data values specified on the right. It returns **TRUE** even when the data value on the left is the same as a boundary value of the comparison target range. If **NOT** comes before the **BETWEEN** keyword, the result of a **NOT** operation on the result of the **BETWEEN** operation is returned.

$i$  **BETWEEN**  $g$  **AND**  $m$  and the compound condition  $i \geq g$  **AND**  $i \leq m$  have the same effect.

```
expression [ NOT ] BETWEEN expression AND expression
```

- *expression* : A column name, path expression (ex.: *tbl\_name.col\_name*), constant value, arithmetic expression or aggregate function can be used. For a character string expression, the conditions are evaluated in alphabetical order. If **NULL** is specified for at least one of the expressions, the **BETWEEN** predicate returns **UNKNOWN** as a result.

```
--selecting rows where 3000000 <= salary <= 4000000
SELECT * FROM condition_tbl WHERE salary BETWEEN 3000000 AND 4000000;
SELECT * FROM condition_tbl WHERE (salary >= 3000000) AND (salary <=
4000000);
```

| salary  | id | name  | dept_name |
|---------|----|-------|-----------|
| =====   |    |       |           |
| =       |    |       |           |
|         | 1  | 'Kim' | 'devel'   |
| 4000000 |    |       |           |

```

3000000      2  'Moy      '      'sales'
3800000      5  'Kim      '      'account'

```

```

--selecting rows where salary < 3000000 or salary > 4000000
SELECT * FROM condition_tbl WHERE salary NOT BETWEEN 3000000 AND
4000000;

```

```

      id  name      dept_name
salary
=====
=
      3  'Jones    '      'sales'
5400000
      4  'Smith    '      'devel'
5500000
      6  'Smith    '      'devel'
2400000

```

```

--selecting rows where name starts from A to E
SELECT * FROM condition_tbl WHERE name BETWEEN 'A' AND 'E';

```

```

      id  name      dept_name
salary
=====
=
      7  'Brown    '      'account'
NULL

```

## EXISTS

The **EXISTS** returns **TRUE** if one or more results of the execution of the subquery specified on the right exist, and returns **FALSE** if the result of the operation is an empty set.

### EXISTS expression

- *expression* : Specifies a subquery and compares to determine whether the result of the subquery execution exists. If the subquery does not produce any result, the result of the conditional expression is **FALSE**.

```
--selecting rows using EXISTS and subquery
SELECT 'raise' FROM db_root WHERE EXISTS(
SELECT * FROM condition_tbl WHERE salary < 2500000);
```

```
'raise'
=====
'raise'
```

```
--selecting rows using NOT EXISTS and subquery
SELECT 'raise' FROM db_root WHERE NOT EXISTS(
SELECT * FROM condition_tbl WHERE salary < 2500000);
```

There are no results.

## IN

The **IN** compares to determine whether the single data value on the left is included in the list specified on the right. That is, the predicate returns **TRUE** if the single data value on the left is an element of the expression specified on the right. If **NOT** comes before the **IN** keyword, the result of a **NOT** operation on the result of the **IN** operation is returned.

```
expression [ NOT ] IN expression
```

- *expression* (left): A single-value column, path expression (ex.: *tbl\_name.col\_name*), constant value or arithmetic function that produces a single value can be used.
- *expression* (right): A column name, path expression, list (set) of constant values or subquery can be used. A list is a set represented within parentheses (()) or braces ({}). If a subquery is used, comparison with expression(left) is performed for all results of the subquery execution.

```
--selecting rows where department is sales or devel
SELECT * FROM condition_tbl WHERE dept_name IN {'devel','sales'};
SELECT * FROM condition_tbl WHERE dept_name = ANY{'devel','sales'};
```

```

      id  name      dept_name
salary
=====
=
      1  'Kim      '      'devel'
4000000
```

```

3000000      2  'Moy      '      'sales'
5400000      3  'Jones    '      'sales'
5500000      4  'Smith    '      'devel'
2400000      6  'Smith    '      'devel'

```

```

--selecting rows where department is neither sales nor devel
SELECT * FROM condition_tbl WHERE dept_name NOT IN {'devel','sales'};

```

```

salary      id  name      dept_name
=====
=
3800000      5  'Kim      '      'account'
NULL         7  'Brown    '      'account'

```

## IS NULL

The **IS NULL** compares to determine whether the expression specified on the left is **NULL**, and if it is **NULL**, returns **TRUE** and it can be used in the conditional expression. If **NOT** comes before the **NULL** keyword, the result of a **NOT** operation on the result of the **IS NULL** operation is returned.

expression IS [ NOT ] NULL

- *expression* : A single-value column, path expression (ex.: *tbl\_name.col\_name*), constant value or arithmetic function that produces a single value can be used.

```

--selecting rows where salary is NULL
SELECT * FROM condition_tbl WHERE salary IS NULL;

```

```

salary      id  name      dept_name
=====
=
NULL         7  'Brown    '      'account'

```

```
--selecting rows where salary is NOT NULL
SELECT * FROM condition_tbl WHERE salary IS NOT NULL;
```

| salary  | id | name    | dept_name |
|---------|----|---------|-----------|
| =====   |    |         |           |
| =       |    |         |           |
| 4000000 | 1  | 'Kim'   | 'devel'   |
| 3000000 | 2  | 'Moy'   | 'sales'   |
| 5400000 | 3  | 'Jones' | 'sales'   |
| 5500000 | 4  | 'Smith' | 'devel'   |
| 3800000 | 5  | 'Kim'   | 'account' |
| 2400000 | 6  | 'Smith' | 'devel'   |

```
--simple comparison operation returns NULL when operand is NULL
SELECT * FROM condition_tbl WHERE salary = NULL;
```

There are no results.

## LIKE

The **LIKE** compares patterns between character string data, and returns **TRUE** if a character string whose pattern matches the search word is found. Pattern comparison target types are **CHAR**, **VARCHAR** and **STRING**. The **LIKE** search cannot be performed on an **BIT** type. If **NOT** comes before the **LIKE** keyword, the result of a **NOT** operation on the result of the **LIKE** operation is returned.

A wild card string corresponding to any character or character string can be included in the search word on the right of the **LIKE** operator. % (percent) and \_ (underscore) can be used. % corresponds to any character string whose length is 0 or greater, and \_ corresponds to one character. An escape character is a character that is used to search for a wild card character itself, and can be specified by the user as another character (**NULL**, alphabet, or number whose length is 1. See below for an example of using a character string that includes wild card or escape characters.

```
expression [ NOT ] LIKE pattern [ ESCAPE char ]
```

- *expression*: Specifies the data type column of the character string. Pattern comparison, which is case-sensitive, starts from the first character of the column.
- *pattern*: Enters the search word. A character string with a length of 0 or greater is required. Wild card characters (%) or (\_) can be included as the pattern of the search word. The length of the character string is 0 or greater.
- **ESCAPE char**: **NULL**, alphabet, or number is allowed for *char*. If the string pattern of the search word includes “\_” or “%” itself, an ESCAPE character must be specified. For example, if you want to search for the character string “10%” after specifying backslash (\) as the ESCAPE character, you must specify “10%” for *pattern*. If you want to search for the character string “C:\”, you can specify “C:\” for *pattern*.

For details about character sets supported in CUBRID, see [Character Strings](#).

Whether to detect the escape characters of the LIKE conditional expression is determined depending on the configuration of **no\_backslash\_escapes** and **require\_like\_escape\_character** in the **cubrid.conf** file. For details, see [Statement/Type-Related Parameters](#).

#### **Note**

- To execute string comparison operation for data entered in the multibyte charset environment such as UTF-8, the parameter setting (**single\_byte\_compare** = yes) which compares strings by 1 byte should be added to the **cubrid.conf** file for a successful search result.
- Versions after CUBRID 9.0 support Unicode charset, so the **single\_byte\_compare** parameter is no longer used.

```
--selection rows where name contains lower case 's', not upper case
SELECT * FROM condition_tbl WHERE name LIKE '%s%';
```

```

      id  name          dept_name
salary
=====
=
      3  'Jones      '      'sales'
5400000
```

```
--selection rows where second letter is 'O' or 'o'
SELECT * FROM condition_tbl WHERE UPPER(name) LIKE '_O%';
```

| salary  | id | name    | dept_name |
|---------|----|---------|-----------|
| =====   |    |         |           |

```
--selection rows where name is 3 characters
SELECT * FROM condition_tbl WHERE name LIKE '___';
```

| salary  | id | name  | dept_name |
|---------|----|-------|-----------|
| =====   |    |       |           |
| =       |    |       |           |
| 4000000 | 1  | 'Kim' | 'devel'   |
| 3000000 | 2  | 'Moy' | 'sales'   |
| 3800000 | 5  | 'Kim' | 'account' |

## CASE

The **CASE** expression uses the SQL statement to perform an **IF ... THEN** statement. When a result of comparison expression specified in a **WHEN** clause is true, a value specified in **THEN** clause is returned. A value specified in an **ELSE** clause is returned otherwise. If no **ELSE** clause exists, **NULL** is returned.

```
CASE control_expression simple_when_list
[ else_clause ]
END
```

```
CASE searched_when_list
[ else_clause ]
END
```

```
simple_when :
WHEN expression THEN result
```

```

searched_when :
WHEN search_condition THEN result

else_clause :
ELSE result

result :
expression | NULL

```

The **CASE** expression must end with the **END** keyword. A *control\_expression* argument and an *expression argument* in *simple\_when* expression should be comparable data types. The data types of *result* specified in the **THEN** ... **ELSE** statement should all same, or they can be convertible to common data type.

The data type for a value returned by the **CASE** expression is determined based on the following rules.

- If data types for result specified in the **THEN** statement are all same, a value with the data type is returned.
- If data types can be convertible to common data type even though they are not all same, a value with the data type is returned.
- If any of values for *result* is a variable length string, a value data type is a variable length string. If values for *result* are all a fixed length string, the longest character string or bit string is returned.
- If any of values for result is an approximate numeric data type, a value with a numeric data type is returned. The number of digits after the decimal point is determined to display all significant figures.

```

--creating a table
CREATE TABLE case_tbl( a INT);
INSERT INTO case_tbl VALUES (1);
INSERT INTO case_tbl VALUES (2);
INSERT INTO case_tbl VALUES (3);
INSERT INTO case_tbl VALUES (NULL);

--case operation with a search when clause
SELECT a,
       CASE WHEN a=1 THEN 'one'
            WHEN a=2 THEN 'two'
            ELSE 'other'
       END
FROM case_tbl;

```

```

## COALESCE

COALESCE(*expression* [, *expression* ]...)

The **COALESCE** function has more than one expression as an argument. If the first argument is non-**NULL**, the corresponding value is returned if it is **NULL**, the second argument is returned. If all expressions which have an argument are **NULL**, **NULL** is returned. Therefore, this function is generally used to replace **NULL** with other default value.

**Parameters:**

**expression** – Specifies more than one expression. Their types must be comparable each other.

**Return type:**

determined with the type of the arguments

Operation is performed by converting the type of every argument into that with the highest priority. If there is an argument whose type cannot be converted, the type of every argument is converted into a **VARCHAR** type. The following list shows priority of conversion based on input argument type.

- **CHAR < VARCHAR**
- **BIT < VARBIT**
- **SHORT < INT < BIGINT < NUMERIC < FLOAT < DOUBLE**
- **DATE < TIMESTAMP < DATETIME**

For example, if a type of a is **INT**, b, **BIGINT**, c, **SHORT**, and d, **FLOAT**, then **COALESCE** (a, b, c, d) returns a **FLOAT** type. If a type of a is **INTEGER**, b, **DOULBE** , c, **FLOAT**, and d, **TIMESTAMP**, then **COALESCE** (a, b, c, d) returns a **VARCHAR** type.

**COALESCE** (a, b) works the same as the **CASE** expression as follows:

```
CASE WHEN a IS NOT NULL
THEN a
ELSE b
END
```

```
SELECT * FROM case_tbl;
```

```
=====
a
1
2
3
NULL
```

```
--substituting a default value 10.0000 for a NULL value
SELECT a, COALESCE(a, 10.0000) FROM case_tbl;
```

```
      a  coalesce(a, 10.0000)
=====
      1  1.0000
      2  2.0000
      3  3.0000
  NULL 10.0000
```

## DECODE

**DECODE**(*expression*, *search*, *result* [, *search*, *result*]\* [, *default*])

As well as a **CASE** expression, the **DECODE** function performs the same functionality as the **IF ... THEN ... ELSE** statement. It compares the *expression* argument with *search* argument, and returns the *result* corresponding to *search* that has the same value. It returns *default* if there is no *search* with the same value, and returns **NULL** if *default* is omitted. An expression argument and a search argument to be comparable should be same or convertible each other. The number of digits after the decimal point is determined to display all significant figures including valid number of all *result*.

Parameters:

- **expression,search** – expressions that are comparable with each other
- **result** – the value to be returned when matched
- **default** – the value to be returned when no match is found

Return type:

determined with the type of *result* and *default*

**DECODE**(*a*, *b*, *c*, *d*, *e*, *f*) has the same meaning as the **CASE** expression below.

```
CASE WHEN a = b THEN c
      WHEN a = d THEN e
      ELSE f
      END
```

```
SELECT * FROM case_tbl;
```

```

      a
=====
      1
      2
      3
    NULL

```

```
--Using DECODE function to compare expression and search values one
by one
SELECT a, DECODE(a, 1, 'one', 2, 'two', 'other') FROM case_tbl;
```

```

      a  decode(a, 1, 'one', 2, 'two', 'other')
=====
      1  'one'
      2  'two'
      3  'other'
    NULL  'other'

```

```
--result types are converted to a single type containing all of
significant figures
SELECT a, DECODE(a, 1, 1, 2, 1.2345, 1.234567890) FROM case_tbl;
```

```

      a  decode(a, 1, 1, 2, 1.2345, 1.234567890)
=====
      1  1.0000000000
      2  1.2345000000
      3  1.234567890
    NULL  1.234567890

```

```
--an error occurs when result types are not convertible
SELECT a, DECODE(a, 1, 'one', 2, 'two', 1.2345) FROM case_tbl;
```

```
ERROR: Cannot coerce 'one' to type double.
```

## GREATEST

GREATEST(*expression* [, *expression*] ...)

The **GREATEST** function compares more than one expression specified as parameters and returns the greatest value. If only one expression has been specified, the expression is returned because there is no expression to be compared with.

Therefore, more than one expression that is specified as parameters must be of the type that can be compared with each other. If the types of the specified parameters are identical, so are the types of the return values; if they are different, the type of the return value becomes a convertible common data type.

That is, the **GREATEST** function compares the values of column 1, column 2 and column 3 in the same row and returns the greatest value while the **MAX** function compares the values of column in all result rows and returns the greatest value.

#### Parameters:

**expression** – Specifies more than one expression. Their types must be comparable each other. One of the arguments is **NULL**, **NULL** is returned.

#### Return type:

same as that of the argument

The following example shows how to retrieve the number of every medals and the highest number that Korea won in the *demodb* database.

```
SELECT gold, silver , bronze, GREATEST (gold, silver, bronze)
FROM participant
WHERE nation_code = 'KOR';
```

|    | gold | silver | bronze | greatest(gold, silver, bronze) |
|----|------|--------|--------|--------------------------------|
| 12 | 9    | 12     | 9      | 12                             |
| 10 | 8    | 10     | 10     | 10                             |
| 15 | 7    | 15     | 5      | 15                             |
| 12 | 12   | 5      | 12     | 12                             |
| 12 | 12   | 10     | 11     | 12                             |

## IF

### IF(*expression1*, *expression2*, *expression3*)

The **IF** function returns *expression2* if the value of the arithmetic expression specified as the first parameter is **TRUE**, or *expression3* if the value is **FALSE** or **NULL**. *expression2* and *expression3* which are returned as a result must be the same or of a convertible common type. If one is explicitly **NULL**, the result of the function follows the type of the non-**NULL** parameter.

#### Parameters:

- **expression1** – comparison expression
- **expression2** – the value to be returned when *expression1* is true
- **expression3** – the value to be returned when *expression1* is not true

#### Return type:

type of *expression2* or *expression3*

IF(*a*, *b*, *c*) has the same meaning as the **CASE** expression in the following example:

```
CASE WHEN a IS TRUE THEN b
ELSE c
END
```

```
SELECT * FROM case_tbl;
```

```

      a
=====
      1
      2
      3
     NULL
```

```
--IF function returns the second expression when the first is TRUE
SELECT a, IF(a=1, 'one', 'other') FROM case_tbl;
```

```

      a    if(a=1, 'one', 'other')
=====
      1    'one'
      2    'other'
      3    'other'
    NULL   'other'

```

```

--If function in WHERE clause
SELECT * FROM case_tbl WHERE IF(a=1, 1, 2) = 1;

```

```

      a
=====
      1

```

## IFNULL, NVL

IFNULL(*expr1*, *expr2*)

NVL(*expr1*, *expr2*)

The **IFNULL** function is working like the **NVL** function; however, only the **NVL** function supports collection type as well. The **IFNULL** function (which has two arguments) returns *expr1* if the value of the first expression is not **NULL** or returns *expr2*, otherwise.

Parameters:

- **expr1** – expression
- **expr2** – the value to be returned when *expr1* is **NULL**

Return type:

determined with the type of *expr1* and *expr2*

Operation is performed by converting the type of every argument into that with the highest priority. If there is an argument whose type cannot be converted, the type of every argument is converted into a **VARCHAR** type. The following list shows priority of conversion based on input argument type.

- **CHAR < VARCHAR**
- **BIT < VARBIT**

· **SHORT < INT < BIGINT < NUMERIC < FLOAT < DOUBLE**

· **DATE < TIMESTAMP < DATETIME**

For example, if a type of a is **INT** and b is **BIGINT**, then **IFNULL** (a, b) returns a **BIGINT** type. If a type of a is **INTEGER** and b is **TIMESTAMP**, then **IFNULL** (a, b) returns a **VARCHAR** type.

**IFNULL**(a, b) or **NVL**(a, b) has the same meaning as the **CASE** expression below.

```
CASE WHEN a IS NULL THEN b
ELSE a
END
```

```
SELECT * FROM case_tbl;
```

```
      a
=====
      1
      2
      3
     NULL
```

```
--returning a specific value when a is NULL
SELECT a, NVL(a, 10.0000) FROM case_tbl;
```

```
      a  nv(a, 10.0000)
=====
      1  1.0000
      2  2.0000
      3  3.0000
     NULL 10.0000
```

```
--IFNULL can be used instead of NVL and return values are converted
to the string type
SELECT a, IFNULL(a, 'UNKNOWN') FROM case_tbl;
```

```
      a  ifnull(a, 'UNKNOWN')
=====
      1  '1'
      2  '2'
      3  '3'
     NULL 'UNKNOWN'
```

## ISNULL

### ISNULL(*expression*)

The **ISNULL** function performs a comparison to determine if the result of the expression specified as an argument is **NULL**. The function returns 1 if it is **NULL** or 0 otherwise. You can check if a certain value is **NULL**. This function is working like the **ISNULL** expression.

#### Parameters:

**expression** – An arithmetic function that has a single-value column, path expression (ex.: *tbl\_name.col\_name*), constant value is specified.

#### Return type:

INT

```
--Using ISNULL function to select rows with NULL value
SELECT * FROM condition_tbl WHERE ISNULL(salary);
```

| salary | id | name    | dept_name |
|--------|----|---------|-----------|
| =====  |    |         |           |
| =      |    |         |           |
|        | 7  | 'Brown' | 'account' |
| NULL   |    |         |           |

## LEAST

### LEAST(*expression* [, *expression*] ...)

The **LEAST** function compares more than one expression specified as parameters and returns the smallest value. If only one expression has been specified, the expression is returned because there is no expression to be compared with.

Therefore, more than one expression that is specified as parameters must be of the type that can be compared with each other. If the types of the specified parameters are identical, so are the types of the return values; if they are different, the type of the return value becomes a convertible common data type.

That is, the **LEAST** function compares the values of column 1, column 2 and column 3 in the same row and returns the smallest value while the **MIN()** compares the values of column in all result rows and returns the smallest value.

**Parameters:**

**expression** – Specifies more than one expression. Their types must be comparable each other. One of the arguments is **NULL**, **NULL** is returned.

**Return type:**

same as that of the argument

The following example shows how to retrieve the number of every medals and the lowest number that Korea won in the *demodb* database.

```
SELECT gold, silver , bronze, LEAST(gold, silver, bronze) FROM
participant
WHERE nation_code = 'KOR';
```

| gold | silver | bronze | least(gold, silver, bronze) |
|------|--------|--------|-----------------------------|
| 9    | 12     | 9      | 9                           |
| 8    | 10     | 10     | 8                           |
| 7    | 15     | 5      | 5                           |
| 12   | 5      | 12     | 5                           |
| 12   | 10     | 11     | 10                          |

**NULLIF****NULLIF(expr1, expr2)**

The **NULLIF** function returns **NULL** if the two expressions specified as the parameters are identical, and returns the first parameter value otherwise.

**Parameters:**

- **expr1** – expression to be compared with *expr2*
- **expr2** – expression to be compared with *expr1*

**Return type:**

type of *expr1*

**NULLIF** (*a, b*) is the same of the **CASE** expression.

```
CASE
WHEN a = b THEN NULL
ELSE a
END
```

```
SELECT * FROM case_tbl;
```

```
      a
=====
      1
      2
      3
    NULL
```

```
--returning NULL value when a is 1
SELECT a, NULLIF(a, 1) FROM case_tbl;
```

```
      a  nullif(a, 1)
=====
      1          NULL
      2           2
      3           3
    NULL          NULL
```

```
--returning NULL value when arguments are same
SELECT NULLIF (1, 1.000) FROM db_root;
```

```
    nullif(1, 1.000)
=====
    NULL
```

```
--returning the first value when arguments are not same
SELECT NULLIF ('A', 'a') FROM db_root;
```

```
    nullif('A', 'a')
=====
    'A'
```

## NVL2

### NVL2(*expr1*, *expr2*, *expr3*)

Three parameters are specified for the **NVL2** function. The second expression (*expr2*) is returned if the first expression (*expr1*) is not **NULL**; the third expression (*expr3*) is returned if it is **NULL**.

#### Parameters:

- **expr1** – expression
- **expr2** – the value to be returned when *expr1* is not **NULL**
- **expr3** – the value to be returned when *expr1* is **NULL**

#### Return type:

determined with the type of *expr1*, *expr2* and *expr3*

Operation is performed by converting the type of every argument into that with the highest priority. If there is an argument whose type cannot be converted, the type of every argument is converted into a **VARCHAR** type. The following list shows priority of conversion based on input argument type.

- **CHAR < VARCHAR**
- **BIT < VARBIT**
- **SHORT < INT < BIGINT < NUMERIC < FLOAT < DOUBLE**
- **DATE < TIMESTAMP < DATETIME**

For example, if a type of a is **INT**, b, **BIGINT**, and c, **SHORT**, then **NVL2** (a, b, c) returns a **BIGINT** type. If a type of a is **INTEGER**, b, **DOUBLE**, and c, **TIMESTAMP**, then **NVL2** (a, b, c) returns a **VARCHAR** type.

```
SELECT * FROM case_tbl;
```

```

      a
=====
      1
      2
      3
    NULL
```

```
--returning a specific value of INT type
SELECT a, NVL2(a, a+1, 10.5678) FROM case_tbl;
```

```

      a  nvl2(a, a+1, 10.5678)
=====
      1                      2
      2                      3
      3                      4
    NULL                    11

```

## Other functions

Contents

### Other functions

744

- SLEEP 744
- SYS\_GUID 745

## SLEEP

### SLEEP(sec)

This function pauses for the specified time then resumes the operations.

Parameters:

**sec** – sleep time. The unit is second and inputs double type value.

Return type:

INT

```
SELECT SLEEP(3);
```

It pauses for 3 seconds.

## SYS\_GUID

### SYS\_GUID()

It returns the unique hexadecimal string of 32 characters randomly.

```
SELECT SYS_GUID();
```

```
sys_guid()
=====
'938210043A7B4455927A8697FB2571FF'
```

## Data Manipulation Statements

### SELECT

The **SELECT** statement specifies columns that you want to retrieve from a table.

```
SELECT [ <qualifier> ] <select_expressions>
    [{TO | INTO} <variable_comma_list>]
    [FROM <extended_table_specification_comma_list>]
    [WHERE <search_condition>]
    [GROUP BY {col_name | expr} [ASC | DESC], ...[WITH ROLLUP]]
    [HAVING <search_condition> ]
    [USING INDEX { index_name [,index_name, ...] | NONE }]
    [ORDER BY {col_name | expr} [ASC | DESC], ... [NULLS {FIRST |
LAST}}]
    [LIMIT [offset,] row_count]
    [FOR UPDATE [OF <spec_name_comma_list>]]

<qualifier> ::= ALL | DISTINCT | DISTINCTROW | UNIQUE

<select_expressions> ::= * | <expression_comma_list> | *,
<expression_comma_list>

<variable_comma_list> ::= [:] identifier, [:] identifier, ...

<extended_table_specification_comma_list> ::=
    <table_specification> [
        {, <table_specification> } ... |
        <join_table_specification> ... |
        <join_table_specification2> ...
    ]
```

```

<table_specification> ::=
    <single_table_spec> [<correlation>] |
    <metaclass_specification> [ <correlation> ] |
    <subquery> <correlation> |
    TABLE ( <expression> ) <correlation>

<correlation> ::= [AS] <identifier> [( <identifier_comma_list> )]

<single_table_spec> ::= [ONLY] [schema_name.]table_name |
                        ALL [schema_name.]table_name [ EXCEPT
[schema_name.]table_name ]

<metaclass_specification> ::= CLASS [schema_name.]class_name

<join_table_specification> ::=
    {
        [INNER | {LEFT | RIGHT} [OUTER]] JOIN

        } <table_specification> ON <search_condition>

<join_table_specification2> ::=
    {
        CROSS JOIN |
        NATURAL [ LEFT | RIGHT ] JOIN
    } <table_specification>

```

- *qualifier*: A qualifier. When omitted, it is set to **ALL**.
  - **ALL**: Retrieves all records of the table.
  - **DISTINCT**: Retrieves only records with unique values without allowing duplicates. **DISTINCT**, **DISTINCTROW**, and **UNIQUE** are used interchangeably.
- <select\_expressions>
  - \*: By using **SELECT** \* statement, you can retrieve all columns from the table specified in the **FROM** clause.
  - *expression\_comma\_list*: *expression* can be a path expression (ex.: *tbl\_name.col\_name*), variable or table name. All general expressions including arithmetic operations can also be used. Use a comma (,) to separate each expression in the list. You can specify aliases by using the **AS** keyword for columns or expressions to be queried. Specified aliases are used as column names in **GROUP BY**, **HAVING** and **ORDER BY** clauses. The position index of a column is assigned based on the order in which the column was specified. The starting value is 1.

As **AVG**, **COUNT**, **MAX**, **MIN**, or **SUM**, an aggregate function that manipulates the retrieved data can also be used in the *expression*.

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name.\**: Specifies the table name and using *\** has the same effect as specifying all columns for the given table.
- *variable\_comma\_list*: The data retrieved by the *select\_expressions* can be stored in more than one variable.
- *[:]identifier*: By using the *:identifier* after **TO** (or **INTO**), you can store the data to be retrieved in the '*identifier*' variable.
- *<single\_table\_spec>*
  - If a superclass name is specified after the **ONLY** keyword, only the superclass, not the subclass inheriting from it, is selected.
  - If a superclass name is specified after the **ALL** keyword, the superclass as well as the subclass inheriting from it are both selected.
  - You can define the list of subclass not to be selected after the **EXCEPT** keyword.

The following example shows how to retrieve host countries of the Olympic Games without any duplicates. This example is performed on the *olympic* table of *demodb*. The **DISTINCT** or **UNIQUE** keyword makes the query result unique. For example, when there are multiple *olympic* records of which each *host\_nation* value is 'Greece', you can use such keywords to display only one value in the query result.

```
SELECT DISTINCT host_nation
FROM olympic;
```

```
host_nation
=====
'Australia'
'Belgium'
'Canada'
'Finland'
'France'
...
```

The following example shows how to define an alias to a column to be queried and sort the result record by using the column alias in the **ORDER BY** clause. At this time, the number of the result records is limited to 5 by using the **LIMIT** clause.

```
SELECT host_year as col1, host_nation as col2
FROM olympic
ORDER BY col2 LIMIT 5;
```

```
col1  col2
=====
2000  'Australia'
1956  'Australia'
1920  'Belgium'
1976  'Canada'
1948  'England'
```

```
SELECT CONCAT(host_nation, ', ', host_city) AS host_place
FROM olympic
ORDER BY host_place LIMIT 5;
```

```
host_place
=====
'Australia, Melbourne'
'Australia, Sydney'
'Belgium, Antwerp'
'Canada, Montreal'
'England, London'
```

## FROM Clause

The **FROM** clause specifies the table in which data is to be retrieved in the query. If no table is referenced, the **FROM** clause can be omitted. Retrieval paths are as follows:

- Single table
- Subquery
- Derived table
- Remote table

```
SELECT [<qualifier>] <select_expressions>
[
    FROM <table_specification> [ {, <table_specification> |
    <join_table_specification> }... ]
]

<select_expressions> ::= * | <expression_comma_list> | *,
```

```

<expression_comma_list>

<table_specification> ::=
    <single_table_spec> [<correlation>] |
    <metaclass_specification> [<correlation>] |
    <subquery> <correlation> |
    TABLE (<expression>) <correlation> |
    DBLINK (<dblink_expr>) <dblink_identifier_col_attrs>

<correlation> ::= [AS] <identifier> [(<identifier_comma_list>)]

<single_table_spec> ::= [ONLY] [schema_name.]table_name |
                        ALL [schema_name.]table_name [EXCEPT
[schema_name.]table_name]

<metaclass_specification> ::= CLASS [schema_name.]class_name

```

- *<select\_expressions>*: One or more columns or expressions to query is specified. Use \* to query all columns in the table. You can also specify an alias for a column or an expression to be queried by using the AS keyword. This keyword can be used in **GROUP BY**, **HAVING** and **ORDER BY** clauses. The position index of the column is given according to the order in which the column was specified. The starting value is 1.
- *<table\_specification>*: At least one table name is specified after the **FROM** clause. Subqueries and derived tables can also be used in the **FROM** clause. For details on subquery derived tables, see [Subquery Derived Table](#).

```

--FROM clause can be omitted in the statement
SELECT 1+1 AS sum_value;

```

```

      sum_value
=====
              2

```

```

SELECT CONCAT('CUBRID', '2008' , 'R3.0') AS db_version;

```

```

      db_version
=====
'CUBRID2008R3.0'

```

## Derived Table

In the query statement, subqueries can be used in the table specification of the **FROM** clause. Such subqueries create derived tables where subquery results are treated as tables. A correlation specification must be used when a subquery that creates a derived table is used.

Derived tables are also used to access the individual element of an attribute that has a set value. In this case, an element of the set value is created as an instance in the derived table.

## Subquery Derived Table

Each instance in the derived table is created from the result of the subquery in the **FROM** clause. A derived table created from a subquery can have any number of columns and records.

```
FROM (subquery) [AS] [derived_table_name [(column_name [{,
column_name } ... ])]]
```

- The number of *column\_name* and the number of columns created by the *subquery* must be identical.
- *derived\_table\_name* can be omitted.

The following example shows how to retrieve the sum of the number of gold (*gold*) medals won by Korea and that of silver medals won by Japan. This example shows a way of getting an intermediate result of the subquery and processing it as a single result, by using a derived table. The query returns the sum of the *gold* values whose *nation\_code* is 'KOR' and the *silver* values whose *nation\_code* column is 'JPN'.

```
SELECT SUM (n)
FROM (SELECT gold FROM participant WHERE nation_code = 'KOR'
      UNION ALL
      SELECT silver FROM participant WHERE nation_code = 'JPN') AS
t(n);
```

Subquery derived tables can be useful when combined with outer queries. For example, a derived table can be used in the **FROM** clause of the subquery used in the **WHERE** clause. The following example shows *nation\_code*, *host\_year* and *gold* records whose number of gold medals is greater than average sum of the number of silver and bronze medals when one or more silver or bronze medals were won. In this example, the query (the outer **SELECT** clause) and the subquery (the inner **SELECT** clause) share the *nation\_code* attribute.

```
SELECT nation_code, host_year, gold
FROM participant p
WHERE gold > (SELECT AVG(s)
```

```

FROM (SELECT silver + bronze
      FROM participant
      WHERE nation_code = p.nation_code
      AND silver > 0
      AND bronze > 0)
AS t(s));

```

| nation_code | host_year | gold |
|-------------|-----------|------|
| 'JPN'       | 2004      | 16   |
| 'CHN'       | 2004      | 32   |
| 'DEN'       | 1996      | 4    |
| 'ESP'       | 1992      | 13   |

## Remote Table

A remote table can be specified in the FROM clause, and when specifying a remote table, '@' is used and a table extension such as `table_name@server_name` is used. The remote server can use not only CUBRID but also other DBMS (ORACLE, MySQL, and MariaDB). The query for remote table is recreated and executed using the DBLINK statement while going through an optimization step.

```

-- at remote-side, "remote_server"
CREATE TABLE remote_tbl (
  id INT,
  name VARCHAR(32)
);

INSERT INTO remote_tbl VALUES (1, 'Kim');
INSERT INTO remote_tbl VALUES (2, 'Lee');
INSERT INTO remote_tbl VALUES (3, 'Park');

```

```

-- at local-side
SELECT *
FROM remote_tbl@remote_server rem
WHERE id < 3;

```

| id | name |
|----|------|
| 1  | Kim  |
| 2  | Lee  |

The query rewritten with the DBLINK statement for the remote table in the optimization stage is as follows.

```
SELECT *
FROM DBLINK(remote_server, 'SELECT id, name FROM remote_tbl WHERE id
< 3') AS dbl (id INT, name VARCHAR(32));
```

### Note

Objects allowed for table extensions include general tables, synonyms, and views. The example below shows three types of table extensions.

```
-- at remote-side
CREATE TABLE remote_table (
    id INT,
    phone VARCHAR(12)
);

CREATE SYNONYM a_remote_tbl FOR user_a.remote_table
CREATE VIEW v_remote_tbl(r_phone) AS SELECT phone FROM remote_tbl
WHERE id > 10;

-- at local-side

-- remote-table
SELECT phone FROM user_a.remote_table@server1 WHERE id > 10;

-- remote-synonym
SELECT phone FROM a_remote_tbl@server1 WHERE id > 10;

-- remote-view
SELECT r_phone FROM v_remote_tbl@server1;
```

All three queries above return the same result.

## DBLINK

The result can be obtained by executing a query in a separate DBMS located at a remote location. The result is a kind of subquery that is created as **Subquery Derived Table**.

```
FROM DBLINK (<dblink_expr>) [AS] <dblink_identifier_col_attrs>

    <dblink_expr> ::= <dblink_conn>, remote_query_sting
    <dblink_conn> ::= server_name | dblink_conn_string
```

```

    <dblink_identifier_col_attrs> ::= dblink_table_alias (
<dblink_column_definition_list> )
    <dblink_column_definition_list> ::= dblink_column_alias
<primitive_type> [{, dblink_column_alias <primitive_type>} ...]

```

- *remote\_query\_string*: Only SELECT query can be specified as the query to be transmitted to the remote DBMS.
- *server\_name*: The name of the server created using: doc:/sql/schema/server\_stmt.
- *dblink\_conn\_string*: Remote access information expressed as a string.
- *dblink\_table\_alias*: The name of a derived table created using DBLINK.
- *dblink\_column\_alias*: Virtual column name corresponding to the select list of *remote\_query\_string* in DBLINK.

#### Note

The attributes of the column supported by DBLINK are as follows.

- INT, BIGINT, SHORT, FLOAT, DOUBLE, MONETARY, NUMERIC
- VARCHAR, CHAR
- DATE, TIME, TIMESTAMP, DATETIME
- DATETIME TZ, DATETIME LTZ, TIME STAMP TZ, TIME STAMP LTZ

#### Warning

DBLINK does not support columns with the following data types.

- COLLECTION TYPE ( SET, MULTISET, SEQUENCE )
- OBJECT
- CLOB / BLOB
- ENUM
- BIT / BIT VARYING

• JSON

### **Note**

*dblink\_conn\_string* is composed of the following structure. Each content is information corresponding to HOST, PORT, DBNAME, USER, PASSWOED, and PROPERTIES in the **SERVER DEFINITION STATEMENTS** syntax. Each item is separated by the character ':

```
<broker-host>:<port#>:<db_name>:<db_user>:<db_password>:[?<properties>]
```

To prevent password exposure, it is recommended to use *server\_name* rather than *dblink\_conn\_string*.

```
CREATE SERVER remote_srv1 ( HOST='127.0.0.1', PORT=3300,
DBNAME=demodb, USER=cub, PASSWORD='cub-password');
SELECT * FROM DBLINK (remote_srv1, 'SELECT col1 FROM remote_t') AS
t(col1 int);

SELECT * FROM DBLINK ('127.0.0.1:3300:demodb:cub:cub-
password:', 'SELECT col1, col2 FROM remote_t') AS t(col1 int, col2
varchar(32));
```

In the example above, the two SELECT statements perform the same function.

## WHERE Clause

In a query, a column can be processed based on conditions. The **WHERE** clause specifies a search condition for data.

```
WHERE <search_condition>

<search_condition> ::=
    <comparison_predicate>
    <between_predicate>
    <exists_predicate>
    <in_predicate>
    <null_predicate>
    <like_predicate>
    <quantified_predicate>
    <set_predicate>
```

The **WHERE** clause specifies a condition that determines the data to be retrieved by *search\_condition* or a query. Only data for which the condition is true is retrieved for the query results. (**NULL** value is not retrieved for the query results because it is evaluated as unknown value.)

• *search\_condition*: It is described in detail in the following sections.

- Simple Comparison Expression
- BETWEEN
- EXISTS
- IN
- IS NULL
- LIKE
- ANY/SOME/ALL quantifiers

The logical operator **AND** or **OR** can be used for multiple conditions. If **AND** is specified, all conditions must be true. If **OR** is specified, only one needs to be true. If the keyword **NOT** is preceded by a condition, the meaning of the condition is reserved. The following table shows the order in which logical operators are evaluated.

| Priority | Operator | Function                                                      |
|----------|----------|---------------------------------------------------------------|
| 1        | ()       | Logical expressions in parentheses are evaluated first.       |
| 2        | NOT      | Negates the result of the logical expression.                 |
| 3        | AND      | All conditions in the logical expression must be true.        |
| 4        | OR       | One of the conditions in the logical expression must be true. |

## GROUP BY ... HAVING Clause

The **GROUP BY** clause is used to group the result retrieved by the **SELECT** statement based on a specific column. This clause is used to sort by group or to get the aggregation by group using the aggregation function. Herein, a group consists of records that have the same value for the column specified in the **GROUP BY** clause.

You can also set a condition for group selection by including the **HAVING** clause after the **GROUP BY** clause. That is, only groups satisfying the condition specified by the **HAVING** clause are queried out of all groups that are grouped by the **GROUP BY** clause.

By SQL standard, you cannot specify a column (hidden column) not defined in the **GROUP BY** clause to the SELECT column list. However, by using extended CUBRID grammars, you can specify the hidden column to the SELECT column list. If you do not use the extended CUBRID grammars, the **only\_full\_group\_by** parameter should be set to **yes**. For details, see [Statement/Type-Related Parameters](#).

```
SELECT ...  
GROUP BY {col_name | expr | position} [ASC | DESC], ...  
        [WITH ROLLUP] [HAVING <search_condition>]
```

- *col\_name | expr | position*: Specifies one or more column names, expressions, aliases or column location. Items are separated by commas. Columns are sorted on this basis.
- [**ASC** | **DESC**]: Specifies the **ASC** or **DESC** sorting option after the columns specified in the **GROUP BY** clause. If the sorting option is not specified, the default value is **ASC**.
- *<search\_condition>*: Specifies the search condition in the **HAVING** clause. In the **HAVING** clause, you can refer to columns and aliases specified in the **GROUP BY** clause, or columns used in aggregate functions.

### Note

Even the hidden columns not specified in the **GROUP BY** clause can be referred to, if the value of the **only\_full\_group\_by** parameter is set to **yes**. At this time, the **HAVING** condition does not affect to the query result.

- **WITH ROLLUP**: If you specify the **WITH ROLLUP** modifier in the **GROUP BY** clause, the aggregate information of the result value of each GROUPed BY column is displayed for each group, and the total of all result rows is displayed at the last row. When a **WITH ROLLUP** modifier is defined in the **GROUP BY** clause, the result value for all rows of the group is additionally displayed. In other words, total aggregation is made for the value aggregated by group. When there are two columns for Group By, the former is considered as a large unit and the latter is

considered as a small unit, so the total aggregation row for the small unit and the total aggregation row for the large unit are added. For example, you can check the aggregation of the sales result per department and salesperson through one query.

```
-- creating a new table
CREATE TABLE sales_tbl
(dept_no INT, name VARCHAR(20), sales_month INT, sales_amount INT
DEFAULT 100, PRIMARY KEY (dept_no, name, sales_month));

INSERT INTO sales_tbl VALUES
(201, 'George' , 1, 450), (201, 'George' , 2, 250), (201, 'Laura' ,
1, 100), (201, 'Laura' , 2, 500),
(301, 'Max' , 1, 300), (301, 'Max' , 2, 300),
(501, 'Stephan', 1, 300), (501, 'Stephan', 2, DEFAULT), (501,
'Chang' , 1, 150), (501, 'Chang' , 2, 150),
(501, 'Sue' , 1, 150), (501, 'Sue' , 2, 200);

-- selecting rows grouped by dept_no
SELECT dept_no, avg(sales_amount)
FROM sales_tbl
GROUP BY dept_no;
```

| dept_no | avg(sales_amount)      |
|---------|------------------------|
| 201     | 3.2500000000000000e+02 |
| 301     | 3.0000000000000000e+02 |
| 501     | 1.7500000000000000e+02 |

```
-- conditions in WHERE clause operate first before GROUP BY
SELECT dept_no, avg(sales_amount)
FROM sales_tbl
WHERE sales_amount > 100
GROUP BY dept_no;
```

| dept_no | avg(sales_amount)      |
|---------|------------------------|
| 201     | 4.0000000000000000e+02 |
| 301     | 3.0000000000000000e+02 |
| 501     | 1.9000000000000000e+02 |

```
-- conditions in HAVING clause operate last after GROUP BY
SELECT dept_no, avg(sales_amount)
FROM sales_tbl
```

```
WHERE sales_amount > 100
GROUP BY dept_no HAVING avg(sales_amount) > 200;
```

| dept_no | avg(sales_amount)     |
|---------|-----------------------|
| 201     | 4.000000000000000e+02 |
| 301     | 3.000000000000000e+02 |

```
-- selecting and sorting rows with using column alias
SELECT dept_no AS a1, avg(sales_amount) AS a2
FROM sales_tbl
WHERE sales_amount > 200 GROUP
BY a1 HAVING a2 > 200
ORDER BY a2;
```

| a1  | a2                    |
|-----|-----------------------|
| 301 | 3.000000000000000e+02 |
| 501 | 3.000000000000000e+02 |
| 201 | 4.000000000000000e+02 |

```
-- selecting rows grouped by dept_no, name with WITH ROLLUP modifier
SELECT dept_no AS a1, name AS a2, avg(sales_amount) AS a3
FROM sales_tbl
WHERE sales_amount > 100
GROUP BY a1, a2 WITH ROLLUP;
```

| a1   | a2        | a3                    |
|------|-----------|-----------------------|
| 201  | 'George'  | 3.500000000000000e+02 |
| 201  | 'Laura'   | 5.000000000000000e+02 |
| 201  | NULL      | 4.000000000000000e+02 |
| 301  | 'Max'     | 3.000000000000000e+02 |
| 301  | NULL      | 3.000000000000000e+02 |
| 501  | 'Chang'   | 1.500000000000000e+02 |
| 501  | 'Stephan' | 3.000000000000000e+02 |
| 501  | 'Sue'     | 1.750000000000000e+02 |
| 501  | NULL      | 1.900000000000000e+02 |
| NULL | NULL      | 2.750000000000000e+02 |

## ORDER BY Clause

The **ORDER BY** clause sorts the query result set in ascending or descending order. If you do not specify a sorting option such as **ASC** or **DESC**, the result set is in ascending order by default. If you do not specify the **ORDER BY** clause, the order of records to be queried may vary depending on query.

```
SELECT ...
ORDER BY {col_name | expr | position} [ASC | DESC], ...] [NULLS
{FIRST | LAST}]
```

- *col\_name | expr | position*: Specifies a column name, expression, alias, or column location. One or more column names, expressions or aliases can be specified. Items are separated by commas. A column that is not specified in the list of **SELECT** columns can be specified.
- **[ASC | DESC]**: **ASC** means sorting in ascending order, and **DESC** is sorting in descending order. If the sorting option is not specified, the default value is **ASC**.
- **[NULLS {FIRST | LAST}]**: **NULLS FIRST** sorts NULL at first, **NULLS LAST** sorts NULL at last. If this syntax is omitted, **ASC** sorts NULL at first, **DESC** sorts NULL at last.

```
-- selecting rows sorted by ORDER BY clause
SELECT *
FROM sales_tbl
ORDER BY dept_no DESC, name ASC;
```

| dept_no | name      | sales_month | sales_amount |
|---------|-----------|-------------|--------------|
| 501     | 'Chang'   | 1           | 150          |
| 501     | 'Chang'   | 2           | 150          |
| 501     | 'Stephan' | 1           | 300          |
| 501     | 'Stephan' | 2           | 100          |
| 501     | 'Sue'     | 1           | 150          |
| 501     | 'Sue'     | 2           | 200          |
| 301     | 'Max'     | 1           | 300          |
| 301     | 'Max'     | 2           | 300          |
| 201     | 'George'  | 1           | 450          |
| 201     | 'George'  | 2           | 250          |
| 201     | 'Laura'   | 1           | 100          |
| 201     | 'Laura'   | 2           | 500          |

```
-- sorting reversely and limiting result rows by LIMIT clause
SELECT dept_no AS a1, avg(sales_amount) AS a2
FROM sales_tbl
GROUP BY a1
```

```
ORDER BY a2 DESC
LIMIT 3;
```

```

a1      a2
=====
201     3.2500000000000000e+02
301     3.0000000000000000e+02
501     1.7500000000000000e+02
```

The following is an example how to specify the NULLS FIRST or NULLS LAST after ORDER BY clause.

```
CREATE TABLE tbl (a INT, b VARCHAR);
```

```
INSERT INTO tbl VALUES
```

```
(1,NULL), (2,NULL), (3,'AB'), (4,NULL), (5,'AB'),
(6,NULL), (7,'ABCD'), (8,NULL), (9,'ABCD'), (10,NULL);
```

```
SELECT * FROM tbl ORDER BY b NULLS FIRST;
```

```

a  b
=====
1  NULL
2  NULL
4  NULL
6  NULL
8  NULL
10 NULL
3  'ab'
5  'ab'
7  'abcd'
9  'abcd'
```

```
SELECT * FROM tbl ORDER BY b NULLS LAST;
```

```

a  b
=====
3  'ab'
5  'ab'
7  'abcd'
9  'abcd'
1  NULL
2  NULL
4  NULL
```

```

6 NULL
8 NULL
10 NULL

```

### Note

#### Translation of GROUP BY alias

```

CREATE TABLE t1(a INT, b INT, c INT);
INSERT INTO t1 VALUES(1,1,1);
INSERT INTO t1 VALUES(2,NULL,2);
INSERT INTO t1 VALUES(2,2,2);

SELECT a, NVL(b,2) AS b
FROM t1
GROUP BY a, b; -- Q1

```

When you run the above SELECT query, “GROUP BY a, b” is translated as:

- “GROUP BY a, NVL(b, 2)” (alias name b) in 9.2 or before. The result is the same as Q2’s result as below.

```

SELECT a, NVL(b,2) AS bxxx
FROM t1
GROUP BY a, bxxx; -- Q2

```

```

      a      b
=====
      1      1
      2      2

```

- “GROUP BY a, b” (column name b) in 9.3 or higher. The result is the same as Q3’s result as below.

```

SELECT a, NVL(b,2) AS bxxx
FROM t1
GROUP BY a, b; -- Q3

```

```

      a      b
=====
      1      1

```

|   |   |
|---|---|
| 2 | 2 |
| 2 | 2 |

## LIMIT Clause

The **LIMIT** clause can be used to limit the number of records displayed. You can specify a very big integer for *row\_count* to display to the last row, starting from a specific row. The **LIMIT** clause can be used as a prepared statement. In this case, the bind parameter (?) can be used instead of an argument.

**INST\_NUM** () and **ROWNUM** cannot be included in the **WHERE** clause in a query that contains the **LIMIT** clause. Also, **LIMIT** cannot be used together with **HAVING GROUPBY\_NUM** ().

```
LIMIT {[offset,] row_count | row_count [OFFSET offset]}

<offset> ::= <limit_expression>
<row_count> ::= <limit_expression>

<limit_expression> ::= <limit_term> | <limit_expression> +
<limit_term> | <limit_expression> - <limit_term>
<limit_term> ::= <limit_factor> | <limit_term> * <limit_factor> |
<limit_term> / <limit_factor>
<limit_factor> ::= <unsigned_int> | <input_hostvar> | (
<limit_expression> )
```

- *offset*: Specifies the offset of the starting row to be displayed. The offset of the starting row of the result set is 0; it can be omitted and the default value is **0**. It can be one of unsigned int, a host variable or a simple expression.
- *row\_count*: Specifies the number of records to be displayed. It can be one of unsigned integer, a host variable or a simple expression.

```
-- LIMIT clause can be used in prepared statement
PREPARE stmt FROM 'SELECT * FROM sales_tbl LIMIT ?, ?';
EXECUTE stmt USING 0, 10;
```

```
-- selecting rows with LIMIT clause
SELECT *
FROM sales_tbl
WHERE sales_amount > 100
LIMIT 5;
```

| dept_no | name     | sales_month | sales_amount |
|---------|----------|-------------|--------------|
| 201     | 'George' | 1           | 450          |
| 201     | 'George' | 2           | 250          |
| 201     | 'Laura'  | 2           | 500          |
| 301     | 'Max'    | 1           | 300          |
| 301     | 'Max'    | 2           | 300          |

```
-- LIMIT clause can be used in subquery
SELECT t1.*
FROM (SELECT * FROM sales_tbl AS t2 WHERE sales_amount > 100 LIMIT
5) AS t1
LIMIT 1,3;

-- above query and below query shows the same result
SELECT t1.*
FROM (SELECT * FROM sales_tbl AS t2 WHERE sales_amount > 100 LIMIT
5) AS t1
LIMIT 3 OFFSET 1;
```

| dept_no | name     | sales_month | sales_amount |
|---------|----------|-------------|--------------|
| 201     | 'George' | 2           | 250          |
| 201     | 'Laura'  | 2           | 500          |
| 301     | 'Max'    | 1           | 300          |

```
-- LIMIT clause allows simple expressions for both offset and
row_count
SELECT *
FROM sales_tbl
WHERE sales_amount > 100
LIMIT ? * ?, (? * ?) + ?;
```

## Join Query

A join is a query that combines the rows of two or more tables or virtual tables (views). In a join query, a condition that compares the columns that are common in two or more tables is called a join condition. Rows are retrieved from each joined table, and are combined only when they satisfy the specified join condition.

A join query using an equality operator (=) is called an equi-join, and one without any join condition is called a cartesian product. Meanwhile, joining a single table is called a self join. In a

self join, table **ALIAS** is used to distinguish columns, because the same table is used twice in the **FROM** clause.

A join that outputs only rows that satisfy the join condition from a joined table is called an inner or a simple join, whereas a join that outputs both rows that satisfy and do not satisfy the join condition from a joined table is called an outer join.

An outer join is divided into a left outer join which outputs all rows of the left table as a result(outputs NULL when the right table's columns don't match conditions), a right outer join which outputs all rows of the right table as a result(outputs NULL when the left table's columns don't match conditions) and a full outer join which outputs all rows of both tables. If there is no column value that corresponds to a table on one side in the result of an outer join query, all rows are returned as **NULL**.

```
FROM <table_specification> [{, <table_specification>
    | { <join_table_specification> |
<join_table_specification2> } ...]

<table_specification> ::=
    <single_table_spec> [<correlation>] |
    <metaclass_specification> [<correlation>] |
    <subquery> <correlation> |
    TABLE (<expression>) <correlation>

<join_table_specification> ::=
{
    [INNER | {LEFT | RIGHT} [OUTER]] JOIN

    } <table_specification> ON <search_condition>

<join_table_specification2> ::=
{
    CROSS JOIN |
    NATURAL [ LEFT | RIGHT ] JOIN
} <table_specification>
```

• <join\_table\_specification>

- **[INNER] JOIN**: Used for inner join and requires join conditions.
- **{LEFT | RIGHT} [OUTER] JOIN**: **LEFT** is used for a left outer join query, and **RIGHT** is for a right outer join query.

• <join\_table\_specification2>

- **CROSS JOIN**: Used for cross join and requires no join conditions.

- **NATURAL [LEFT | RIGHT] JOIN**: Used for natural join and join condition is not used. It operates in the equivalent same way to have a condition between columns equivalent of the same name.

## Inner Join

The inner join requires join conditions. The **INNER JOIN** keyword can be omitted. When it is omitted, the table is separated by a comma (.). The **ON** join condition can be replaced with the **WHERE** condition.

The following example shows how to retrieve the years and host countries of the Olympic Games since 1950 where a world record has been set. The following query retrieves instances whose values of the *host\_year* column in the *history* table are greater than 1950. The following two queries output the same result.

```
SELECT DISTINCT h.host_year, o.host_nation
FROM history h INNER JOIN olympic o ON h.host_year = o.host_year AND
o.host_year > 1950;
```

```
SELECT DISTINCT h.host_year, o.host_nation
FROM history h, olympic o
WHERE h.host_year = o.host_year AND o.host_year > 1950;
```

| host_year | host_nation                |
|-----------|----------------------------|
| 1968      | 'Mexico'                   |
| 1980      | 'U.S.S.R.'                 |
| 1984      | 'United States of America' |
| 1988      | 'Korea'                    |
| 1992      | 'Spain'                    |
| 1996      | 'United States of America' |
| 2000      | 'Australia'                |
| 2004      | 'Greece'                   |

## Outer Join

CUBRID does not support full outer joins; it supports only left and right joins. Path expressions that include subqueries and sub-columns cannot be used in the join conditions of an outer join.

Join conditions of an outer join are specified in a different way from those of an inner join. In an inner join, join conditions can be expressed in the **WHERE** clause; in an outer join, they appear after the **ON** keyword within the **FROM** clause. Other retrieval conditions can be used in the **WHERE** or **ON** clause, but the retrieval result depends on whether the condition is used in the **WHERE** or **ON** clause.

The table execution order is fixed according to the order specified in the **FROM** clause. Therefore, when using an outer join, you should create a query statement in consideration of the table order. It is recommended to use standard statements using { **LEFT** | **RIGHT** } [ **OUTER** ] **JOIN**, because using an Oracle-style join query statements by specifying an outer join operator (**+**) in the **WHERE** clause, even if possible, might lead the execution result or plan in an unwanted direction.

The following example shows how to retrieve the years and host countries of the Olympic Games since 1950 where a world record has been set, but including the Olympic Games where any world records haven't been set in the result. This example can be expressed in the following right outer join query. In this example, all instances whose values of the *host\_year* column in the *history* table are not greater than 1950 are also retrieved. All instances of *host\_nation* are included because this is a right outer join. *host\_year* that does not have a value is represented as **NULL**.

```
SELECT DISTINCT h.host_year, o.host_year, o.host_nation
FROM history h RIGHT OUTER JOIN olympic o ON h.host_year =
o.host_year
WHERE o.host_year > 1950;
```

| host_year | host_year | host_nation |
|-----------|-----------|-------------|
| NULL      | 1952      | 'Finland'   |
| NULL      | 1956      | 'Australia' |
| NULL      | 1960      | 'Italy'     |
| NULL      | 1964      | 'Japan'     |
| NULL      | 1972      | 'Germany'   |
| NULL      | 1976      | 'Canada'    |
| 1968      | 1968      | 'Mexico'    |
| 1980      | 1980      | 'USSR'      |
| 1984      | 1984      | 'USA'       |
| 1988      | 1988      | 'Korea'     |
| 1992      | 1992      | 'Spain'     |
| 1996      | 1996      | 'USA'       |
| 2000      | 2000      | 'Australia' |
| 2004      | 2004      | 'Greece'    |

A right outer join query can be converted to a left outer join query by switching the position of two tables in the **FROM** clause. The right outer join query in the previous example can be expressed as a left outer join query as follows:

```
SELECT DISTINCT h.host_year, o.host_year, o.host_nation
FROM olympic o LEFT OUTER JOIN history h ON h.host_year = o.host_year
WHERE o.host_year > 1950;
```

| host_year | host_year | host_nation |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|      |      |             |
|------|------|-------------|
| NULL | 1952 | 'Finland'   |
| NULL | 1956 | 'Australia' |
| NULL | 1960 | 'Italy'     |
| NULL | 1964 | 'Japan'     |
| NULL | 1972 | 'Germany'   |
| NULL | 1976 | 'Canada'    |
| 1968 | 1968 | 'Mexico'    |
| 1980 | 1980 | 'USSR'      |
| 1984 | 1984 | 'USA'       |
| 1988 | 1988 | 'Korea'     |
| 1992 | 1992 | 'Spain'     |
| 1996 | 1996 | 'USA'       |
| 2000 | 2000 | 'Australia' |
| 2004 | 2004 | 'Greece'    |

Outer joins can also be represented by using **(+)** in the **WHERE** clause. The above example is a query that has the same meaning as the example using the **LEFT OUTER JOIN**. The **(+)** syntax is not ISO/ANSI standard, so it can lead to ambiguous situations. It is recommended to use the standard syntax **LEFT OUTER JOIN** (or **RIGHT OUTER JOIN**) if possible.

```
SELECT DISTINCT h.host_year, o.host_year, o.host_nation
FROM history h, olympic o
WHERE o.host_year = h.host_year(+) AND o.host_year > 1950;
```

| host_year | host_year | host_nation |
|-----------|-----------|-------------|
| =====     |           |             |
| NULL      | 1952      | 'Finland'   |
| NULL      | 1956      | 'Australia' |
| NULL      | 1960      | 'Italy'     |
| NULL      | 1964      | 'Japan'     |
| NULL      | 1972      | 'Germany'   |
| NULL      | 1976      | 'Canada'    |
| 1968      | 1968      | 'Mexico'    |
| 1980      | 1980      | 'USSR'      |
| 1984      | 1984      | 'USA'       |
| 1988      | 1988      | 'Korea'     |
| 1992      | 1992      | 'Spain'     |
| 1996      | 1996      | 'USA'       |
| 2000      | 2000      | 'Australia' |
| 2004      | 2004      | 'Greece'    |

In the above examples, *h.host\_year=o.host\_year* is an outer join condition, and *o.host\_year > 1950* is a search condition. If the search condition is not written in the **WHERE** clause but in the **ON** clause, the meaning and the result will be different. The following query also includes instances whose values of *o.host\_year* are not greater than 1950.

```
SELECT DISTINCT h.host_year, o.host_year, o.host_nation
FROM olympic o LEFT OUTER JOIN history h ON h.host_year =
o.host_year AND o.host_year > 1950;
```

| host_year | host_year | host_nation      |
|-----------|-----------|------------------|
| NULL      | 1896      | 'Greece'         |
| NULL      | 1900      | 'France'         |
| NULL      | 1904      | 'USA'            |
| NULL      | 1908      | 'United Kingdom' |
| NULL      | 1912      | 'Sweden'         |
| NULL      | 1920      | 'Belgium'        |
| NULL      | 1924      | 'France'         |
| NULL      | 1928      | 'Netherlands'    |
| NULL      | 1932      | 'USA'            |
| NULL      | 1936      | 'Germany'        |
| NULL      | 1948      | 'England'        |
| NULL      | 1952      | 'Finland'        |
| NULL      | 1956      | 'Australia'      |
| NULL      | 1960      | 'Italy'          |
| NULL      | 1964      | 'Japan'          |
| NULL      | 1972      | 'Germany'        |
| NULL      | 1976      | 'Canada'         |
| 1968      | 1968      | 'Mexico'         |
| 1980      | 1980      | 'USSR'           |
| 1984      | 1984      | 'USA'            |
| 1988      | 1988      | 'Korea'          |
| 1992      | 1992      | 'Spain'          |
| 1996      | 1996      | 'USA'            |
| 2000      | 2000      | 'Australia'      |
| 2004      | 2004      | 'Greece'         |

In the above example, **LEFT OUTER JOIN** should attach all rows to the result rows even if the left table's rows do not match to the condition; therefore, the left table's condition, "AND o.host\_year > 1950" is ignored. But "WHERE o.host\_year > 1950" is applied after the join operation is completed. Please consider that a condition after **ON** clause and a condition after **WHERE** clause can be applied differently in **OUTER JOIN**.

## Cross Join

The cross join is a cartesian product, meaning that it is a combination of two tables, without any condition. For the cross join, the **CROSS JOIN** keyword can be omitted. When it is omitted, the table is separated by a comma (,).

The following example shows how to write cross join.

```

SELECT DISTINCT h.host_year, o.host_nation
FROM history h CROSS JOIN olympic o;

SELECT DISTINCT h.host_year, o.host_nation
FROM history h, olympic o;

```

The above two queries output the same results.

```

      host_year  host_nation
=====
      1968      'Australia'
      1968      'Belgium'
      1968      'Canada'
      1968      'England'
      1968      'Finland'
      1968      'France'
      1968      'Germany'
      ...
      2004      'Spain'
      2004      'Sweden'
      2004      'USA'
      2004      'USSR'
      2004      'United Kingdom'

144 rows selected. (1.283548 sec) Committed.

```

## Natural Join

When column names to be joined to each table are the same, that is, when you want to grant equivalent conditions between each column with the same name, a natural join, which can replace inner/outer join, can be used.

```

CREATE TABLE t1 (a int, b1 int);
CREATE TABLE t2 (a int, b2 int);

INSERT INTO t1 values(1,1);
INSERT INTO t1 values(3,3);
INSERT INTO t2 values(1,1);
INSERT INTO t2 values(2,2);

```

The below is an example of running **NATURAL JOIN**.

```

SELECT /** RECOMPILE*/ *
FROM t1 NATURAL JOIN t2;

```

Running the above query is the same as running the below query, and they display the same result.

```
SELECT /** RECOMPILE*/ *
FROM t1 INNER JOIN t2 ON t1.a=t2.a;
```

| a     | b1    | a     | b2    |
|-------|-------|-------|-------|
| ===== | ===== | ===== | ===== |
| 1     | 1     | 1     | 1     |

The below is an example of running **NATURAL LEFT JOIN**.

```
SELECT /** RECOMPILE*/ *
FROM t1 NATURAL LEFT JOIN t2;
```

Running the above query is the same as running the below query, and they display the same result.

```
SELECT /** RECOMPILE*/ *
FROM t1 LEFT JOIN t2 ON t1.a=t2.a;
```

| a     | b1    | a     | b2    |
|-------|-------|-------|-------|
| ===== | ===== | ===== | ===== |
| 1     | 1     | 1     | 1     |
| 3     | 3     | NULL  | NULL  |

The below is an example of running **NATURAL RIGHT JOIN**.

```
SELECT /** RECOMPILE*/ *
FROM t1 NATURAL RIGHT JOIN t2;
```

Running the above query is the same as running the below query, and they display the same result.

```
SELECT /** RECOMPILE*/ *
FROM t1 RIGHT JOIN t2 ON t1.a=t2.a;
```

| a     | b1    | a     | b2    |
|-------|-------|-------|-------|
| ===== | ===== | ===== | ===== |

|      |      |   |   |
|------|------|---|---|
| 1    | 1    | 1 | 1 |
| NULL | NULL | 2 | 2 |

## Subquery

A subquery can be used wherever expressions such as **SELECT** or **WHERE** clause can be used. If the subquery is represented as an expression, it must return a single column; otherwise it can return multiple rows. Subqueries can be divided into single-row subquery and multiple-row subquery depending on how they are used.

### Single-Row Subquery

A single-row subquery outputs a row that has a single column. If no row is returned by the subquery, the subquery expression has a **NULL** value. If the subquery is supposed to return more than one row, an error occurs.

The following example shows how to retrieve the *history* table as well as the host country where a new world record has been set. This example shows a single-row subquery used as an expression. In this example, the subquery returns *host\_nation* values for the rows whose values of the *host\_year* column in the *olympic* table are the same as those of the *host\_year* column in the *history* table. If there are no values that meet the condition, the result of the subquery is **NULL**.

```
SELECT h.host_year, (SELECT host_nation FROM olympic o WHERE
o.host_year=h.host_year) AS host_nation,
       h.event_code, h.score, h.unit
FROM history h;
```

| host_year | host_nation | event_code |
|-----------|-------------|------------|
| score     | unit        |            |
| =====     |             |            |
| =====     |             |            |
| 2004      | 'Greece'    | 20283      |
| '07:53.0' | 'time'      |            |
| 2004      | 'Greece'    | 20283      |
| '07:53.0' | 'time'      |            |
| 2004      | 'Greece'    | 20281      |
| '03:57.0' | 'time'      |            |
| 2004      | 'Greece'    | 20281      |
| '03:57.0' | 'time'      |            |
| 2004      | 'Greece'    | 20281      |
| '03:57.0' | 'time'      |            |
| 2004      | 'Greece'    | 20281      |
| '03:57.0' | 'time'      |            |
| 2004      | 'Greece'    | 20326      |

```
'210'          'kg'
  2000      'Australia'      20328
'225'          'kg'
  2004      'Greece'        20331
'237.5'        'kg'
...
```

## Multiple-Row Subquery

The multiple-row subquery returns one or more rows that contain the specified column. The result of the multiple-row subquery can create **SET**, **MULTISET** and **LIST**) by using an appropriate keyword.

The following example shows how to retrieve nations, capitals and host cities for Olympic Game all together in the *nation* table. In this example, the subquery result is used to create a **List** from the values of the *host\_city* column in the *olympic* table. This query returns *name* and *capital* value for *nation* table, as well as a set that contains *host\_city* values of the *olympic* table with *host\_nation* value. If the *name* value is an empty set in the query result, it is excluded. If there is no *olympic* table that has the same value as the *name*, an empty set is returned.

```
SELECT name, capital, list(SELECT host_city FROM olympic WHERE
host_nation = name) AS host_cities
FROM nation;
```

| name                                       | capital                     | host_cities  |
|--------------------------------------------|-----------------------------|--------------|
| 'Somalia'                                  | 'Mogadishu'                 | {}           |
| 'Sri Lanka'                                | 'Sri Jayewardenepura Kotte' | {}           |
| 'Sao Tome & Principe'                      | 'Sao Tome'                  | {}           |
| ...                                        |                             |              |
| 'U.S.S.R.'                                 | 'Moscow'                    | {'Moscow'}   |
| 'Uruguay'                                  | 'Montevideo'                | {}           |
| 'United States of America'                 | 'Washington.D.C'            | {'Atlanta ', |
| 'St. Louis', 'Los Angeles', 'Los Angeles'} |                             |              |
| 'Uzbekistan'                               | 'Tashkent'                  | {}           |
| 'Vanuatu'                                  | 'Port Vila'                 | {}           |

Such multiple-row subquery expressions can be used anywhere a collection-type value expression is allowed. However, they cannot be used where a collection-type constant value is required as in the **DEFAULT** specification in the class attribute definition.

If the **ORDER BY** clause is not used explicitly in the subquery, the order of the multiple-row query result is not set. Therefore, the order of the multiple-row subquery result that creates **LIST** must be specified by using the **ORDER BY** clause.

## VALUES

The **VALUES** clause prints out the values of rows defined in the expression. In most cases, the **VALUES** clause is used for creating a constant table, however, the clause itself can be used. When one or more rows are specified in the **VALUES** clause, all rows should have the same number of the elements.

```
VALUES (expression[, ...])[, ...]
```

- *expression* : An expression enclosed within parentheses stands for one row in a table.

The **VALUES** clause can be used to express the **UNION ALL** query, which consists of constant values in a simpler way. For example, the following query can be executed.

```
VALUES (1 AS col1, 'first' AS col2), (2, 'second'), (3, 'third'),
(4, 'fourth');
```

The above query prints out the following result.

```
SELECT 1 AS col1, 'first' AS col2
UNION ALL
SELECT 2, 'second'
UNION ALL
SELECT 3, 'third'
UNION ALL
SELECT 4, 'fourth';
```

The following example shows use of the **VALUES** clause with multiple rows in the **INSERT** statement.

```
INSERT INTO athlete (code, name, gender, nation_code, event)
VALUES ('21111', 'Jang Mi-Ran ', 'F', 'KOR', 'Weight-lifting'),
('21112', 'Son Yeon-Jae ', 'F', 'KOR', 'Rhythmic gymnastics');
```

The following example shows how to use subquery in the **FROM** statement.

```
SELECT a.*
FROM athlete a, (VALUES ('Jang Mi-Ran', 'F'), ('Son Yeon-Jae', 'F'))
AS t(name, gender)
WHERE a.name=t.name AND a.gender=t.gender;
```

| code  | name          | gender | nation_code | event |
|-------|---------------|--------|-------------|-------|
| 21111 | 'Jang Mi-Ran' | 'F'    | 'KOR'       |       |

```
'Weight-lifting'
      21112 'Son Yeon-Jae'      'F'      'KOR'
'Rhythmic gymnastics'
```

## FOR UPDATE

The **FOR UPDATE** clause can be used in **SELECT** statements for locking rows returned by the statement for a later **UPDATE/DELETE**.

```
SELECT ... [FOR UPDATE [OF <spec_name_comma_list>]]

      <spec_name_comma_list> ::= <spec_name> [, <spec_name>, ... ]
      <spec_name> ::= [schema_name.]table_name |
[schema_name.]view_name
```

- <spec\_name\_comma\_list>: A list of table/view names referenced from the **FROM** clause.

Only table/view referenced in <spec\_name\_comma\_list> will be locked. If the <spec\_name\_comma\_list> is missing but **FOR UPDATE** is present then we assume that all tables/views from the **FROM** clause of the **SELECT** statement are referenced. Rows are locked using **X\_LOCK**.

### Note

#### Restrictions

- It cannot be used in subqueries (but it can reference subqueries).
- It cannot be used in a statement that has **GROUP BY**, **DISTINCT** or aggregate functions.
- It cannot reference **UNIONs**.

The following shows how to use **SELECT ... FOR UPDATE** statements.

```
CREATE TABLE t1(i INT);
INSERT INTO t1 VALUES (1), (2), (3), (4), (5);

CREATE TABLE t2(i INT);
INSERT INTO t2 VALUES (1), (2), (3), (4), (5);
CREATE INDEX idx_t2_i ON t2(i);

CREATE VIEW v12 AS SELECT t1.i AS i1, t2.i AS i2 FROM t1 INNER JOIN
t2 ON t1.i=t2.i;
```

```

SELECT * FROM t1 ORDER BY 1 FOR UPDATE;
SELECT * FROM t1 ORDER BY 1 FOR UPDATE OF t1;
SELECT * FROM t1 INNER JOIN t2 ON t1.i=t2.i ORDER BY 1 FOR UPDATE OF
t1, t2;

SELECT * FROM t1 INNER JOIN (SELECT * FROM t2 WHERE t2.i > 0) r ON
t1.i=r.i WHERE t1.i > 0 ORDER BY 1 FOR UPDATE;

SELECT * FROM v12 ORDER BY 1 FOR UPDATE;
SELECT * FROM t1, (SELECT * FROM v12, t2 WHERE t2.i > 0 AND
t2.i=v12.i1) r WHERE t1.i > 0 AND t1.i=r.i ORDER BY 1 FOR UPDATE OF
r;

```

## Hierarchical Query

Hierarchical Query is used to obtain a set of data organized in a hierarchy. The **START WITH ... CONNECT BY** clause is used in combination with the **SELECT** clause in the following form.

You can execute the queries by changing the order of two clauses like **CONNECT BY ... START WITH**.

```

SELECT column_list
FROM table_joins | tables
[WHERE join_conditions and/or filtering_conditions]
[hierarchical_clause]

hierarchical_clause :
    [START WITH condition] CONNECT BY [NOCYCLE] condition
    | CONNECT BY [NOCYCLE] condition [START WITH condition]

```

### START WITH Clause

The **START WITH** clause will filter the rows from which the hierarchy will start. The rows that satisfy the **START WITH** condition will be the root nodes of the hierarchy. If **START WITH** is omitted, then all the rows will be considered as root nodes.

#### Note

If **START WITH** clause is omitted or the rows that satisfy the **START WITH** condition does not exist, all of rows in the table are considered as root nodes; which means that hierarchy relationship of sub rows which belong each root is searched. Therefore, some of results can be duplicate.

## CONNECT BY Clause

- **PRIOR** : The **CONNECT BY** condition is tested for a pair of rows. If it evaluates to true, the two rows satisfy the parent-child relationship of the hierarchy. We need to specify the columns that are used from the parent row and the columns that are used from the child row. We can use the **PRIOR** operator when applied to a column, which will refer to the value of the parent row for that column. If **PRIOR** is not used for a column, the value in the child row is used.
- **NOCYCLE** : In some cases, the resulting rows of the table joins may contain cycles, depending on the **CONNECT BY** condition. Because cycles cause an infinite loop in the result tree construction, CUBRID detects them and either returns an error doesn't expand the branches beyond the point where a cycle is found (if the **NOCYCLE** keyword is specified). This keyword may be specified after the **CONNECT BY** keywords. It makes CUBRID run a statement even if the processed data contains cycles.

If a **CONNECT BY** statement causes a cycle at runtime and the **NOCYCLE** keyword is not specified, CUBRID will return an error and the statement will be canceled. When specifying the **NOCYCLE** keyword, if CUBRID detects a cycle while processing a hierarchy node, it will set the **CONNECT\_BY\_ISCYCLE** attribute for that node to the value of 1 and it will stop further expansion of that branch.

The following example shows how to execute hierarchical query.

```
-- Creating tree table and then inserting data
CREATE TABLE tree(ID INT, MgrID INT, Name VARCHAR(32), BirthYear
INT);

INSERT INTO tree VALUES (1,NULL,'Kim', 1963);
INSERT INTO tree VALUES (2,NULL,'Moy', 1958);
INSERT INTO tree VALUES (3,1,'Jonas', 1976);
INSERT INTO tree VALUES (4,1,'Smith', 1974);
INSERT INTO tree VALUES (5,2,'Verma', 1973);
INSERT INTO tree VALUES (6,2,'Foster', 1972);
INSERT INTO tree VALUES (7,6,'Brown', 1981);

-- Executing a hierarchical query with CONNECT BY clause
SELECT id, mgrid, name
FROM tree
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name    |
|----|-------|---------|
| 1  | NULL  | 'Kim'   |
| 2  | NULL  | 'Moy'   |
| 3  | 1     | 'Jonas' |
| 3  | 1     | 'Jonas' |

```

4      1  'Smith'
4      1  'Smith'
5      2  'Verma'
5      2  'Verma'
6      2  'Foster'
6      2  'Foster'
7      6  'Brown'
7      6  'Brown'
7      6  'Brown'

```

```

-- Executing a hierarchical query with START WITH clause
SELECT id, mgrid, name
FROM tree
START WITH mgrid IS NULL
CONNECT BY prior id=mgrid
ORDER BY id;

```

```

  id      mgrid  name
=====
  1         NULL  'Kim'
  2         NULL  'Moy'
  3          1   'Jonas'
  4          1   'Smith'
  5          2   'Verma'
  6          2   'Foster'
  7          6   'Brown'

```

## Hierarchical Query Execution

### Hierarchical Query for Table Join

When target table is joined in **SELECT** statement, **WHERE** clause can include not only searching conditions but also joining conditions. At this time, CUBRID applies the joining conditions in **WHERE** clause at first, then conditions in **CONNECT BY** clause; at last, the left searching conditions.

When specifying joining conditions and searching conditions together in **WHERE** clause, joining conditions can be applied as searching conditions even if there was no intention; so the operating order can be different; therefore, we recommend that you specify the table joining conditions in **FROM** clause, not in **WHERE** conditions.

### Query Results

The resulting rows of the table joins are filtered according to the **START WITH** condition to obtain the root nodes for the hierarchy. If no **START WITH** condition is specified, then all the rows

resulting from the table joins will be considered as root nodes. After the root nodes are obtained, CUBRID will select the child rows for the root nodes. These are all nodes from the table joins that respect the **CONNECT BY** condition. This step will be repeated for the child nodes to determine their child nodes and so on until no more child nodes can be added.

In addition, CUBRID evaluates the **CONNECT BY** clause first and all the rows of the resulting hierarchy tree by using the filtering condition in the **WHERE** clause.

The example illustrates how joins can be used in **CONNECT BY** queries.

```
-- Creating tree2 table and then inserting data
CREATE TABLE tree2(id int, treeid int, job varchar(32));

INSERT INTO tree2 VALUES(1,1,'Partner');
INSERT INTO tree2 VALUES(2,2,'Partner');
INSERT INTO tree2 VALUES(3,3,'Developer');
INSERT INTO tree2 VALUES(4,4,'Developer');
INSERT INTO tree2 VALUES(5,5,'Sales Exec. ');
INSERT INTO tree2 VALUES(6,6,'Sales Exec. ');
INSERT INTO tree2 VALUES(7,7,'Assistant');
INSERT INTO tree2 VALUES(8,null,'Secretary');

-- Executing a hierarchical query onto table joins
SELECT t.id,t.name,t2.job,level
FROM tree t INNER JOIN tree2 t2 ON t.id=t2.treeid
START WITH t.mgrid is null
CONNECT BY prior t.id=t.mgrid
ORDER BY t.id;
```

| id | name     | job            | level |
|----|----------|----------------|-------|
| 1  | 'Kim'    | 'Partner'      | 1     |
| 2  | 'Moy'    | 'Partner'      | 1     |
| 3  | 'Jonas'  | 'Developer'    | 2     |
| 4  | 'Smith'  | 'Developer'    | 2     |
| 5  | 'Verma'  | 'Sales Exec. ' | 2     |
| 6  | 'Foster' | 'Sales Exec. ' | 2     |
| 7  | 'Brown'  | 'Assistant'    | 3     |

## Ordering Data with the Hierarchical Query

The **ORDER SIBLINGS BY** clause will cause the ordering of the rows while preserving the hierarchy ordering so that the child nodes with the same parent will be stored according to the column list.

```
ORDER SIBLINGS BY col_1 [ASC|DESC] [, col_2 [ASC|DESC] [...[, col_n
[ASC|DESC]]...]]
```

The following example shows how to display information about seniors and subordinates in a company in the order of birth year.

The result with hierarchical query shows parent and child nodes in a row according to the column list specified in **ORDER SIBLINGS BY** statement by default. Sibling nodes that share the same parent node have outputted in a specified order.

```
-- Outputting a parent node and its child nodes, which sibling nodes
-- that share the same parent are sorted in the order of birthyear.
SELECT id, mgrid, name, birthyear, level
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER SIBLINGS BY birthyear;
```

| id | mgrid | name     | birthyear | level |
|----|-------|----------|-----------|-------|
| 2  | NULL  | 'Moy'    | 1958      | 1     |
| 6  | 2     | 'Foster' | 1972      | 2     |
| 7  | 6     | 'Brown'  | 1981      | 3     |
| 5  | 2     | 'Verma'  | 1973      | 2     |
| 1  | NULL  | 'Kim'    | 1963      | 1     |
| 4  | 1     | 'Smith'  | 1974      | 2     |
| 3  | 1     | 'Jonas'  | 1976      | 2     |

The following example shows how to display information about seniors and subordinates in a company in the order of joining. For the same level, the employee ID numbers are assigned in the order of joining. *id* indicates employee ID numbers (parent and child nodes) and *mgrid* indicates the employee ID numbers of their seniors.

```
-- Outputting a parent node and its child nodes, which sibling nodes
-- that share the same parent are sorted in the order of id.
SELECT id, mgrid, name, LEVEL
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER SIBLINGS BY id;
```

| id | mgrid | name    | level |
|----|-------|---------|-------|
| 1  | NULL  | 'Kim'   | 1     |
| 3  | 1     | 'Jonas' | 2     |
| 4  | 1     | 'Smith' | 2     |
| 2  | NULL  | 'Moy'   | 1     |
| 5  | 2     | 'Verma' | 2     |

|   |   |          |   |
|---|---|----------|---|
| 6 | 2 | 'Foster' | 2 |
| 7 | 6 | 'Brown'  | 3 |

## Pseudo Columns for Hierarchical Query

### LEVEL

**LEVEL** is a pseudocolumn representing depth of hierarchical queries. The **LEVEL** of root node is 1 and the LEVEL of its child node is 2.

The **LEVEL** (pseudocolumn) can be used in the **WHERE** clause, **ORDER BY** clause, and **GROUP BY ... HAVING** clause of the **SELECT** statement. And it can also be used in the statement using aggregate functions.

The following example shows how to retrieve the **LEVEL** value to check level of node.

```
-- Checking the LEVEL value
SELECT id, mgrid, name, LEVEL
FROM tree
WHERE LEVEL=2
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name     | level |
|----|-------|----------|-------|
| 3  | 1     | 'Jonas'  | 2     |
| 4  | 1     | 'Smith'  | 2     |
| 5  | 2     | 'Verma'  | 2     |
| 6  | 2     | 'Foster' | 2     |

The following example shows how to add **LEVEL** conditions after the **CONNECT BY** statement.

```
SELECT LEVEL FROM db_root CONNECT BY LEVEL <= 10;
```

| level |
|-------|
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
| 6     |

```

7
8
9
10

```

Note that the format of “CONNECT BY expr(LEVEL) < expr”, for example “CONNECT BY LEVEL +1 < 5”) is not supported.

## CONNECT\_BY\_ISLEAF

**CONNECT\_BY\_ISLEAF** is a pseudocolumn representing that the result of hierarchical query is leaf node. If the current row is a leaf node, it returns 1; otherwise, it returns 0.

The following example shows how to retrieve the **CONNECT\_BY\_ISLEAF** value to check whether it is a leaf node or not.

```

-- Checking a CONNECT_BY_ISLEAF value
SELECT id, mgrid, name, CONNECT_BY_ISLEAF
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER BY id;

```

| id | mgrid | name     | connect_by_isleaf |
|----|-------|----------|-------------------|
| 1  | NULL  | 'Kim'    | 0                 |
| 2  | NULL  | 'Moy'    | 0                 |
| 3  | 1     | 'Jonas'  | 1                 |
| 4  | 1     | 'Smith'  | 1                 |
| 5  | 2     | 'Verma'  | 1                 |
| 6  | 2     | 'Foster' | 0                 |
| 7  | 6     | 'Brown'  | 1                 |

## CONNECT\_BY\_ISCYCLE

**CONNECT\_BY\_ISCYCLE** is a pseudocolumn representing that a cycle was detected while processing the node, meaning that a child was also found to be an ancestor. A value of 1 for a row means a cycle was detected; the pseudo-column's value is 0, otherwise.

The **CONNECT\_BY\_ISCYCLE** pseudo-column can be used in the **WHERE**, **ORDER BY** and **GROUP BY ... HAVING** clauses of the **SELECT** statement. It can also be used in aggregate functions.

### Note

This pseudocolumn is available only when the **NOCYCLE** keyword is used in the statement.

The following example shows how to retrieve the **CONNECT\_BY\_ISCYCLE** value to check a row that occurs loop.

```
-- Creating a tree_cycle table and inserting data
CREATE TABLE tree_cycle(ID INT, MgrID INT, Name VARCHAR(32));

INSERT INTO tree_cycle VALUES (1,NULL,'Kim');
INSERT INTO tree_cycle VALUES (2,11,'Moy');
INSERT INTO tree_cycle VALUES (3,1,'Jonas');
INSERT INTO tree_cycle VALUES (4,1,'Smith');
INSERT INTO tree_cycle VALUES (5,3,'Verma');
INSERT INTO tree_cycle VALUES (6,3,'Foster');
INSERT INTO tree_cycle VALUES (7,4,'Brown');
INSERT INTO tree_cycle VALUES (8,4,'Lin');
INSERT INTO tree_cycle VALUES (9,2,'Edwin');
INSERT INTO tree_cycle VALUES (10,9,'Audrey');
INSERT INTO tree_cycle VALUES (11,10,'Stone');

-- Checking a CONNECT_BY_ISCYCLE value
SELECT id, mgrid, name, CONNECT_BY_ISCYCLE
FROM tree_cycle
START WITH name IN ('Kim', 'Moy')
CONNECT BY NOCYCLE PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name     | connect_by_iscycle |
|----|-------|----------|--------------------|
| 1  | NULL  | 'Kim'    | 0                  |
| 2  | 11    | 'Moy'    | 0                  |
| 3  | 1     | 'Jonas'  | 0                  |
| 4  | 1     | 'Smith'  | 0                  |
| 5  | 3     | 'Verma'  | 0                  |
| 6  | 3     | 'Foster' | 0                  |
| 7  | 4     | 'Brown'  | 0                  |
| 8  | 4     | 'Lin'    | 0                  |
| 9  | 2     | 'Edwin'  | 0                  |
| 10 | 9     | 'Audrey' | 0                  |
| 11 | 10    | 'Stone'  | 1                  |

## Operators for Hierarchical Query

### CONNECT\_BY\_ROOT

The **CONNECTION\_BY\_ROOT** operator returns the value of a root row as a column value. This operator can be used in the **WHERE** and **ORDER BY** clauses of the **SELECT** statement. The **CONNECT\_BY\_ROOT** operator returns the root row's value as a column expression. It is permitted for use in the **WHERE** and **ORDER BY** clauses of a **SELECT** statement. When used, the **WHERE** clause must precede the **START WITH** and **CONNECT BY** clauses, while the **ORDER BY** clause must follow the hierarchical query specification.

The following example shows how to retrieve the root row's *id* value.

```
-- Checking the id value of a root row for each row
SELECT id, mgrid, name, CONNECT_BY_ROOT id
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name     | connect_by_root id |
|----|-------|----------|--------------------|
| 1  | NULL  | 'Kim'    | 1                  |
| 2  | NULL  | 'Moy'    | 2                  |
| 3  | 1     | 'Jonas'  | 1                  |
| 4  | 1     | 'Smith'  | 1                  |
| 5  | 2     | 'Verma'  | 2                  |
| 6  | 2     | 'Foster' | 2                  |
| 7  | 6     | 'Brown'  | 2                  |

```
-- Correct Example
SELECT id, CONNECT_BY_ROOT name
FROM tree
WHERE CONNECT_BY_ROOT name = 'Kim'
START WITH mgrid IS NULL
CONNECT BY PRIOR id = mgrid

-- Incorrect Example
SELECT id, CONNECT_BY_ROOT name
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id = mgrid
WHERE CONNECT_BY_ROOT name = 'Kim'; -- Syntax error
```

## PRIOR

The PRIOR operator returns the value of a parent row as a column value and returns NULL for the root row. This operator can be used in the **WHERE**, **ORDER BY** and **CONNECT BY** clauses of the **SELECT** statement.

The following example shows how to retrieve the parent row's *id* value.

```
-- Checking the id value of a parent row for each row
SELECT id, mgrid, name, PRIOR id as "prior_id"
FROM tree
START WITH mgrid IS NULL
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name     | prior_id |
|----|-------|----------|----------|
| 1  | NULL  | 'Kim'    | NULL     |
| 2  | NULL  | 'Moy'    | NULL     |
| 3  | 1     | 'Jonas'  | 1        |
| 4  | 1     | 'Smith'  | 1        |
| 5  | 2     | 'Verma'  | 2        |
| 6  | 2     | 'Foster' | 2        |
| 7  | 6     | 'Brown'  | 6        |

## Functions for Hierarchical Query

### SYS\_CONNECT\_BY\_PATH

The **SYS\_CONNECT\_BY\_PATH** function returns the hierarchical path from a root to the specified row in string. The column and separator specified as an argument must be a character type. Each path separated by specified separator will be displayed consecutively. This function can be used in the **WHERE** and **ORDER BY** clauses of the **SELECT** statement.

```
SYS_CONNECT_BY_PATH (column_name, separator_char)
```

The following example shows how to retrieve path from a root to the specified row.

```
-- Executing a hierarchical query with SYS_CONNECT_BY_PATH function
SELECT id, mgrid, name, SYS_CONNECT_BY_PATH(name, '/') as [hierarchy]
FROM tree
START WITH mgrid IS NULL
```

```
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

| id | mgrid | name     | hierarchy           |
|----|-------|----------|---------------------|
| 1  | NULL  | 'Kim'    | '/Kim'              |
| 2  | NULL  | 'Moy'    | '/Moy'              |
| 3  | 1     | 'Jonas'  | '/Kim/Jonas'        |
| 4  | 1     | 'Smith'  | '/Kim/Smith'        |
| 5  | 2     | 'Verma'  | '/Moy/Verma'        |
| 6  | 2     | 'Foster' | '/Moy/Foster'       |
| 7  | 6     | 'Brown'  | '/Moy/Foster/Brown' |

### Examples of Hierarchical Query

The examples in this page shows how to write hierarchical queries by specifying the **CONNECT BY** clause within the **SELECT** statement.

A table that have relationship with recursive reference is create and the table consists of two columns named *ID* and *ParentID*; assume that *ID* is a primary key for the table and *ParentID* is a foreign key for the same table. In this context, the root node will have a *ParentID* value of **NULL**.

Once a table is create, you can get the entire data with hierarchical structure and a value of **LEVEL** by using the **UNION ALL** as shown below.

```
CREATE TABLE tree_table (ID int PRIMARY KEY, ParentID int, name
VARCHAR(128));
```

```
INSERT INTO tree_table VALUES (1,NULL,'Kim');
INSERT INTO tree_table VALUES (2,1,'Moy');
INSERT INTO tree_table VALUES (3,1,'Jonas');
INSERT INTO tree_table VALUES (4,1,'Smith');
INSERT INTO tree_table VALUES (5,3,'Verma');
INSERT INTO tree_table VALUES (6,3,'Foster');
INSERT INTO tree_table VALUES (7,4,'Brown');
INSERT INTO tree_table VALUES (8,4,'Lin');
INSERT INTO tree_table VALUES (9,2,'Edwin');
INSERT INTO tree_table VALUES (10,9,'Audrey');
INSERT INTO tree_table VALUES (11,10,'Stone');
```

```
SELECT L1.ID, L1.ParentID, L1.name, 1 AS [Level]
FROM tree_table AS L1
WHERE L1.ParentID IS NULL
UNION ALL
SELECT L2.ID, L2.ParentID, L2.name, 2 AS [Level]
FROM tree_table AS L1
INNER JOIN tree_table AS L2 ON L1.ID=L2.ParentID
```

```

WHERE L1.ParentID IS NULL
UNION ALL
SELECT L3.ID, L3.ParentID, L3.name, 3 AS [Level]
FROM tree_table AS L1
INNER JOIN tree_table AS L2 ON L1.ID=L2.ParentID
INNER JOIN tree_table AS L3 ON L2.ID=L3.ParentID
WHERE L1.ParentID IS NULL
UNION ALL
SELECT L4.ID, L4.ParentID, L4.name, 4 AS [Level]
FROM tree_table AS L1
INNER JOIN tree_table AS L2 ON L1.ID=L2.ParentID
INNER JOIN tree_table AS L3 ON L2.ID=L3.ParentID
INNER JOIN tree_table AS L4 ON L3.ID=L4.ParentID
WHERE L1.ParentID IS NULL;

```

| ID | ParentID | name     | Level |
|----|----------|----------|-------|
| 1  | NULL     | 'Kim'    | 1     |
| 2  | 1        | 'Moy'    | 2     |
| 3  | 1        | 'Jonas'  | 2     |
| 4  | 1        | 'Smith'  | 2     |
| 9  | 2        | 'Edwin'  | 3     |
| 5  | 3        | 'Verma'  | 3     |
| 6  | 3        | 'Foster' | 3     |
| 7  | 4        | 'Brown'  | 3     |
| 8  | 4        | 'Lin'    | 3     |
| 10 | 9        | 'Audrey' | 4     |

Because you do not know how many levels exist in the data, you can rewrite the query above as a stored procedure that loops until no new row is retrieved.

However, the hierarchical structure should be checked every step while looping, specify the **CONNECT BY** clause within the **SELECT** statement as follows; the example below shows how to get the entire data with hierarchical structure and the level of each row in the hierarchy.

```

SELECT ID, ParentID, name, Level
FROM tree_table
START WITH ParentID IS NULL
CONNECT BY ParentID=PRIOR ID;

```

| ID | ParentID | name     | level |
|----|----------|----------|-------|
| 1  | NULL     | 'Kim'    | 1     |
| 2  | 1        | 'Moy'    | 2     |
| 9  | 2        | 'Edwin'  | 3     |
| 10 | 9        | 'Audrey' | 4     |
| 11 | 10       | 'Stone'  | 5     |

|   |   |          |   |
|---|---|----------|---|
| 3 | 1 | 'Jonas'  | 2 |
| 5 | 3 | 'Verma'  | 3 |
| 6 | 3 | 'Foster' | 3 |
| 4 | 1 | 'Smith'  | 2 |
| 7 | 4 | 'Brown'  | 3 |
| 8 | 4 | 'Lin'    | 3 |

You can specify **NOCYCLE** to prevent an error from occurring as follows. When you run the following query, a loop does not appear; therefore, the result is the same as the above.

```
SELECT ID, ParentID, name, Level
FROM tree_table
START WITH ParentID IS NULL
CONNECT BY NOCYCLE ParentID=PRIOR ID;
```

CUBRID judges that this hierarchical query has a loop if the same row is found during searching process on the query. The below is an example that the loop exists; we define **NOCYCLE** to end the additional searching process if a loop exists.

```
CREATE TABLE tbl(seq INT, id VARCHAR(10), parent VARCHAR(10));

INSERT INTO tbl VALUES (1, 'a', null);
INSERT INTO tbl VALUES (2, 'b', 'a');
INSERT INTO tbl VALUES (3, 'b', 'c');
INSERT INTO tbl VALUES (4, 'c', 'b');
INSERT INTO tbl VALUES (5, 'c', 'b');

SELECT seq, id, parent, LEVEL,
       CONNECT_BY_ISCYCLE AS iscycle,
       CAST(SYS_CONNECT_BY_PATH(id, '/') AS VARCHAR(10)) AS idpath
FROM tbl
START WITH PARENT is NULL
CONNECT BY NOCYCLE PARENT = PRIOR id;
```

| seq   | id  | parent | level | iscycle | idpath        |
|-------|-----|--------|-------|---------|---------------|
| ===== |     |        |       |         |               |
| ===== |     |        |       |         |               |
| 1     | 'a' | NULL   | 1     | 0       | '/'a'         |
| 2     | 'b' | 'a'    | 2     | 0       | '/'a/b'       |
| 4     | 'c' | 'b'    | 3     | 0       | '/'a/b/c'     |
| 3     | 'b' | 'c'    | 4     | 1       | '/'a/b/c/b'   |
| 5     | 'c' | 'b'    | 5     | 1       | '/'a/b/c/b/c' |
| 5     | 'c' | 'b'    | 3     | 0       | '/'a/b/c'     |
| 3     | 'b' | 'c'    | 4     | 1       | '/'a/b/c/b'   |
| 4     | 'c' | 'b'    | 5     | 1       | '/'a/b/c/b/c' |

The below shows to output dates of March, 2013(201303) with a hierarchical query.

```
SELECT TO_CHAR(base_month + lvl -1, 'YYYYMMDD') h_date
FROM (
    SELECT LEVEL lvl, base_month
    FROM (
        SELECT TO_DATE('201303', 'YYYYMM') base_month FROM
db_root
    )
    CONNECT BY LEVEL <= LAST_DAY(base_month) - base_month + 1
);
```

h\_date

## Performance of Hierarchical Query

### Hierarchical query with single-table

A single-table hierarchical query can improve performance by adding an index to the columns corresponding to the child in the **CONNECT BY** clause. The following example shows how to improve performance by adding an index to the *mgrid* column.

```
-- Creating tree table and then inserting data
CREATE TABLE tree(ID INT, MgrID INT, Name VARCHAR(32), BirthYear
INT);

INSERT INTO tree VALUES (1,NULL,'Kim', 1963);
INSERT INTO tree VALUES (2,NULL,'Moy', 1958);
INSERT INTO tree VALUES (3,1,'Jonas', 1976);
INSERT INTO tree VALUES (4,1,'Smith', 1974);
INSERT INTO tree VALUES (5,2,'Verma', 1973);
INSERT INTO tree VALUES (6,2,'Foster', 1972);
INSERT INTO tree VALUES (7,6,'Brown', 1981);

-- Copy data
INSERT INTO tree select * from tree;
INSERT INTO tree select * from tree;
INSERT INTO tree select * from tree;
INSERT INTO tree select * from tree;
INSERT INTO tree select * from tree;

-- Executing a single table hierarchical query
SELECT count(*)
FROM tree
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

```
Trace Statistics:
  SELECT (time: 1686, fetch: 155971, fetch_time: 11, ioread: 0)
    SCAN (table: dba.tree), (heap time: 1, fetch: 1, ioread: 0,
readrows: 224, rows: 224)
    CONNECTBY (time: 1685, fetch: 155970, fetch_time: 0, ioread: 0)
      SCAN (table: dba.tree), (heap time: 1607, fetch: 38112,
ioread: 0, readrows: 8537088, rows: 37888)
        ORDERBY (time: 11, sort: true, page: 105, ioread: 0)
```

```
-- Create index
CREATE INDEX idx ON tree(mgrid);

-- Executing a single table hierarchical query with index
SELECT count(*)
```

```
FROM tree
CONNECT BY PRIOR id=mgrid
ORDER BY id;
```

```
Trace Statistics:
  SELECT (time: 128, fetch: 195206, fetch_time: 9, ioread: 0)
    SCAN (table: dba.tree), (heap time: 0, fetch: 1, ioread: 0,
readrows: 224, rows: 224)
    CONNECTBY (time: 128, fetch: 195203, fetch_time: 0, ioread: 0)
      SCAN (index: dba.tree.idx), (btree time: 35, fetch: 77344,
ioread: 0, readkeys: 1120, filteredkeys: 0, rows: 37888) (lookup
time: 10, rows: 37888)
      ORDERBY (time: 11, sort: true, page: 105, ioread: 0)
```

### Hierarchical query with join-table

A hierarchical query for table join is optimized using a hash list scan when applying the condition in the **CONNECT BY** clause after performing the table join operation. The following example shows the difference in performance between a hash list scan and a list scan.

```
-- Creating tree2 table and then inserting data
CREATE TABLE tree2(id int, treeid int, job varchar(32));

INSERT INTO tree2 VALUES(1,1,'Partner');
INSERT INTO tree2 VALUES(2,2,'Partner');
INSERT INTO tree2 VALUES(3,3,'Developer');
INSERT INTO tree2 VALUES(4,4,'Developer');
INSERT INTO tree2 VALUES(5,5,'Sales Exec. ');
INSERT INTO tree2 VALUES(6,6,'Sales Exec. ');
INSERT INTO tree2 VALUES(7,7,'Assistant');
INSERT INTO tree2 VALUES(8,null,'Secretary');

-- Copy data
INSERT INTO tree2 select * from tree2;

-- Executing a hierarchical query onto table joins
SELECT count(*)
FROM tree t INNER JOIN tree2 t2 ON t.id=t2.treeid
START WITH t.mgrid is null
CONNECT BY prior t.id=t.mgrid
ORDER BY t.id;
```

```
Trace Statistics:
  SELECT (time: 663, fetch: 877290, fetch_time: 54, ioread: 0)
    SCAN (table: dba.tree), (heap time: 0, fetch: 225, ioread: 0,
readrows: 224, rows: 224)
```

```

SCAN (table: dba.tree2), (heap time: 0, fetch: 224, ioread: 0,
readrows: 3584, rows: 448)
CONNECTBY (time: 662, fetch: 876841, fetch_time: 0, ioread: 0)
SCAN (hash temp(m), build time: 0, time: 53, fetch: 0, ioread:
0, readrows: 278976, rows: 278528)
ORDERBY (time: 92, sort: true, page: 1560, ioread: 0)

```

```

-- Executing a hierarchical query onto table joins without hash list
scan
SELECT /*+ NO_HASH_LIST_SCAN */ count(*)
FROM tree t INNER JOIN tree2 t2 ON t.id=t2.treeid
START WITH t.mgrid is null
CONNECT BY prior t.id=t.mgrid
ORDER BY t.id;

```

```

Trace Statistics:
SELECT (time: 8977, fetch: 877335, fetch_time: 57, ioread: 0)
SCAN (table: dba.tree), (heap time: 0, fetch: 225, ioread: 0,
readrows: 224, rows: 224)
SCAN (table: dba.tree2), (heap time: 0, fetch: 224, ioread: 0,
readrows: 3584, rows: 448)
CONNECTBY (time: 8977, fetch: 876886, fetch_time: 0, ioread: 0)
SCAN (temp time: 8353, fetch: 0, ioread: 0, readrows:
124837888, rows: 278528)
ORDERBY (time: 91, sort: true, page: 1560, ioread: 0)

```

### Note

**HASH LIST SCAN** optimization for a hierarchical query with join table is supported starting from CUBRID 11.0.

## INSERT

You can insert a new record into a table in a database by using the **INSERT** statement. CUBRID supports **INSERT ... VALUES**, **INSERT ... SET** and **INSERT ... SELECT** statements.

**INSERT ... VALUES** and **INSERT ... SET** statements are used to insert a new record based on the value that is explicitly specified while the **INSERT ... SELECT** statement is used to insert query result records obtained from different tables. Use the **INSERT VALUES** or **INSERT ... SELECT** statement to insert multiple rows by using the single **INSERT** statement.

```

<INSERT ... VALUES statement>
INSERT [INTO] <table_specification> [(column_name, ...)]
    {VALUES | VALUE}({expr | DEFAULT}, ...)[,({expr |
DEFAULT}, ...),...]
    [ON DUPLICATE KEY UPDATE column_name = expr, ... ]
INSERT [INTO] <table_specification> DEFAULT [ VALUES ]

<INSERT ... SET statement>
INSERT [INTO] <table_specification>
    SET column_name = {expr | DEFAULT}[, column_name = {expr |
DEFAULT},...]
    [ON DUPLICATE KEY UPDATE column_name = expr, ... ]

<INSERT ... SELECT statement>
INSERT [INTO] <table_specification> [(column_name, ...)]
    SELECT...
    [ON DUPLICATE KEY UPDATE column_name = expr, ... ]

<table_specification> ::= [schema_name.]table_name |
<remote_table_spec>
<remote_table_spec> ::=
[schema_name.]table_name@[schema_name.]server_name

```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: Specifies the name of the target table into which you want to insert a new record.
- *server\_name*: Specifies the name of the remote server to connect to with dblink.
- *column\_name*: Specifies the name of the column into which you want to insert the value. If you omit to specify the column name, it is considered that all columns defined in the table have been specified. Therefore, you must specify the values for all columns next to the **VALUES** keyword. If you do not specify all the columns defined in the table, a **DEFAULT** value is assigned to the non-specified columns; if the **DEFAULT** value is not defined, a **NULL** value is assigned.
- *expr | DEFAULT*: Specifies values that correspond to the columns next to the **VALUES** keyword. Expressions or the **DEFAULT** keyword can be specified as a value. At this time, the order and number of the specified column list must correspond to the column value list. The column value list for a single record is described in parentheses.
- **DEFAULT**: You can use the **DEFAULT** keyword to specify a default value as the column value. If you specify **DEFAULT** in the column value list next to the **VALUES** keyword, a default value column is stored for the given column: if you specify **DEFAULT** before the **VALUES** keyword, default values are stored for all columns in the table. **NULL** is stored for the column whose default value has not been defined.

- **ON DUPLICATE KEY UPDATE:** In case constraints are violated because a duplicated value for a column where **PRIMARY KEY** or **UNIQUE** attribute is defined is inserted, the value that makes constraints violated is changed into a specific value by performing the action specified in the **ON DUPLICATE KEY UPDATE** statement.

```
CREATE TABLE a_tbl1(
    id INT UNIQUE,
    name VARCHAR,
    phone VARCHAR DEFAULT '000-0000'
);

--insert default values with DEFAULT keyword before VALUES
INSERT INTO a_tbl1 DEFAULT VALUES;

--insert multiple rows
INSERT INTO a_tbl1 VALUES (1,'aaa', DEFAULT),(2,'bbb', DEFAULT);

--insert a single row specifying column values for all
INSERT INTO a_tbl1 VALUES (3,'ccc', '333-3333');

--insert two rows specifying column values for only
INSERT INTO a_tbl1(id) VALUES (4), (5);

--insert a single row with SET clauses
INSERT INTO a_tbl1 SET id=6, name='eee';
INSERT INTO a_tbl1 SET id=7, phone='777-7777';

SELECT * FROM a_tbl1;
```

| id   | name  | phone      |
|------|-------|------------|
| NULL | NULL  | '000-0000' |
| 1    | 'aaa' | '000-0000' |
| 2    | 'bbb' | '000-0000' |
| 3    | 'ccc' | '333-3333' |
| 4    | NULL  | '000-0000' |
| 5    | NULL  | '000-0000' |
| 6    | 'eee' | '000-0000' |
| 7    | NULL  | '777-7777' |

```
INSERT INTO a_tbl1 SET id=6, phone='000-0000'
ON DUPLICATE KEY UPDATE phone='666-6666';
SELECT * FROM a_tbl1 WHERE id=6;
```

| id | name  | phone      |
|----|-------|------------|
| 6  | 'eee' | '666-6666' |

```
INSERT INTO a_tbl1 SELECT * FROM a_tbl1 WHERE id=7 ON DUPLICATE KEY
UPDATE name='ggg';
SELECT * FROM a_tbl1 WHERE id=7;
```

| id | name  | phone      |
|----|-------|------------|
| 7  | 'ggg' | '777-7777' |

In **INSERT ... SET** syntax, the evaluation of an assignment expression is performed from left to right. If the column value is not specified, then the default value is assigned. If there is no default value, **NULL** is assigned.

```
CREATE TABLE tbl (a INT, b INT, c INT);
INSERT INTO tbl SET a=1, b=a+1, c=b+2;
SELECT * FROM tbl;
```

| a | b | c |
|---|---|---|
| 1 | 2 | 4 |

In the above example, b's value will be 2 and c's value will be 4 since a's value is 1.

```
CREATE TABLE tbl2 (a INT, b INT, c INT);
INSERT INTO tbl2 SET a=b+1, b=1, c=b+2;
```

In the above example, a's value will be **NULL** since b's value is not specified yet when assigning a's value.

```
SELECT * FROM tbl2;
```

| a    | b | c |
|------|---|---|
| NULL | 1 | 3 |

```
CREATE TABLE tbl3 (a INT, b INT default 10, c INT);
INSERT INTO tbl3 SET a=b+1, b=1, c=b+2;
```

In the above example, a's value will be 11 since b's value is not specified yet and b's default is 10.

```
SELECT * FROM tbl3;
```

| a  | b | c |
|----|---|---|
| 11 | 1 | 3 |

### INSERT ... SELECT Statement

If you use the **SELECT** query in the **INSERT** statement, you can insert query results which satisfy the specified retrieval condition from one or many tables to the target table.

```
INSERT [INTO] [schema_name.]table_name [(column_name, ...)]
    SELECT...
    [ON DUPLICATE KEY UPDATE column_name = expr, ... ]
```

The **SELECT** statement can be used in place of the **VALUES** keyword, or be included as a subquery in the column value list next to **VALUES**. If you specify the **SELECT** statement in place of the **VALUES** keyword, you can insert multiple query result records into the column of the table at once. However, there should be only one query result record if the **SELECT** statement is specified in the column value list.

```
--creating an empty table which schema replicated from a_tbl1
CREATE TABLE a_tbl2 LIKE a_tbl1;

--inserting multiple rows from SELECT query results
INSERT INTO a_tbl2 SELECT * FROM a_tbl1 WHERE id IS NOT NULL;

--inserting column value with SELECT subquery specified in the value list
INSERT INTO a_tbl2 VALUES(8, SELECT name FROM a_tbl1 WHERE name
<'bbb', DEFAULT);

SELECT * FROM a_tbl2;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'aaa' | '000-0000' |

|   |       |            |
|---|-------|------------|
| 2 | 'bbb' | '000-0000' |
| 3 | 'ccc' | '333-3333' |
| 4 | NULL  | '000-0000' |
| 5 | NULL  | '000-0000' |
| 6 | 'eee' | '000-0000' |
| 7 | NULL  | '777-7777' |
| 8 | 'aaa' | '000-0000' |

## INSERT INTO <remote-table-spec>... SELECT statement

If a remote table of the same remote server used in the SELECT query is used in the INSERT statement, query results that satisfy specific search conditions from one or more remote tables can be inserted into the remote table. However, an error occurs when the remote table of the INSERT statement among the tables specified in the SELECT statement and the table of another server (local table or table of another remote server) are used.

```
--at remote-side
--creating an empty table which schema replicated from a_tbl1
CREATE TABLE a_tbl2 LIKE a_tbl1;

--at local-side
--inserting multiple rows from SELECT query results
INSERT INTO a_tbl2@server1 SELECT * FROM a_tbl1@server1 WHERE id IS
NOT NULL;

--inserting column value with SELECT subquery specified in the value
list
INSERT INTO a_tbl2@server1 VALUES(8, SELECT name FROM a_tbl1@server1
WHERE name <'bbb', DEFAULT);

SELECT * FROM a_tbl2@server1;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'aaa' | '000-0000' |
| 2  | 'bbb' | '000-0000' |
| 3  | 'ccc' | '333-3333' |
| 4  | NULL  | '000-0000' |
| 5  | NULL  | '000-0000' |
| 6  | 'eee' | '000-0000' |
| 7  | NULL  | '777-7777' |
| 8  | 'aaa' | '000-0000' |

Data from a remote table can be inserted into a local table, but queries that insert data from a local table into a remote table cannot be used, so care must be taken when using it. The query below throws an error.

```
--inserting multiple rows from SELECT query results
INSERT INTO a_tbl2@server1 SELECT * FROM a_tbl1 WHERE id IS NOT NULL;
```

dblink: local mixed remote DML **is not** allowed

Also, if the server of the remote table used in the INSERT statement and the SELECT statement are different, query execution is not allowed. The query below throws an error.

```
--inserting multiple rows from SELECT query results
INSERT INTO a_tbl2@server1 SELECT * FROM a_tbl1@server2 WHERE id IS
NOT NULL;
```

dblink: multi-remote DML **is not** allowed

## ON DUPLICATE KEY UPDATE Clause

In a situation in which a duplicate value is inserted into a column for which the **UNIQUE** index or the **PRIMARY KEY** constraint has been set, you can update to a new value by specifying the **ON DUPLICATE KEY UPDATE** clause in the **INSERT** statement.

### Note

- If **PRIMARY KEY** and **UNIQUE** or multiple **UNIQUE** constraints exist on a table together, constraint violation can happen by one of them; so in this case, **ON DUPLICATE KEY UPDATE** clause is not recommended.
- Even if **UPDATE** is executed after failing executing **INSERT**, **AUTO\_INCREMENT** value which is increased once cannot be rolled back into the previous value.

```
<INSERT ... VALUES statement>
<INSERT ... SET statement>
<INSERT ... SELECT statement>
  INSERT ...
  [ON DUPLICATE KEY UPDATE column_name = expr, ... ]
```

- *column\_name = expr*: Specifies the name of the column whose value you want to change next to **ON DUPLICATE KEY UPDATE** and a new column value by using the equal sign.

```
--creating a new table having the same schema as a_tbl1
CREATE TABLE a_tbl3 LIKE a_tbl1;
INSERT INTO a_tbl3 SELECT * FROM a_tbl1 WHERE id IS NOT NULL and
name IS NOT NULL;
SELECT * FROM a_tbl3;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'aaa' | '000-0000' |
| 2  | 'bbb' | '000-0000' |
| 3  | 'ccc' | '333-3333' |
| 6  | 'eee' | '000-0000' |

```
--insert duplicated value violating UNIQUE constraint
INSERT INTO a_tbl3 VALUES(2, 'bbb', '222-2222');
```

ERROR: Operation would have caused one or more unique constraint violations.

With ON DUPLICATE KEY UPDATE, “affected rows” value per row will be 1 if a new row is inserted, and 2 if an existing row is updated.

```
--insert duplicated value with specifying ON DUPLICATE KEY UPDATE
clause
INSERT INTO a_tbl3 VALUES(2, 'ggg', '222-2222')
ON DUPLICATE KEY UPDATE name='ggg', phone = '222-2222';

SELECT * FROM a_tbl3 WHERE id=2;
```

| id | name  | phone      |
|----|-------|------------|
| 2  | 'ggg' | '222-2222' |

2 rows affected.

## UPDATE

You can update the column value of a record stored in the target table or view to a new one by using the **UPDATE** statement. Specify the name of the column to update and the new value in the **SET** clause, and specify the condition to extract the record to be updated in the **WHERE Clause**. You can update one or more tables with a single **UPDATE** statement.

```

<UPDATE single table>
UPDATE [schema_name.]table_name | <remote_table_spec> | view_name
SET column_name = {<expr> | DEFAULT} [, column_name = {<expr> |
DEFAULT} ...]
    [WHERE <search_condition>]
    [ORDER BY {col_name | <expr>}]
    [LIMIT row_count]

<remote_table_spec> ::=
[schema_name.]table_name@[schema.name.]server_name [correlation>]
<UPDATE multiple tables>
UPDATE <table_specifications> SET column_name = {<expr> | DEFAULT}
[, column_name = {<expr> | DEFAULT} ...]
    [WHERE <search_condition>]

```

- *<table\_specifications>*: You can specify the statement such as **FROM** clause of the **SELECT** statement and one or more tables can be specified.
- *server\_name*: Used when specifying a table of a remote server connected by dblink, not the current server.
- *column\_name*: Specifies the column name to be updated. Columns for one or more tables can be specified.
- *<expr> | DEFAULT*: Specifies a new value for the column and expression or **DEFAULT** keyword can be specified as a value. The **SELECT** statement returning result record also can be specified.
- *<search\_condition>*: Update only data that meets the *<search\_condition>* if conditions are specified in the **WHERE Clause**.
- *col\_name | <expr>*: Specifies base column to be updated.
- *row\_count*: Specifies the number of records to be updated after the **LIMIT Clause**. It can be one of unsigned integer, a host variable or a simple expression.

The following are allowed only when a single table is specified in *<table\_specifications>*:

- The **ORDER BY Clause** can be specified. If the **ORDER BY Clause** is specified, records are updated in the order of the specified column. This is useful for maintaining the order of trigger execution and the order of locking.
- The **LIMIT Clause** can be specified. If the **LIMIT Clause** is specified, the number of records to be updated can be limited.
- Analytic functions can be used in the *<expr>* of the **SET** clause. However, if a **SELECT** query is specified in *<expr>*, analytic functions can be used in the **SELECT** query regardless of the number of tables specified in *<table\_specifications>*.

**Note**

In CUBRID versions prior to 9.0, only a single table can be specified in *<table\_specifications>*.

**Note**

From CUBRID 10.0 onward, updates to views containing **JOIN** clauses are possible.

### Example 1. Single Table Update Using ORDER BY Clause

```
DROP TABLE IF EXISTS t1;

CREATE TABLE t1 (id INT);
INSERT INTO t1 VALUES (11), (1), (12), (13), (2), (3), (14), (4);

CREATE TRIGGER trigger1 BEFORE UPDATE ON t1 IF NEW.id < 10 EXECUTE
PRINT 'trigger1 executed';
CREATE TRIGGER trigger2 BEFORE UPDATE ON t1 IF NEW.id > 10 EXECUTE
PRINT 'trigger2 executed';

UPDATE t1 SET id = id + 1;

trigger2 executed
trigger1 executed
trigger2 executed
trigger2 executed
trigger1 executed
trigger1 executed
trigger2 executed
trigger1 executed
```

Using the **ORDER BY Clause** can change the order in which records are updated.

```
TRUNCATE TABLE t1;
INSERT INTO t1 VALUES (11), (1), (12), (13), (2), (3), (14), (4);

UPDATE t1 SET id = id + 1 ORDER BY id;

trigger1 executed
trigger1 executed
trigger1 executed
trigger1 executed
trigger2 executed
trigger2 executed
```

```
trigger2 executed
trigger2 executed
```

### Example 2. Single Table Update Using LIMIT Clause

This example uses the *LIMIT 3* clause to update only up to 3 records with *name IS NULL*.

```
DROP TABLE IF EXISTS t1;
```

```
CREATE TABLE t1 (id int, name varchar, phone varchar);
```

```
INSERT INTO t1 VALUES (NULL, NULL, '000-0000');
```

```
INSERT INTO t1 VALUES ( 1, 'aaa', '111-1111');
```

```
INSERT INTO t1 VALUES ( 2, 'bbb', '222-2222');
```

```
INSERT INTO t1 VALUES ( 3, 'ccc', '333-3333');
```

```
INSERT INTO t1 VALUES ( 4, NULL, '000-0000');
```

```
INSERT INTO t1 VALUES ( 5, NULL, '000-0000');
```

```
INSERT INTO t1 VALUES ( 6, 'ddd', '000-0000');
```

```
INSERT INTO t1 VALUES ( 7, NULL, '777-7777');
```

```
SELECT * FROM t1 WHERE name IS NULL;
```

| id    | name  | phone      |
|-------|-------|------------|
| ===== | ===== | =====      |
| NULL  | NULL  | '000-0000' |
| 4     | NULL  | '000-0000' |
| 5     | NULL  | '000-0000' |
| 7     | NULL  | '777-7777' |

```
UPDATE t1 SET name='update', phone='999-9999' WHERE name IS NULL
LIMIT 3;
```

```
SELECT * FROM t1;
```

| id    | name     | phone      |
|-------|----------|------------|
| ===== | =====    | =====      |
| NULL  | 'update' | '999-9999' |
| 1     | 'aaa'    | '111-1111' |
| 2     | 'bbb'    | '222-2222' |
| 3     | 'ccc'    | '333-3333' |
| 4     | 'update' | '999-9999' |
| 5     | 'update' | '999-9999' |
| 6     | 'ddd'    | '000-0000' |
| 7     | NULL     | '777-7777' |

### Example 3. Update Using Joins

When a record in table **A** is joined with multiple records in table **B** in an **UPDATE** statement, the record in **A** is updated using only the value from the first matching record in **B**.

In this example, a record in table *t1* with an *id* of 3 is joined with two records in table *t2* where *rate\_id* is 3. However, the *charge* column in the *t1* table is updated using only the *rate* value from the first matching record in the *t2* table.

```
DROP TABLE IF EXISTS t1, t2;

CREATE TABLE t1 (id INT PRIMARY KEY, charge DOUBLE);
INSERT INTO t1 VALUES (1, 100.0);
INSERT INTO t1 VALUES (2, 100.0);
INSERT INTO t1 VALUES (3, 100.0);

CREATE TABLE t2 (rate_id INT, rate DOUBLE);
INSERT INTO t2 VALUES (1, 0.1);
INSERT INTO t2 VALUES (2, 0.2);
INSERT INTO t2 VALUES (3, 0.3);
INSERT INTO t2 VALUES (3, 0.5);

UPDATE t1 a INNER JOIN t2 b ON a.id = b.rate_id
SET a.charge = a.charge * (1 + b.rate);

SELECT id, TO_CHAR (charge) AS charge FROM t1;
```

| id | charge |
|----|--------|
| 1  | '110'  |
| 2  | '120'  |
| 3  | '150'  |

For details, see [Join Query](#).

#### Example 4. View Update

```
DROP TABLE IF EXISTS t1, t2;
DROP VIEW v1;

CREATE TABLE t1 (id INT, val INT) DONT_REUSE_OID;
INSERT INTO t1 VALUES (1, 1);
INSERT INTO t1 VALUES (2, 2);
INSERT INTO t1 VALUES (3, 3);
INSERT INTO t1 VALUES (4, 4);
INSERT INTO t1 VALUES (5, 5);

CREATE TABLE t2 (id INT, val INT) DONT_REUSE_OID;
INSERT INTO t2 VALUES (1, 1);
INSERT INTO t2 VALUES (2, 2);
INSERT INTO t2 VALUES (3, 3);
INSERT INTO t2 VALUES (4, 4);
INSERT INTO t2 VALUES (6, 6);
```

```
CREATE VIEW v1 AS
  SELECT b.id, b.val FROM t2 b LEFT JOIN t1 a ON b.id = a.id WHERE
  b.id <= 3;
```

```
UPDATE v1 SET val = -1;
```

```
SELECT * from v1;
```

| id | val |
|----|-----|
| 1  | -1  |
| 2  | -1  |
| 3  | -1  |

```
SELECT * from t2;
```

| id | val |
|----|-----|
| 1  | -1  |
| 2  | -1  |
| 3  | -1  |
| 4  | 4   |
| 6  | 6   |

### Warning

Records in views that include tables with REUSE OID cannot be updated.

For details, see [REUSE\\_OID](#) and [DONT\\_REUSE\\_OID](#).

### Example 5. Update Using the update\_use\_attribute\_references Parameter

The result of this example depends on the value of the [update\\_use\\_attribute\\_references](#) parameter.

- If the value of this parameter is yes, c2 is updated to 10, influenced by c1 = 10.
- If the value of this parameter is no, c2 is not influenced by c1 = 10 and is updated to 1, based on the value of c1 stored in the record.

```
DROP TABLE IF EXISTS t1;
```

```
CREATE TABLE t1 (c1 INT, c2 INT);
INSERT INTO t1 values (1, NULL);
```

```
SET SYSTEM PARAMETERS 'update_use_attribute_references=yes';
```

```
UPDATE t1 SET c1 = 10, c2 = c1;
```

```
SELECT * FROM t1;
```

| c1 | c2 |
|----|----|
| 10 | 10 |

```
TRUNCATE TABLE t1;
```

```
INSERT INTO t1 values (1, NULL);
```

```
SET SYSTEM PARAMETERS 'update_use_attribute_references=no';
```

```
UPDATE t1 SET c1 = 10, c2 = c1;
```

```
SELECT * FROM t1;
```

| c1 | c2 |
|----|----|
| 10 | 1  |

#### Example 6. Single Table Update Using Analytic Functions

When only one table is specified in the **UPDATE** statement, analytic functions can be used in the **SET** clause.

```
DROP TABLE IF EXISTS t1, t2;
```

```
CREATE TABLE t1 (id INT);
```

```
INSERT INTO t1 VALUES (1), (2), (3), (4), (5);
```

```
CREATE TABLE t2 (id INT, val INT, update_val DOUBLE, join_update_val DOUBLE);
```

```
INSERT INTO t2 (id, val) SELECT a.id, b.id FROM t1 a, t1 b WHERE b.id <= a.id;
```

```
UPDATE t2 SET update_val = AVG (val) OVER (PARTITION BY id);
```

```
SELECT DISTINCT id, TO_CHAR (update_val) AS update_val FROM t2;
```

| id | update_val |
|----|------------|
| 1  | '1'        |
| 2  | '1.5'      |
| 3  | '2'        |
| 4  | '2.5'      |
| 5  | '3'        |

## Example 7. Multiple Tables Update Using Analytic Functions

This example continues from [Example 6. Single Table Update Using Analytic Functions](#).

When multiple tables are specified in the **UPDATE** statement, analytic functions cannot be used in the **SET** clause. However, if a **SELECT** query is specified in the **SET** clause, analytic functions can be used within that **SELECT** query, regardless of the number of tables specified.

```
UPDATE t1 a, t2 b SET b.join_update_val = AVG (b.val) OVER
(PARTITION BY b.id) WHERE a.id = b.id;
```

```
ERROR: before ' where a.id = b.id; '
Nested analytic functions are not allowed.
```

```
UPDATE t2 c SET c.join_update_val = (SELECT AVG (b.val) OVER
(PARTITION BY b.id) FROM t1 a, t2 b WHERE a.id = b.id AND a.id =
c.id LIMIT 1);
```

```
SELECT DISTINCT id, TO_CHAR (join_update_val) AS join_update_val
FROM t2;
```

| id | join_update_val |
|----|-----------------|
| 1  | '1'             |
| 2  | '1.5'           |
| 3  | '2'             |
| 4  | '2.5'           |
| 5  | '3'             |

## Example 8. Remote Table Update

By using table extension names, it is possible to update tables not only on the local server but also on remote servers.

```
/**
 * on the remote server (e.g., 192.168.6.21)
 */

-- DROP SERVER origin;
CREATE SERVER origin (HOST='localhost', PORT=33000, DBNAME=demodb,
USER=public);

DROP TABLE IF EXISTS t1;

CREATE TABLE t1 (id int, name varchar, phone varchar);
INSERT INTO t1@origin VALUES (NULL, NULL, '000-0000');
INSERT INTO t1@origin VALUES ( 1, 'aaa', '111-1111');
INSERT INTO t1@origin VALUES ( 2, 'bbb', '222-2222');
```

```

INSERT INTO t1@origin VALUES ( 3, 'ccc', '333-3333');
INSERT INTO t1@origin VALUES ( 4, NULL, '000-0000');
INSERT INTO t1@origin VALUES ( 5, NULL, '000-0000');
INSERT INTO t1@origin VALUES ( 6, 'ddd', '000-0000');
INSERT INTO t1@origin VALUES ( 7, NULL, '777-7777');

```

```
SELECT * FROM t1;
```

|  | id   | name  | phone      |
|--|------|-------|------------|
|  | NULL | NULL  | '000-0000' |
|  | 1    | 'aaa' | '111-1111' |
|  | 2    | 'bbb' | '222-2222' |
|  | 3    | 'ccc' | '333-3333' |
|  | 4    | NULL  | '000-0000' |
|  | 5    | NULL  | '000-0000' |
|  | 6    | 'ddd' | '000-0000' |
|  | 7    | NULL  | '777-7777' |

```

/**
 * on the local server (e.g., 192.168.6.22)
 */

-- DROP SERVER remote;
CREATE SERVER remote (HOST='192.168.6.21', PORT=33000,
DBNAME=demodb, USER=public);

```

```
SELECT * FROM t1@remote WHERE name IS NULL;
```

|  | id   | name | phone      |
|--|------|------|------------|
|  | NULL | NULL | '000-0000' |
|  | 4    | NULL | '000-0000' |
|  | 5    | NULL | '000-0000' |
|  | 7    | NULL | '777-7777' |

```
UPDATE t1@remote SET name='update', phone='999-9999' WHERE name IS
NULL LIMIT 3;
```

```
SELECT * FROM t1@remote;
```

|  | id   | name     | phone      |
|--|------|----------|------------|
|  | NULL | 'update' | '999-9999' |
|  | 1    | 'aaa'    | '111-1111' |
|  | 2    | 'bbb'    | '222-2222' |
|  | 3    | 'ccc'    | '333-3333' |
|  | 4    | 'update' | '999-9999' |
|  | 5    | 'update' | '999-9999' |

|   |       |            |
|---|-------|------------|
| 6 | 'ddd' | '000-0000' |
| 7 | NULL  | '777-7777' |

### Example 9. Local Table Update Using Joins with Remote Tables

```

/**
 * on the remote server (e.g., 192.168.6.21)
 */

DROP TABLE IF EXISTS t2;

CREATE TABLE t2 (rate_id INT, rate DOUBLE);

/**
 * on the local server (e.g., 192.168.6.22)
 */

-- DROP SERVER remote;
CREATE SERVER remote (HOST='192.168.6.21', PORT=33000,
DBNAME=demodb, USER=public);

DROP TABLE IF EXISTS t1;

CREATE TABLE t1 (id INT PRIMARY KEY, charge DOUBLE);
INSERT INTO t1 VALUES (1, 100.0);
INSERT INTO t1 VALUES (2, 100.0);
INSERT INTO t1 VALUES (3, 100.0);

INSERT INTO t2@remote VALUES (1, 0.1);
INSERT INTO t2@remote VALUES (2, 0.2);
INSERT INTO t2@remote VALUES (3, 0.3);
INSERT INTO t2@remote VALUES (3, 0.5);

UPDATE t1 a INNER JOIN t2@remote b ON a.id = b.rate_id
SET a.charge = a.charge * (1 + b.rate);

SELECT id, TO_CHAR (charge) AS charge FROM t1;

      id  charge
=====
      1  '110'
      2  '120'
      3  '150'

```

**Warning**

In **UPDATE** statements that join local and remote tables, records in the remote table cannot be updated.

```
UPDATE t1 a INNER JOIN t2@remote b ON a.id = b.rate_id
SET b.rate = b.rate + 0.1;

ERROR: before ' a INNER JOIN t2@remote b ON a.id = b.rate_id
SET b.rate = b....'
dblink: local mixed remote DML is not allowed
```

## REPLACE

The **REPLACE** statement works like **INSERT**, but the difference is that it inserts a new record after deleting the existing record without displaying the error when a duplicate value is to be inserted into a column for which **PRIMARY KEY** or **UNIQUE** constraints have defined. You must have both **INSERT** and **DELETE** authorization to use the **REPLACE** statement, because it performs insertion or insertion after deletion operations. Please see **GRANT** for more information about authorization.

```
<REPLACE ... VALUES statement>
REPLACE [INTO] <table_specification> [(column_name, ...)]
    {VALUES | VALUE}({expr | DEFAULT}, ...)[,({expr |
DEFAULT}, ...),...]

<REPLACE ... SET statement>
REPLACE [INTO] <table_specification>
    SET column_name = {expr | DEFAULT}[, column_name = {expr |
DEFAULT},...]

<REPLACE ... SELECT statement>
REPLACE [INTO] <table_specification> [column_name, ...)]
    SELECT...

<table_specification> ::= [schema_name.]table_name
                        |
                        [schema_name.]table_name@[schema_name.]server_name
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: Specifies the name of the target table into which you want to insert a new record.
- *server\_name*: Specifies the remote server name of the target table. For local tables, do not specify *server\_name*.

- *column\_name*: Specifies the name of the column into which you want to insert the value. If you omit to specify the column name, it is considered that all columns defined in the table have been specified. Therefore, you must specify the value for the column next to **VALUES**. If you do not specify all the columns defined in the table, a **DEFAULT** value is assigned to the non-specified columns; if the **DEFAULT** value is not defined, a **NULL** value is assigned.
- *expr* | **DEFAULT**: Specifies values that correspond to the columns after **VALUES**. Expressions or the **DEFAULT** keyword can be specified as a value. At this time, the order and number of the specified column list must correspond to the column value list. The column value list for a single record is described in parentheses.

The **REPLACE** statement determines whether a new record causes the duplication of **PRIMARY KEY** or **UNIQUE** index column values. Therefore, for performance reasons, it is recommended to use the **INSERT** statement for a table for which a **PRIMARY KEY** or **UNIQUE** index has not been defined.

```
--creating a new table having the same schema as a_tbl1
CREATE TABLE a_tbl4 LIKE a_tbl1;
INSERT INTO a_tbl4 SELECT * FROM a_tbl1 WHERE id IS NOT NULL and
name IS NOT NULL;

SELECT * FROM a_tbl4;
```

| id | name  | phone      |
|----|-------|------------|
| 1  | 'aaa' | '000-0000' |
| 2  | 'bbb' | '000-0000' |
| 3  | 'ccc' | '333-3333' |
| 6  | 'eee' | '000-0000' |

```
--insert duplicated value violating UNIQUE constraint
REPLACE INTO a_tbl4 VALUES(1, 'aaa', '111-1111'),(2, 'bbb',
'222-2222');
REPLACE INTO a_tbl4 SET id=6, name='fff', phone=DEFAULT;

SELECT * FROM a_tbl4;
```

| id | name  | phone      |
|----|-------|------------|
| 3  | 'ccc' | '333-3333' |
| 1  | 'aaa' | '111-1111' |
| 2  | 'bbb' | '222-2222' |
| 6  | 'fff' | '000-0000' |

## DELETE

You can delete records in the table by using the **DELETE** statement. You can specify delete conditions by combining the statement with the **WHERE Clause**. You can delete one or more tables with one **DELETE** statement.

```
<DELETE single table>
DELETE [FROM] [schema_name.]table_name[@[schema_name.]server_name]
[<correlation>] WHERE <search_condition> ] [LIMIT row_count]

<DELETE multiple tables FROM ...>
DELETE [schema_name.]table_name[@[schema_name.]server_name] |
<correlation> [{,
[schema_name.]table_name[@[schema_name.]server_name] |
<correlation>}]
FROM <table_specifications> [ WHERE <search_condition> ]

<DELETE FROM multiple tables USING ...>
DELETE FROM [schema_name.]table_name[@[schema_name.]server_name] |
<correlation> [{,
[schema_name.]table_name[@[schema_name.]server_name] |
<correlation>}]
USING <table_specifications> [ WHERE <search_condition> ]
```

- *<table\_specifications>*: You can specify the same syntax as the **FROM** clause of the **SELECT** statement, and you can specify one or more tables. Starting with version 11.3, you can specify not only local tables but also remote tables.
- *server\_name*: Used when specifying a table of a remote server connected by dblink, not the current server.
- *correlation*: alias of the specified local table or remote table
- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name*: Specifies the name of a table where the data to be deleted is contained. If the number of table is one, the **FROM** keyword can be omitted.
- *search\_condition*: Deletes only data that meets *search\_condition* by using **WHERE Clause**. If it is specified, all data in the specified tables will be deleted.
- *row\_count*: Specifies the number of records to be deleted in the **LIMIT Clause**. It can be one of unsigned integer, a host variable or a simple expression.

When a table to delete records is only one, **LIMIT Clause** can be specified. You can limit the number of records by specifying the **LIMIT Clause**. If the number of records satisfying the **WHERE Clause** exceeds *row\_count*, only the number of records specified in *row\_count* will be deleted.

**Note**

- On the **DELETE** statement with multiple tables, the table alias can be defined within `<table_specifications>` only. At the outside of `<table_specifications>`, the table alias defined in `<table_specifications>` can be used.
- Previous versions of CUBRID 9.0 allow only one table for `<table_specifications>`.

```
CREATE TABLE a_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));
INSERT INTO a_tbl VALUES(1, '111-1111'), (2, '222-2222'), (3,
'333-3333'), (4, NULL), (5, NULL);

--delete one record only from a_tbl
DELETE FROM a_tbl WHERE phone IS NULL LIMIT 1;
SELECT * FROM a_tbl;
```

```
      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      5  NULL
```

```
--delete all records from a_tbl
DELETE FROM a_tbl;
```

Below tables are created to explain **DELETE JOIN**.

```
CREATE TABLE a_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));
CREATE TABLE b_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));
CREATE TABLE c_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));

INSERT INTO a_tbl VALUES(1, '111-1111'), (2, '222-2222'), (3,
'333-3333'), (4, NULL), (5, NULL);
INSERT INTO b_tbl VALUES(1, '111-1111'), (2, '222-2222'), (3,
```

```
'333-3333'), (4, NULL);
INSERT INTO c_tbl VALUES(1, '111-1111'), (2, '222-2222'), (10,
'333-3333'), (11, NULL), (12, NULL);
```

The below queries delete rows after joining multiple tables. They show the same result.

```
-- Below four queries show the same result.
-- <DELETE multiple tables FROM ...>

DELETE a, b FROM a_tbl a, b_tbl b, c_tbl c
WHERE a.id=b.id AND b.id=c.id;

DELETE a, b FROM a_tbl a INNER JOIN b_tbl b ON a.id=b.id
INNER JOIN c_tbl c ON b.id=c.id;

-- <DELETE FROM multiple tables USING ...>

DELETE FROM a, b USING a_tbl a, b_tbl b, c_tbl c
WHERE a.id=b.id AND b.id=c.id;

DELETE FROM a, b USING a_tbl a INNER JOIN b_tbl b ON a.id=b.id
INNER JOIN c_tbl c ON b.id=c.id;
```

For more details on join syntax, see [Join Query](#).

You can also delete remote table data using the extended table name. The query below is for deleting remote table data.

```
--at remote srv1
CREATE TABLE a_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));
INSERT INTO a_tbl VALUES(1, '111-1111'), (2, '222-2222'), (3,
'333-3333'), (4, NULL), (5, NULL);

--at local
--delete one record only from remote a_tbl
DELETE FROM a_tbl@srv1 WHERE phone IS NULL LIMIT 1;
SELECT * FROM a_tbl@srv1;
      id  phone
=====
      1  '111-1111'
      2  '222-2222'
      3  '333-3333'
      5    NULL

--delete all records from remote a_tbl
DELETE FROM a_tbl@srv1;
```

The tables below were created to explain remote DELETE JOIN.

```
--at remote srv1
CREATE TABLE a_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));

CREATE TABLE b_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));

CREATE TABLE c_tbl(
    id INT NOT NULL,
    phone VARCHAR(10));

--at local
INSERT INTO a_tbl@srv1 VALUES(1,'111-1111'), (2,'222-2222'), (3,
'333-3333'), (4, NULL), (5, NULL);
INSERT INTO b_tbl@srv1 VALUES(1,'111-1111'), (2,'222-2222'), (3,
'333-3333'), (4, NULL);
INSERT INTO c_tbl@srv1 VALUES(1,'111-1111'), (2,'222-2222'), (10,
'333-3333'), (11, NULL), (12, NULL);
```

The following queries perform deletion after joining tables including remote tables (2 local tables, 1 remote table), and all show the same result.

```
-- Below four queries show the same result.
-- <DELETE multiple tables FROM ...>

DELETE a, b FROM a_tbl@srv1 a, b_tbl@srv1 b, c_tbl@srv1 c
WHERE a.id=b.id AND b.id=c.id;

DELETE a, b FROM a_tbl@srv1 a INNER JOIN b_tbl@srv1 b ON a.id=b.id
INNER JOIN c_tbl@srv1 c ON b.id=c.id;

-- <DELETE FROM multiple tables USING ...>

DELETE FROM a, b USING a_tbl@srv1 a, b_tbl@srv1 b, c_tbl@srv1 c
WHERE a.id=b.id AND b.id=c.id;

DELETE FROM a, b USING a_tbl@srv1 a INNER JOIN b_tbl@srv1 b ON
a.id=b.id
INNER JOIN c_tbl@srv1 c ON b.id=c.id;
```

## Caution

As shown below, DELETE JOIN queries that include local tables and remote tables and delete remote tables are not allowed. This is because it does not send local data to the remote.

```
DELETE c FROM a_tbl a, b_tbl b, c_tbl@srv1 c
WHERE a.id=b.id AND b.id=c.id;

DELETE a, b, c FROM a_tbl a, b_tbl b, c_tbl@srv1 c
WHERE a.id=b.id AND b.id=c.id;
```

## MERGE

The **MERGE** statement is used to select rows from a source and to update or to insert the rows onto one table or view. You can specify the condition whether to update or to insert the rows onto the target table or view. The **MERGE** statement is a deterministic statement, so you cannot update the same rows on the target table several times within one sentence.

```
MERGE [<merge_hint>] INTO <target> [[AS] <alias>]
USING <source> [[AS] <alias>]
ON <join_condition>
[ <merge_update_clause> ]
[ <merge_insert_clause> ]

<merge_update_clause> ::=
WHEN MATCHED THEN UPDATE
SET <col = expr> [, <col = expr>, ...] [WHERE <update_condition>]
[DELETE WHERE <delete_condition>]

<merge_insert_clause> ::=
WHEN NOT MATCHED THEN INSERT [(<attributes_list>)] VALUES
(<expr_list>) [WHERE <insert_condition>]

<merge_hint> ::=
/** [ USE_UPDATE_IDX (<update_index_list>) ] [ USE_INSERT_IDX
(<insert_index_list>) ] */
```

- *<target>*: The target table to update or insert into. It can be multiple tables or views, and you can also specify remote tables like `table-name@server-name`.
- *<source>*: The source table from which to import data. It can be a single table or view, and a subquery is also possible. If *target* is a remote table, *source* must also be a remote table or view specified on the same server as *target*. Or, it must be a subquery that includes the server specified in the target.
- *<join\_condition>*: Specifies the updated conditions
- *<merge\_update\_clause>*: If *<join\_condition>* is TRUE, the new column value of a target table will be specified.
  - When the **UPDATE** clause is executed, all **UPDATE** triggers defined in *<target>* are enabled.

- **<col>**: The column to be updated should be the column of the target table.
- **<expr>**: Allows the expression including columns of **<source>** and **<target>**. Or it can be the **DEFAULT** keyword. **<expr>** cannot include the aggregate functions.
- **<update\_condition>**: Performs the **UPDATE** operation only when a specific condition is TRUE. For the condition, both of the source tables and the target tables can be referenced. The rows which do not satisfy the condition are not updated.
- **<delete\_condition>**: Specifies a target to be deleted after update. At this time, the **DELETE** condition is executed with the updated result value. When **DELETE** statement is executed, the **DELETE** trigger defined in **<target>** will be enabled.
- The column referred by the **ON** condition clause cannot be updated.
- When you update view, you cannot specify **DEFAULT**.
- **<merge\_insert\_clause>**: If the **<join\_condition>** condition is FALSE, the column value of the target table will be inserted.
  - When the **INSERT** clause is executed, all **INSERT** triggers defined in the target table are enabled.
  - **<insert\_condition>**: Performs the INSERT operation only when the specified condition is TRUE. <Columns of **<source>** can be included in the condition.
  - **<attribute\_list>**: Columns to be inserted in **<target>**.
  - **<expr\_list>**: Integer filter condition can be used to insert all source rows to the target table. ON (0=1) is an example of integer filter condition.
  - This clause can be specified as it is or as **<merge\_update\_clause>**. If both of two are defined, the order does not matter.
- **<merge\_hint>**: Index hint of **MERGE** statement
  - **USE\_UPDATE\_IDX** (**<update\_index\_list>**): Index hint used in **UPDATE** clause of **MERGE** statement. Index names are listed on the **update\_index\_list** when **UPDATE** clause is run. This hint is applied to **<join\_condition>** and **<update\_condition>**.
  - **USE\_INSERT\_IDX** (**<insert\_index\_list>**): Index hint used in **INSERT** clause of **MERGE** statement. Index names are listed on the **insert\_index\_list** when **INSERT** clause is run. This hint is applied to **<join\_condition>**.

To execute the **MERGE** statement, the **SELECT** authorization for the source table should be granted. When the **UPDATE** clause is included in the target table, the **UPDATE** authorization should be granted. When the **DELETE** clause is included in the target table, the **DELETE** should be granted. When the **INSERT** clause is included in the target table, the **INSERT** should be granted.

The following example shows how to merge the value of *source\_table* to *target\_table*.

```
-- source_table
CREATE TABLE source_table (a INT, b INT, c INT);
INSERT INTO source_table VALUES (1, 1, 1);
INSERT INTO source_table VALUES (1, 3, 2);
INSERT INTO source_table VALUES (2, 4, 5);
INSERT INTO source_table VALUES (3, 1, 3);

-- target_table
CREATE TABLE target_table (a INT, b INT, c INT);
INSERT INTO target_table VALUES (1, 1, 4);
INSERT INTO target_table VALUES (1, 2, 5);
INSERT INTO target_table VALUES (1, 3, 2);
INSERT INTO target_table VALUES (3, 1, 6);
INSERT INTO target_table VALUES (5, 5, 2);

MERGE INTO target_table tt USING source_table st
ON (st.a=tt.a AND st.b=tt.b)
WHEN MATCHED THEN UPDATE SET tt.c=st.c
      DELETE WHERE tt.c = 1
WHEN NOT MATCHED THEN INSERT VALUES (st.a, st.b, st.c);

-- the result of above query
SELECT * FROM target_table;
```

| a | b | c |
|---|---|---|
| 1 | 2 | 5 |
| 1 | 3 | 2 |
| 3 | 1 | 3 |
| 5 | 5 | 2 |
| 2 | 4 | 5 |

In the above example, when column A and B of *source\_table* are identical with the values of column A and B in *target\_table*, column C of *target\_table* is updated with the column C of *source\_table*. Otherwise, the records in *source\_table* are inserted to *target\_table*. However, if the value of column C in *target\_table* is 1 in the updated record, the record is deleted.

The following example shows how to use the **MERGE** statement to arrange the records of *bonus* score table to give to students.

```
CREATE TABLE bonus (std_id INT, addscore INT);
CREATE INDEX i_bonus_std_id ON bonus (std_id);

INSERT INTO bonus VALUES (1,10);
INSERT INTO bonus VALUES (2,10);
```

```

INSERT INTO bonus VALUES (3,10);
INSERT INTO bonus VALUES (4,10);
INSERT INTO bonus VALUES (5,10);
INSERT INTO bonus VALUES (6,10);
INSERT INTO bonus VALUES (7,10);
INSERT INTO bonus VALUES (8,10);
INSERT INTO bonus VALUES (9,10);
INSERT INTO bonus VALUES (10,10);

CREATE TABLE std (std_id INT, score INT);
CREATE INDEX i_std_std_id ON std (std_id);
CREATE INDEX i_std_std_id_score ON std (std_id, score);

INSERT INTO std VALUES (1,60);
INSERT INTO std VALUES (2,70);
INSERT INTO std VALUES (3,80);
INSERT INTO std VALUES (4,35);
INSERT INTO std VALUES (5,55);
INSERT INTO std VALUES (6,30);
INSERT INTO std VALUES (7,65);
INSERT INTO std VALUES (8,65);
INSERT INTO std VALUES (9,70);
INSERT INTO std VALUES (10,22);
INSERT INTO std VALUES (11,67);
INSERT INTO std VALUES (12,20);
INSERT INTO std VALUES (13,45);
INSERT INTO std VALUES (14,30);

MERGE INTO bonus t USING (SELECT * FROM std WHERE score < 40) s
ON t.std_id = s.std_id
WHEN MATCHED THEN
UPDATE SET t.addscore = t.addscore + s.score * 0.1
WHEN NOT MATCHED THEN
INSERT (t.std_id, t.addscore) VALUES (s.std_id, 10 + s.score * 0.1)
WHERE s.score <= 30;

SELECT * FROM bonus ORDER BY 1;

```

```

std_id      addscore
=====
1           10
2           10
3           10
4           14
5           10
6           13
7           10
8           10
9           10
10          12

```

|    |    |
|----|----|
| 12 | 12 |
| 14 | 13 |

In the above example, the source table is a set of *std* table records, where the score is less than 40 and the target table is *bonus*. The student numbers (*std\_id*) where the score (*std.score*) is less than 40 are 4, 6, 10, 12, and 14. Among them, for 4, 6, and 10 on the *bonus* table, the **UPDATE** clause adds 10% of the score of their own to the existing bonus. For 12 and 14 which are not on the *bonus* table, the **INSERT** clause adds 10 scores and 10% of the score of their own.

The following shows how to use index hints in **MERGE** statement.

```
CREATE TABLE target (i INT, j INT);
CREATE TABLE source (i INT, j INT);

INSERT INTO target VALUES (1,1),(2,2),(3,3);
INSERT INTO source VALUES (1,11),(2,22),(4,44),(5,55),(7,77),(8,88);

CREATE INDEX i_t_i ON target(i);
CREATE INDEX i_t_ij ON target(i,j);
CREATE INDEX i_s_i ON source(i);
CREATE INDEX i_s_ij ON source(i,j);

MERGE /*+ RECOMPILE USE_UPDATE_IDX(i_s_ij) USE_INSERT_IDX(i_t_ij,
i_t_i) */
INTO target t USING source s ON t.i=s.i
WHEN MATCHED THEN UPDATE SET t.j=s.j WHERE s.i <> 1
WHEN NOT MATCHED THEN INSERT VALUES (i,j);
```

To execute the MERGE statement, you must have SELECT privilege on the source table, UPDATE privilege if the UPDATE clause is included, DELETE privilege if the DELETE clause is included, and INSERT privilege if the INSERT clause is included on the target table.

The following is an example of combining source\_table values of the remote server with target\_table of the remote server.

```
-- at remote server
-- source_table
CREATE TABLE source_table (a INT, b INT, c INT);
CREATE TABLE target_table (a INT, b INT, c INT);

-- at local server
-- source table
INSERT INTO source_table@srv1 VALUES (1, 1, 1);
INSERT INTO source_table@srv1 VALUES (1, 3, 2);
INSERT INTO source_table@srv1 VALUES (2, 4, 5);
INSERT INTO source_table@srv1 VALUES (3, 1, 3);

-- target_table
```

```

INSERT INTO target_table@srv1 VALUES (1, 1, 4);
INSERT INTO target_table@srv1 VALUES (1, 2, 5);
INSERT INTO target_table@srv1 VALUES (1, 3, 2);
INSERT INTO target_table@srv1 VALUES (3, 1, 6);
INSERT INTO target_table@srv1 VALUES (5, 5, 2);

MERGE INTO target_table@srv1 tt USING source_table@srv1 st
ON (st.a=tt.a AND st.b=tt.b)
WHEN MATCHED THEN UPDATE SET tt.c=st.c
    DELETE WHERE tt.c = 1
WHEN NOT MATCHED THEN INSERT VALUES (st.a, st.b, st.c);

-- the result of above query
SELECT * FROM target_table@srv1;

=====
a          b          c
=====
1          2          5
1          3          2
3          1          3
5          5          2
2          4          5

```

The following is an example of combining source\_table values of the remote server with target\_table of the local server.

```

-- at remote server
-- source_table
CREATE TABLE source_table (a INT, b INT, c INT);

-- at local server
CREATE TABLE target_table (a INT, b INT, c INT);

-- source table insert
INSERT INTO source_table@srv1 VALUES (1, 1, 1);
INSERT INTO source_table@srv1 VALUES (1, 3, 2);
INSERT INTO source_table@srv1 VALUES (2, 4, 5);
INSERT INTO source_table@srv1 VALUES (3, 1, 3);

-- target_table insert
INSERT INTO target_table VALUES (1, 1, 4);
INSERT INTO target_table VALUES (1, 2, 5);
INSERT INTO target_table VALUES (1, 3, 2);
INSERT INTO target_table VALUES (3, 1, 6);
INSERT INTO target_table VALUES (5, 5, 2);

MERGE INTO target_table tt USING source_table@srv1 st
ON (st.a=tt.a AND st.b=tt.b)
WHEN MATCHED THEN UPDATE SET tt.c=st.c
    DELETE WHERE tt.c = 1
WHEN NOT MATCHED THEN INSERT VALUES (st.a, st.b, st.c);

```

```
-- the result of above query
SELECT * FROM target_table;

      a      b      c
=====
      1      2      5
      1      3      2
      3      1      3
      5      5      2
      2      4      5
```

### Warning

As in the example below, if the target is remote and the source is local, an error occurs.

```
MERGE INTO target_table@srv1 tt USING source_table st
ON (st.a=tt.a AND st.b=tt.b)
WHEN MATCHED THEN UPDATE SET tt.c=st.c
      DELETE WHERE tt.c = 1
WHEN NOT MATCHED THEN INSERT VALUES (st.a, st.b, st.c);
```

Also, an error occurs when the target and source are different servers, as in the example below.

```
MERGE INTO target_table@srv1 tt USING source_table@srv2 st
ON (st.a=tt.a AND st.b=tt.b)
WHEN MATCHED THEN UPDATE SET tt.c=st.c
      DELETE WHERE tt.c = 1
WHEN NOT MATCHED THEN INSERT VALUES (st.a, st.b, st.c);
```

## TRUNCATE

You can delete all records in the specified table by using the **TRUNCATE** statement.

It has the following advantages over using the **DELETE FROM** *[schema\_name.]table\_name* statement without a **WHERE** clause.

- It's way faster due to deleting all indexes and constraints in advance and deleting records at once.
- There is no vacuum cost.
- It generates way lesser log records so that it is better in terms of HA replication, Recovery, and Rollback.

**Note**

- The **DELETE** trigger is disabled while deleting records with the **TRUNCATE** statement.
- The **TRUNCATE** statement initializes the **AUTO INCREMENT** column of the table. Therefore, if data is inserted, the **AUTO INCREMENT** column value increases from the initial value.
- To execute the **TRUNCATE** statement, the authorization of **ALTER**, **INDEX**, and **DELETE** is required on the table. For granting authorization, see **GRANT**.
- If a table is created with **DONT\_REUSE\_OID** option (**DONT\_REUSE\_OID**), other tables can refer to it as a column. When the specified table is referred to like this, it is impossible to truncate the table and it's done with **DELETE FROM** statement internally.

```
TRUNCATE [ TABLE ] [schema_name.]table_name [ CASCADE ]
```

- *schema\_name*: Specifies the schema name. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table that contains the data to be deleted.
- **CASCADE** : Deletes all records in all tables referring to the specified table with a foreign key. This is propagated to all tables in the foreign key relationship. A **PRIMARY KEY** constraint has to be defined in the table and this has to be referred to by one or more **FOREIGN KEY**, and the foreign key action has to be **ON DELETE**. It fails without this option when a foreign key referring to the specified table is defined. It also fails when even one **ON DELETE** action is not **CASCADE** in all foreign key relationships. See **FOREIGN KEY Constraint** for more information about the foreign key constraint.

```
CREATE TABLE a_tbl(A INT AUTO_INCREMENT(3,10) PRIMARY KEY);
INSERT INTO a_tbl VALUES (NULL),(NULL),(NULL);
SELECT * FROM a_tbl;
```

```
      a
=====
      3
     13
     23
```

```
--AUTO_INCREMENT column value increases from the initial value after
truncating the table
```

```
TRUNCATE TABLE a_tbl;
INSERT INTO a_tbl VALUES (NULL);
SELECT * FROM a_tbl;
```

```

a
=====
3
```

The following example uses the **CASCADE** option. Note that even a record refers to nothing, but the propagated **TRUNCATE** deletes all records.

```
-- a_tbl <- b_tbl <- c_tbl
--      <- d_tbl
CREATE TABLE a_tbl(a1 INT PRIMARY KEY);
CREATE TABLE b_tbl(b1 INT PRIMARY KEY, b2 INT FOREIGN KEY REFERENCES
a_tbl (a1) ON DELETE CASCADE);
CREATE TABLE c_tbl(c1 INT PRIMARY KEY, c2 INT FOREIGN KEY REFERENCES
b_tbl (b1) ON DELETE CASCADE);
CREATE TABLE d_tbl(d1 INT PRIMARY KEY, d2 INT FOREIGN KEY REFERENCES
a_tbl (a1) ON DELETE CASCADE);
INSERT INTO a_tbl VALUES (1);
INSERT INTO b_tbl VALUES (2, 1);
INSERT INTO c_tbl VALUES (3, 2);
INSERT INTO d_tbl VALUES (5, 1);
INSERT INTO d_tbl VALUES (4, NULL); -- not refer to any record in
a_tbl, but will be deleted.
SELECT * FROM a_tbl;
SELECT * FROM b_tbl;
SELECT * FROM c_tbl;
SELECT * FROM d_tbl;

TRUNCATE a_tbl CASCADE;
SELECT * FROM a_tbl, b_tbl, c_tbl, d_tbl;
```

```

a1
=====
1

b1          b2
=====
2           1

c1          c2
=====
3           2

d1          d2
```

```
=====
          5          1
          4          NULL

-- after TRUNCATE a_tbl CASCADE;
There are no results.
```

## PREPARED STATEMENT

In general, the prepared statement is executed through the interface functions of JDBC, PHP, or ODBC; it can also be executed in the SQL level. The following SQL statements are provided for execution of prepared statement.

- Prepare the SQL statement to execute.

```
PREPARE stmt_name FROM preparable_stmt
```

- Execute the prepared statement.

```
EXECUTE stmt_name [USING value [, value] ...]
```

- Drop the prepared statement.

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

### Note

- In SQL level, PREPARE statement is recommended to use only in CSQL interpreter. If it is used in the application program, it is not guaranteed to work normally.
- In SQL level, the number of PREPARE statements is limited to 20 per DB connection. It is limited to protect abusing DB server memory, because PREPARE statement in SQL level uses the memory of DB server.
- In the interface function, the number of prepared statements is limited to `MAX_PREPARED_STMT_COUNT` of broker parameter per DB connection.

## PREPARE Statement

The **PREPARE** statement prepares the query specified in *preparable\_stmt* of the **FROM** clause and assigns the name to be used later when the SQL statement is referenced to *stmt\_name*. See [EXECUTE Statement](#) for example.

```
PREPARE stmt_name FROM preparable_stmt
```

- *stmt\_name* : The prepared statement is specified. If an SQL statement with the same *stmt\_name* exists in the given client session, clear the existing prepared statement and prepare a new SQL statement. If the **PREPARE** statement is not executed properly due to an error in the given SQL statement, it is processed as if the *stmt\_name* assigned to the SQL statement does not exist.
- *preparable\_stmt* : You must use only one SQL statement. Multiple SQL statements cannot be specified. You can use a question mark (?) as a bind parameter in the *preparable\_stmt* statement and it should not be enclosed with quotes.

### Remark

The **PREPARE** statement starts by connecting an application to a server and will be maintained until the application terminates the connection. The connection maintained during this period is called a session. You can set the session time with the **session\_state\_timeout** parameter of **cubrid.conf**; the default value is **21600** seconds (=6 hours).

The data managed by the session includes the **PREPARE** statement, user-defined variables, the last ID inserted (**LAST\_INSERT\_ID**), and the number of rows affected by the statement (**ROW\_COUNT**) that you execute at the end.

## EXECUTE Statement

The **EXECUTE** statement executes the prepared statement. You can bind the data value after the **USING** clause if a bind parameter (?) is included in the prepared statement. You cannot specify user-defined variables like an attribute in the **USING** clause. A value such as literal and an input parameter only can be specified.

```
EXECUTE stmt_name [USING value [, value] ...]
```

- *stmt\_name* : The name given to the prepared statement to be executed is specified. An error message is displayed if the *stmt\_name* is not valid, or if the prepared statement does not exist.
- *value* : The data to bind is specified if there is a bind parameter in the prepared statement. The number and the order of the data must correspond to that of the bind parameter. If it does not, an error message is displayed.

```
PREPARE st FROM 'SELECT 1 + ?';
EXECUTE st USING 4;
```

```
1+ ?:0
=====
5
```

```
PREPARE st FROM 'SELECT 1 + ?';
SET @a=3;
EXECUTE st USING @a;
```

```
1+ ?:0
=====
4
```

```
PREPARE st FROM 'SELECT ? + ?';
EXECUTE st USING 1,3;
```

```
?:0 + ?:1
=====
4
```

```
PREPARE st FROM 'SELECT ? + ?';
EXECUTE st USING 'a','b';
```

```
?:0 + ?:1
=====
'ab'
```

```
PREPARE st FROM 'SELECT FLOOR(?)';
EXECUTE st USING '3.2';
```

```
floor( ?:0 )
=====
3.0000000000000000e+000
```

## DEALLOCATE PREPARE/DROP PREPARE Statements

The statements **DEALLOCATE PREPARE** and **DROP PREPARE** are used interchangeably and they clear the prepared statement. All prepared statements are cleared automatically by the server when the client session is terminated even if the **DEALLOCATE PREPARE** or **DROP PREPARE** statement is not executed.

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

- *stmt\_name* : The name given to the prepared statement to be cleared is specified. An error message is displayed if the *stmt\_name* is not valid, or if the prepared statement does not exist.

```
DEALLOCATE PREPARE stmt1;
```

## DO

The **DO** statement executes the specified expression, but does not return the result. This can be used to determine whether or not the syntax of the expression is correct because an error is returned when a specified expression does not comply with the syntax. In general, the execution speed of the **DO** statement is higher than that of the **SELECT** statement because the database server does not return the operation result or errors.

```
DO expression
```

- *expression* : Specifies an expression.

```
DO 1+1;  
DO SYSDATE + 1;  
DO (SELECT count(*) FROM athlete);
```

## CTE

Common Table Expressions (CTEs) are temporary tables (list of results) associated with a statement. A CTE can be referenced multiple times within the statement, and is visible only within the statement scope. It enables better separation of statement logic and may enhance execution performance. Moreover, recursive CTEs can be used to generate a hierarchical statement based on parent-child relationships, being able to reproduce **CONNECT BY** statements and other more complex queries.

A CTE is introduced using the **WITH** clause. A list of sub-queries is expected, and final query which uses the sub-queries. Each sub-query (table expression) has a name and a query definition. A

table expression may refer another table expression which previously defined in the same statement. The general syntax is:

```
WITH
  [RECURSIVE <recursive_cte_name> [ (<recursive_column_names>) ] AS
  <recursive_sub-query>]
  <cte_name1> [ (<cte1_column_names>) ] AS <sub-query1>
  <cte_name2> [ (<cte2_column_names>) ] AS <sub-query2>
  ...
  <final_query>
```

- *recursive\_cte\_name*, *cte\_name1*, *cte\_name2* : identifiers for the table expressions (sub-queries)
- *recursive\_column\_names*, *cte1\_column\_names*, *cte2\_column\_names* : identifiers for the columns of the results of each table expression
- *sub-query1*, *sub-query2* : sub-queries which define each table expression.
- *final\_query* : query using table expression previously defined. Usually, the **FROM** clause of this will contain the CTEs identifiers.

Simplest usage is to combine result lists of table expressions:

```
CREATE TABLE products (id INTEGER PRIMARY KEY, parent_id INTEGER,
item VARCHAR(100), price INTEGER);
INSERT INTO products VALUES (1, -1, 'Drone', 2000);
INSERT INTO products VALUES (2, 1, 'Blade', 10);
INSERT INTO products VALUES (3, 1, 'Brushless motor', 20);
INSERT INTO products VALUES (4, 1, 'Frame', 50);
INSERT INTO products VALUES (5, -1, 'Car', 20000);
INSERT INTO products VALUES (6, 5, 'Wheel', 100);
INSERT INTO products VALUES (7, 5, 'Engine', 4000);
INSERT INTO products VALUES (8, 5, 'Frame', 4700);

WITH
  of_drones AS (SELECT item, 'drones' FROM products WHERE parent_id =
1),
  of_cars AS (SELECT item, 'cars' FROM products WHERE parent_id = 5)
SELECT * FROM of_drones UNION ALL SELECT * FROM of_cars ORDER BY 1;
```

| item              | 'drones' |
|-------------------|----------|
| 'Blade'           | 'drones' |
| 'Brushless motor' | 'drones' |
| 'Car'             | 'cars'   |
| 'Drone'           | 'drones' |
| 'Engine'          | 'cars'   |
| 'Frame'           | 'drones' |

```
'Frame'      'cars'
'Wheel'      'cars'
```

A sub-query of one CTE may be referenced by other sub-query of another CTE (the referenced CTE needs to be defined before):

```
WITH
  of_drones AS (SELECT item FROM products WHERE parent_id = 1),
  filter_common_with_cars AS (SELECT * FROM of_drones INTERSECT
  SELECT item FROM products WHERE parent_id = 5)
SELECT * FROM filter_common_with_cars ORDER BY 1;
```

```
item
=====
'Frame'
```

#### Error will be prompted if:

- More than one CTE uses the same identifier name.
- using nested **WITH** clauses.

```
WITH
  my_cte AS (SELECT item FROM products WHERE parent_id = 1),
  my_cte AS (SELECT * FROM my_cte INTERSECT SELECT item FROM products
  WHERE parent_id = 5)
SELECT * FROM my_cte ORDER BY 1;
```

```
before '
  SELECT * FROM my_cte ORDER BY 1;
'
```

CTE name ambiguity, there are more than one CTEs **with** the same name: 'my\_cte'.

```
WITH
  of_drones AS (SELECT item FROM products WHERE parent_id = 1),
  of_cars1 AS (WITH
    of_cars2 AS (SELECT item FROM products WHERE
parent_id = 5)
    SELECT * FROM of_cars2
  )
SELECT * FROM of_drones, of_cars1 ORDER BY 1;
```

```
before '
    SELECT * FROM of_drones, of_cars1 ORDER BY 1;
'
Nested WITH clauses are not supported.
```

## CTE column names

The column names of each CTE result may be specified after the CTE name. The number of elements in the CTE column list must match the number of columns in the CTE sub-query.

```
WITH
  of_drones (product_name, product_type, price) AS (SELECT item,
' drones', price FROM products WHERE parent_id = 1),
  of_cars (product_name, product_type, price) AS (SELECT item,
' cars', price FROM products WHERE parent_id = 5)
SELECT * FROM of_drones UNION ALL SELECT * FROM of_cars ORDER BY
product_type, price;

WITH
  of_drones (product_name, product_type, price) AS (SELECT item,
' drones' as type, MAX(price) FROM products WHERE parent_id = 1 GROUP
BY type),
  of_cars (product_name, product_type, price) AS (SELECT item,
' cars' as type, MAX (price) FROM products WHERE parent_id = 5 GROUP
BY type)
SELECT * FROM of_drones UNION ALL SELECT * FROM of_cars ORDER BY
product_type, price;
```

| product_name      | product_type | price |
|-------------------|--------------|-------|
| 'Wheel'           | 'cars'       | 100   |
| 'Engine'          | 'cars'       | 4000  |
| 'Frame'           | 'cars'       | 4700  |
| 'Blade'           | 'drones'     | 10    |
| 'Brushless motor' | 'drones'     | 20    |
| 'Frame'           | 'drones'     | 50    |

| product_name | product_type | price |
|--------------|--------------|-------|
| 'Wheel'      | 'cars'       | 4700  |
| 'Blade'      | 'drones'     | 50    |

If no column names are given in the CTE, the column names are extracted from the first inner select list of the CTE. The expressions result columns will be named according to their original text.

```

WITH
  of_drones AS (SELECT item, 'drones', MAX(price) FROM products WHERE
parent_id = 1 GROUP BY 2),
  of_cars AS (SELECT item, 'cars', MAX (price) FROM products WHERE
parent_id = 5 GROUP BY 2)
SELECT * FROM of_drones UNION ALL SELECT * FROM of_cars ORDER BY 1;

```

| item    | 'drones' | max(products.price) |
|---------|----------|---------------------|
| 'Blade' | 'drones' | 50                  |
| 'Wheel' | 'cars'   | 4700                |

## RECURSIVE clause

The **RECURSIVE** keyword allows construction recurrent queries (the table expression sub-queries definition contains its own name). A recursive table expression is composed of the non-recursive part and a recursive part (which references the sub-queries by its CTE name). The recursive and non-recursive parts **must** be combined using the **UNION ALL** query operator. The recursive part should be defined in such way, that no cycle will be generated. Also if the recursive part contains aggregate functions, it should also contain a **GROUP BY** clause, because aggregate functions will return always a tuple and the recursive iterations will never stop. The recursive part will stop iterating when the conditions from **WHERE** clause are no longer true, and the current iteration return no results.

```

WITH
  RECURSIVE cars (id, parent_id, item, price) AS (
    SELECT id, parent_id, item, price
      FROM products WHERE item LIKE 'Car%'
    UNION ALL
    SELECT p.id, p.parent_id, p.item, p.price
      FROM products p
    INNER JOIN cars rec_cars ON p.parent_id =
rec_cars.id)
SELECT item, price FROM cars ORDER BY 1;

```

| item     | price |
|----------|-------|
| 'Car'    | 20000 |
| 'Engine' | 4000  |
| 'Frame'  | 4700  |
| 'Wheel'  | 100   |

Recursive CTEs may fall into an infinite loop. To avoid such case, set the system parameter **cte\_max\_recurSIONs** to a desired threshold. Its default value is 2000 recursive iterations, maximum is 1000000 and minimum 2.

```
SET SYSTEM PARAMETERS 'cte_max_recurSIONs=2';
WITH
  RECURSIVE cars (id, parent_id, item, price) AS (
    SELECT id, parent_id, item, price
      FROM products WHERE item LIKE 'Car%'
    UNION ALL
    SELECT p.id, p.parent_id, p.item, p.price
      FROM products p
      INNER JOIN cars rec_cars ON p.parent_id =
rec_cars.id)
SELECT item, price FROM cars ORDER BY 1;
```

In the command **from** line 9,  
Maximum recursions 2 reached executing CTE.

#### Warning

- Depending on the complexity of the CTE sub-queries, the result set can grow very large for sub-queries which produces large amount of data. Even the default value of **cte\_max\_recurSIONs** may not be enough to avoid starvation of disk space.

#### The execution algorithm of a recursive CTE may be summarized as:

- execute the non recursive part of CTE and add its results to then final result set
- execute the recursive part using the result set obtained by the non recursive part, add its results to the final result set and memorize the start and end of the current iteration within the result set.
- repeat the non recursive part execution using the result set from previous iteration and add its results to the final result set
- if a recursive iteration produces no results, then stop
- if the configured maximum number of iterations is reached, also stop

The recursive CTE must be referenced directly in the **FROM** clause, referencing it in sub-query will prompt an error:

```
WITH
  RECURSIVE cte1(x) AS SELECT c FROM t1 UNION ALL SELECT * FROM
  (SELECT cte1.x + 1 FROM cte1 WHERE cte1.x < 5)
  SELECT * FROM cte1;
```

```
before '
SELECT * FROM cte1;
'
```

Recursive CTE 'cte1' must be referenced directly **in** its recursive query.

## CTE Usage in DMLs and CREATE

Besides their use for **SELECT** statements, CTEs can also be used for other statements. CTEs can be used in **CREATE TABLE** *table\_name* **AS SELECT**:

```
CREATE TABLE inc AS
  WITH RECURSIVE cte (n) AS (
    SELECT 1
    UNION ALL
    SELECT n + 1
    FROM cte
    WHERE n < 3)
  SELECT n FROM cte;

SELECT * FROM inc;
```

```
      n
=====
      1
      2
      3
```

Also, **INSERT/REPLACE INTO** *table\_name* **SELECT** can use CTE:

```
INSERT INTO inc
  WITH RECURSIVE cte (n) AS (
    SELECT 1
    UNION ALL
    SELECT n + 1
    FROM cte
    WHERE n < 3)
  SELECT * FROM cte;
```

```

REPLACE INTO inc
  WITH cte AS (SELECT * FROM inc)
  SELECT * FROM cte;

```

Also, in subclauses of **UPDATE** statement:

```

CREATE TABLE green_products (producer_id INTEGER, sales_n INTEGER,
product VARCHAR, product_type INTEGER, price INTEGER);
INSERT INTO green_products VALUES (1, 99, 'bicycle', 1, 99);
INSERT INTO green_products VALUES (2, 337, 'bicycle', 1, 129);
INSERT INTO green_products VALUES (3, 5012, 'bicycle', 1, 199);
INSERT INTO green_products VALUES (1, 989, 'scooter', 2, 899);
INSERT INTO green_products VALUES (3, 3211, 'scooter', 2, 599);
INSERT INTO green_products VALUES (4, 2312, 'scooter', 2, 1009);

WITH price_increase_th AS (
  SELECT SUM (sales_n) * 7 / 10 AS threshold, product_type
  FROM green_products
  GROUP BY product_type
)
  UPDATE green_products gp JOIN price_increase_th th ON
gp.product_type = th.product_type
  SET price = price + (price / 10)
  WHERE sales_n >= threshold;

```

And also, in subclauses of **DELETE** statement:

```

WITH product_removal_th AS (
  SELECT SUM (sales_n) / 20 AS threshold, product_type
  FROM green_products
  GROUP BY product_type
)
  DELETE
  FROM green_products gp
  WHERE sales_n < (select threshold from product_removal_th WHERE
product_type = gp.product_type);

```

## CALL

The **CALL** statement invokes a stored routine defined in the database. The stored routines supported by CUBRID are as follows.

- **CREATE PROCEDURE**
- **CREATE FUNCTION**

• Method

```
CALL <routine_clause> ;

<routine_clause> ::=
    routine_name ([<arg_value> [{, <arg_value> } ...]])
[<method_call_target>] [<to_variable>]

<arg_value>
    literal |
    :host_variable |
    any CSQL expression

<method_call_target> ::=
    ON [CLASS] object-valued-expression

<to_variable> ::=
    INTO :host_variable |
    TO :host_variable
```

- *routine\_name*: Specifies the method name or stored function/procedure name. It is not case-sensitive.
- *<arg\_value>*: Specifies the arguments of the stored routine. The argument can be a literal value, host variable, and any expression.
- *<method\_call\_target>*: Specifies only when using a method written in C. Specifies an object-valued-expression containing a class name, a variable, or another method call (which returns an object). To call a class method for a class object, you must place the **CLASS** keyword before the *<call\_target>*. In this case, the table name must be the name of the class where the table method is defined. To call a record method, you must specify the expression representing the record object.
- *<to\_variable>*: The value returned by the stored routine can be stored in a host variable.

For *routine\_name* of the **CALL** statement, CUBRID searches a stored routine as follows.

1 It is processed as a method if there is a target class in the **CALL** statement. 2 If there is no target class in the **CALL** statement, it is checked whether a Java stored function/procedure is executed or not; a Java stored function/procedure will be executed if one exists. 3 If no Java stored function/procedure exists in step 2 above, it is checked whether a method is executed or not; a method will be executed if one with the same name exists.

```
CALL Hello() INTO :HELLO;
CALL Sp_int(3) INTO :i;
CALL phone_info('Tom', '016-111-1111');
```

The following error occurs if you call a Java stored function/procedure that does not exist.

- If there is **no argument** in the **CALL** statement, a message “ERROR: Stored procedure/function ‘deposit’ does not exist.” appears because it can be distinguished from a method.
- if there is **an argument** in the **CALL** statement, a message “ERROR: Methods require an object as their target.” appears because it cannot be distinguished from a method.

```
// there is not argument in the CALL statement  
CALL deposit();
```

```
ERROR: Stored procedure/function 'deposit' does not exist.
```

```
// there are arguments in the CALL statement  
CALL deposit('Tom', 3000000);
```

```
ERROR: Methods require an object as their target.
```

If the **CALL** statement is nested within another **CALL** statement calling a Java stored function/procedure, or if a subquery is used in calling the Java function/procedure, the **CALL** statement is not executed.

```
CALL phone_info('Tom', CALL sp_int(999));  
CALL phone_info((SELECT * FROM Phone WHERE id='Tom'));
```

## Query Optimization

### Join Methods

A Relational database stores data by dividing it into multiple tables through normalization. This approach effectively reduces data redundancy and ensures data integrity. However, to query the divided data in an integrated manner, relationships between tables must be combined. A join operation combines these relationships and returns results as if they were from a single table.

#### Join Type

The records included in the join results depend on the specified type of join. For more details, refer to [Join Query](#).

## Join Method

The way records are combined between tables depends on the join method used. CUBRID supports the following join methods:

- [Nested Loop Join](#)
- [Sort-Merge Join](#)
- [Hash Join](#)

Join methods are determined by the query optimizer based on a cost comparison, though users can also specify them manually. The query optimizer calculates the cost of each join method using statistics collected by the database. It then selects the method with the lowest cost. When a query includes two or more joins, different join methods can be applied to each join. Each join method operates on only two tables at a time and is executed sequentially. In other words, the next join is performed only after the previous one has been completed.

By default, CUBRID does not generate execution plans for **Sort-Merge Joins** or **Hash Joins**. [SQL hints](#) are required for the optimizer to consider these join methods. The **optimizer\_enable\_merge\_join** parameter can be set to **yes** (default is **no**) to enable a **Sort-Merge Join** without requiring the **USE\_MERGE** hint. For more details, refer to [Other Parameters](#).

### Note

The term **table** here is used broadly to include not only physical tables but also views (virtual tables) and derived tables.

## Nested Loop Join

A nested loop join reads records from the outer table one at a time and combines each record with matching records from the inner table. This approach is similar to the concept of nested loops in programming. The table used in the outer loop is referred to as the **driving table**, while the table in the inner loop is called the **driven table**.

### Driving Table

When selecting a driving table from two tables, it is generally more efficient to choose the table with fewer records. Fewer records in the driving table result in fewer join operations, reducing the overall cost of the join. Since random access costs are typically constant, fewer join operations on the driven table lead to lower join costs and better performance. The query optimizer automatically selects the driving table by comparing join costs, but users can specify the driving table explicitly using **ORDERED** or **LEADING** hints.

## Driven Table

A nested loop join performs efficiently when random access to the driven table is possible. For random access, a join-compatible index must be created on the driven table. If no such index exists, all records in the driven table must be read sequentially, which degrades join performance. When random access to the driven table is enabled through a join-compatible index, the nested loop join is displayed as an **Index Join (idx-join)** in the execution plan.

## Partial Range Processing

Nested loop joins can perform join operations by reading just one record from each table, and they maintain join results that can be returned immediately, even if the join is not completed for all records. This behavior enables partial range processing: if only the first N results are needed, they are returned as soon as those N results are ready. Partial range processing improves overall join performance by avoiding unnecessary join operations.

## Hash List Scan

If the driven table is a view or a derived table, the index cannot be used, so the join is performed using the list scan method, which sequentially reads records from the temporary result. Hash list scan is a type of list scan that allows random access to records in the temporary result that satisfy the join condition. Since list scan reads records from a temporary result, it cannot be used for physical tables. Therefore, hash list scan can only be used when the driven table is a view or a derived table. Hash list scan operates similarly to a **hash join** and can be used only when all join conditions are equality conditions. The use of hash list scan can be verified through **query profiling**.

The differences between hash list scan and hash join are as follows:

1. Hash list scan builds the hash table using only the driven table.
2. Hash list scan is part of a nested loop join, enabling partial range processing.

The query optimizer does not consider whether a hash list scan is performed when calculating the cost of a join.

### Example 1. Nested Loop Join without Index Scans

In this example, the driven table does not utilize an index scan during the nested loop join. The **ORDERED** hint is applied to enforce the join order, making the nation table the driving table and the athlete table the driven table. Since the driven table lacks an index appropriate for the join condition, all records in the athlete table are read sequentially for each record in the nation table.

```
select /*+ recompile ordered use_nl */  
      n.name, a.name  
from  
      nation as n
```

```
inner join athlete as a on n.code = a.nation_code
where
  n.continent = 'Asia'
  and a.event = 'Baseball';
```

Query plan:

```
nl-join (inner join)
  edge: term[0]
  outer: sscan
    class: n node[0]
    sargs: term[2]
    cost: 2 card 31
  inner: sscan
    class: a node[1]
    sargs: term[0] AND term[1]
    cost: 49 card 202
  cost: 4697 card 29
```

Trace Statistics:

```
SELECT (time: 92, fetch: 1720, fetch_time: 0, ioread: 0)
  SCAN (table: public.nation), (heap time: 0, fetch: 216,
ioread: 0, readrows: 215, rows: 47)
    SCAN (table: public.athlete), (heap time: 92, fetch:
1504, ioread: 0, readrows: 313819, rows: 103)
```

### Execution Steps:

1. Read a record from the nation table that satisfies the filter condition (`n.continent = 'Asia'`).
2. Read a record from the athlete table that satisfies both the filter condition (`a.event = 'Baseball'`) and join condition (`n.code = a.nation_code`).
3. If the condition is met, combine the two records and add them to the result.
4. Repeat **step 2** for the next record in the athlete table.
5. Repeat **steps 1-3** for the next record in the nation table.
6. Continue until all records from both tables are processed.

### Example 2. Nested Loop Join with Index Scans

This example demonstrates a nested loop join where the driven table uses an index scan. An index suitable for the join condition is created on the driven table (athlete). As a result, not all

records in the athlete table need to be scanned for each record in the nation table, enabling random access.

```
create index i_athlete_nation_code on athlete (nation_code);

select /*+ recompile ordered use_nl */
      n.name, a.name
from
      nation as n
    inner join athlete as a on n.code = a.nation_code
where
      n.continent = 'Asia'
    and a.event = 'Baseball';

drop index i_athlete_nation_code on athlete;
```

Query plan:

```
idx-join (inner join)
  outer: sscan
        class: n node[0]
        sargs: term[2]
        cost: 2 card 31
  inner: iscan
        class: a node[1]
        index: i_athlete_nation_code term[0]
        sargs: term[1]
        cost: 4 card 202
  cost: 68 card 29
```

Trace Statistics:

```
SELECT (time: 1, fetch: 1265, fetch_time: 0, ioread: 0)
  SCAN (table: public.nation), (heap time: 1, fetch: 216,
ioread: 0, readrows: 215, rows: 47)
    SCAN (index: public.athlete.i_athlete_nation_code),
(btrees time: 0, fetch: 1045, ioread: 0, readkeys: 24,
filteredkeys: 0, rows: 948) (lookup time: 0, rows: 103)
```

Compared to [Example 1](#), the number of records read from the athlete table before comparing the join conditions is significantly reduced (`readrows: 313,819` -> `rows: 948`).

### Example 3. Performance Differences Depending on the Driving Table

This example changes the driving table to athlete, unlike previous examples where nation was the driving table. The **LEADING** hint is used to specify the join order, making athlete the driving table and nation the driven table.

```
select /** recompile leading(a, n) use_nl */
       n.name, a.name
from
       nation as n
       inner join athlete as a on n.code = a.nation_code
where
       n.continent = 'Asia'
       and a.event = 'Baseball';
```

Query plan:

```
idx-join (inner join)
  outer: sscan
        class: a node[0]
        sargs: term[1]
        cost:  49 card 202
  inner: iscan
        class: n node[1]
        index: pk_nation_code term[0]
        sargs: term[2]
        cost:  2 card 31
cost:  161 card 29
```

Trace Statistics:

```
SELECT (time: 5, fetch: 7168, fetch_time: 0, ioread: 0)
  SCAN (table: public.athlete), (heap time: 5, fetch:
6709, ioread: 0, readrows: 6677, rows: 229)
    SCAN (index: public.nation.pk_nation_code), (btree
time: 0, fetch: 458, ioread: 0, readkeys: 229,
filteredkeys: 0, rows: 229) (lookup time: 0, rows: 103)
```

Using athlete as the driving table leads to a decrease in performance due to its higher number of records.

#### Example 4. Nested Loop Join with Hash List Scan

This example demonstrates a nested loop join where a hash list scan is performed on the driven table. By combining the **ORDERED** and **NO\_MERGE** hints, an inline view that cannot perform an index scan is used as the driven table. Additionally, the query retrieves only the first 20 results, allowing partial range processing to be combined with the hash list scan.

```
select /** recompile ordered use_nl */
       n.name, v.name
from
       nation as n
       inner join (
```

```

select /** no_merge */
  a.name, a.nation_code
from
  athlete as a
where
  a.event = 'Baseball'
) as v on n.code = v.nation_code
where
  n.continent = 'Asia'
limit 20;

```

Query plan:

```

nl-join (inner join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        sargs: term[1] AND term[2]
        cost: 2 card 31
  inner: sscan
        class: v node[1]
        sargs: term[0]
        cost: 2 card 202
  sargs: term[1]
  cost: 148 card 29

```

Trace Statistics:

```

SELECT (time: 2, fetch: 33, fetch_time: 0, ioread: 0)
  SCAN (table: public.nation), (heap time: 0, fetch: 1,
ioread: 0, readrows: 26, rows: 8)
    SCAN (hash temp(m), build time: 0, time: 0, fetch: 0,
ioread: 0, readrows: 249, rows: 20)
      SUBQUERY (uncorrelated)
        SELECT (time: 2, fetch: 32, fetch_time: 0, ioread: 0)
          SCAN (table: public.athlete), (heap time: 2, fetch:
32, ioread: 0, readrows: 6677, rows: 229)

```

Hash list scans can be confirmed through query profiling but are not explicitly shown in the execution plan.

## Sort-Merge Join

A sort merge join combines records from two tables by first sorting them based on the join condition and then sequentially comparing the sorted records. This method can only be performed when the join condition is an equality condition.

The process of sorting data from two tables before joining is similar to creating an index in real time. However, the sorting process is not skipped even if a join-compatible index exists. The process of combining the sorted data is similar to a nested loop join in that it performs the join operation by reading one record from each of the two sorted temporary results. The buffer size used during the sorting process can be set with the **sort\_buffer\_size** parameter. For more details, refer to [Memory-Related Parameters](#).

### Join Cost

Sort-merge joins can become inefficient when the sorting step incurs a high cost. When the query optimizer compares the costs of join methods, nested loop joins are often evaluated as having relatively low cost because they do not require preprocessing, Hash joins also tend to have lower cost since they build a hash table using data from only one of the two tables. In contrast, sort-merge joins are evaluated as having higher cost because they need to sort the data from both tables.

### Partial Range Processing

Sort-merge joins cannot perform partial range processing because they can only proceed after the sorting of both tables is complete. As a result, even if only the first N results are needed, the query will return results only after the entire join process has finished.

### Example 1. Execution Process of a Sort-Merge Join

This example demonstrates the steps involved in executing a sort-merge join. Although the **ORDERED** hint does not directly impact join performance, it is included here to ensure the join is performed in the specified order.

```
create index i_nation_continent_code on nation (continent,
code);
create index i_athlete_event_nation_code on athlete (event,
nation_code);

select /*+ recompile ordered use_merge */
      n.name, a.name
from
      nation as n
      inner join athlete as a on n.code = a.nation_code
where
      n.continent = 'Asia'
      and a.event = 'Baseball';

drop index i_nation_continent_code on nation;
drop index i_athlete_event_nation_code on athlete;
```

Query plan:

```

temp
  order: UNORDERED
  subplan: m-join (inner join)
    edge: term[0]
    outer: temp
      order: code[0]
      subplan: iscan
        class: n node[0]
        index:
i_nation_continent_code term[1]
      cost: 2 card 1
      cost: 8 card 1
      inner: temp
        order: nation_code[1]
        subplan: iscan
          class: a node[1]
          index:
i_athlete_event_nation_code term[2]
      cost: 2 card 7
      cost: 8 card 7
      cost: 17 card 1
cost: 23 card 1

```

```

Trace Statistics:
  SELECT (time: 1, fetch: 287, fetch_time: 1, ioread: 0)
    SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 103,
rows: 103)
      MERGELIST
        SELECT (time: 0, fetch: 52, fetch_time: 0, ioread:
0)
          SCAN (index:
public.nation.i_nation_continent_code), (btree time: 0,
fetch: 49, ioread: 0, readkeys: 47, filteredkeys: 0, rows:
47) (lookup time: 0, rows: 47)
            ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
              SELECT (time: 1, fetch: 235, fetch_time: 1, ioread:
0)
                SCAN (index:
public.athlete.i_athlete_event_nation_code), (btree time:
1, fetch: 231, ioread: 0, readkeys: 6, filteredkeys: 0,
rows: 229) (lookup time: 1, rows: 229)
                  ORDERBY (time: 0, sort: true, page: 0, ioread: 0)

```

### Execution Steps:

1. Retrieve records from the nation table that meet the filter condition (`n.continent = 'Asia'`) and sort them by the code column.

```
select n.code, n.name from nation as n where n.continent =  
'Asia' order by n.code;
```

1. Retrieve records from the athlete table that meet the filter condition ( `a.event = 'Baseball'` ) and sort them by the `nation_code` column.

```
select a.nation_code, a.name from athlete as a where  
a.event = 'Baseball' order by a.nation_code;
```

1. Sequentially read records from the two sorted results, compare the join condition ( `n.code = a.nation_code` ), and if the condition is satisfied, combine the two records and add them to the result.
2. Repeat this process until all records have been processed and the join is complete.

## Hash Join

A hash join combines records from two tables by using a hash function to match records with the same hash value. To efficiently compare records with the same hash value, a hash table is used. One of the two tables is used to **build** the hash table, while the other is used to **probe** it. The hash value is generated by applying a hash function to the join column values. When different input values produce the same hash value, a hash collision occurs. In such cases, records with the same hash value are sequentially examined, and the join condition is checked. A hash join can only be performed when all join conditions are equality conditions.

## SQL Hints

There are two hints associated with hash joins:

- **USE\_HASH**: Allows the query optimizer to generate an execution plan using a hash join.
- **NO\_USE\_HASH**: Prevents the query optimizer from generating an execution plan using a hash join.

Both hints can specify one or more tables. The hint applies to the inner table (driven table) if a table is explicitly specified. If no table is specified, the hint applies to all tables. If the same table is specified in both the **USE\_HASH** and **NO\_USE\_HASH** hints, the **NO\_USE\_HASH** hint takes precedence.

## Cost Calculation

Each table in a hash join can either be used to build the hash table or to probe it. To determine the most efficient approach, the costs of both options are calculated and compared, with the

lower cost being selected as the hash join cost. For example, the following scenarios are compared, and the one with the lower cost is selected:

- Building the hash table with the outer table (driving table) and probing it with the inner table (driven table).
- Building the hash table with the inner table (driven table) and probing it with the outer table (driving table).

Table used to build the hash table

The table used to build the hash table cannot be explicitly specified using **ORDERED** or **LEADING** hints. The table with fewer records is typically chosen for building the hash table. However, in the case of outer joins, the table used to build the hash table is fixed based on the join direction:

- **Left Outer Join:** The right table is used to build the hash table.
- **Right Outer Join:** The left table is used to build the hash table.

How to build the hash table

The method used to build the hash table depends on the size of the temporary results and the maximum size of the hash table. The maximum hash table size can be configured using the **max\_hash\_list\_scan\_size** parameter. For more details, refer to [Memory-Related Parameters](#).

CUBRID supports the following hashing methods:

- **Memory Hash:** Used when all temporary results can fit in the hash table.

```
Number of temporary result pages * Page size <= Maximum
hash table size
```

- **Hybrid Hash:** Used when the hash table can store the positions of all temporary result records.

```
Number of temporary result records * (Hash entry size +
Position information size <= Maximum hash table size
```

- **File Hash:** Used when neither of the above methods is applicable.
- **Skip Hash:** If either of the two temporary results is empty or unnecessary (in the case of an outer join), building the hash table is skipped.

**Hybrid Hash** and **File Hash** store record positions in the hash table, requiring an additional step to locate records before reading them.

**Memory Hash** and **Hybrid Hash** use memory pages to build the hash table, whereas **File Hash** uses temporary volume pages. Accessing pages in a temporary volume incurs additional logical I/O, which can lead to performance degradation.

During query execution, once the join is complete, the hash table is deleted, and the memory it occupied is released. The specific hash method used during a hash join can be identified through query profiling. For details, refer to [Query Profiling](#).

### Partial Range Processing

Hash joins cannot perform partial range processing because the join can only proceed after the hash table has been fully built.

### Example 1. Execution Process of a Hash Join

This example explains the steps involved in performing a hash join. Even with the **ORDERED** hint, the table used to build the hash table cannot be explicitly specified.

```
select /* recompile ordered use_hash */
      n.name, a.name
from
      nation as n
      inner join athlete as a on n.code = a.nation_code
where
      n.continent = 'Asia'
      and a.event = 'Baseball';
```

### Query plan:

```
hash-join (inner join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        sargs: term[2]
        cost: 2 card 31
  inner: sscan
        class: a node[1]
        sargs: term[1]
        cost: 49 card 202
  cost: 63 card 29
```

### Trace Statistics:

```
SELECT (time: 2, fetch: 33, fetch_time: 0, ioread: 0)
  SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 103,
rows: 103)
  HASHJOIN (time: 2, fetch: 33, fetch_time: 0, ioread:
0)
```

```

BUILD (time: 0, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: memory)
  SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
    SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 47)
      PROBE (time: 2, probe_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, readkeys: 103, rows: 103,
max_collisions: 1)
        SELECT (time: 2, fetch: 32, fetch_time: 0,
ioread: 0)
          SCAN (table: public.athlete), (heap time: 1,
fetch: 32, ioread: 0, readrows: 6677, rows: 229)

```

The nation table contains 47 records that satisfy the filter condition (`n.continent = 'Asia'`), and the athlete table contains 229 records that satisfy the filter condition (`a.event = 'Baseball'`). Thus, the nation table with fewer records is selected to build the hash table.

### Query Profiling Results:

This section describes only the query profiling items related to hash joins. For details on other items, refer to [Query Profiling](#).

#### 1. HASHJOIN

- **time**: Total execution time for hash join (ms)
- **fetch**: Pages fetched during the hash join
- **fetch\_time**: Time spent fetching pages for the hash join (ms)
- **ioread**: Number of physical I/O reads during page fetches for the hash join

1. **BUILD**: Except for **time**, the remaining items do not include cumulative information when querying temporary results.

- **time**: Total time for building the hash table, including temporary results (ms)
- **build\_time**: : Time specifically spent building the hash table (ms)
- **fetch**: Pages fetched during the hash table build
- **fetch\_time**: Time spent fetching pages for the hash table build (ms)
- **ioread**: Physical I/O reads during the hash table build

- **hash\_method**: Method used to build the hash table (**memory**, **hybrid**, **file**, or **skip**)
  - **memory**: Use the memory hashing method
  - **hybrid**: Use the hybrid hashing method
  - **file**: Use the file hashing method
  - **skip**: Skip building the hash table
- 1. **PROBE**: Except for **time**, the remaining items do not include cumulative information when querying temporary results.
  - **time**: Total time for probing the hash table, including temporary results (ms)
  - **probe\_time**: Time specifically spent probing the hash table (ms)
  - **fetch**: Pages fetched during the hash table probe
  - **fetch\_time**: Time spent fetching pages for the hash table probe (ms)
  - **ioread**: Physical I/O reads during the hash table probe
  - **readkeys**: Number of records with matching hash values during the probe
  - **rows**: Number of records satisfying the join condition (**readkeys** >= **rows**)
  - **max\_collisions**: Maximum number of records read for a single hash value during probing

### Execution Steps:

1. Retrieve records from the nation table that satisfy the filter condition ( `n.continent = 'Asia'` ) and create a temporary result.

```
select n.code, n.name from nation as n where
n.continent = 'Asia';
```

1. Retrieve records from the athlete table that satisfy the filter condition ( `a.event = 'Baseball'` ) and create a temporary result.

```
select a.nation_code, a.name from athlete as a
where a.event = 'Baseball';
```

1. Read the temporary result from the nation table and build a hash table.
2. For each record in the temporary result from the athlete table, probe the hash table of the nation table.
3. Match records( `readkeys` ) in the hash table with the same hash value and compare them against the join condition ( `n.code = a.nation_code` ). If the condition is satisfied( `rows` ), combine the records and add them to the result.
4. Repeat **step 5** for subsequent records with the same hash value.
5. Repeat **steps 4-6** for the next record in the athlete table.
6. Continue until all join operations are complete.

## 예시 2. Hash join using hints

This example demonstrates how to use the **USE\_HASH** and **NO\_USE\_HASH** hints to control which tables perform a hash join. The **ORDERED** hint is used to fix the inner table (driven table) for applying the hint.

```
select /** recompile ordered use_hash no_use_hash(r) */
       n.name, a.name, a.code, r.medal
from
  nation as n
  inner join athlete as a on n.code = a.nation_code
  inner join record as r on a.code = r.athlete_code
where
  n.continent = 'Asia'
  and a.event = 'Shooting'
  and r.host_year = 1992;
```

Query plan:

```
idx-join (inner join)
  outer: hash-join (inner join)
    edge: term[0]
    outer: sscan
      class: n node[0]
      sargs: term[3]
      cost: 2 card 31
    inner: sscan
      class: a node[1]
      sargs: term[2]
```

```

                                cost: 49 card 202
                                cost: 63 card 29
inner: iscan
      class: r node[2]
      index:
pk_record_host_year_event_code_athlete_code_medal term[4]
(covers)
      filtr: term[1]
      cost: 5 card 400
cost: 109 card 2

```

The **USE\_HASH** hint specifies that a hash join is performed for the nation and athlete tables.

The **NO\_USE\_HASH** hint ensures that a hash join is not performed for the record table.

```

Trace Statistics:
  SELECT (time: 5, fetch: 139, fetch_time: 0, ioread: 0)
    SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 35,
rows: 35)
      SCAN (index:
public.record.pk_record_host_year_event_code_athlete_code_me
dal), (btree time: 3, fetch: 105, ioread: 0, readkeys: 7,
filteredkeys: 0, rows: 7, covered: true)
        HASHJOIN (time: 2, fetch: 33, fetch_time: 0, ioread:
0)
          BUILD (time: 1, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: memory)
            SELECT (time: 1, fetch: 1, fetch_time: 0, ioread:
0)
              SCAN (table: public.nation), (heap time: 1,
fetch: 1, ioread: 0, readrows: 215, rows: 47)
                PROBE (time: 1, probe_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, readkeys: 35, rows: 35,
max_collisions: 1)
                  SELECT (time: 1, fetch: 32, fetch_time: 0,
ioread: 0)
                    SCAN (table: public.athlete), (heap time: 1,
fetch: 32, ioread: 0, readrows: 6677, rows: 173)

```

Example 3. Hash join with index skip scan

This example demonstrates using an index skip scan to retrieve temporary results during a hash join.

```

/* for nested loop join */
create index i_athlete_nation_code_event on athlete
(nation_code, event);

/* for hash join */

```

```

create index i_nation_continent_code on nation (continent,
code);

select /** recompile use_hash index_ss */
      n.name, a.name
from
      nation as n
      inner join athlete as a on n.code = a.nation_code
where
      n.continent = 'Asia'
      and a.event = 'Baseball';

drop index i_athlete_nation_code_event on athlete;
drop index i_nation_continent_code on nation;

```

Query plan:

```

hash-join (inner join)
  edge: term[0]
  outer: iscan
        class: n node[0]
        index: i_nation_continent_code term[1]
        cost: 2 card 1
  inner: iscan
        class: a node[1]
        index: i_athlete_nation_code_event term[2]
(index skip scan)
        cost: 13 card 202
  cost: 25 card 1

```

Trace Statistics:

```

SELECT (time: 1, fetch: 748, fetch_time: 0, ioread: 0)
  SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 103,
rows: 103)
    HASHJOIN (time: 1, fetch: 748, fetch_time: 0, ioread:
0)
      BUILD (time: 0, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: memory)
        SELECT (time: 0, fetch: 52, fetch_time: 0,
ioread: 0)
          SCAN (index:
public.nation.i_nation_continent_code), (btree time: 0,
fetch: 49, ioread: 0, readkeys: 47, filteredkeys: 0, rows:
47) (lookup time: 0, rows: 47)
            PROBE (time: 1, probe_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, readkeys: 103, rows: 103,
max_collisions: 1)
              SELECT (time: 1, fetch: 696, fetch_time: 0,
ioread: 0)

```

```

SCAN (index:
public.athlete.i_athlete_nation_code_event), (btree time:
1, fetch: 692, ioread: 0, readkeys: 121, filteredkeys: 0,
rows: 229) (lookup time: 0, rows: 229)

```

#### Example 4. Hash Right Outer Join

This example illustrates how the direction of an outer join determines which table is used to build the hash table.

```

select /*+ recompile use_hash */
      n.name, p.host_year, p.gold
from
      participant as p
      right outer join nation as n on n.code = p.nation_code
and p.gold > 0
where
      n.continent = 'Asia';

```

#### Query plan:

```

hash-join (right outer join)
  edge: term[0]
  outer: sscan
        class: p node[0]
        sargs: term[1]
        cost: 5 card 92
  inner: sscan
        class: n node[1]
        sargs: term[2]
        cost: 2 card 31
cost: 15 card 31

```

#### Trace Statistics:

```

SELECT (time: 1, fetch: 4, fetch_time: 0, ioread: 0)
  SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 70,
rows: 70)
    HASHJOIN (time: 0, fetch: 4, fetch_time: 0, ioread: 0)
      BUILD (time: 0, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: memory)
        SELECT (time: 0, fetch: 3, fetch_time: 0, ioread:
0)
          SCAN (table: public.participant), (heap time:
0, fetch: 3, ioread: 0, readrows: 916, rows: 228)
            PROBE (time: 0, probe_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, readkeys: 36, rows: 70,
max_collisions: 5)

```

```
SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
      SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 47)
```

The participant table contains 228 records that satisfy the filter condition (`p.gold > 0`), while the nation table contains 47 records that meet the filter condition (`n.continent = 'Asia'`). Even though the participant table has more records, in a right outer join, the left table (participant) is used to build the hash table.

#### Example 5. Hash Outer Join Skipping Hash Table Build

This example demonstrates a hash outer join where the hash table build is skipped. In a left outer join, the right table is typically used to build the hash table. However, since no records in the participant table satisfy the filter condition (`p.gold > 100`), the hash table build is skipped. Instead, records from the nation table that satisfy the filter condition (`n.continent = 'Asia'`) are directly returned as the query result.

```
select /*+ recompile use_hash */
      n.name, p.host_year, p.gold
from
      nation as n
      left outer join participant as p on n.code =
p.nation_code and p.gold > 100
where
      n.continent = 'Asia';
```

#### Query plan:

```
hash-join (left outer join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        sargs: term[2]
        cost: 2 card 31
  inner: sscan
        class: p node[1]
        sargs: term[1]
        cost: 5 card 92
cost: 15 card 31
```

#### Trace Statistics:

```
SELECT (time: 1, fetch: 4, fetch_time: 0, ioread: 0)
      SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 47,
rows: 47)
      HASHJOIN (time: 1, fetch: 4, fetch_time: 0, ioread: 0)
```

```

        BUILD (time: 1, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: skip)
        SELECT (time: 1, fetch: 3, fetch_time: 0, ioread:
0)
            SCAN (table: public.participant), (heap time:
1, fetch: 3, ioread: 0, readrows: 916, rows: 0)
            PROBE (time: 0, probe_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, readkeys: 0, rows: 47,
max_collisions: 0)
            SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
                SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 47)

```

In the **BUILD** section, the hash table build method is displayed as `hash_method: skip`. This indicates that the hash table was not built. Instead, the records from the nation table satisfying the filter condition (`n.continent = 'Asia'`) constitute the query result.

#### Example 6. Hash Join Using the Hybrid Hash Method

This example demonstrates how to perform a hash join using the hybrid hash method. Because the data set is small, the hash table's maximum size must be reduced to use the hybrid hash method. To do this, set the **max\_hash\_list\_scan\_size** parameter to **12K** (default: **8M**).

```

set system parameters 'max_hash_list_scan_size=12k';

select /*+ recompile use_hash */
    count (*)
from
    nation as n
    inner join athlete as a on n.code = a.nation_code;

set system parameters 'max_hash_list_scan_size=8M';

```

Query plan:

```

hash-join (inner join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        cost: 2 card 215
  inner: sscan
        class: a node[1]
        cost: 49 card 6677
  cost: 400 card 6677

```

```

Trace Statistics:
  SELECT (time: 5, fetch: 126, fetch_time: 0, ioread: 0)
    SCAN (temp time: 0, fetch: 19, ioread: 0, readrows:
6677, rows: 6677)
      HASHJOIN (time: 5, fetch: 105, fetch_time: 0, ioread:
0)
        BUILD (time: 0, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: hybrid)
          SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
            SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 215)
              PROBE (time: 5, probe_time: 2, fetch: 49,
fetch_time: 0, ioread: 0, readkeys: 6692, rows: 6677,
max_collisions: 2)
                SELECT (time: 3, fetch: 53, fetch_time: 0,
ioread: 0)
                  SCAN (table: public.athlete), (heap time: 2,
fetch: 32, ioread: 0, readrows: 6677, rows: 6677)

```

When more than one join hint is used on the same table, the query optimizer compares the costs of the specified join methods and selects the one with the lower cost. The selected join method can be verified through the generated execution plan. The following is an example where the **USE\_HASH** and **USE\_NL** hints are used together, and the query optimizer selects the hybrid hash method, generating and executing the execution plan as a hash join.

```

set system parameters 'max_hash_list_scan_size=12k';

select /*+ recompile use_hash use_nl */
  count (*)
from
  nation as n
  inner join athlete as a on n.code = a.nation_code;

set system parameters 'max_hash_list_scan_size=8M';

```

Query plan:

```

hash-join (inner join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        cost: 2 card 215
  inner: sscan
        class: a node[1]
        cost: 49 card 6677
  cost: 400 card 6677

```

```

Trace Statistics:
  SELECT (time: 5, fetch: 126, fetch_time: 0, ioread: 0)
    SCAN (temp time: 1, fetch: 19, ioread: 0, readrows:
6677, rows: 6677)
      HASHJOIN (time: 4, fetch: 105, fetch_time: 0, ioread:
0)
        BUILD (time: 0, build_time: 0, fetch: 0,
fetch_time: 0, ioread: 0, hash_method: hybrid)
          SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
            SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 215)
              PROBE (time: 4, probe_time: 2, fetch: 49,
fetch_time: 0, ioread: 0, readkeys: 6692, rows: 6677,
max_collisions: 2)
                SELECT (time: 2, fetch: 53, fetch_time: 0,
ioread: 0)
                  SCAN (table: public.athlete), (heap time: 2,
fetch: 32, ioread: 0, readrows: 6677, rows: 6677)

```

#### Example 7. Hash Join Using the File Hash Method

This example demonstrates how to perform a hash join using the file hash method. Because the data set is small, the hash table's maximum size must be reduced to below **12K** to use the file hash method. To do this, set the **max\_hash\_list\_scan\_size** parameter to **8K** (default: **8M**).

```

set system parameters 'max_hash_list_scan_size=8k';

select /*+ recompile use_hash */
  count (*)
from
  nation as n
  inner join athlete as a on n.code = a.nation_code;

set system parameters 'max_hash_list_scan_size=8M';

```

#### Query plan:

```

hash-join (inner join)
  edge: term[0]
  outer: sscan
        class: n node[0]
        cost: 2 card 215
  inner: sscan
        class: a node[1]
        cost: 49 card 6677
cost: 3846 card 6677

```

The query optimizer evaluates whether memory hashing or hybrid hashing can be used by calculating based on statistics collected by the database:

```
Temporary result record count * (Hash entry size + Location
info size) <= Maximum hash table size
                                     215 * (32 byte
* 16 byte) <= 8,192 byte
10,320 <= 8192 byte (False)
```

Since the calculated size exceeds the maximum size of the hash table, the file hash method is chosen instead of the memory or hybrid method. File hash methods (cost: 3,846) are more expensive than other hash methods (cost: 400) due to the use of temporary volume pages.

```
Trace Statistics:
  SELECT (time: 10, fetch: 27510, fetch_time: 3, ioread: 0)
    SCAN (temp time: 0, fetch: 19, ioread: 0, readrows:
6677, rows: 6677)
      HASHJOIN (time: 10, fetch: 27489, fetch_time: 3,
ioread: 0)
        BUILD (time: 1, build_time: 1, fetch: 645,
fetch_time: 1, ioread: 0, hash_method: file)
          SELECT (time: 0, fetch: 1, fetch_time: 0, ioread:
0)
            SCAN (table: public.nation), (heap time: 0,
fetch: 1, ioread: 0, readrows: 215, rows: 215)
              PROBE (time: 9, probe_time: 7, fetch: 26772,
fetch_time: 2, ioread: 0, readkeys: 6692, rows: 6677,
max_collisions: 2)
                SELECT (time: 2, fetch: 53, fetch_time: 0,
ioread: 0)
                  SCAN (table: public.athlete), (heap time: 1,
fetch: 32, ioread: 0, readrows: 6677, rows: 6677)
```

When compared with the query profiling results from [Example 6](#), it can be seen that the execution time of the file hash method is slow in proportion to the cost.

When more than one join hint is used on the same table, the query optimizer compares the costs of the specified join methods and selects the one with the lower cost. The selected join method can be verified through the generated execution plan. The following is an example where the **USE\_HASH** and **USE\_NL** hints are used together, and the query optimizer generates and executes a plan with a nested loop join (cost: 3,405) because the cost of a hash join (cost: 3,846) using the file hash method) is high.

```
set system parameters 'max_hash_list_scan_size=8k';
```

```
select /** recompile use_hash use_nl */
       count (*)
from
  nation as n
  inner join athlete as a on n.code = a.nation_code;

set system parameters 'max_hash_list_scan_size=8M';
```

Query plan:

```
idx-join (inner join)
  outer: sscan
        class: a node[1]
        cost:  49 card 6677
  inner: iscan
        class: n node[0]
        index: pk_nation_code term[0] (covers)
        cost:  2 card 215
cost:  3405 card 6677
```

Trace Statistics:

```
SELECT (time: 19, fetch: 13387, fetch_time: 1, ioread: 0)
SCAN (table: public.athlete), (heap time: 4, fetch:
6709, ioread: 0, readrows: 6677, rows: 6677)
SCAN (index: public.nation.pk_nation_code), (btree
time: 10, fetch: 6677, ioread: 0, readkeys: 6677,
filteredkeys: 0, rows: 0, covered: true, count_only: true)
```

## Updating Statistics

Statistics for tables and indexes enables queries of the database system to process efficiently. Statistics are not updated automatically for DDL statements such as **CREATE INDEX**, **CREATE TABLE** and DML statements such as **INSERT** and **DELETE**. **UPDATE STATISTICS** statement is the only way to update statistics. So it is necessary to update the statistics by **UPDATE STATISTICS** statement(See [Checking Statistics Information](#)).

**UPDATE STATISTICS** statement is recommended to be executed periodically. It is also recommended to execute when a new index is added or when a mass of **INSERT** or **DELETE** statements make the big difference between the statistics and the actual information.

When updating statistics, the execution plan cache related to those statistics is not deleted. The execution plan is regenerated when the following two criteria are met during query execution.

1. 6 minutes have passed since the execution plan cache creation or regeneration check

2. The page size increases or decreases by more than 10 times, and statistics are updated

The user can delete plan cache using the **PLANDUMP** utility. For more information about **PLANDUMP**, see [plandump](#).

```
UPDATE STATISTICS ON [schema_name.]class-name [{,  
[schema_name.]class-name}] [WITH FULLSCAN];  
  
UPDATE STATISTICS ON ALL CLASSES [WITH FULLSCAN];  
  
UPDATE STATISTICS ON CATALOG CLASSES [WITH FULLSCAN];
```

- **WITH FULLSCAN**: It updates the statistics with all the data in the specified table. If this is omitted, it updates the statistics with sampling data. The sampling data is 5000 pages regardless of total pages of table.
- **ALL CLASSES**: If the **ALL CLASSES** keyword is specified, the statistics on all the tables existing in the database are updated.
- **CATALOG CLASSES**: It updates the statistics of the catalog tables.

```
CREATE TABLE foo (a INT, b INT);  
CREATE INDEX idx1 ON foo (a);  
CREATE INDEX idx2 ON foo (b);  
  
UPDATE STATISTICS ON foo;  
UPDATE STATISTICS ON foo WITH FULLSCAN;  
  
UPDATE STATISTICS ON ALL CLASSES;  
UPDATE STATISTICS ON ALL CLASSES WITH FULLSCAN;  
  
UPDATE STATISTICS ON CATALOG CLASSES;  
UPDATE STATISTICS ON CATALOG CLASSES WITH FULLSCAN;
```

When starting and ending an update of statistics information, NOTIFICATION message is written on the server error log. You can check the updating term of statistics information by these two messages.

```
Time: 05/07/13 15:06:25.052 - NOTIFICATION *** file ../../src/  
storage/statistics_sr.c, line 123 CODE = -1114 Tran = 1, CLIENT =  
testhost:csql(21060), EID = 4  
Started to update statistics (class "code", oid : 0|522|3).
```

```
Time: 05/07/13 15:06:25.053 - NOTIFICATION *** file ../../src/  
storage/statistics_sr.c, line 330 CODE = -1115 Tran = 1, CLIENT =  
testhost:csql(21060), EID = 5
```

```
Finished to update statistics (class "code", oid : 0|522|3, error  
code : 0).
```

#### Note

From version 10.0 of CUBRID, on the HA environment, **UPDATE STATISTICS** on the master node is replicated to the slave/replica node.

#### Note

From version 11.3 of CUBRID, synonyms cannot be used when executing **UPDATE STATISTICS** statement.

```
/* CURRENT_USER: PUBLIC */  
CREATE TABLE t (c int);  
CREATE SYNONYM s for t;  
  
UPDATE STATISTICS ON t;  
/* Execute OK. */  
  
UPDATE STATISTICS ON s;  
/* ERROR: before ' ; '  
* Class public.s does not exist. */
```

#### Note

From version 11.4 of CUBRID, **SELECT** authorization is required when executing **UPDATE STATISTICS** statement.

## Checking Statistics Information

You can check the statistics Information with the session command of the CSQL Interpreter.

```
csql> ;info stats table_name
```

- *schema\_name*: Specifies the schema of the table. If omitted, the schema name of the current session is used.
- *table\_name*: Table name to check the statistics Information

The following shows the statistical information of *t1* table in CSQL interpreter.

```
CREATE TABLE t1 (code INT, name VARCHAR(20));
INSERT INTO t1 VALUES(1,'Park'),(2,'Park'),(3,'Joo'),(4,'Joo'),
(5,'Song');
CREATE INDEX i_t1_code ON t1(code,name);
UPDATE STATISTICS ON t1;
;info stats t1
```

```
CLASS STATISTICS
*****
Class name: t1 Timestamp: Thu Dec 19 15:15:10 2024
Total pages in class heap: 1
Total objects: 5
Number of attributes: 2
Attribute: code (integer)
    Number of Distinct Values: 5
    B+tree statistics:
        BTID: { 0 , 5760 }
        Cardinality: 5 (5,5) , Total pages: 3 , Leaf pages: 1 ,
Height: 2

Attribute: name (character varying)
    Number of Distinct Values: 3
```

- *Timestamp*: The time when the statistics were updated.
- *Total pages*: The number of pages in the table.
- *Total objects*: The total number of rows in the table.
- *Number of Distinct Values*: The number of values, with duplicates removed. The column **code** consists of all different values, so the NDV is 5. If type of the column is **LOB** or **VARCHAR** exceeding 4,000 characters, NDV is not generated. NDV is used to calculate **SELECTIVITY** in the optimizer. For more information, see [Optimizer Principle](#).

- B+tree statistics: Index statistics
  - *B+tree Cardinality*: The number of values from which the accumulated duplicates of the index key values have been removed. In the example above, **(5,5)** matches the index column **(code,name)**. The first **5** is the number of values from which the duplicates of the **code** column have been removed, and the second **5** is the number of values from which the duplicates of the two columns **code,name** have been removed.
  - *Total pages*: The total number of index pages.
  - *Leaf pages*: The number of pages in the index leaf block.
  - *Height*: The height of the B+tree index including the leaf block.

## Viewing Query Plan

To view a query plan for a CUBRID SQL query, you can use following methods.

- Press “show plan” button on CUBRID Manager.

- Change the value of the optimization level by running “;plan simple” or “;plan detail” on CSQL interpreter, or by using the **SET OPTIMIZATION** statement. You can get the current optimization level value by using the **GET OPTIMIZATION** statement. For details on CSQL Interpreter, see [Session Commands](#).

**SET OPTIMIZATION** or **GET OPTIMIZATION LEVEL** syntax is as following.

```
SET OPTIMIZATION LEVEL opt-level [;]  
GET OPTIMIZATION LEVEL [ { TO | INTO } variable ] [;]
```

- *opt-level* : This value specifies the optimization level and is associated with the following settings. Any other value will result in an error.
  - 1: Creates a query plan by performing query optimization and executes the query. This is a default value used in CUBRID, and does not have to be changed in most cases.
  - 2: Creates a query plan by performing query optimization. However, the query itself is not executed. In general, this value is not used; it is used together with the following values to be set for viewing query plans.
  - 257: Performs query optimization and outputs the created query plan. This value works for displaying the query plan by internally interpreting the value as 256+1 related with the value 1.
  - 258: Performs query optimization and outputs the created query plan, but does not execute the query. That is, this value works for displaying the query plan by internally interpreting the value as 256+2 related with the value 2. This setting is useful to examine the query plan but not to intend to see the query results.
  - 513: Performs query optimization and outputs the detailed query plan. This value works for displaying more detailed query plan than the value 257 by internally interpreting the value as 512+1.
  - 514: Performs query optimization and outputs the detailed query plan. However, the query is not executed. This value works for displaying more detailed query plan than the value 258 by internally interpreting the value as 512+2.

#### Note

If you configure the optimization level as not executing the query like 2, 258, or 514, all queries(not only SELECT, but also INSERT, UPDATE, DELETE, REPLACE, TRIGGER, SERIAL, etc.) are not executed.

The CUBRID query optimizer determines whether to perform query optimization and output the query plan by referring to the optimization level value set by the user.

The following shows the result which ran the query after inputting “;plan simple” or “SET OPTIMIZATION LEVEL 257;” in CSQL.

```
SET OPTIMIZATION LEVEL 257;
-- csql> ;plan simple
SELECT /** RECOMPILE */ DISTINCT h.host_year, o.host_nation
FROM history h INNER JOIN olympic o
ON h.host_year = o.host_year AND o.host_year > 1950;
```

Query plan:

```
Sort(distinct)
  Nested-loop join(h.host_year=o.host_year)
    Index scan(olympic o, pk_olympic_host_year, (o.host_year> ? :
0 ))
    Sequential scan(history h)
```

- Sort(distinct): Perform DISTINCT.
- Nested-loop join: Join method is Nested-loop.
- Index scan: Perform index-scan by using pk\_olympic\_host\_year index about olympic table. At that time, the condition which used this index is “o.host\_year > ?”.

The following shows the result which ran the query after inputting “;plan detail” or “SET OPTIMIZATION LEVEL 513;” in CSQL.

```
SET OPTIMIZATION LEVEL 513;
-- csql> ;plan detail

SELECT /** RECOMPILE */ DISTINCT h.host_year, o.host_nation
FROM history h INNER JOIN olympic o
ON h.host_year = o.host_year AND o.host_year > 1950;
```

```
Join graph segments (f indicates final):
seg[0]: [0]
seg[1]: host_year[0] (f)
seg[2]: [1]
seg[3]: host_nation[1] (f)
seg[4]: host_year[1]
Join graph nodes:
node[0]: history h(147/1)
node[1]: olympic o(25/1) (sargs 1)
Join graph equivalence classes:
eqclass[0]: host_year[0] host_year[1]
Join graph edges:
term[0]: h.host_year=o.host_year (sel 0.04) (join term) (mergeable)
(inner-join) (indexable host_year[1]) (loc 0)
Join graph terms:
```

```
term[1]: o.host_year range (1950 gt_inf max) (sel 0.1) (rank 2)
(sarg term) (not-join eligible) (indexable host_year[1]) (loc 0)
```

Query plan:

```
temp(distinct)
  subplan: nl-join (inner join)
    edge: term[0]
    outer: iscan
      class: o node[1]
      index: pk_olympic_host_year term[1]
      cost: 1 card 2
    inner: sscan
      class: h node[0]
      sargs: term[0]
      cost: 1 card 147
    cost: 3 card 15
  cost: 9 card 15
```

Query stmt:

```
select distinct h.host_year, o.host_nation from history h, olympic o
where h.host_year=o.host_year and (o.host_year> ?:0 )
```

On the above output, the information which is related to the query plan is “Query plan:”. Query plan is performed sequentially from the inside above line. In other words, “outer: iscan -> inner:scan” is repeatedly performed and at last, “temp(distinct)” is performed. “Join graph segments” is used for checking more information on “Query plan:”. For example, “term[0]” in “Query plan:” is represented as “term[0]: h.host\_year=o.host\_year (sel 0.04) (join term) (mergeable) (inner-join) (indexable host\_year[1]) (loc 0)” in “Join graph segments”.

The following shows the explanation of the above items of “Query plan:”.

- temp(distinct): (distinct) means that CUBRID performs DISTINCT query. temp means that it saves the result to the temporary space.
  - nl-join: “nl-join” means nested loop join.
  - (inner join): join type is “inner join”.
    - outer: iscan: performs iscan(index scan) in the outer table.
      - class: o node[1]: It uses o table. For details, see node[1] of “Join graph segments”.
      - index: pk\_olympic\_host\_year term[1]: use pk\_olympic\_host\_year index and for details, see term[1] of “Join graph segments”.
      - cost: a cost to perform this syntax.
        - card: It means cardinality. Note that this is an approximate value.

- inner: sscan: It performs sscan(sequential scan) in the inner table.
  - class: h node[0]: It uses h table. For details, see node[0] of “Join graph segments”.
  - sargs: term[0]: sargs represent data filter(WHERE condition which does not use an index); it means that term[0] is the condition used as data filter.
  - cost: A cost to perform this syntax.
    - card: It means cardinality. Note that this is an approximate value.
- cost: A cost to perform all syntaxes. It includes the previously performed cost.
  - card: It means cardinality. Note that this is an approximate value.

### Query Plan Related Terms

The following show the meaning for each term which is printed as a query plan.

- Join method: It is printed as “nl-join” on the above. The following are the join methods which are printed on the query plan.
  - nl-join: Nested loop join
  - m-join: Sort merge join
  - idx\_join: Nested loop join, and it is a join which uses an index in the inner table as reading rows of the outer table.
  - hash-join: Hash join
- Join type: It is printed as “(inner join)” on the above. The following are the join types which are printed on the query plan.
  - inner join
  - left outer join
  - right outer join: On the query plan, the different “outer” direction with the query’s direction can be printed. For example, even if you specified “right outer” on the query, but “left outer” can be printed on the query plan.
  - cross join
- Types of join tables: It is printed as outer or inner on the above. They are separated as outer table and inner table which are based on the position on either side of the loop, on the nested loop join.
  - outer table: The first base table to read when joining.

- inner table: The target table to read later when joining.
- Scan method: It is printed as iscan or sscan. You can judge that if the query uses index or not.
  - sscan: sequential scan. Also it can be called as full table scan; it scans all of the table without using an index.
  - iscan: index scan. It limits the range to scan by using an index.
- cost: It internally calculate the cost related to CPU, IO etc., mainly the use of resources.
- card: It means cardinality. It is a number of rows which are predicted as selected.

The following is an example of performing m-join(sort merge join) as specifying USE\_MERGE hint. In general, sort merge join is used when sorting and merging an outer table and an inner table is judged as having an advantage than performing nested loop join. In most cases, it is desired that you do not perform sort merge join.

**Note**

From 9.3 version, if USE\_MERGE hint is not specified or the **optimizer\_enable\_merge\_join** parameter of cubrid.conf is not specified as yes, sort merge join will not be considered to be applied.

```
SET OPTIMIZATION LEVEL 513;
-- csql> ;plan detail

SELECT /*+ RECOMPILE USE_MERGE*/  DISTINCT h.host_year, o.host_nation
FROM history h LEFT OUTER JOIN olympic o ON h.host_year =
o.host_year AND o.host_year > 1950;
```

```
Query plan:
temp(distinct)
  subplan: temp
    order: host_year[0]
    subplan: m-join (left outer join)
      edge: term[0]
      outer: temp
        order: host_year[0]
        subplan: sscan
          class: h
node[0]
cost: 1 card
147
```

```
Query plan:
temp(distinct)
  subplan: temp
    order: host_year[0]
    subplan: m-join (left outer join)
      edge: term[0]
      outer: temp
        order: host_year[0]
        subplan: sscan
          class: h
node[0]
cost: 1 card
147
```

```
Query plan:
temp(distinct)
  subplan: temp
    order: host_year[0]
    subplan: m-join (left outer join)
      edge: term[0]
      outer: temp
        order: host_year[0]
        subplan: sscan
          class: h
node[0]
cost: 1 card
147
```

```

                                cost: 10 card 147
                                inner: temp
                                order: host_year[1]
                                subplan: iscan
                                class: o
node[1]
                                index:
pk_olympic_host_year term[1]
                                cost: 1 card 2
                                cost: 7 card 2
                                cost: 18 card 147
                                cost: 24 card 147
cost: 30 card 147

```

The following performs the idx-join(index join). If performing join by using an index of inner table is judged as having an advantage, you can ensure performing idx-join by specifying **USE\_IDX** hint.

```

SET OPTIMIZATION LEVEL 513;
-- csql> ;plan detail

CREATE INDEX i_history_host_year ON history(host_year);

SELECT /*+ RECOMPILE */ DISTINCT h.host_year, o.host_nation
FROM history h INNER JOIN olympic o ON h.host_year = o.host_year;

```

Query plan:

```

temp(distinct)
  subplan: idx-join (inner join)
    outer: sscan
      class: o node[1]
      cost: 1 card 25
    inner: iscan
      class: h node[0]
      index: i_history_host_year term[0]
(covers)
      cost: 1 card 147
    cost: 2 card 147
cost: 9 card 147

```

On the above query plan, “(covers)” is printed on the “index: i\_history\_host\_year term[0]” of “inner: iscan”, it means that **Covering Index** functionality is applied. In other words, it does not retrieve data storage additionally because there are required data inside the index in inner table.

If you ensure that left table’s row number is a lot smaller than the right table’s row number on the join tables, you can specify **ORDERED** hint. Then always the left table will be outer table, and the right table will be inner table.

```
SELECT /*+ RECOMPILE ORDERED */ DISTINCT h.host_year, o.host_nation
FROM history h INNER JOIN olympic o ON h.host_year = o.host_year;
```

You can specify the table order by specifying the **LEADING** hint. Unlike the **ORDERED** hint, it can be specified regardless of the order in which the tables are written.

```
SELECT /*+ RECOMPILE LEADING(o,h) */ DISTINCT h.host_year,
o.host_nation
FROM history h INNER JOIN olympic o ON h.host_year = o.host_year;
```

## Optimizer Principle

**CUBRID**'s optimizer performs cost-based optimization when generating a query execution plan, and calculates **selectivity** and **expected number of rows and pages** through statistics. Based on this, it calculates the cost and selects the execution plan with the lowest cost.

### Selectivity

**Selectivity** is the ratio of data to be selected when a specific predicate is evaluated. The optimizer calculates the selectivity for each predicate in the **WHERE** clause. **CUBRID** assumes that the entire data is evenly distributed and calculates the **selectivity** using the **Number of Distinct Value** of statistics.

```
SELECTIVITY = 1 / Number of Distinct Value
```

```
CREATE TABLE t1 (code INT, name VARCHAR(20));
INSERT INTO t1 VALUES(1,'Park'),(2,'Park'),(3,'Park'),(4,'joo'),
(5,'joo'),(5,'joo');
CREATE INDEX i_t1_code ON t1(code,name);
UPDATE STATISTICS ON t1;

;info stats t1
```

### CLASS STATISTICS

```
*****
```

```
Class name: t1 Timestamp: Fri Dec 20 13:07:58 2024
Total pages in class heap: 1
Total objects: 6
Number of attributes: 2
Attribute: code (integer)
    Number of Distinct Values: 5
B+tree statistics:
```

```

      BTID: { 0 , 5760 }
      Cardinality: 5 (5,5) , Total pages: 3 , Leaf pages: 1 ,
Height: 2

```

```

Attribute: name (character varying)
Number of Distinct Values: 2

```

```

;plan detail
SELECT /*+ recompile */ * FROM t1 WHERE code = 3 AND name IN
('Song', 'Ham');

```

```

Join graph terms:
term[0]: [dba.t1].code=3 (sel 0.2)
term[1]: [dba.t1].[name] range ('Ham' = or 'Song' = ) (sel 0.75)

```

**term[0]: [dba.t1].code=3** The **Number of Distinct Values** of **code** in the statistics is 5, so the selectivity is 1/5 or 0.2. **term[1]: [dba.t1].[name] range ('Ham' = or 'Song' = )** performs an **OR** operation on two values of name. Since the **Number of Distinct Values** for **name** is 2, the selectivity for each value is 1/2. Adding the two values and subtracting the intersection gives the calculation **0.5 + 0.5 - (0.5 x 0.5)**, resulting in 0.75.

Expected number of rows

The **expected number of rows** is calculated by multiplying the **selectivity** by the **total number of data rows**.

```

Number of expected rows = total rows of a table * selectivity

```

```

;plan detail
SELECT /*+ recompile */ * FROM t1 WHERE name = 'Park';

```

```

Join graph nodes:
node[0]: dba.t1 dba.t1(6/1)
Join graph terms:
term[0]: [dba.t1].[name]='Park' (sel 0.5)

```

Query plan:

```

sscan
  class: t1 node[0]
  sargs: term[0]
  cost: 1 card 3

```

**dba.t1(6/1)** indicates that the total number of rows in the t1 table is 6 and the number of pages is 1. Since the selectivity of **[dba.t1].[name]='Park'** is 0.5, the expected number of rows is 3, which is calculated as **6 x 0.5. cost: 1 card 3** in the execution plan indicates that the cost is 1 and the expected number of rows is 3.

## Cost of sequential scan

When estimating costs, the optimizer considers two things:

1. The cost of reading a page
2. The CPU cost of repetitive routines

The following example shows how the cost of a sequential scan is calculated.

```
Page cost = number of pages in table
CPU cost = total number of rows in table X CPU weight
```

```
drop table if exists t1;
create table t1 (col1 int, col2 int, col3 int, col4 int);
insert into t1 select mod(rownum,2), mod(rownum,4), rownum, rownum
from dual connect by level <= 4000;
update statistics on t1;

;plan detail
select /** recompile */ count(*) from t1 where col2 = 2;
```

```
Join graph nodes:
node[0]: dba.t1 dba.t1(4000/9)
Join graph terms:
term[0]: [dba.t1].col2=2 (sel 0.25)
```

Query plan:

```
sscan
  class: t1 node[0]
  sargs: term[0]
  cost: 19 card 1000
```

**node[0]: dba.t1 dba.t1(4000/9)** shows that the total number of rows in the t1 table is 4000 and the number of pages is 9. Therefore, the page cost is 9, which is the total number of pages in the t1 table. The CPU cost is the total number of rows in the table multiplied by the CPU weight, which is **4000 x 0.0025**, resulting in a cost of 10. Adding the two values gives 19, and from **cost: 19 card 1000**, we can see that the cost is 19 and the expected number of rows to be retrieved is 1000.

## Cost of index scan

Index scan is performed by searching non-leaf nodes, leaf nodes, and heap areas. The index scan starts by searching non-leaf nodes including the root node to find the starting point of the leaf node. Then, it searches the leaf nodes, looks up the satisfying key, and scans the heap area with the **OID**. The following example shows how the index scan is performed.

```
drop table if exists t2;
create table t2 (col1 int, col2 int, col3 int, col4 int);
insert into t2 select mod(rownum,20), mod(rownum,80), rownum, rownum
from dual connect by level <= 4000;
create index idx on t2(col1,col2,col3);
update statistics on t2;

;plan detail
select /*+ recompile */ count(*) from t2 where col1 = 1 and col3 = 1
and col4 = 1;
```

```
Join graph terms:
term[0]: [dba.t2].col4=1 (sel 0.00025)
term[1]: [dba.t2].col3=1 (sel 0.0125)
term[2]: [dba.t2].col1=1 (sel 0.05)
```

Query plan:

```
iscan
  class: t2 node[0]
  index: idx term[2]
  filtr: term[1]
  sargs: term[0]
  cost: 4 card 1
```

You can check the predicates in the execution plan through the information in **Join graph terms**. **index: idx term[2]** is the predicate for searching the non-leaf node during the index vertical scan. The **filtr: term[1]** predicate is for filtering the key in the leaf node during the index horizontal scan. When accessing the heap and filtering data, the **sargs: term[0]** predicate is used to filter.

```
;info stats t2
```

```
Attribute: col1 (integer)
  Number of Distinct Values: 20
  B+tree statistics:
    BTID: { 0 , 5760 }
    Cardinality: 4000 (20,4000,4000) , Total pages: 11 , Leaf
pages: 9 , Height: 2
```

The cost of an index scan is calculated as follows:

1. Cost of reading a page = predicted non-leaf node pages accessed + leaf node pages  
+ heap pages
2. CPU cost of a repeated routine = predicted number of leaf node keys accessed

The number of pages in a non-leaf node is 1 because the index **Height** of the statistics is 2 and the number of pages to be read excluding the leaf node is **2 - 1**. The number of leaf node pages is obtained by multiplying **Leaf pages** by the selectivity of the predicate **index: idx term[2]** used to search the non-leaf node. Since it is **MAX(9 X 0.05, 1)**, the number of leaf node pages to be read is 1. The number of heap pages to be read is obtained by multiplying the total number of pages in the table by the selectivity of **index** and **filtr** conditions. Here, it is calculated as **MAX(9 X 0.05 X 0.0125, 1)**, so it is calculated that 1 page must be read. Finally, the CPU cost is obtained by multiplying the selectivity of **index: idx term[2]** by the CPU weight from the total number of rows in the table. If you calculate it as **MAX(4000 X 0.05 X 0.0025, 1)**, you get 1, and if you add up all the results so far, you can see that the cost is 4. If you look at **cost: 4 card 1** in the execution plan, you can see that the cost is 4 and the expected number of rows is 1.

### Cost of join

The cost of a join is generated by calculating the cost of the preceding table and the cost of the succeeding table separately, and the cost is calculated according to the join method. The following example below shows how the cost is calculated in a nested loop join method.

```
create index idx1 on t2(col4);

--;plan detail
select /*+ recompile */ count(*)
from t1 a, t2 b
where a.col4 = b.col4
and b.col1 = 1
and b.col3 = 1
and a.col2 = 2;
```

Query plan:

```
idx-join (inner join)
  outer: sscan
        class: a node[0]
        sargs: term[3]
        cost: 19 card 1000
  inner: iscan
        class: b node[1]
        index: idx1 term[0]
        sargs: term[1] AND term[2]
```

```

cost: 2 card 3
cost: 572 card 1

```

The preceding table is *a* and the succeeding table is *b*. Since the execution of the succeeding table is repeated as many times as the number of rows of the preceding table due to the nature of the nested loop join, the cost of the succeeding table can be calculated by multiplying the variable cost of the *b* table by the expected number of rows of the *a* table. **CUBRID** internally manages fixed costs and variable costs separately, and this information cannot be displayed in the execution plan. The variable cost of the succeeding table is approximately 0.553, and the cost of the succeeding table incurred during the join is 553 when calculated by  $0.553 * 1000$ , and the final cost is 572 when adding the cost of the preceding table 19.

## Query Profiling

If the performance analysis of SQL is required, you can use query profiling feature. To use query profiling, specify SQL trace with **SET TRACE ON** syntax; to print out the profiling result, run **SHOW TRACE** syntax.

And if you want to always include the query plan when you run **SHOW TRACE**, you need to add `/*+ RECOMPILE */` hint on the query.

The format of **SET TRACE ON** syntax is as follows.

```
SET TRACE {ON | OFF} [OUTPUT {TEXT | JSON}]
```

- ON: set on SQL trace.
- OFF: set off SQL trace.
- OUTPUT TEXT: print out as a general TEXT format. If you omit OUTPUT clause, TEXT format is specified.
- OUTPUT JSON: print out as a JSON format.

As below, if you run **SHOW TRACE** syntax, the trace result is shown.

```
SHOW TRACE;
```

Below is an example that prints out the query tracing result after setting SQL trace ON.

```

csql> SET TRACE ON;
csql> SELECT /*+ RECOMPILE */ o.host_year, o.host_nation,
o.host_city, SUM(p.gold)
FROM OLYMPIC o, PARTICIPANT p

```

```

WHERE o.host_year = p.host_year AND p.gold > 20
GROUP BY o.host_nation;
csql> SHOW TRACE;

```

```

=== <Result of SELECT Command in Line 2> ===

```

```

    trace
=====
    ,
Query Plan:
    SORT (group by)
      NESTED LOOPS (inner join)
        TABLE SCAN (o)
        INDEX SCAN (p.fk_participant_host_year) (key range:
o.host_year=p.host_year)

    rewritten query: select o.host_year, o.host_nation, o.host_city,
sum(p.gold) from OLYMPIC o, PARTICIPANT p where
o.host_year=p.host_year and (p.gold> ?:0 ) group by o.host_nation

Trace Statistics:
    SELECT (time: 2, fetch: 975, fetch_time: 1, ioread: 2)
      SCAN (table: olympic), (heap time: 0, fetch: 26, ioread: 0,
readrows: 25, rows: 25)
        SCAN (index: participant.fk_participant_host_year), (btree
time: 1, fetch: 941, ioread: 2, readkeys: 5, filteredkeys: 5, rows:
916) (lookup time: 0, rows: 14)
      GROUPBY (time: 0, sort: true, page: 0, ioread: 0, rows: 5)
    ,

```

In the above example, under lines of “Trace Statistics:” are the result of tracing. Each items of tracing result are as below.

- **SELECT** (time: 2, fetch: 975, fetch\_time: 1, ioread: 2)
  - time: 2 => Total query time took 2ms.
  - fetch: 975 => 975 times were fetched regarding pages. (not the number of pages, but the count of accessing pages. even if the same pages are fetched, the count is increased.).
  - fetch\_time: 1=> Total fetch time took 1ms.
  - ioread: disk accessed 2 times.

: Total statistics regarding SELECT query. If the query is rerun, fetching count and ioread count can be shrinken because some of query result are read from buffer.

◦ **SCAN** (table: olympic), (heap time: 0, fetch: 26, ioread: 0, readrows: 25, rows: 25)

- heap time: 0 => It took less than 1ms. CUBRID rounds off a value less than millisecond, so a time value less than 1ms is displayed as 0.
- fetch: 26 => page fetching count is 26.
- ioread: 0 => disk accessing count is 0.
- readrows: 25 => the number of rows read when scanning is 25.
- rows: 25 => the number of rows in result is 25.

: Heap scan statistics for the olympic table.

▪ **SCAN** (index: participant.fk\_participant\_host\_year), (btree time: 1, fetch: 941, ioread: 2, readkeys: 5, filteredkeys: 5, rows: 916) (lookup time: 0, rows: 14)

- btree time: 1 => It took 1ms.
- fetch: 941 => page fetching count is 941.
- ioread: 2 => disk accessing count is 2.
- readkeys: 5 => the number of keys read is 5.
- filteredkeys: 5 => the number of keys which the key filter is applied is 5.
- rows: 916 => the number of rows scanning is 916.
- lookup time: 0 => It took less than 1ms when accessing data after index scan.
- rows: 14 => the number of rows after applying data filter; in the query, the number of rows is 14 when data filter “p.gold > 20” is applied.

: Index scanning statistics regarding participant.fk\_participant\_host\_year index.

◦ **GROUPBY** (time: 0, sort: true, page: 0, ioread: 0, rows: 5)

- time: 0 => It took less than 1ms when “group by” is applied.
- sort: true => It’s true because sorting is applied.
- page: 0 => the number or temporary pages used in sorting is 0.
- ioread: 0 => It took less than 1ms to access disk.
- rows: 5 => the number of result rows regarding “group by” is 5.

: Group by statistics.

The following is an example to join 3 tables.

```

csql> SET TRACE ON;
csql> SELECT /*+ RECOMPILE ORDERED */ o.host_year, o.host_nation,
o.host_city, n.name, SUM(p.gold), SUM(p.silver), SUM(p.bronze)
      FROM OLYMPIC o,
           (select /*+ NO_MERGE */ * from PARTICIPANT p where
p.gold > 10) p,
           NATION n
      WHERE o.host_year = p.host_year AND p.nation_code = n.code
      GROUP BY o.host_nation;
csql> SHOW TRACE;

      trace
=====
'
Query Plan:
  TABLE SCAN (p)

  rewritten query: (select p.host_year, p.nation_code, p.gold,
p.silver, p.bronze from PARTICIPANT p where (p.gold> ?:0 ))

  SORT (group by)
    NESTED LOOPS (inner join)
      NESTED LOOPS (inner join)
        TABLE SCAN (o)
        TABLE SCAN (p)
      INDEX SCAN (n.pk_nation_code) (key range: p.nation_code=n.code)

  rewritten query: select /*+ ORDERED */ o.host_year, o.host_nation,
o.host_city, n.[name], sum(p.gold), sum(p.silver), sum(p.bronze)
from OLYMPIC o, (select p.host_year, p.nation_code, p.gold,
p.silver, p.bronze from PARTICIPANT p where (p.gold> ?:0 )) p
(host_year, nation_code, gold,
silver, bronze), NATION n where o.host_year=p.host_year and
p.nation_code=n.code group by o.host_nation

Trace Statistics:
  SELECT (time: 6, fetch: 880, fetch_time: 2, ioread: 0)
    SCAN (table: olympic), (heap time: 0, fetch: 104, ioread: 0,
readrows: 25, rows: 25)
      SCAN (hash temp(m), buildtime : 0, time: 0, fetch: 0, ioread:
0, readrows: 76, rows: 38)
        SCAN (index: nation.pk_nation_code), (btree time: 2, fetch:
760, ioread: 0, readkeys: 38, filteredkeys: 0, rows: 38) (lookup
time: 0, rows: 38)
          GROUPBY (time: 0, hash: true, sort: true, page: 0, ioread: 0,
rows: 5)

```

```

SUBQUERY (uncorrelated)
  SELECT (time: 2, fetch: 12, ioread: 0)
    SCAN (table: participant), (heap time: 2, fetch: 12, ioread:
0, readrows: 916, rows: 38)

```

The following are the explanation regarding items of trace statistics.

### SELECT

- time: total estimated time when this query is performed(ms)
- fetch: total page fetching count about this query
- fetch\_time : total fetch time when this query is performed(ms)
- ioread: total I/O read count about this query. disk access count when the data is read

**FUNC:** Outputs the results of the stored procedure call accumulated from the current query and subqueries. The fetch and ioread counts do not include those that occur during the execution of queries within the stored procedure.

- time: total execution time of the stored procedure (ms)
- fetch: the number of times pages are fetched during the stored procedure call
- ioread: total I/O read count during the stored procedure call; indicates the number of disk accesses when reading data
- calls: the number of stored procedure calls

### SCAN

- heap: data scanning job without index
  - time, fetch, ioread: the estimated time(ms), page fetching count and I/O read count in the heap of this operation
  - readrows: the number of rows read when this operation is performed
  - rows: the number of result rows when this operation is performed
- btree: index scanning job
  - time, fetch, ioread: the estimated time(ms), page fetching count and I/O read count in the btree of this operation
  - readkeys: the number of the keys which are read in btree when this operation is performed
  - filteredkeys: the number of the keys to which the key filter is applied from the read keys

- rows: the number of result rows when this operation is performed; the number of result rows to which key filter is applied
- temp: data scanning job with temp file
  - hash temp(m): hash list scan or not. depending on the amount of data, the IN-MEMORY(m), HYBRID(h), FILE(f) hash data structure is used.
  - buildtime: the estimated time(ms) in building hash table.
  - time: the estimated time(ms) in probing hash table.
  - fetch, ioread: page fetching count and I/O read count in the temp file of this operation
  - readrows: the number of rows read when this operation is performed
  - rows: the number of result rows when this operation is performed
- lookup: data accessing job after index scanning
  - time: the estimated time(ms) in this operation
  - rows: the number of the result rows in this operation; the number of result rows to which the data filter is applied
- noscan: An operation that uses statistical information of index headers without scanning when executing an aggregate operation. (aggregate: count, min, max)
  - agl: aggregate lookup, index list used for aggregate operation

The following is an example for noscan and agl.

```
SET TRACE ON;
CREATE TABLE agl_tbl (id INTEGER PRIMARY KEY, phone VARCHAR(20));
INSERT INTO agl_tbl VALUES (1, '123-456-789');
INSERT INTO agl_tbl VALUES (999, '999-999-999');

SELECT count(*), min(id), max(id) FROM agl_tbl;

SHOW TRACE;
```

```
Trace Statistics:
  SELECT (time: 0, fetch: 16, fetch_time: 0, ioread: 0)
    SCAN (table: agl_tbl), (noscan time: 0, fetch: 0, ioread: 0,
  readrows: 0, rows: 0, agl: pk_agl_tbl_id)
```

## GROUPBY

- time: the estimated time(ms) in this operation
- sort: sorting or not
- page: the number of pages which is read in this operation; the number of used pages except the internal sorting buffer
- rows: the number of the result rows in this operation
- hash: hash aggregate evaluation or not, when sorting tuples in the aggregate function(true/false). See `NO_HASH_AGGREGATE` hint.

## INDEX SCAN

- key range: the range of a key
- covered: covered index or not(true/false)
- loose: loose index scan or not(true/false)

The above example can be output as JSON format.

```
csql> SET TRACE ON OUTPUT JSON;
csql> SELECT n.name, a.name FROM athlete a, nation n WHERE
n.code=a.nation_code;
csql> SHOW TRACE;
```

```

```

SQL hints are specified by using a plus sign(+) to comments. To use a hint, there are three styles as being introduced on [Comment](#). Therefore, also SQL hint can be used as three styles.

- /\*+ hint \*/
- --+ hint

- `//+ hint`

The hint comment must appear after the keyword such as **SELECT**, **UPDATE** or **DELETE**, and the comment must begin with a plus sign (+), following the comment delimiter. When you specify several hints, they are separated by blanks.

The following hints can be specified in **UPDATE**, **DELETE** and **SELECT** statements.

- **USE\_NL**: Related to a table join, the query optimizer creates a nested loop join execution plan with this hint.
- **USE\_MERGE**: Related to a table join, the query optimizer creates a sort merge join execution plan with this hint.
- **USE\_HASH**: Related to a table join, the query optimizer creates a hash join execution plan with this hint. see [Hash Join](#).
- **NO\_USE\_HASH**: Related to a table join, The query optimizer does not create a hash join execution plan with this hint. see [Hash Join](#).
- **ORDERED**: Related to a table join, the query optimizer create a join execution plan with this hint, based on the order of tables specified in the **FROM** clause. The left table in the **FROM** clause becomes the outer table; the right one becomes the inner table.
- **LEADING**: Related to a table join, the query optimizer create a join execution plan with this hint, based on the order of tables specified in the **LEADING** hint.
- **USE\_IDX**: Related to an index, the query optimizer creates an index join execution plan corresponding to a specified table with this hint.
- **USE\_DESC\_IDX**: This is a hint for the scan in descending index. For more information, see [Index Scan in Descending Order](#).
- **USE\_SBR**: This is a hint for the statement-based replication. It supports data replication for tables without a primary key.

#### Note

The data inconsistency of a table may occur between nodes since the corresponding statement is executed when the transaction log is applied in the slave node.

- **INDEX\_SS**: Consider the query plan of index skip scan. For more information, see [Index Skip Scan](#).

- **INDEX\_LS**: Consider the query plan of loose index scan. For more information, see [Loose Index Scan](#).
- **NO\_DESC\_IDX**: This is a hint not to use the descending index.
- **NO COVERING\_IDX**: This is a hint not to use the covering index. For details, see [Covering Index](#).
- **NO\_MULTI\_RANGE\_OPT**: This is a hint not to use the multi-key range optimization. For details, see [Multiple Key Ranges Optimization](#).
- **NO\_SORT\_LIMIT**: This is a hint not to use the SORT-LIMIT optimization. For more details, see [SORT-LIMIT optimization](#).
- **NO\_SUBQUERY\_CACHE**: This is a hint not to use the SUBQUERY CACHE optimization. For more details, see [SUBQUERY CACHE \(correlated\)](#).
- **NO\_PUSH\_PRED**: This is a hint not to use the PREDICATE-PUSH optimization.
- **NO\_MERGE**: This is a hint not to use the VIEW-MERGE optimization.
- **NO\_ELIMINATE\_JOIN**: This is a hint not to use join elimination optimization. For more details, see [Join transforming Optimization](#).
- **NO\_HASH\_AGGREGATE**: This is a hint not to use hashing for the sorting tuples in aggregate functions. Instead, external sorting is used in aggregate functions. By using an in-memory hash table, we can reduce or even eliminate the amount of data that needs to be sorted. However, in some scenarios the user may know beforehand that hash aggregation will fail and can use the hint to skip hash aggregation entirely. For setting the memory size of hashing aggregate, see [max\\_agg\\_hash\\_size](#).

**Note**

Hash aggregate evaluation will not work for functions evaluated on distinct values (e.g. `AVG(DISTINCT x)`) and for the `GROUP_CONCAT` and `MEDIAN` functions, since they require an extra sorting step for the tuples of each group.

- **NO\_HASH\_LIST\_SCAN**: This is a hint not to use hash list scan for scanning sub-query's result. Instead, list scan is used to scan temp file. By building and probing hash table, we can reduce the amount of data that needs to be searched. However, in some scenarios, the user may know beforehand that outer cardinality is very small and can use the hint to skip hash list scan entirely. For setting the memory size of hash scan, see [max\\_hash\\_list\\_scan\\_size](#).

**Note**

Hash List scan only works for predicates having a equal operation and does NOT work for predicates having OID type.

- **NO\_LOGGING**: This is a hint not to include the redo in the log generated when inserting, updating, or deleting records to a table.

#### Note

Currently, The NO\_LOGGING hint only affects the log created from the heap file when inserting, updating, or deleting records to a table. Therefore, problems such as the inconsistency between the data of the table and the data of the index might occur after recovery; and the situation of committed record cannot be recovered might also occur, etc. You should use it carefully.

- **PARALLEL** ( *degree* ): This is a hint to enable parallel query execution (parallel scan over heap/ list/index inputs, parallel subquery execution, parallel hash join, parallel sort) and specify the degree of parallelism. *degree* must be an integer value of 0 or higher, indicating the number of worker threads to use for parallel processing. When set to 0 or 1, parallel processing is disabled, and a value larger than the number of system CPU cores is lowered to the core count. Even with the hint, parallel execution is not applied if the target's page count does not meet the activation conditions. For more details, see [Parallel Execution](#).

```
SELECT /*+ PARALLEL(4) */ * FROM large_table WHERE condition;
```

- **NO\_PARALLEL\_SCAN**: This is a hint to disable every parallel scan flavor (heap, list, and index) within the query block. When used together with the **PARALLEL** hint, **NO\_PARALLEL\_SCAN** takes precedence. For more details, see [Parallel Execution](#).

```
SELECT /*+ NO_PARALLEL_SCAN */ * FROM large_table WHERE condition;
```

- **NO\_PARALLEL\_HASH\_JOIN**: This is a hint to disable parallel hash join within the query block. The hash join itself is kept; only its parallelization is disabled. When used together with the **PARALLEL** hint, **NO\_PARALLEL\_HASH\_JOIN** takes precedence. For more details, see [Parallel Execution](#).

```
SELECT /*+ NO_PARALLEL_HASH_JOIN */ o.order_id, t.category
FROM orders o JOIN large_table t ON o.order_id = t.id;
```

- **NO\_PARALLEL\_SUBQUERY**: This is a hint to disable parallel execution of subqueries. For more details, see [Parallel Execution](#).

```
SELECT /*+ NO_PARALLEL_SUBQUERY */ *
FROM table1
WHERE id IN (SELECT id FROM table2 WHERE status = 'active');
```

- **RECOMPILE** : Recompiles the query execution plan. This hint is used to delete the query execution plan stored in the cache and establish a new query execution plan.
- **QUERY\_CACHE**: This is a hint for caching the query with its results. This hint can be specified in **SELECT** statements only. For more information, see [QUERY CACHE](#).

#### **Note**

If *<spec\_name>* is specified together with **USE\_NL**, **USE\_IDX** or **USE\_MERGE**, the specified join method applies only to the *<spec\_name>*.

```
SELECT /*+ ORDERED USE_NL(B) USE_NL(C) USE_MERGE(D) */ *
FROM A INNER JOIN B ON A.col=B.col
INNER JOIN C ON B.col=C.col INNER JOIN D ON C.col=D.col;
```

If you run the above query, **USE\_NL** is applied when A and B are joined; **USE\_NL** is applied when C is joined, too; **USE\_MERGE** is applied when D is joined.

If **USE\_NL** and **USE\_MERGE** are specified together without *<spec\_name>*, the given hint is ignored. In some cases, the query optimizer cannot create a query execution plan based on the given hint. For example, if **USE\_NL** is specified for a right outer join, the query is converted to a left outer join internally, and the join order may not be guaranteed.

#### **Note**

If you specify the **ORDERED** hint, all **LEADING** hint is ignored. If you specify two or more **LEADING** hints, then only the first one is activated and all of them except the first are ignored.

```
SELECT /*+ ORDERED LEADING(b, d) */ *
FROM a INNER JOIN b ON a.col=b.col
INNER JOIN c ON b.col=c.col INNER JOIN d ON c.col=d.col;
```

If you run the above query, the **LEADING** hint is ignored, and tables a, b, c, and d are joined in the order of the **FROM** clause according to the **ORDERED** hint.

```
SELECT /*+ LEADING(b, d) LEADING(c, d) */ *
FROM a INNER JOIN b ON a.col=b.col
INNER JOIN c ON b.col=c.col INNER JOIN d ON c.col=d.col;
```

If you run the above query, the second **LEADING** hint is ignored, and join order in which tables b and d are joined first is generated.

MERGE statement can have below hints.

- **USE\_INSERT\_IDX** (<insert\_index\_list>): An index hint which is used in **INSERT** clause of **MERGE** statement. Lists index names to *insert\_index\_list* to use when executing **INSERT** clause. This hint is applied to <join\_condition> of **MERGE** statement.
- **USE\_UPDATE\_IDX** (<update\_index\_list>): An index hint which is used in **UPDATE** clause of **MERGE** statement. Lists index names to *update\_index\_list* to use when executing **UPDATE** clause. This hint is applied to <join\_condition> and <update\_condition> of **MERGE** statement.
- **RECOMPILE**: See the above **RECOMPILE**.

Table/view names to join can be specified to the joining hint; at this time, table/view names are separated by “,”.

```
SELECT /*+ USE_NL(a, b) */ *
FROM a INNER JOIN b ON a.col=b.col;
```

The following example shows how to retrieve the years when ‘Sim Kwon Ho’ won medals and the types of medals. It can be expressed by the following query. The query optimizer creates a nested loop join execution plan that has the *athlete* table as an outer table and the *game* table as an inner table.

```
-- csql> ;plan_detail

SELECT /*+ USE_NL ORDERED */ a.name, b.host_year, b.medal
FROM athlete a, game b
WHERE a.name = 'Sim Kwon Ho' AND a.code = b.athlete_code;
```

Query plan:

```
idx-join (inner join)
  outer: sscan
        class: a node[0]
        sargs: term[1]
        cost: 44 card 7
  inner: iscan
        class: b node[1]
        index: fk_game_athlete_code term[0]
        cost: 3 card 8653
cost: 73 card 9
```

The following example shows how to specify tables when using a **USE\_NL** hint.

```
-- csql> ;plan_detail

SELECT /*+ USE_NL(a,b) */ a.name, b.host_year, b.medal
FROM athlete a, game b
WHERE a.name = 'Sim Kwon Ho' AND a.code = b.athlete_code;
```

## Index Hint

The index hint syntax allows the query processor to select a proper index by specifying the index in the query. You can specify the index hint by **USING INDEX** clause or by { **USE** | **FORCE** | **IGNORE** } **INDEX** syntax after “**FROM** table” clause.

### USING INDEX

**USING INDEX** clause should be specified after **WHERE** clause of **SELECT**, **DELETE** or **UPDATE** statement. **USING INDEX** clause forces a sequential/index scan to be used or an index that can improve the performance to be included.

If **USING INDEX** clause is specified with the list of index names, query optimizer creates optimized execution plan by calculating the query execution cost based on the specified indexes only and comparing the index scan cost and the sequential scan cost of the specified indexes(CUBRID performs cost-based query optimization to select an execution plan).

The **USING INDEX** clause is useful to get the results in the desired order without **ORDER BY**. When index scan is performed by CUBRID, the results are created in the order they were saved in the index. When there are more than one indexes in one table, you can use **USING INDEX** to get the query results in a given order of indexes.

```

SELECT ... WHERE ...
[USING INDEX { NONE | [ ALL EXCEPT ] <index_spec> [ {,
<index_spec> } ...] } ] [ ; ]

DELETE ... WHERE ...
[USING INDEX { NONE | [ ALL EXCEPT ] <index_spec> [ {,
<index_spec> } ...] } ] [ ; ]

UPDATE ... WHERE ...
[USING INDEX { NONE | [ ALL EXCEPT ] <index_spec> [ {,
<index_spec> } ...] } ] [ ; ]

<index_spec> ::=
    [table_spec.]index_name [(+) | (-)] |
    table_spec.NONE

```

- **NONE**: If **NONE** is specified, a sequential scan is used on all tables.
- **ALL EXCEPT**: All indexes except the specified indexes can be used when the query is executed.
- *index\_name*(+): If (+) is specified after the *index\_name*, it is the first priority in index selection. If this index is not proper to run the query, it is not selected.
- *index\_name*(-): If (-) is specified after the *index\_name*, it is excluded from index selection.
- *table\_spec*.**NONE**: All indexes are excluded from the selection, so sequential scan is used.

## USE, FORCE, IGNORE INDEX

Index hints can be specified through **USE, FORCE, IGNORE INDEX** syntax after table specification of **FROM** clause.

```

FROM table_spec [ <index_hint_clause> ] ...

<index_hint_clause> ::=
    { USE | FORCE | IGNORE } INDEX ( <index_spec> [,
<index_spec> ...] )

<index_spec> ::=
    [table_spec.]index_name

```

- **USE INDEX** ( <index\_spec> ): Only specified indexes are considered when choose them.
- **FORCE INDEX** ( <index\_spec> ): Specified indexes are chosen as the first priority.
- **IGNORE INDEX** ( <index\_spec> ): Specified indexes are excluded from the choice.

**USE**, **FORCE**, **IGNORE INDEX** syntax is automatically rewritten as the proper **USING INDEX** syntax by the system.

## Examples of index hint

```
CREATE TABLE athlete2 (
  code          SMALLINT PRIMARY KEY,
  name          VARCHAR(40) NOT NULL,
  gender        CHAR(1),
  nation_code   CHAR(3),
  event         VARCHAR(30)
);
CREATE UNIQUE INDEX athlete2_idx1 ON athlete2 (code, nation_code);
CREATE INDEX athlete2_idx2 ON athlete2 (gender, nation_code);
```

Below two queries do the same behavior and they select index scan if the specified index, *athlete2\_idx2*'s scan cost is lower than sequential scan cost.

```
SELECT /** RECOMPILE */ *
FROM athlete2 USE INDEX (athlete2_idx2)
WHERE gender='M' AND nation_code='USA';

SELECT /** RECOMPILE */ *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX athlete2_idx2;
```

Below two queries do the same behavior and they always use *athlete2\_idx2*

```
SELECT /** RECOMPILE */ *
FROM athlete2 FORCE INDEX (athlete2_idx2)
WHERE gender='M' AND nation_code='USA';

SELECT /** RECOMPILE */ *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX athlete2_idx2(+);
```

Below two queries do the same behavior and they always don't use *athlete2\_idx2*

```
SELECT /** RECOMPILE */ *
FROM athlete2 IGNORE INDEX (athlete2_idx2)
WHERE gender='M' AND nation_code='USA';

SELECT /** RECOMPILE */ *
```

```
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX athlete2_idx2(-);
```

Below query always do the sequential scan.

```
SELECT *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX NONE;

SELECT *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX athlete2.NONE;
```

Below query forces to be possible to use all indexes except *athlete2\_idx2* index.

```
SELECT *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX ALL EXCEPT athlete2_idx2;
```

When two or more indexes have been specified in the **USING INDEX** clause, the query optimizer selects the proper one of the specified indexes.

```
SELECT *
FROM athlete2 USE INDEX (athlete2_idx2, athlete2_idx1)
WHERE gender='M' AND nation_code='USA';

SELECT *
FROM athlete2
WHERE gender='M' AND nation_code='USA'
USING INDEX athlete2_idx2, athlete2_idx1;
```

When a query is run for several tables, you can specify a table to perform index scan by using a specific index and another table to perform sequential scan. The query has the following format.

```
SELECT *
FROM tab1, tab2
WHERE ...
USING INDEX tab1.idx1, tab2.NONE;
```

When executing a query with the index hint syntax, the query optimizer considers all available indexes on the table for which no index has been specified. For example, when the *tab1* table

includes *idx1* and *idx2* and the *tab2* table includes *idx3*, *idx4*, and *idx5*, if indexes for only *tab1* are specified but no indexes are specified for *tab2*, the query optimizer considers the indexes of *tab2*.

```
SELECT ...
FROM tab1, tab2 USE INDEX(tab1.idx1)
WHERE ... ;
```

```
SELECT ...
FROM tab1, tab2
WHERE ...
USING INDEX tab1.idx1;
```

The above query select the scan method of table *tab1* after comparing the cost between the sequential scan of the table *tab1* and the index scan of the index *idx1*, and select the scan method of table *tab2* after comparing the cost between the sequential scan of the table *tab2* and the index scan of the indexes *idx3*, *idx4*, *idx5*.

## Special Indexes

### Filtered Index

The filtered index is used to sort, search, or operate a well-defined partials set for one table. It is called the partial index since only some data that satisfy the condition are kept in that index.

```
CREATE /** hints */ INDEX index_name
ON [schema_name.]table_name (col1, col2, ...)
WHERE <filter_predicate>;

ALTER /** hints */ INDEX index_name
[ ON [schema_name.]table_name (col1, col2, ...)
[ WHERE <filter_predicate> ] ]
REBUILD;

<filter_predicate> ::= <filter_predicate> AND <expression> |
<expression>
```

- *<filter\_predicate>*: Condition to compare the column and the constant. When there are several conditions, filtering is available only when they are connected by using **AND**. The filter conditions can include most of the operators and functions supported by CUBRID. However, the date/time function that shows the current date/time (ex: `SYS_DATETIME()`) or random functions (ex: `RAND()`), which outputs different results for one input are not allowed.

If you want to apply the filtered index, that filtered index must be specified by **USE INDEX** syntax or **FORCE INDEX** syntax.

- When a filtered index is specified by **USING INDEX** clause or **USE INDEX** syntax:

If columns of which the index consists are not included on the conditions of **WHERE** clause, the filtered index is not used.

```
CREATE TABLE blogtopic
(
    blogID BIGINT NOT NULL,
    title VARCHAR(128),
    author VARCHAR(128),
    content VARCHAR(8096),
    postDate TIMESTAMP NOT NULL,
    deleted SMALLINT DEFAULT 0
);

CREATE INDEX my_filter_index ON blogtopic(postDate) WHERE deleted=0;
```

On the below query, *postDate*, a column of which *my\_filter\_index* consists, is included on the conditions of **WHERE** condition. Therefore, this index can be used by **USE INDEX** clause.

```
SELECT *
FROM blogtopic USE INDEX (my_filter_index)
WHERE postDate > '2010-01-01' AND deleted=0;
```

- When a filtered index is specified by **USING INDEX** <index\_name>(+) clause or **FORCE INDEX** syntax:

Even if a column of which the index consists is not included on the condition of **WHERE** clause, the filtered index is used.

On the below query, *my\_filter\_index* cannot be used by **“USE INDEX”** syntax because a column of which *my\_filter\_index* consists is not included on the **WHERE** condition.

```
SELECT *
FROM blogtopic USE INDEX (my_filter_index)
WHERE author = 'David' AND deleted=0;
```

Therefore, to use *my\_filter\_index*, it should be forced by **“FORCE INDEX”**.

```
SELECT *
FROM blogtopic FORCE INDEX (my_filter_index)
WHERE author = 'David' AND deleted=0;
```

The following example shows a bug tracking system that maintains bugs/issues. After a specified period of development, the bugs table records bugs. Most of the bugs have already been closed. The bug tracking system makes queries on the table to find new open bugs. In this case, the indexes on the bug table do not need to know the records on closed bugs. Then the filtered indexes allow indexing of open bugs only.

```
CREATE TABLE bugs
(
    bugID BIGINT NOT NULL,
    CreationDate TIMESTAMP NOT NULL,
    Author VARCHAR(255),
    Subject VARCHAR(255),
    Description VARCHAR(255),
    CurrentStatus INTEGER,
    Closed SMALLINT
);
```

Indexes for open bugs can be created by using the following sentence:

```
CREATE INDEX idx_open_bugs ON bugs(bugID) WHERE Closed = 0;
```

To process queries that are interested in open bugs, specify the index as an index hint. It will allow creating query results by accessing less index pages through filtered indexes.

```
SELECT *
FROM bugs
WHERE Author = 'madden' AND Subject LIKE '%fopen%' AND Closed = 0
USING INDEX idx_open_bugs(+);

SELECT *
FROM bugs FORCE INDEX (idx_open_bugs)
WHERE CreationDate > CURRENT_DATE - 10 AND Closed = 0;
```

On the above example, if you use “**USING INDEX** *idx\_open\_bugs*” or “**USE INDEX** (*idx\_open\_bugs*)”, a query is processed without using the *idx\_open\_bugs* index.

#### Warning

If you execute queries by specifying indexes with index hint syntax even though the conditions of creating filtered indexes does not match the query conditions, CUBRID performs a query by choosing a specified index. Therefore, query results can be different with the given searching conditions.

**Note****Constraints**

Only generic indexes are allowed as filtered indexes. For example, the filtered unique index is not allowed. Also, it is not allowed that columns which compose an index are all NULLable. For example, below is not allowed because Author is NULLable.

```
CREATE INDEX idx_open_bugs ON bugs (Author) WHERE Closed = 0;
```

```
ERROR: before ' ; '
Invalid filter expression (bugs.Closed=0) for index.
```

However, below is allowed because Author is NULLable, but CreationDate is not NULLable.

```
CREATE INDEX idx_open_bugs ON bugs (Author, CreationDate) WHERE
Closed = 0;
```

The following cases are not allowed as filtering conditions.

- Functions, which output different results with the same input, such as date/time function or random function

```
CREATE INDEX idx ON bugs(creationdate) WHERE creationdate >
SYS_DATETIME;
```

```
ERROR: before ' ; '
'sys_datetime ' is not allowed in a filter expression for index.
```

```
CREATE INDEX idx ON bugs(bugID) WHERE bugID > RAND();
```

```
ERROR: before ' ; '
'rand ' is not allowed in a filter expression for index.
```

- In case of using the **OR** operator

```
CREATE INDEX IDX ON bugs (bugID) WHERE bugID > 10 OR bugID = 3;
```

```
ERROR: before ' ; '
' or ' is not allowed in a filter expression for index.
```

- In case of including functions like `INCR()`, `DECR()` functions, which modify the data of a table.
- In case of Serial-related functions and including pseudo columns.
- In case of including aggregate functions such as `MIN()`, `MAX()`, `STDDEV()`
- In case of using the types where indexes cannot be created
  - The operators and functions where an argument is the **SET** type
  - The functions to use LOB file( `CHAR_TO_BLOB()`, `CHAR_TO_CLOB()`, `BIT_TO_BLOB()`, `BLOB_FROM_FILE()`, `CLOB_FROM_FILE()` )
- The **IS NULL** operator can be used only when at least one column of an index is not **NULL**.

```
CREATE TABLE t (a INT, b INT);

-- IS NULL cannot be used with expressions
CREATE INDEX idx ON ta (a) WHERE (not ta.a<>0 ) IS NULL;
```

```
ERROR: before ' ; '
Invalid filter expression (( not [dba.ta].a<>0) is null ) for
index.
```

```
CREATE INDEX idx ON t (a) WHERE (a+1) IS NULL;
```

```
ERROR: before ' ; '
Invalid filter expression ((t.a+1) is null ) for index.
```

```
-- At least one attribute must not be used with IS NULL
CREATE INDEX idx ON t(a,b) WHERE a IS NULL ;
```

```
ERROR: before ' ; '
Invalid filter expression (t.a is null ) for index.
```

```
CREATE INDEX idx ON t(a,b) WHERE a IS NULL and b IS NULL;
```

```
ERROR: before ' ; '
Invalid filter expression (t.a is null and t.b is null ) for
index.
```

```
CREATE INDEX idx ON t(a,b) WHERE a IS NULL and b IS NOT NULL;
```

- Index Skip Scan (ISS) is not allowed for the filtered indexes.
- The length of condition string used for the filtered index is limited to 128 characters.

```
CREATE TABLE t(VeryLongColumnNameOfTypeInteger INT);

CREATE INDEX idx ON t(VeryLongColumnNameOfTypeInteger)
WHERE VeryLongColumnNameOfTypeInteger > 3 AND
VeryLongColumnNameOfTypeInteger < 10 AND
SQRT(VeryLongColumnNameOfTypeInteger) < 3 AND
SQRT(VeryLongColumnNameOfTypeInteger) < 10;
```

```
ERROR: before ' ; '
The maximum length of filter predicate string must be 128.
```

## Function-based Index

Function-based index is used to sort or find the data based on the combination of values of table rows by using a specific function. For example, to find the space-ignored string, it can be used to optimize the query by using the function that provides the feature. In addition, it is useful to search the non-case-sensitive names.

```
CREATE /** hints */ INDEX index_name
ON [schema_name.]table_name (function_name (argument_list));

ALTER /** hints */ INDEX index_name
[ ON [schema_name.]table_name (function_name (argument_list)) ]
REBUILD;
```

After the following indexes have been created, the **SELECT** query automatically uses the function-based index.

```
CREATE INDEX idx_trim_post ON posts_table(TRIM(keyword));

SELECT *
FROM posts_table
WHERE TRIM(keyword) = 'SQL';
```

If a function-based index is created by using the **LOWER** function, it can be used to search the non-case-sensitive names.

```
CREATE INDEX idx_last_name_lower ON clients_table(LOWER(LastName));

SELECT *
FROM clients_table
WHERE LOWER(LastName) = LOWER('Timothy');
```

To make an index selected while creating a query plan, the function used for the index should be used for the query condition in the same way. The **SELECT** query above uses the last\_name\_lower index created above. However, this index is not used for the following condition:

```
SELECT *
FROM clients_table
WHERE LOWER(CONCAT('Mr. ', LastName)) = LOWER('Mr. Timothy');
```

In addition, to make the function-based index used by force, use the **USING INDEX** syntax.

```
CREATE INDEX i_tbl_first_four ON tbl(LEFT(col, 4));
SELECT *
FROM clients_table
WHERE LEFT(col, 4) = 'CAT5'
USING INDEX i_tbl_first_four;
```

Functions with the function-based indexes are as follows:

|             |       |            |            |      |
|-------------|-------|------------|------------|------|
| ABS         | ACOS  | ADD_MONTHS | ADDDATE    | ASIN |
| ATAN        | ATAN2 | BIT_COUNT  | BIT_LENGTH | CEIL |
| CHAR_LENGTH | CHR   | COS        | COT        | DATE |

|            |             |              |                 |           |
|------------|-------------|--------------|-----------------|-----------|
| DATE_ADD   | DATE_FORMAT | DATE_SUB     | DATEDIFF        | DAY       |
| DAYOFMONTH | DAYOFWEEK   | DAYOFYEAR    | DEGREES         | EXP       |
| FLOOR      | FORMAT      | FROM_DAYS    | FROM_UNIXTIME   | GREATEST  |
| HOUR       | IFNULL      | INET_ATON    | INET_NTOA       | INSTR     |
| LAST_DAY   | LEAST       | LEFT         | LN              | LOCATE    |
| LOG        | LOG10       | LOG2         | LOWER           | LPAD      |
| LTRIM      | MAKEDATE    | MAKETIME     | MD5             | MID       |
| MINUTE     | MOD         | MONTH        | MONTHS_BETWEEN  | NULLIF    |
| NVL        | NVL2        | OCTET_LENGTH | POSITION        | POWER     |
| QUARTER    | RADIANS     | REPEAT       | REPLACE         | REVERSE   |
| RIGHT      | ROUND       | RPAD         | RTRIM           | SECOND    |
| SECTOTIME  | SIN         | SQRT         | STR_TO_DATE     | STRCMP    |
| SUBDATE    | SUBSTR      | SUBSTRING    | SUBSTRING_INDEX | TAN       |
| TIME       | TIME_FORMAT | TIMEDIFF     | TIMESTAMP       | TIMETOSEC |

|                |              |             |         |           |
|----------------|--------------|-------------|---------|-----------|
| TO_CHAR        | TO_DATE      | TO_DATETIME | TO_DAYS | TO_NUMBER |
| TO_TIME        | TO_TIMESTAMP | TRANSLATE   | TRIM    | TRUNC     |
| UNIX_TIMESTAMP | UPPER        | WEEK        | WEEKDAY | YEAR      |

Arguments of functions which can be used in the function-based indexes, only column names and constants are allowed; nested expressions are not allowed. For example, a statement below will cause an error.

```
CREATE INDEX my_idx ON tbl (TRIM(LEFT(col, 3)));
CREATE INDEX my_idx ON tbl (LEFT(col1, col2 + 3));
```

However, implicit cast is allowed. In the example below, the first argument type of the **LEFT** () function should be **VARCHAR** and the second argument type should be **INTEGER**; it works normally.

```
CREATE INDEX my_idx ON tbl (LEFT(int_col, str_col));
```

Function-based indexes cannot be used with filtered indexes. The example will cause an error.

```
CREATE INDEX my_idx ON tbl (TRIM(col)) WHERE col > 'SQL';
```

Function-based indexes cannot become multiple-columns indexes. The example will cause an error.

```
CREATE INDEX my_idx ON tbl (TRIM(col1), col2, LEFT(col3, 5));
```

## Optimization Using Indexes

### Covering Index

The covering index is the index including the data of all columns in the **SELECT** list and the **WHERE**, **HAVING**, **GROUP BY**, and **ORDER BY** clauses.

You only need to scan the index pages, as the covering index contains all the data necessary for executing a query, and it also reduces the I/O costs as it is not necessary to scan the data storage any further. To increase data search speed, you can consider creating a covering index but you should be aware that the **INSERT** and the **DELETE** processes may be slowed down due to the increase in index size.

The rules about the applicability of the covering index are as follows:

- If the covering index is applicable, you should use the CUBRID query optimizer first.
- For the join query, if the index includes columns of the table in the **SELECT** list, use this index.
- You cannot use the covering index if an index cannot be used.

```
CREATE TABLE t (col1 INT, col2 INT, col3 INT);
CREATE INDEX i_t_col1_col2_col3 ON t (col1,col2,col3);
INSERT INTO t VALUES (1,2,3),(4,5,6),(10,8,9);
```

The following example shows that the index is used as a covering index because columns of both **SELECT** and **WHERE** condition exist within the index.

```
-- csql> ;plan simple
SELECT * FROM t WHERE col1 < 6;
```

```
Query plan:
Index scan(t t, i_t_col1_col2_col3, [(t.col1 range (min inf_lt
t.col3))] (covers))
```

| col1 | col2 | col3 |
|------|------|------|
| 1    | 2    | 3    |
| 4    | 5    | 6    |

The following example shows an optimization that reduces unnecessary scans when the **SELECT** list only contains **COUNT(\*)** when using a covering index.

```
-- insert dummy data
INSERT INTO t select rownum % 8, rownum % 100, rownum % 1000 FROM
dual connect by level <= 40000;

-- csql> ;trace on

-- count(*) optimization
SELECT count(*) FROM t WHERE col1 < 9;
```

```
Trace Statistics:
  SELECT (time: 1, fetch: 66, fetch_time: 0, ioread: 0)
    SCAN (index: dba.t.i_t_col1_col2_col3), (btree time: 1, fetch:
65, ioread: 0, readkeys: 1002, filteredkeys: 0, rows: 0, covered:
true, count_only: true)
```

```
-- no count(*) optimization
SELECT count(col1) FROM t WHERE col1 < 9;
```

```
Trace Statistics:
  SELECT (time: 13, fetch: 180, fetch_time: 0, ioread: 0)
    SCAN (index: dba.t.i_t_col1_col2_col3), (btree time: 8, fetch:
179, ioread: 0, readkeys: 1002, filteredkeys: 0, rows: 40002,
covered: true)
```

#### Note

**COUNT(\*)** optimization for a single table when using a covering index is supported from CUBRID 11.2, and **COUNT(\*)** optimization for join tables is supported from CUBRID 11.3.

#### Warning

When a covering index is applied to retrieve values from a **VARCHAR** type column, any trailing empty strings will be truncated. This occurs because the empty string is stored in the index with the trailing spaces removed, affecting the query results when the index is used for query optimization.

If you don't want this, use the **NO\_COVERING\_IDX** hint, which does not use the covering index function. If you use the hint, you can get the result value from the data area rather than from the index area.

The following is a detailed example of the above situation. First, create a table with columns in **VARCHAR** types, and then **INSERT** the value with the same start character string value but the number of empty characters. Next, create an index in the column.

```
CREATE TABLE tab(c VARCHAR(32));
INSERT INTO tab VALUES('abcd'),('abcd  '),('abcd ');
CREATE INDEX i_tab_c ON tab(c);
```

If you must use the index (the covering index applied), the query result is as follows:

```
-- csql>plan simple
SELECT * FROM tab WHERE c='abcd' USING INDEX i_tab_c(+);
```

```
Query plan:
  Index scan(tab tab, i_tab_c, (tab.c='abcd' ) (covers))

  c
=====
'abcd'
'abcd'
'abcd'
```

The following is the query result when you don't use the index.

```
SELECT * FROM tab WHERE c='abcd' USING INDEX tab.NONE;
```

```
Query plan:
  Sequential scan(tab tab)

  c
=====
'abcd'
'abcd  '
'abcd  '
```

As you can see in the above comparison result, the value in the **VARCHAR** type retrieved from the index will appear with the following empty string truncated when the covering index has been applied.

### **Note**

If covering index optimization is available to be applied, the I/O performance can be improved because the disk I/O is decreased. But if you don't want covering index optimization in a special condition, specify a **NO\_COVERING\_IDX** hint to the query. For how to add a query, see [Using SQL Hint](#).

## Optimizing ORDER BY Clause

The index including all columns in the **ORDER BY** clause is referred to as the ordered index. Optimizing the query with **ORDER BY** clause is no need for the additional sorting process(skip order by), because the query results are searched by the ordered index. In general, for an ordered index, the columns in the **ORDER BY** clause should be located at the front of the index.

```
SELECT *  
FROM tab  
WHERE col1 > 0  
ORDER BY col1, col2;
```

- The index consisting of *tab (col1, col2)* is an ordered index.
- The index consisting of *tab (col1, col2, col3)* is also an ordered index. This is because the *col3*, which is not referred to by the **ORDER BY** clause, comes after *col1* and *col2*.
- The index consisting of *tab (col1)* is not an ordered index.
- You can use the index consisting of *tab (col3, col1, col2)* or *tab (col1, col3, col2)* for optimization. This is because *col3* is not located at the back of the columns in the **ORDER BY** clause.

Although the columns composing an index do not exist in the **ORDER BY** clause, you can use an ordered index if the column condition is a constant.

```
SELECT *  
FROM tab  
WHERE col2=val  
ORDER BY col1,col3;
```

If the index consisting of *tab (col1, col2, col3)* exists and the index consisting of *tab (col1, col2)* do not exist when executing the above query, the query optimizer uses the index consisting of *tab (col1, col2, col3)* as an ordered index. You can get the result in the requested order when you execute an index scan, so you don't need to sort records.

If you can use the sorted index and the covering index, use the latter first. If you use the covering index, you don't need to retrieve additional data, because the data result requested is included in the index page, and you won't need to sort the result if you are satisfied with the index order.

If the query doesn't include any conditions and uses an ordered index, the ordered index will be used under the condition that the first column meets the **NOT NULL** condition.

```
CREATE TABLE tab (i INT, j INT, k INT);  
CREATE INDEX i_tab_j_k on tab (j,k);  
INSERT INTO tab VALUES (1,2,3),(6,4,2),(3,4,1),(5,2,1),(1,5,5),(2,6,6),(3,5,4);
```

The following example shows that indexes consisting of *tab* (*j*, *k*) become sorted indexes and no separate sorting process is required because **GROUP BY** is executed by *j* and *k* columns.

```
SELECT i,j,k
FROM tab
WHERE j > 0
ORDER BY j,k;
```

```
-- the selection from the query plan dump shows that the ordering
index i_tab_j_k was used and sorting was not necessary
-- (/* --> skip ORDER BY */)
Query plan:
iscan
  class: tab node[0]
  index: i_tab_j_k term[0]
  sort:  2 asc, 3 asc
  cost:  1 card 0
Query stmt:
select tab.i, tab.j, tab.k from tab tab where ((tab.j> ?:0 )) order
by 2, 3
/* ---> skip ORDER BY */
```

| i | j | k |
|---|---|---|
| 5 | 2 | 1 |
| 1 | 2 | 3 |
| 3 | 4 | 1 |
| 6 | 4 | 2 |
| 3 | 5 | 4 |
| 1 | 5 | 5 |
| 2 | 6 | 6 |

The following example shows that *j* and *k* columns execute **ORDER BY** and the index including all columns are selected so that indexes consisting of *tab* (*j*, *k*) are used as covering indexes; no separate process is required because the value is selected from the indexes themselves.

```
SELECT /*+ RECOMPILE */ j,k
FROM tab
WHERE j > 0
ORDER BY j,k;
```

```
-- in this case the index i_tab_j_k is a covering index and also
respects the ordering index property.
-- Therefore, it is used as a covering index and sorting is not
performed.
```

Query plan:

iscan

```
class: tab node[0]
index: i_tab_j_k term[0] (covers)
sort:  1 asc, 2 asc
cost:  1 card 0
```

Query stmt: select tab.j, tab.k from tab tab where ((tab.j> ?:0 ))  
order by 1, 2  
/\* ---> skip ORDER BY \*/

| j | k |
|---|---|
| 2 | 1 |
| 2 | 3 |
| 4 | 1 |
| 4 | 2 |
| 5 | 4 |
| 5 | 5 |
| 6 | 6 |

The following example shows that *i* column exists, **ORDER BY** is executed by *j* and *k* columns, and columns that perform **SELECT** are *i*, *j*, and *k*. Therefore, indexes consisting of *tab* (*i*, *j*, *k*) are used as covering indexes; separate sorting process is required for **ORDER BY** *j*, *k* even though the value is selected from the indexes themselves.

```
CREATE INDEX i_tab_j_k ON tab (i,j,k);
SELECT /** RECOMPILE */ i,j,k
FROM tab
WHERE i > 0
ORDER BY j,k;
```

-- since an index on (i,j,k) is now available, it will be used as covering index. However, sorting the results according to -- the ORDER BY clause is needed.

Query plan:

temp(order by)

subplan: iscan

```
class: tab node[0]
index: i_tab_i_j_k term[0] (covers)
sort:  1 asc, 2 asc, 3 asc
cost:  1 card 1

sort:  2 asc, 3 asc
cost:  7 card 1
```

Query stmt: select tab.i, tab.j, tab.k from tab tab where ((tab.i> ?:0 )) order by 2, 3

| i     | j     | k     |
|-------|-------|-------|
| ===== | ===== | ===== |
| 5     | 2     | 1     |
| 1     | 2     | 3     |
| 3     | 4     | 1     |
| 6     | 4     | 2     |
| 3     | 5     | 4     |
| 1     | 5     | 5     |
| 2     | 6     | 6     |

**Note**

Even if the type of a column in the **ORDER BY** clause is converted by using `CAST()`, **ORDER BY** optimization is executed when the sorting order is the same as before.

| Before       | After        |
|--------------|--------------|
| numeric type | numeric type |
| string type  | string type  |
| DATETIME     | TIMESTAMP    |
| TIMESTAMP    | DATETIME     |
| DATETIME     | DATE         |
| TIMESTAMP    | DATE         |
| DATE         | DATETIME     |

## Index Scan in Descending Order

When a query is executed by sorting in descending order as follows, it usually creates a descending index. In this way, you do not have to go through addition procedure.

```
SELECT *  
FROM tab  
[WHERE ...]  
ORDER BY a DESC;
```

However, if you create an ascending index and an descending index in the same column, the possibility of deadlock increases. In order to decrease the possibility of such case, CUBRID supports the descending scan only with ascending index. Users can use the **USE\_DESC\_IDX** hint to specify the use of the descending scan. If the hint is not specified, the following three query executions should be considered, provided that the columns listed in the **ORDER BY** clause can use the index.

- Sequential scan + Sort in descending order
- Scan in general ascending order + sort in descending
- Scan in descending order that does not require a separate scan

Although the **USE\_DESC\_IDX** hint is omitted for the scan in descending order, the query optimizer decides the last execution plan of the three listed for an optimal plan.

### Note

The **USE\_DESC\_IDX** hint is not supported for the join query.

```
CREATE TABLE di (i INT);  
CREATE INDEX i_di_i ON di (i);  
INSERT INTO di VALUES (5),(3),(1),(4),(3),(5),(2),(5);
```

The query will be executed as an ascending scan without **USE\_DESC\_IDX** hint.

```
-- The query will be executed with an ascending scan.  
  
SELECT *  
FROM di  
WHERE i > 0  
LIMIT 3;
```

Query plan:

```
Index scan(di di, i_di_i, (di.i range (0 gt_inf max) and inst_num()
range (min inf_le 3)) (covers))
```

```

      i
=====
      1
      2
      3
```

If you add **USE\_DESC\_IDX** hint to the above query, a different result will be shown by descending scan.

```
-- We now run the following query, using the 'use_desc_idx' SQL
hint:
```

```
SELECT /*+ USE_DESC_IDX */ *
FROM di
WHERE i > 0
LIMIT 3;
```

Query plan:

```
Index scan(di di, i_di_i, (di.i range (0 gt_inf max) and inst_num()
range (min inf_le 3)) (covers) (desc_index))
```

```

      i
=====
      5
      5
      5
```

The following example requires descending **ORDER BY** clause. In this case, there is no **USE\_DESC\_IDX** but do the descending scan.

```
-- We also run the same query, this time asking that the results are
displayed in descending order.
-- However, no hint is given.
-- Since ORDER BY...DESC clause exists, CUBRID will use descending
scan, even though the hint is not given,
-- thus avoiding to sort the records.
```

```
SELECT *
FROM di
WHERE i > 0
ORDER BY i DESC LIMIT 3;
```

```
Query plan:
  Index scan(di di, i_di_i, (di.i range (0 gt_inf max)) (covers)
(desc_index))
```

```

          i
=====
          5
          5
          5
```

## Optimizing GROUP BY Clause

**GROUP BY** clause optimization works on the premise that if all columns in the **GROUP BY** clause are included in an index, CUBRID can use the index upon executing a query, so CUBRID don't execute a separate sorting job. The columns in the **GROUP BY** clause must exist in front side of the column forming the index.

```
SELECT *
FROM tab
WHERE col1 > 0
GROUP BY col1,col2;
```

- You can use the index consisting of *tab ( col1, col2 )* for optimization.
- The index consisting of *tab ( col1, col2, col3 )* can be used because *col3* which is not referred to by **GROUP BY** comes after *col1* and *col2*.
- You cannot use the index consisting of *tab ( col1 )* for optimization.
- You also cannot use the index consisting of *tab ( col3, col1, col2 )* or *tab ( col1, col3, col2 )*, because *col3* is not located at the back of the column in the **GROUP BY** clause.

You can use the index if the column condition is a constant although the column consisting of the index doesn't exist in the **GROUP BY** clause.

```
SELECT *
FROM tab
WHERE col2=val
GROUP BY col1,col3;
```

If there is any index that consists of *tab ( col1, col2, col3 )* in the above example, use the index for optimizing **GROUP BY**.

Row sorting by **GROUP BY** is not required, because you can get the result as the requested order on the index scan.

If the index consisting of the **GROUP BY** column and the first column of the index is **NOT NULL**, even though there is no **WHERE** clause, the **GROUP BY** optimization will be applied.

If there is an index made of **GROUP BY** columns even when using aggregate functions, **GROUP BY** optimization is applied.

```
CREATE INDEX i_T_a_b_c ON T(a, b, c);
SELECT a, MIN(b), c, MAX(b) FROM T WHERE a > 18 GROUP BY a, b;
```

#### Note

When a column of **DISTINCT** or a **GROUP BY** clause contains the subkey of a index, loose index scan adjusts the scope dynamically to unique values of the each columns constituting the partial key, and starts the search of a B-tree. Regarding this, see [Loose Index Scan](#).

### Example

```
CREATE TABLE tab (i INT, j INT, k INT);
CREATE INDEX i_tab_j_k ON tab (j, k);
INSERT INTO tab VALUES (1,2,3),(6,4,2),(3,4,1),(5,2,1),(1,5,5),(2,6,6),(3,5,4);

UPDATE STATISTICS on tab;
```

The following example shows that indexes consisting of *tab ( j, k )* are used and no separate sorting process is required because **GROUP BY** is executed by *j* and *k* columns.

```
SELECT /*+ RECOMPILE */ j,k
FROM tab
WHERE j > 0
GROUP BY j,k;

-- the selection from the query plan dump shows that the index
i_tab_j_k was used and sorting was not necessary
-- (/* ---> skip GROUP BY */)

```

```
Query plan:
iscan
  class: tab node[0]
```

```

index: i_tab_j_k term[0]
sort:  2 asc, 3 asc
cost:  1 card 0

```

Query stmt:

```

select tab.i, tab.j, tab.k from tab tab where ((tab.j > ? : 0 )) group
by tab.j, tab.k

```

```

/* ---> skip GROUP BY */

```

| i | j | k |
|---|---|---|
| 5 | 2 | 1 |
| 1 | 2 | 3 |
| 3 | 4 | 1 |
| 6 | 4 | 2 |
| 3 | 5 | 4 |
| 1 | 5 | 5 |
| 2 | 6 | 6 |

The following example shows that an index consisting of *tab ( j, k )* is used and no separate sorting process is required while **GROUP BY** is executed by *j* and *k* columns, no condition exists for *j*, and *j* column has **NOT NULL** attribute.

```

ALTER TABLE tab CHANGE COLUMN j j INT NOT NULL;

```

```

SELECT *
FROM tab
GROUP BY j,k;

```

```

-- the selection from the query plan dump shows that the index
i_tab_j_k was used (since j has the NOT NULL constraint )

```

```

-- and sorting was not necessary (/* ---> skip GROUP BY */)

```

Query plan:

iscan

```

class: tab node[0]
index: i_tab_j_k
sort:  2 asc, 3 asc
cost:  1 card 0

```

Query stmt: select tab.i, tab.j, tab.k from tab tab group by tab.j, tab.k

```

/* ---> skip GROUP BY */

```

```

=== <Result of SELECT Command in Line 1> ===

```

| i | j | k |
|---|---|---|
| 5 | 2 | 1 |
| 1 | 2 | 3 |
| 3 | 4 | 1 |
| 6 | 4 | 2 |
| 3 | 5 | 4 |

|   |   |   |
|---|---|---|
| 1 | 5 | 5 |
| 2 | 6 | 6 |

```
CREATE TABLE tab (k1 int, k2 int, k3 int, v double);
INSERT INTO tab
  SELECT
    RAND(CAST(UNIX_TIMESTAMP() AS INT)) MOD 5,
    RAND(CAST(UNIX_TIMESTAMP() AS INT)) MOD 10,
    RAND(CAST(UNIX_TIMESTAMP() AS INT)) MOD 100000,
    RAND(CAST(UNIX_TIMESTAMP() AS INT)) MOD 100000
  FROM db_class a, db_class b, db_class c, db_class d LIMIT 20000;
CREATE INDEX idx ON tab(k1, k2, k3);
```

If you create tables and indexes of the above, the following example runs the **GROUP BY** with *k1*, *k2* columns and performs an aggregate function in *k3*; therefore, the index which consists of *tab* (*k1*, *k2*, *k3*) is used and no sort processing is required. In addition, because all columns of *k1*, *k2*, *k3* of **SELECT** list are present in the index configured in the *tab* (*k1*, *k2*, *k3*), covering index is applied.

```
SELECT /*+ RECOMPILE INDEX_SS */ k1, k2, SUM(DISTINCT k3)
FROM tab
WHERE k2 > -1 GROUP BY k1, k2;
```

Query plan:

```
iscan
  class: tab node[0]
  index: idx term[0] (covers) (index skip scan)
  sort:  1 asc, 2 asc
  cost:  85 card 2000
```

Query stmt:

```
select tab.k1, tab.k2, sum(distinct tab.k3) from tab tab where
(tab.k2> ?:0 ) group by tab.k1, tab.k2
```

```
/* ---> skip GROUP BY */
```

The following example performs **GROUP BY** clause with *k1*, *k2* columns; therefore, the index composed with *tab* (*k1*, *k2*, *k3*) is used and no sort processing is required. However, *v* column in the **SELECT** list is not present in the index composed of *tab* (*k1*, *k2*, *k3*); therefore, it does not apply covering index.

```
SELECT /*+ RECOMPILE INDEX_SS */ k1, k2, stddev_samp(v)
FROM tab
WHERE k2 > -1 GROUP BY k1, k2;
```

Query plan:

```
iscan
  class: tab node[0]
  index: idx term[0] (index skip scan)
  sort:  1 asc, 2 asc
  cost:  85 card 2000
```

Query stmt:

```
select tab.k1, tab.k2, stddev_samp(tab.v) from tab tab where
(tab.k2> ?:0 ) group by tab.k1, tab.k2
```

```
/* --->skip GROUP BY */
```

## Multiple Key Ranges Optimization

Optimizing the **LIMIT** clause is crucial for performance because the most queries have limit filter. A representative optimization of this case is Multiple Key Ranges Optimization.

Multiple Key Ranges Optimization generate the query result with Top N Sorting to scan only some key ranges in an index rather than doing a full index scan. Top N Sorting always keeps the best N tuples sorted rather than selecting all tuples and then sorting. Therefore, it shows the outstanding performance.

For example, when you search only the recent 10 posts which your friends wrote, CUBRID which applied Multiple KEY Ranges Optimization finds the result not by sorting after finding all your friends' posts, but by scanning the index which keeps the recent 10 sorted posts of each friends.

An example of Multiple Key Ranges Optimization is as follows.

```
CREATE TABLE t (a int, b int);
CREATE INDEX i_t_a_b ON t (a,b);

-- Multiple key range optimization
SELECT *
FROM t
WHERE a IN (1,2,3)
ORDER BY b
LIMIT 2;
```

```

Query plan:
iscan
class: t node[0]
index: i_t_a_b term[0] (covers) (multi_range_opt)
sort: 1 asc, 2 asc
cost: 1 card 0

```

On a single table, multiple key range optimization can be applied if below conditions are satisfied.

```

SELECT /*+ hints */ ...
FROM table
WHERE col_1 = ? AND col_2 = ? AND ... AND col(j-1) = ?
AND col_(j) IN (?, ?, ...)
AND col_(j+1) = ? AND ... AND col_(p-1) = ?
AND key_filter_terms
ORDER BY col_(p) [ASC|DESC], col_(p+1) [ASC|DESC], ... col_(p+k-1)
[ASC|DESC]
LIMIT n;

```

Firstly, upper limit( $n$ ) for **LIMIT** should be less than or equal to the value of **multi\_range\_optimization\_limit** system parameter.

And you need the proper index to the multiple key range optimization, this index should cover all  $k$  columns specified in the **ORDER BY** clause. In other words, this index should include all  $k$  columns specified in the **ORDER BY** clause and the sorting order should be the same as the columns' order. Also this index should include all columns used in **WHERE** clause.

Among columns that comprise the index,

- Columns in front of range condition(e.g. IN condition) are represented as equivalent condition(=).
- Only one column with range condition exists.
- Columns after range condition exist as key filters.
- There should be no data filtering condition. In other words, the index should include all columns used in **WHERE** clause.
- Columns after the key filter exist in **ORDER BY** clause.
- Columns of key filter condition always should not the column of **ORDER BY** clause.
- If key filter condition with correlated subquery exists, related columns to this should be included into **WHERE** clause with no range condition.

On the below example, Multiple Key Ranges Optimization can be applied.

```
CREATE TABLE t (a INT, b INT, c INT, d INT, e INT);
CREATE INDEX i_t_a_b ON t (a,b,c,d,e);

SELECT *
FROM t
WHERE a = 1 AND b = 3 AND c IN (1,2,3) AND d = 3
ORDER BY e
LIMIT 2;
```

Queries with multiple joined tables can also support Multiple Key Ranges Optimization:

```
SELECT /*+ hints */ ...
FROM table_1, table_2, ... table_(sort), ...
WHERE col_1 = ? AND col_2 = ? AND ...
AND col_(j) IN (?, ?, ... )
AND col_(j+1) = ? AND ... AND col_(p-1) = ?
AND key_filter_terms
AND join_terms
ORDER BY col_(p) [ASC|DESC], col_(p+1) [ASC|DESC], ... col_(p+k-1)
[ASC|DESC]
LIMIT n;
```

If queries with multiple joined tables can support Multiple Key Ranges Optimization, below conditions should be satisfied:

- Columns in **ORDER BY** clause only exist on one table, and this table should satisfy all required conditions by Multiple Key Ranges Optimization on a single table query. Let the “sort table” be the table that contains all sorting columns.
- All columns of “sort table” specified in a JOIN condition between “sort table” and “outer tables” should be included on an index. In other words, there should be no data filtering condition.
- All columns of “sort table” specified in a JOIN condition between “sort table” and “outer tables” should be included on the **WHERE** clause with no range condition.

#### Note

In most cases available to apply Multiple Key Ranges Optimization, this optimization shows the best performance. However, if you do not want this optimization on the special case, specify **NO\_MULTI\_RANGE\_OPT** hint to the query. For details, see [Using SQL Hint](#).

## Index Skip Scan

Index Skip Scan (here after ISS) is an optimization method that allows ignoring the first column of an index when the first column of the index is not included in the condition but the following column is included in the condition (in most cases, =).

Applying ISS is considered when **INDEX\_SS** for specific tables is specified through a query hint and the below cases are satisfied.

1. The query condition should be specified from the second column of the composite index.
2. The used index should not be a filtered index.
3. The first column of an index should not be a range filter or key filter.
4. A hierarchical query is not supported.
5. A query which an aggregate function is included is not supported.

In a **INDEX\_SS** hint, a list of table to consider applying ISS, can be input; if a list of table is omitted, applying ISS for all tables can be considered.

```
/** INDEX_SS */
/** INDEX_SS(tbl1) */
/** INDEX_SS(tbl1, tbl2) */
```

### Note

When "INDEX\_SS" is input, the ISS hint is applied to all tables; when "INDEX\_SS()" is input, this hint is ignored.

```
CREATE TABLE t1 (id INT PRIMARY KEY, a INT, b INT, c INT);
CREATE TABLE t2 (id INT PRIMARY KEY, a INT, b INT, c INT);
CREATE INDEX i_t1_ac ON t1(a,c);
CREATE INDEX i_t2_ac ON t2(a,c);

INSERT INTO t1 SELECT rownum, rownum, rownum, rownum
FROM db_class x1, db_class x2, db_class LIMIT 10000;

INSERT INTO t2 SELECT id, a%5, b, c FROM t1;

SELECT /** INDEX_SS */ *
FROM t1, t2
WHERE t1.b<5 AND t1.c<5 AND t2.c<5
USING INDEX i_t1_ac, i_t2_ac limit 1;
```

```

SELECT /*+ INDEX_SS(t1) */ *
FROM t1, t2
WHERE t1.b<5 AND t1.c<5 AND t2.c<5
USING INDEX i_t1_ac, i_t2_ac LIMIT 1;

SELECT /*+ INDEX_SS(t1, t2) */ *
FROM t1, t2
WHERE t1.b<5 AND t1.c<5 AND t2.c<5
USING INDEX i_t1_ac, i_t2_ac LIMIT 1;

```

Generally, ISS should consider several columns (C1, C2, ..., Cn). Here, a query has the conditions for the consecutive columns and the conditions are started from the second column (C2) of the index.

```

INDEX (C1, C2, ..., Cn);

SELECT ... WHERE C2 = x AND C3 = y AND ... AND Cp = z; -- p <= n
SELECT ... WHERE C2 < x AND C3 >= y AND ... AND Cp BETWEEN (z AND
w); -- other conditions than equal

```

The query optimizer eventually determines whether ISS is the most optimum access method based on the cost. ISS is applied under very specific situations, such as when the first column of an index has a very small number of **DISTINCT** values compared to the number of records. In this case, ISS provides higher performance compared to Index Full Scan. For example, when the first column of index columns has very low cardinality, such as the value of men/women or millions of records with the value of 1-100, it may be inefficient to perform index scan by using the first column value. So ISS is useful in this case.

ISS skips reading most of the index pages in the disk and uses range search which is dynamically readjusted. Generally, ISS can be applied to a specific scenario when the number of **DISTINCT** values in the first column is very small. If ISS is applied to this case, ISS provides significantly higher performance than the index full scan. However, it means improper index creation that ISS is applied to a lot queries. So DBA should consider whether readjusting the indexes or not.

```

CREATE TABLE tbl (name STRING, gender CHAR (1), birthday DATETIME);

INSERT INTO tbl
SELECT ROWNUM, CASE (ROWNUM MOD 2) WHEN 1 THEN 'M' ELSE 'F' END,
SYSDATETIME
FROM db_class a, db_class b, db_class c, db_class d, db_class e
LIMIT 360000;

CREATE INDEX idx_tbl_gen_name ON tbl (gender, name);
-- Note that gender can only have 2 values, 'M' and 'F' (low
cardinality)

```

```
UPDATE STATISTICS ON ALL CLASSES;
```

```
-- csql>;plan simple
-- this will qualify to use Index Skip Scanning
SELECT /*+ RECOMPILE INDEX_SS */ *
FROM tbl
WHERE name = '1000';
```

Query plan:

```
Index scan(tbl tbl, idx_tbl_gen_name, tbl.[name]=?:0 (index skip scan))
```

```
-- csql>;plan simple
-- this will qualify to use Index Skip Scanning
SELECT /*+ RECOMPILE INDEX_SS */ *
FROM tbl
WHERE name between '1000' and '1050';
```

Query plan:

```
Index scan(tbl tbl, idx_tbl_gen_name, (tbl.[name]>=?:0 and tbl.[name]<=?:1) (index skip scan))
```

## Loose Index Scan

When **GROUP BY** clause or **DISTINCT** column includes a subkey of a index, loose index scan starts B-tree search by adjusting the range dynamically for unique value of each of the columns that make up the subkey. Therefore, it is possible to significantly reduce the scanning area of B-tree.

Applying loose index scan is advantageous when the cardinality of the grouped column is very small, compared to the total data amount.

Loose index scan optimization is considered to be applied when **INDEX\_LS** is input as a hint and the below cases are satisfied:

1. when an index covers all **SELECT** list, that is, covered index is applied.
2. when the statement is **SELECT DISTINCT, SELECT ... GROUP BY** statement or a single tuple **SELECT**.
3. all aggregate functions (with the exception of **MIN/MAX**) must have **DISTINCT** input

4. **COUNT(\*)** should not be used
5. when cardinality of the used subkey is 100 times smaller than the cardinality of the whole index  
a subkey is a prefix part in a composite index; e.g. when there is INDEX(a, b, c, d), (a), (a, b) or (a, b, c) belongs to the subkey.

When you run the below query regarding the above table,

```
SELECT /*+ INDEX_LS */ a, b FROM tbl GROUP BY a;
```

CUBRID cannot use a subkey because there is no condition for the column a. However, if the condition of the subkey is specified as follows, loose index scan can be applied.

```
SELECT /*+ INDEX_LS */ a, b FROM tbl WHERE a > 10 GROUP BY a;
```

As follows, a subkey can be used when the grouped column is on the first and the WHERE-condition column is on the following position; therefore, also in this case, loose index scan can be applied.

```
SELECT /*+ INDEX_LS */ a, b FROM tbl WHERE b > 10 GROUP BY a;
```

The following shows the cases when loose index scan optimization is applied.

```
CREATE TABLE tbl1 (  
    k1 INT,  
    k2 INT,  
    k3 INT,  
    k4 INT  
);  
  
INSERT INTO tbl1  
SELECT ROWNUM MOD 2, ROWNUM MOD 400, ROWNUM MOD 80000, ROWNUM  
FROM db_class a, db_class b, db_class c, db_class d, db_class e  
LIMIT 360000;  
  
CREATE INDEX idx ON tbl1 (k1, k2, k3);  
  
CREATE TABLE tbl2 (  
    k1 INT,  
    k2 INT  
);  
  
INSERT INTO tbl2 VALUES (0, 0), (1, 1), (0, 2), (1, 3), (0, 4), (0,  
100), (1000, 1000);
```

```
UPDATE STATISTICS ON ALL CLASSES;
```

```
-- csql>;plan simple
-- add a condition to the grouped column, k1 to enable loose index
scan
SELECT /*+ RECOMPILE INDEX_LS */ DISTINCT k1
FROM tbl1
WHERE k1 > -1000000 LIMIT 20;
```

Query plan:

```
Sort(distinct)
  Index scan(tbl1 tbl1, idx, (tbl1.k1> ?:0 ) (covers) (loose index
scan on prefix 1))
```

```
-- csql>;plan simple
-- different key ranges/filters
SELECT /*+ RECOMPILE INDEX_LS */ DISTINCT k1
FROM tbl1
WHERE k1 >= 0 AND k1 <= 1;
```

Query plan:

```
Sort(distinct)
  Index scan(tbl1 tbl1, idx, (tbl1.k1>= ?:0 and tbl1.k1<= ?:1 )
(covers) (loose index scan on prefix 1))
```

```
-- csql>;plan simple
SELECT /*+ RECOMPILE INDEX_LS */ DISTINCT k1, k2
FROM tbl1
WHERE k1 >= 0 AND k1 <= 1 AND k2 > 3 AND k2 < 11;
```

Query plan:

```
Sort(distinct)
  Index scan(tbl1 tbl1, idx, (tbl1.k1>= ?:0 and tbl1.k1<= ?:1 ),
[(tbl1.k2> ?:2 and tbl1.k2< ?:3 )] (covers) (loose index scan on
prefix 2))
```

```
-- csql>;plan simple
SELECT /*+ RECOMPILE INDEX_LS */ DISTINCT k1, k2
```

```
FROM tbl1
WHERE k1 >= 0 AND k1 + k2 <= 10;
```

Query plan:

```
Sort(distinct)
  Index scan(tbl1 tbl1, idx, (tbl1.k1>= ?:0 ),
[tbl1.k1+tbl1.k2<=10] (covers) (loose index scan on prefix 2))
```

```
-- csql>;plan simple
SELECT /** RECOMPILE INDEX_LS */ tbl1.k1, tbl1.k2
FROM tbl2 INNER JOIN tbl1
ON tbl2.k1 = tbl1.k1 AND tbl2.k2 = tbl1.k2
GROUP BY tbl1.k1, tbl1.k2;
```

```
Sort(group by)
  Nested loops
    Sequential scan(tbl2 tbl2)
    Index scan(tbl1 tbl1, idx, tbl2.k1=tbl1.k1 and
tbl2.k2=tbl1.k2 (covers) (loose index scan on prefix 2))
```

```
SELECT /** RECOMPILE INDEX_LS */ MIN(k2), MAX(k2)
FROM tbl1;
```

Query plan:

```
Index scan(tbl1 tbl1, idx (covers) (loose index scan on prefix 2))
```

```
-- csql>;plan simple
SELECT /** RECOMPILE INDEX_LS */ SUM(DISTINCT k1), SUM(DISTINCT k2)
FROM tbl1;
```

Query plan:

```
Index scan(tbl1 tbl1, idx (covers) (loose index scan on prefix 2))
```

```
-- csql>;plan simple
SELECT /** RECOMPILE INDEX_LS */ DISTINCT k1
FROM tbl1
WHERE k2 > 0;
```

Query plan:

```
Sort(distinct)
  Index scan(tbl1 tbl1, idx, [(tbl1.k2> ?:0 )] (covers) (loose
index scan on prefix 2))
```

The following shows the cases when loose index scan optimization is not applied.

```
-- csql>;plan simple
-- not enabled when full key is used
SELECT /*+ RECOMPILE INDEX_LS */ DISTINCT k1, k2, k3
FROM tbl1
ORDER BY 1, 2, 3 LIMIT 10;
```

Query plan:

```
Sort(distinct)
  Sequential scan(tbl1 tbl1)
```

```
-- csql>;plan simple
SELECT /*+ RECOMPILE INDEX_LS */ k1, k2, k3
FROM tbl1
WHERE k1 > -10000 GROUP BY k1, k2, k3 LIMIT 10;
```

Query plan:

```
Index scan(tbl1 tbl1, idx, (tbl1.k1> ?:0 ) (covers))
skip GROUP BY
```

```
-- csql>;plan simple
-- not enabled when using count star
SELECT /*+ RECOMPILE INDEX_LS */ COUNT(*), k1
FROM tbl1
WHERE k1 > -10000 GROUP BY k1;
```

Query plan:

```
Index scan(tbl1 tbl1, idx, (tbl1.k1> ?:0 ) (covers))
skip GROUP BY
```

```
-- csql>;plan simple
-- not enabled when index is not covering
SELECT /*+ RECOMPILE INDEX_LS */ k1, k2, SUM(k4)
FROM tbl1
WHERE k1 > -1 AND k2 > -1 GROUP BY k1, k2 LIMIT 10;
```

Query plan:

```
Index scan(tbl1 tbl1, idx, (tbl1.k1> ?:0 ), [(tbl1.k2> ?:1 )])
skip GROUP BY
```

```
-- csql>;plan simple
-- not enabled for non-distinct aggregates
SELECT /*+ RECOMPILE INDEX_LS */ k1, SUM(k2)
FROM tbl1
WHERE k1 > -1 GROUP BY k1;
```

Query plan:

```
Index scan(tbl1 tbl1, idx, (tbl1.k1> ?:0 ) (covers))
skip GROUP BY
```

```
-- csql>;plan simple
SELECT /*+ RECOMPILE */ SUM(k1), SUM(k2)
FROM tbl1;
```

Query plan:

```
Sequential scan(tbl1 tbl1)
```

## In Memory Sort

The “in memory sort(IMS)” feature is an optimization applied to the **LIMIT** queries specifying **ORDER BY**. Normally, when executing a query which specifies **ORDER BY** and **LIMIT** clauses, CUBRID generates the full sorted result set and then applies the **LIMIT** operator to this result set. With the IMS optimization, instead of generating the whole result set, CUBRID uses an in-memory binary heap in which only tuples satisfying the **ORDER BY** and **LIMIT** clauses are allowed. This optimization improves performance by eliminating the need for a full unordered result set.

Whether this optimization is applied or not is not transparent to users. CUBRID decides to use in memory sort in the following situation:

- The query specifies **ORDER BY** and **LIMIT** clauses.
- The size of the final result (after applying the **LIMIT** clause) is less than the amount of memory used by external sort (see **sort\_buffer\_size** in [Memory-Related Parameters](#)).

Note that IMS considers the actual size of the result and not the count of tuples the result contains. For example, for the default sort buffer size (two megabytes), this optimization will be applied for a **LIMIT** value of 524,288 tuples consisting of one 4 byte **INTEGER** type but only for ~2,048 tuples of **CHAR** (1024) values. This optimization is not applied to queries requiring **DISTINCT** ordered result sets.

## SORT-LIMIT optimization

The SORT-LIMIT optimization applies to queries specifying **ORDER BY** and **LIMIT** clauses. The idea behind it is to evaluate the **LIMIT** operator as soon as possible in the query plan in order to benefit from the reduced cardinality during joins.

A SORT-LIMIT plan can be generated when the following conditions are met:

- All referred tables in the **ORDER BY** clause belong to the SORT-LIMIT plan.
- A table belonging to a SORT-LIMIT plan is either:
  - The owner of a foreign key from a fk->pk join
  - The left side of a **LEFT JOIN**.
  - The right side of a **RIGHT JOIN**.
- **LIMIT** rows should be specified as less rows than the value of **sort\_limit\_max\_count** system parameter(default: 1000).
- Query does not have cross joins.
- Query joins at least two relations.
- Query does not have a **GROUP BY** clause.
- Query does not specify **DISTINCT**.
- **ORDER BY** expressions can be evaluated during scan.

For example, the below query cannot apply SORT-LIMIT plan because **SUM** cannot be evaluated during scan.

```
SELECT SUM(u.i) FROM u, t where u.i = t.i ORDER BY 1 LIMIT 5;
```

The below is an example of planning SORT-LIMIT.

```
CREATE TABLE t(i int PRIMARY KEY, j int, k int);
CREATE TABLE u(i int, j int, k int);
ALTER TABLE u ADD constraint fk_t_u_i FOREIGN KEY(i) REFERENCES t(i);
CREATE INDEX i_u_j ON u(j);

INSERT INTO t SELECT ROWNUM, ROWNUM, ROWNUM FROM _DB_CLASS a,
_DB_CLASS b LIMIT 1000;
INSERT INTO u SELECT 1+(ROWNUM % 1000), RANDOM(1000), RANDOM(1000)
FROM _DB_CLASS a, _DB_CLASS b, _DB_CLASS c LIMIT 5000;

SELECT /*+ RECOMPILE */ * FROM u, t WHERE u.i = t.i AND u.j > 10
ORDER BY u.j LIMIT 5;
```

The above **SELECT** query's plan is printed out as below; we can see "(sort limit)".

Query plan:

```
idx-join (inner join)
  outer: temp(sort limit)
    subplan: iscan
      class: u node[0]
      index: i_u_j term[1]
      cost: 1 card 0
    cost: 1 card 0
  inner: iscan
    class: t node[1]
    index: pk_t_i term[0]
    cost: 6 card 1000
  sort: 2 asc
  cost: 7 card 0
```

## Optimization Using Rewrite

### Join transforming Optimization

The join transforming optimization is a method to reduce join operations and improve the query performance by transforming the joins with the tables that do not affect the query results.

In the join transforming optimization, there are three operations:

1. Transforming **OUTER JOIN** to **INNER JOIN**
2. Eliminating **INNER JOIN**
3. Eliminating **LEFT OUTER JOIN**

To disable the join elimination optimization, use the **NO\_ELIMINATE\_JOIN** hint.

### Transforming **OUTER JOIN** to **INNER JOIN**

**OUTER JOIN** has a predefined join order with the leading table and trailing table, which restricts join order optimization. For performance improvement, **CUBRID** converts **OUTER JOIN** to **INNER JOIN** if there is a predicate which is not nullable on the trailing table. A nullable predicate is excluded from this transformation and satisfy the following conditions:

1. Predicates written in the **ON** clause.
2. Using **NULL** transformation functions. This includes **COALESCE (), NVL (), NVL2 (), DECODE (), IF (), IFNULL (), CONCAT\_WS ()**.
3. **IS NULL ,CASE** statements are also not targets for **Predicate Push**.

The following example shows an optimization that transform **OUTER JOIN** to **INNER JOIN**.

```
--create table
CREATE TABLE t1 (col1 int, col2 int);
INSERT INTO t1 values (1,1),(2,2),(3,2);

-- csql> ;plan simple
SELECT /** recompile */ *
FROM t1 a LEFT OUTER JOIN t1 b on a.col1 = b.col2
WHERE b.col1 = 2;
```

```
Query Plan:
  NESTED LOOPS (inner join)
    TABLE SCAN (a)
    TABLE SCAN (b)
```

The following example demonstrates that the transformation from **OUTER JOIN** to **INNER JOIN** is not possible due to the nullable predicate.

```
-- csql> ;plan simple
SELECT /** recompile */ *
```

```
FROM t1 a LEFT OUTER JOIN t1 b on a.col1 = b.col2
WHERE nvl(b.col1,2) = 2;
```

```
Query Plan:
  NESTED LOOPS (left outer join)
    TABLE SCAN (a)
    TABLE SCAN (b)
```

## Eliminating **INNER JOIN**

The relationship between a table with a primary key (**PK**) and a table with a foreign key (**FK**) that refers to that primary key (**PK**) is called a parent-child relationship. In **INNER JOIN** of a parent-child relationship, if there are no references to the parent table other than the join conditions, eliminating the join with the parent table does not affect the query results. In this case, by elimination the join with the parent table, the join operation is reduced and the query performance is improved.

To eliminate the **INNER JOIN**, the following conditions must be satisfied:

1. Perform the **INNER JOIN** of the parent-child relationship.
2. All columns of the primary key (**PK**) and the foreign key (**FK**) must be used in the join condition.
3. The primary key (**PK**) column must be used in the same join condition as a foreign key (**FK**) column that refers to the corresponding primary key (**PK**) column.
4. All join conditions must use the equality (=) comparison.
5. There must be no references to the parent table other than the join conditions.
6. The **ALL** keyword must not be used when querying the tables that have an inheritance relationship.

When eliminating the join with the parent table, if the foreign key (**FK**) column in the child table does not have the **NOT NULL** constraint, the **IS NOT NULL** condition is added to that column.

The following is an example of eliminating the **INNER JOIN**.

```
call login ('public') on class db_user;

/* current_user: public */
drop table if exists child_tbl, parent_tbl;

create table parent_tbl (
  id int,
```

```

        sub_id int,
        name varchar (100),
        filter int,
        primary key (id, sub_id)
    );

insert into parent_tbl
select
    ((rownum - 1) / 10) + 1 as id,
    (((rownum - 1) % 10) + 1) * 10 as sub_id,
    'Parent-' || lpad (rownum, 3) as name,
    ((rownum - 1) % 10) + 1 as filter
from db_root
connect by level <= 100;

create table child_tbl (
    id int,
    name varchar (100),
    filter int,
    parent_id int not null,
    parent_sub_id int,
    primary key (id),
    foreign key (parent_id, parent_sub_id) references parent_tbl
(id, sub_id)
);

insert into child_tbl
select
    rownum as id,
    'Child-' || lpad (rownum, 5) as name,
    ((rownum - 1) % 100) + 1 as filter,
    id as parent_id,
    sub_id as parent_sub_id
from parent_tbl, (select level from db_root connect by level <= 100);

update statistics on parent_tbl, child_tbl with fullscan;

```

```

/* current_user: public */
set optimization level 513;

select /*+ recompile */
    c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
    parent_tbl p
    inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where
    c.filter = 1 and c.parent_id = 1
order by
    c.name;

```

The join with the *parent\_tbl* table has been eliminated, and the **IS NOT NULL** condition for the *parent\_sub\_id* column of the *child\_tbl* table has been added.

Query plan:

```
temp(order by)
  subplan: iscan
            class: c node[0]
            index: fk_child_tbl_parent_id_parent_sub_id term[1]
            filtr: term[2]
            sargs: term[0]
            sort: 5 asc
            cost: 8 card 1
    sort: 2 asc
    cost: 14 card 1
```

Query stmt:

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
child_tbl c where c.parent_id= ?:0 and c.filter= ?:1 and
c.parent_sub_id is not null order by 2
```

|               | id  | name    | filter | parent_id |
|---------------|-----|---------|--------|-----------|
| parent_sub_id |     |         |        |           |
| =====         |     |         |        |           |
| =====         |     |         |        |           |
|               | 1   | 'Child- | 1'     | 1         |
| 1             | 10  |         |        |           |
|               | 101 | 'Child- | 101'   | 1         |
| 1             | 20  |         |        |           |
|               | 201 | 'Child- | 201'   | 1         |
| 1             | 30  |         |        |           |
|               | 301 | 'Child- | 301'   | 1         |
| 1             | 40  |         |        |           |
|               | 401 | 'Child- | 401'   | 1         |
| 1             | 50  |         |        |           |
|               | 501 | 'Child- | 501'   | 1         |
| 1             | 60  |         |        |           |
|               | 601 | 'Child- | 601'   | 1         |
| 1             | 70  |         |        |           |
|               | 701 | 'Child- | 701'   | 1         |
| 1             | 80  |         |        |           |
|               | 801 | 'Child- | 801'   | 1         |
| 1             | 90  |         |        |           |
|               | 901 | 'Child- | 901'   | 1         |
| 1             | 100 |         |        |           |

The following is an example of using the **NO\_ELIMINATE\_JOIN** hint.

```

/* current_user: public */
set optimization level 513;

select /*+ recompile no_eliminate_join */
      c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
      parent_tbl p
      inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where
      c.filter = 1 and c.parent_id = 1
order by
      c.name;

```

The join with the *parent\_tbl* table was not eliminated because the **NO\_ELIMINATE\_JOIN** hint was used.

Query plan:

```

temp(order by)
  subplan: idx-join (inner join)
    outer: iscan
      class: p node[0]
      index: pk_parent_tbl_id_sub_id term[4]
(covers)
      cost: 1 card 10
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[1] AND term[3]
      sargs: term[2]
      cost: 3 card 1
    cost: 4 card 1
  sort: 2 asc
  cost: 10 card 1

```

Query stmt:

```

select /*+ NO_ELIMINATE_JOIN */ c.id, c.[name], c.filter,
c.parent_id, c.parent_sub_id from parent_tbl p, child_tbl c where
p.sub_id=c.parent_sub_id and p.id=?:0 and c.parent_id=?:1 and
c.filter=?:2 and p.id=c.parent_id order by 2

```

| id            | name    | filter | parent_id |
|---------------|---------|--------|-----------|
| parent_sub_id |         |        |           |
| =====         |         |        |           |
| =====         |         |        |           |
| 1             | 'Child- | 1'     | 1         |

```

1          10
          101 'Child- 101'
1          20
          201 'Child- 201'
1          30
          301 'Child- 301'
1          40
          401 'Child- 401'
1          50
          501 'Child- 501'
1          60
          601 'Child- 601'
1          70
          701 'Child- 701'
1          80
          801 'Child- 801'
1          90
          901 'Child- 901'
1         100

```

All columns of the primary key (**PK**) and the foreign key (**FK**) must be used in the join condition.

The following is an example where only the *id* column of the *parent\_tbl* table and the *parent\_id* column of the *child\_tbl* table are used as the join conditions.

```

/* current_user: public */
set optimization level 513;

select /*+ recompile */
      c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
      parent_tbl p
      inner join child_tbl c on p.id = c.parent_id
where
      c.filter = 2 and c.parent_id = 2 and c.parent_sub_id = 20
order by
      c.name;

```

The join with the *parent\_tbl* table was not eliminated because the *sub\_id* column of the *parent\_tbl* table and the *parent\_sub\_id* column of the *child\_tbl* table were not used as join conditions.

Query plan:

temp(order by)

```

subplan: nl-join (cross join)
    outer: iscan
        class: c node[1]
        index:
fk_child_tbl_parent_id_parent_sub_id term[2] AND term[3]
        sargs: term[1]
        cost: 3 card 1
    inner: iscan
        class: p node[0]
        index: pk_parent_tbl_id_sub_id term[4]
(covers)
        cost: 1 card 10
    cost: 4 card 10
    sort: 2 asc
    cost: 10 card 10

Query stmt:

select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, child_tbl c where p.id= ?:0  and c.parent_sub_id= ?:1
and c.parent_id= ?:2  and c.filter= ?:3  and p.id=c.parent_id order
by 2

```

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, child_tbl c where p.id= ?:0  and c.parent_sub_id= ?:1
and c.parent_id= ?:2  and c.filter= ?:3  and p.id=c.parent_id order
by 2
```

[illegible]

The primary key (**PK**) column must be used in the same join condition as the foreign key (**FK**) column that refers to the corresponding primary key (**PK**).

The following is an example where the join conditions compare the *id* column with the *parent\_sub\_id* column, and the *sub\_id* column with the *parent\_id* column.

```
/* current_user: public */
set optimization level 513;

select /*+ recompile */
      c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
      parent_tbl p
      inner join child_tbl c on p.id = c.parent_sub_id and p.sub_id =
c.parent_id
where
      c.filter = 3 and c.parent_id = 3
order by
      c.name;
```

The join with the *parent\_tbl* table was not eliminated because the *id* column was not compared to the *parent\_id* column, and the *sub\_id* column was not compared to the *parent\_sub\_id* column.

Query plan:

```
temp(order by)
  subplan: idx-join (inner join)
    outer: sscan
      class: p node[0]
      sargs: term[3]
      cost: 1 card 1
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[0] AND term[4]
      sargs: term[2]
      cost: 3 card 1
    cost: 5 card 1
  sort: 2 asc
  cost: 11 card 1
```

Query stmt:

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, child_tbl c where p.id=c.parent_sub_id and p.sub_id= ? :
0 and c.parent_id= ? :1 and c.filter= ? :2 and p.sub_id=c.parent_id
order by 2
```

```
There are no results.
0 row selected.
```

All join conditions must use the equality (=) comparison.

The following is an example where the join conditions do not use the equality (=) comparison.

```
/* current_user: public */
set optimization level 513;

select /*+ recompile */
      c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
      parent_tbl p
      inner join child_tbl c on p.id = c.parent_id and p.sub_id <
c.parent_sub_id
where
      c.filter = 4 and c.parent_id = 4 and c.parent_sub_id = 40
order by
      c.name;
```

The join with the *parent\_tbl* table was not eliminated because the comparison between the *sub\_id* column of the *parent\_tbl* table and the *parent\_sub\_id* column of the *child\_tbl* table in the join condition does not use the equality (=) comparison.

Query plan:

```
temp(order by)
  subplan: nl-join (cross join)
    outer: iscan
      class: p node[0]
      index: pk_parent_tbl_id_sub_id term[5]
AND term[6] (covers)
  cost: 1 card 1
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[3] AND term[4]
      sargs: term[2]
      cost: 3 card 1
    cost: 4 card 1
  sort: 2 asc
  cost: 10 card 1
```

Query stmt:

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, child_tbl c where (p.sub_id<?:0 ) and p.id=?:1 and
c.parent_sub_id=?:2 and c.parent_id=?:3 and c.filter=?:4 and
p.id=c.parent_id and (p.sub_id<c.parent_sub_id) order by 2
```

|               | id   | name          | filter | parent_id |
|---------------|------|---------------|--------|-----------|
| parent_sub_id |      |               |        |           |
| =====         |      |               |        |           |
| =====         |      |               |        |           |
|               | 3304 | 'Child- 3304' | 4      |           |
| 4             |      | 40            |        |           |
|               | 3304 | 'Child- 3304' | 4      |           |
| 4             |      | 40            |        |           |
|               | 3304 | 'Child- 3304' | 4      |           |
| 4             |      | 40            |        |           |

There must be no references to the parent table other than the join conditions. The following is an example that retrieves the *name* column from the *parent\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /** recompile */
      c.id, c.name, c.filter, c.parent_id, c.parent_sub_id, p.name
from
      parent_tbl p
      inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where
      c.filter = 5 and c.parent_id = 5
order by
      c.name;
```

The join with the *parent\_tbl* table was not eliminated because it is retrieving the values from the *name* column of the *parent\_tbl* table.

Query plan:

```
temp(order by)
  subplan: idx-join (inner join)
    outer: iscan
          class: p node[0]
          index: pk_parent_tbl_id_sub_id term[4]
          cost:  1 card 10
    inner: iscan
```

```

class: c node[1]
index:
fk_child_tbl_parent_id_parent_sub_id term[1] AND term[3]
sargs: term[2]
cost: 3 card 1
cost: 4 card 1
sort: 2 asc
cost: 10 card 1

```

Query stmt:

```

select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id, p.
[name] from parent_tbl p, child_tbl c where p.sub_id=c.parent_sub_id
and p.id=?:0 and c.parent_id=?:1 and c.filter=?:2 and
p.id=c.parent_id order by 2

```

|               | id   | name          | filter | parent_id |
|---------------|------|---------------|--------|-----------|
| parent_sub_id |      | name          |        |           |
| =====         |      |               |        |           |
| =====         |      |               |        |           |
|               | 4005 | 'Child- 4005' | 5      |           |
| 5             | 10   | 'Parent- 41'  |        |           |
|               | 4105 | 'Child- 4105' | 5      |           |
| 5             | 20   | 'Parent- 42'  |        |           |
|               | 4205 | 'Child- 4205' | 5      |           |
| 5             | 30   | 'Parent- 43'  |        |           |
|               | 4305 | 'Child- 4305' | 5      |           |
| 5             | 40   | 'Parent- 44'  |        |           |
|               | 4405 | 'Child- 4405' | 5      |           |
| 5             | 50   | 'Parent- 45'  |        |           |
|               | 4505 | 'Child- 4505' | 5      |           |
| 5             | 60   | 'Parent- 46'  |        |           |
|               | 4605 | 'Child- 4605' | 5      |           |
| 5             | 70   | 'Parent- 47'  |        |           |
|               | 4705 | 'Child- 4705' | 5      |           |
| 5             | 80   | 'Parent- 48'  |        |           |
|               | 4805 | 'Child- 4805' | 5      |           |
| 5             | 90   | 'Parent- 49'  |        |           |
|               | 4905 | 'Child- 4905' | 5      |           |
| 5             | 100  | 'Parent- 50'  |        |           |

The following is an example with a condition on the *filter* column of the *parent\_tbl* table.

```

/* current_user: public */
set optimization level 513;

select /*+ recompile */
c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from

```

```

parent_tbl p
  inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where
  c.filter = 5 and c.parent_id = 5 and p.filter = 5
order by
  c.name;

```

The join with the *parent\_tbl* table was not eliminated because it is retrieving the records where the *filter* column of the *parent\_tbl* table has a value of 5.

Query plan:

```

temp(order by)
  subplan: idx-join (inner join)
    outer: iscan
      class: p node[0]
      index: pk_parent_tbl_id_sub_id term[5]
      sargs: term[3]
      cost: 1 card 1
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[1] AND term[4]
      sargs: term[2]
      cost: 3 card 1
    cost: 4 card 1
  sort: 2 asc
  cost: 10 card 1

```

Query stmt:

```

select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, child_tbl c where p.sub_id=c.parent_sub_id and p.id= ?:
0 and p.filter= ?:1 and c.parent_id= ?:2 and c.filter= ?:3 and
p.id=c.parent_id order by 2

```

|               | id   | name          | filter | parent_id |
|---------------|------|---------------|--------|-----------|
| parent_sub_id |      |               |        |           |
| =====         |      |               |        |           |
| =====         |      |               |        |           |
|               | 4405 | 'Child- 4405' | 5      |           |
| 5             | 50   |               |        |           |

The following is an example that sorts the results based on the *name* column of the *parent\_tbl* table.

```

select /** recompile */
       c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from   parent_tbl p
       inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where  c.filter = 5 and c.parent_id = 5
order by
       p.name desc;

```

The join with the *parent\_tbl* table was not eliminated because it is sorting the results based on the *name* column of the *parent\_tbl* table in descending order.

Query plan:

```

temp(order by)
  subplan: idx-join (inner join)
    outer: iscan
      class: p node[0]
      index: pk_parent_tbl_id_sub_id term[4]
      cost:  1 card 10
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[1] AND term[3]
      sargs: term[2]
      cost:  3 card 1
    cost:  4 card 1
  sort:  6 desc
  cost: 10 card 1

```

Query stmt:

```

select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id, p.
[name] from parent_tbl p, child_tbl c where p.sub_id=c.parent_sub_id
and p.id=?:0 and c.parent_id=?:1 and c.filter=?:2 and
p.id=c.parent_id order by 6 desc

```

|               | id   | name          | filter | parent_id |
|---------------|------|---------------|--------|-----------|
| parent_sub_id |      |               |        |           |
| =====         |      |               |        |           |
| =====         |      |               |        |           |
|               | 4905 | 'Child- 4905' | 5      |           |
| 5             | 100  |               |        |           |
|               | 4805 | 'Child- 4805' | 5      |           |
| 5             | 90   |               |        |           |
|               | 4705 | 'Child- 4705' | 5      |           |

```

5          80
          4605 'Child- 4605'
5          70
          4505 'Child- 4505'
5          60
          4405 'Child- 4405'
5          50
          4305 'Child- 4305'
5          40
          4205 'Child- 4205'
5          30
          4105 'Child- 4105'
5          20
          4005 'Child- 4005'
5          10

```

### Implicit Equality (=)

Even if there are conditions related to the parent table in the **WHERE** clause other than the join conditions, if the column used in the join conditions is also used in those conditions, the join with the parent table can be eliminated based on implicit equality (=). That condition must use an equality (=) comparison and be compared to a constant value.

The following is an example with an equality (=) comparison condition on the *sub\_id* column of the *parent\_tbl* table.

```

/* current_user: public */
set optimization level 513;

select /** recompile */
       c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from   parent_tbl p
       inner join child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where  c.filter = 6 and c.parent_id = 6 and p.sub_id = 60
order by
       c.name;

```

The join with the *parent\_tbl* table was eliminated because the condition being queried, which retrieves records where the *sub\_id* column of the *parent\_tbl* table has a value of 60, is equivalent to the condition where the *parent\_sub\_id* column of the *child\_tbl* table has a value of 60.

Query plan:

```
temp(order by)
  subplan: iscan
            class: c node[0]
            index: fk_child_tbl_parent_id_parent_sub_id term[1]
AND term[2]
            filtr: term[3]
            sargs: term[0]
            cost: 3 card 1
  sort: 2 asc
  cost: 9 card 1
```

Query stmt:

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
child_tbl c where c.parent_sub_id=?:0 and c.parent_id=?:1 and
c.filter=?:2 and c.parent_sub_id is not null order by 2
```

|               | id   | name          | filter | parent_id |
|---------------|------|---------------|--------|-----------|
| parent_sub_id |      |               |        |           |
| =====         |      |               |        |           |
| =====         |      |               |        |           |
|               | 5506 | 'Child- 5506' | 6      |           |
| 6             |      | 60            |        |           |

The **ALL** keyword must not be used when querying the tables that have an inheritance relationship.

If the **ALL** keyword is used on either the parent or the child table that has an inheritance relationship, the join with the parent table cannot be eliminated.

The following is an example where the **ALL** keyword is used on the *child\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /*+ recompile */
  c.id, c.name, c.filter, c.parent_id, c.parent_sub_id
from
  parent_tbl p
  inner join all child_tbl c on p.id = c.parent_id and p.sub_id =
c.parent_sub_id
where
  c.filter = 7 and c.parent_id = 7
order by
  c.name;
```

The join with the *parent\_tbl* table was not eliminated.

Query plan:

```
temp(order by)
  subplan: idx-join (inner join)
    outer: iscan
      class: p node[0]
      index: pk_parent_tbl_id_sub_id term[4]
    (covers)
      cost: 1 card 10
    inner: iscan
      class: c node[1]
      index:
fk_child_tbl_parent_id_parent_sub_id term[1] AND term[3]
      sargs: term[2]
      cost: 3 card 1
    cost: 4 card 1
  sort: 2 asc
  cost: 10 card 1
```

Query stmt:

```
select c.id, c.[name], c.filter, c.parent_id, c.parent_sub_id from
parent_tbl p, all child_tbl c where p.sub_id=c.parent_sub_id and
p.id=?:0 and c.parent_id=?:1 and c.filter=?:2 and
p.id=c.parent_id order by 2
```

```

## Eliminating **LEFT OUTER JOIN**

In **LEFT OUTER JOIN** of an N:1 relationship, if there are no references to the right table other than the join conditions, eliminating the join with the right table does not affect the query result. In this case, by elimination the join with the right table, the join operation is reduced and the query performance is improved.

To eliminate the **LEFT OUTER JOIN**, the following conditions must be satisfied:

1. Perform the **LEFT OUTER JOIN**.
2. The right table must have the primary key (**PK**) or the **UNIQUE** constraint.
3. All columns of the primary key (**PK**) or the **UNIQUE** constraint must be used in the join conditions.
4. All join conditions must use the equality (=) comparison.
5. There must be no references to the right table other than the join conditions.
6. The **ALL** keyword must not be used when querying the tables that have an inheritance relationship.

The following is an example of eliminating the **LEFT OUTER JOIN**.

```

call login ('public') on class db_user;

/* current_user: public */
drop table if exists left_tbl, right_tbl;

```

```
create table left_tbl (  
    id int,  
    sub_id int,  
    other_id int,  
    name varchar (100),  
    filter int,  
    primary key (id, sub_id, other_id)  
);  
  
insert into left_tbl  
select  
    ((rownum - 1) / 100) + 1 as id,  
    (((rownum - 1) % 10) + 1) * 10 as sub_id,  
    (((rownum - 1) % 100) + 1) * 100 as other_id,  
    'Left-' || lpad (rownum, 4) as name,  
    ((rownum - 1) % 100) + 1 as filter  
from db_root  
connect by level <= 1000;  
  
create table right_tbl (  
    id int,  
    sub_id int,  
    name varchar (100),  
    filter int,  
    primary key (id, sub_id)  
);  
  
insert into right_tbl  
select  
    id as id,  
    sub_id as sub_id,  
    'Right-' || lpad (rownum, 3) as name,  
    ((rownum - 1) % 10) + 1 as filter  
from (select distinct id, sub_id from left_tbl);  
  
update statistics on left_tbl, right_tbl with fullscan;
```

```
/* current_user: public */  
set optimization level 513;  
  
select /** recompile */  
    l.id, l.sub_id, l.other_id, l.name, l.filter  
from  
    left_tbl as l  
    left outer join right_tbl as r on l.id = r.id and l.sub_id =  
r.sub_id  
where  
    l.filter = 1
```

```
order by
  l.name;
```

The join with the *right\_tbl* table was eliminated.

Query plan:

```
temp(order by)
  subplan: sscan
        class: l node[0]
        sargs: term[0]
        cost:  6 card 1
    sort:  4 asc
    cost: 13 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l where l.filter= ?:0 order by 4
```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| =====  |    |        |          |        |
| =====  |    |        |          |        |
| 1'     | 1  | 10     | 100      | 'Left- |
| 101'   | 2  | 10     | 100      | 'Left- |
| 201'   | 3  | 10     | 100      | 'Left- |
| 301'   | 4  | 10     | 100      | 'Left- |
| 401'   | 5  | 10     | 100      | 'Left- |
| 501'   | 6  | 10     | 100      | 'Left- |
| 601'   | 7  | 10     | 100      | 'Left- |
| 701'   | 8  | 10     | 100      | 'Left- |
| 801'   | 9  | 10     | 100      | 'Left- |
| 901'   | 10 | 10     | 100      | 'Left- |

The following is an example of using the **NO\_ELIMINATE\_JOIN** hint.

```

/* current_user: public */
set optimization level 513;

select /* recompile no_eliminate_join */
      l.id, l.sub_id, l.other_id, l.name, l.filter
from
      left_tbl as l
      left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
      l.filter = 1
order by
      l.name;

```

The join with the *right\_tbl* table was not eliminated because the **NO\_ELIMINATE\_JOIN** hint was used.

Query plan:

```

temp(order by)
  subplan: idx-join (left outer join)
    outer: sscan
      class: l node[0]
      sargs: term[2]
      cost: 6 card 1
    inner: iscan
      class: r node[1]
      index: pk_right_tbl_id_sub_id term[0]
AND term[1] (covers)
      cost: 1 card 100
      cost: 9 card 1
  sort: 4 asc
  cost: 15 card 1

```

Query stmt:

```

select /* NO_ELIMINATE_JOIN */ l.id, l.sub_id, l.other_id, l.
[name], l.filter from left_tbl l left outer join right_tbl r on
l.sub_id=r.sub_id and l.id=r.id where l.filter=?:0 order by 4

```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| =====  |    |        |          |        |
| =====  |    |        |          |        |
| 1'     | 1  | 10     | 100      | 'Left- |
|        |    | 1      |          |        |
|        | 2  | 10     | 100      | 'Left- |
| 101'   |    | 1      |          |        |

|      |    |    |     |        |
|------|----|----|-----|--------|
| 201' | 3  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 301' | 4  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 401' | 5  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 501' | 6  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 601' | 7  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 701' | 8  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 801' | 9  | 10 | 100 | 'Left- |
|      |    | 1  |     |        |
| 901' | 10 | 10 | 100 | 'Left- |
|      |    | 1  |     |        |

The right table must have the primary key (**PK**) or the **UNIQUE** constraint.

If the right table does not have the primary key (**PK**) or the **UNIQUE** constraint, it is not an N:1 relationship for the **LEFT OUTER JOIN**, and therefore the join with the right table cannot be eliminated.

The following is an example where the primary key (**PK**) of the *right\_tbl* table is removed, and a general index is created on the *id* and the *sub\_id* columns.

```
/* current_user: public */
set optimization level 513;

alter table right_tbl drop primary key;
alter table right_tbl add index i_right_id_sub_id (id, sub_id);
update statistics on right_tbl with fullscan;

select /** recompile */
  l.id, l.sub_id, l.other_id, l.name, l.filter
from
  left_tbl as l
  left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
  l.filter = 2
order by
  l.name;

drop index i_right_id_sub_id on right_tbl;
alter table right_tbl add primary key (id, sub_id);
update statistics on right_tbl with fullscan;
```

The join with the *right\_tbl* table was not eliminated because the *right\_tbl* table does not have the primary key (**PK**) or the **UNIQUE** constraint.

Query plan:

```
temp(order by)
  subplan: idx-join (left outer join)
    outer: sscan
      class: l node[0]
      sargs: term[2]
      cost: 6 card 1
    inner: iscan
      class: r node[1]
      index: i_right_id_sub_id term[0] AND
term[1] (covers)
      cost: 1 card 100
      cost: 9 card 1
      sort: 4 asc
      cost: 15 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l left outer join right_tbl r on l.sub_id=r.sub_id and l.id=r.id
where l.filter=?:0 order by 4
```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| =====  |    |        |          |        |
| =====  |    |        |          |        |
|        | 1  | 20     | 200      | 'Left- |
| 2'     |    | 2      |          |        |
|        | 2  | 20     | 200      | 'Left- |
| 102'   |    | 2      |          |        |
|        | 3  | 20     | 200      | 'Left- |
| 202'   |    | 2      |          |        |
|        | 4  | 20     | 200      | 'Left- |
| 302'   |    | 2      |          |        |
|        | 5  | 20     | 200      | 'Left- |
| 402'   |    | 2      |          |        |
|        | 6  | 20     | 200      | 'Left- |
| 502'   |    | 2      |          |        |
|        | 7  | 20     | 200      | 'Left- |
| 602'   |    | 2      |          |        |
|        | 8  | 20     | 200      | 'Left- |
| 702'   |    | 2      |          |        |
|        | 9  | 20     | 200      | 'Left- |
| 802'   |    | 2      |          |        |

|      |    |    |     |        |
|------|----|----|-----|--------|
| 902' | 10 | 20 | 200 | 'Left- |
|      |    | 2  |     |        |

The following is an example of removing the primary key (**PK**) of the *right\_tbl* table and creating the **UNIQUE** constraint consisting of the *id* column and the *sub\_id* column.

```
/* current_user: public */
set optimization level 513;

alter table right_tbl drop primary key;
alter table right_tbl add constraint unique (id, sub_id);
update statistics on right_tbl with fullscan;

select /** recompile */
    l.id, l.sub_id, l.other_id, l.name, l.filter
from
    left_tbl as l
    left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
    l.filter = 2
order by
    l.name;

alter table right_tbl drop constraint u_right_tbl_id_sub_id;
alter table right_tbl add primary key (id, sub_id);
update statistics on right_tbl with fullscan;
```

The join with the *right\_tbl* table was eliminated because the *right\_tbl* table does not have the primary key (**PK**) or the **UNIQUE** constraint.

Query plan:

```
temp(order by)
  subplan: sscan
        class: 1 node[0]
        sargs: term[0]
        cost: 6 card 1
  sort: 4 asc
  cost: 13 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l where l.filter= ?:0 order by 4
```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| =====  |    |        |          |        |
| =====  |    |        |          |        |
|        | 1  | 20     | 200      | 'Left- |
| 2'     |    | 2      |          |        |
|        | 2  | 20     | 200      | 'Left- |
| 102'   |    | 2      |          |        |
|        | 3  | 20     | 200      | 'Left- |
| 202'   |    | 2      |          |        |
|        | 4  | 20     | 200      | 'Left- |
| 302'   |    | 2      |          |        |
|        | 5  | 20     | 200      | 'Left- |
| 402'   |    | 2      |          |        |
|        | 6  | 20     | 200      | 'Left- |
| 502'   |    | 2      |          |        |
|        | 7  | 20     | 200      | 'Left- |
| 602'   |    | 2      |          |        |
|        | 8  | 20     | 200      | 'Left- |
| 702'   |    | 2      |          |        |
|        | 9  | 20     | 200      | 'Left- |
| 802'   |    | 2      |          |        |
|        | 10 | 20     | 200      | 'Left- |
| 902'   |    | 2      |          |        |

All columns of the primary key (**PK**) or the **UNIQUE** constraint must be used in the join conditions.

The following is an example where only the *id* column of the *left\_tbl* table and the *id* column of the *right\_tbl* table are used as the join conditions.

```
/* current_user: public */
set optimization level 513;

select /*+ recompile */
  l.id, l.sub_id, l.other_id, l.name, l.filter
from
  left_tbl as l
  left outer join right_tbl as r on l.id = r.id
where
  l.filter = 3 and l.id = 3
order by
  l.name;
```

The join with the *right\_tbl* table was not eliminated because the *sub\_id* column of the *left\_tbl* table and the *sub\_id* column of the *right\_tbl* table were not used as the join conditions.

Query plan:

```
temp(order by)
  subplan: idx-join (left outer join)
    outer: iscan
      class: l node[0]
      index: pk_left_tbl_id_sub_id_other_id
term[2]
  sargs: term[1]
  cost: 3 card 1
  inner: iscan
    class: r node[1]
    index: pk_right_tbl_id_sub_id term[0]
(covers)
  filtr: term[3]
  cost: 1 card 10
  sort: 2 asc, 3 asc
  cost: 4 card 1
sort: 4 asc
cost: 10 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l left outer join right_tbl r on l.id=r.id and r.id=?:0  where
l.id=?:1  and l.filter=?:2  order by 4
```

```

203'      3      30      300 'Left-
          3

```

All join conditions must use the equality (=) comparison.

The following is an example where the join conditions do not use the equality (=) comparison.

```

/* current_user: public */
set optimization level 513;

select /** recompile */
      l.id, l.sub_id, l.other_id, l.name, l.filter
from
      left_tbl as l
      left outer join right_tbl as r on l.id = r.id and l.sub_id <
r.sub_id
where
      l.filter = 4 and l.id = 4
order by
      l.name;

```

The join with the *right\_tbl* table was not eliminated because the comparison between the *sub\_id* column of the *left\_tbl* table and the *sub\_id* column of the *right\_tbl* table in the join conditions does not use the equality (=) comparison.

Query plan:

```

temp(order by)
  subplan: idx-join (left outer join)
    outer: iscan
      class: l node[0]
      index: pk_left_tbl_id_sub_id_other_id
term[3]
      sargs: term[2]
      cost: 3 card 1
    inner: iscan
      class: r node[1]
      index: pk_right_tbl_id_sub_id term[0]
(covers)
      filtr: term[1] AND term[4]
      cost: 1 card 10
    sort: 2 asc, 3 asc
    cost: 4 card 1
  sort: 4 asc
  cost: 10 card 1

```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l left outer join right_tbl r on l.id=r.id and r.id= ?:0 and
(l.sub_id<r.sub_id) where l.id= ?:1 and l.filter= ?:2 order by 4
```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |
| 304'   | 4  | 40     | 400      | 'Left- |

There must be no references to the right table other than the join conditions. The following is an example that retrieves the *name* column from the *right\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /** recompile */
l.id, l.sub_id, l.other_id, l.name, l.filter, r.name
from
left_tbl as l
left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
l.filter = 5
order by
l.name;
```

The join with the *right\_tbl* table was not eliminated because it is retrieving the values from the *name* column of the *right\_tbl* table.

Query plan:

temp(order by)

```

subplan: idx-join (left outer join)
  outer: sscan
    class: l node[0]
    sargs: term[2]
    cost: 6 card 1
  inner: iscan
    class: r node[1]
    index: pk_right_tbl_id_sub_id term[0]
AND term[1]
    cost: 1 card 100
cost: 9 card 1
sort: 4 asc
cost: 15 card 1

```

Query stmt:

```

select l.id, l.sub_id, l.other_id, l.[name], l.filter, r.[name] from
left_tbl l left outer join right_tbl r on l.sub_id=r.sub_id and
l.id=r.id where l.filter=?:0 order by 4

```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| 5'     | 1  | 50     | 500      | 'Left- |
| 105'   | 2  | 50     | 500      | 'Left- |
| 205'   | 3  | 50     | 500      | 'Left- |
| 305'   | 4  | 50     | 500      | 'Left- |
| 405'   | 5  | 50     | 500      | 'Left- |
| 505'   | 6  | 50     | 500      | 'Left- |
| 605'   | 7  | 50     | 500      | 'Left- |
| 705'   | 8  | 50     | 500      | 'Left- |
| 805'   | 9  | 50     | 500      | 'Left- |
| 905'   | 10 | 50     | 500      | 'Left- |

The following is an example where there are conditions on the *filter* column of the *right\_tbl* table before performing the **LEFT OUTER JOIN**.

```

/* current_user: public */
set optimization level 513;

select /*+ recompile */
      l.id, l.sub_id, l.other_id, l.name, l.filter
from
      left_tbl as l
      left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id and r.filter = 5
where
      l.filter = 5
order by
      l.name;

```

The join with the *right\_tbl* table was eliminated because the query is filtering the records to retrieve only those where the *filter* column of the *right\_tbl* table has a value of 5 before performing the **LEFT OUTER JOIN**.

Query plan:

```

temp(order by)
  subplan: sscan
            class: 1 node[0]
            sargs: term[0]
            cost:  6 card 1
    sort:    4 asc
    cost:    13 card 1

```

Query stmt:

```

select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l where l.filter= ?:0  order by 4

```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| =====  |    |        |          |        |
| =====  |    |        |          |        |
| 5'     | 1  | 50     | 500      | 'Left- |
| 105'   | 2  | 50     | 500      | 'Left- |
| 205'   | 3  | 50     | 500      | 'Left- |
| 305'   | 4  | 50     | 500      | 'Left- |
| 405'   | 5  | 50     | 500      | 'Left- |
|        | 6  | 50     | 500      | 'Left- |

|      |    |    |     |        |
|------|----|----|-----|--------|
| 505' |    | 5  |     |        |
|      | 7  | 50 | 500 | 'Left- |
| 605' |    | 5  |     |        |
|      | 8  | 50 | 500 | 'Left- |
| 705' |    | 5  |     |        |
|      | 9  | 50 | 500 | 'Left- |
| 805' |    | 5  |     |        |
|      | 10 | 50 | 500 | 'Left- |
| 905' |    | 5  |     |        |

The following is an example that sorts the results based on the *name* column of the *right\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /** recompile */
  l.id, l.sub_id, l.other_id, l.name, l.filter, r.name
from
  left_tbl as l
  left outer join right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
  l.filter = 5
order by
  r.name desc;
```

The join with the *right\_tbl* table was not eliminated because it is sorting the results based on the *name* column of the *right\_tbl* table in descending order.

Query plan:

```
temp(order by)
  subplan: idx-join (left outer join)
    outer: sscan
      class: l node[0]
      sargs: term[2]
      cost: 6 card 1
    inner: iscan
      class: r node[1]
      index: pk_right_tbl_id_sub_id term[0]
  AND term[1]
    cost: 1 card 100
  cost: 9 card 1
  sort: 6 desc
  cost: 15 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter, r.[name] from
left_tbl l left outer join right_tbl r on l.sub_id=r.sub_id and
l.id=r.id where l.filter= ?:0 order by 6 desc
```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| 905'   | 10 | 50     | 500      | 'Left- |
| 805'   | 9  | 50     | 500      | 'Left- |
| 705'   | 8  | 50     | 500      | 'Left- |
| 605'   | 7  | 50     | 500      | 'Left- |
| 505'   | 6  | 50     | 500      | 'Left- |
| 405'   | 5  | 50     | 500      | 'Left- |
| 305'   | 4  | 50     | 500      | 'Left- |
| 205'   | 3  | 50     | 500      | 'Left- |
| 105'   | 2  | 50     | 500      | 'Left- |
| 5'     | 1  | 50     | 500      | 'Left- |
|        |    | 5      | 'Right-  | 5'     |

The **ALL** keyword must not be used when querying the tables that have an inheritance relationship.

If the **ALL** keyword is used on the right table that has an inheritance relationship, the join with the right table cannot be eliminated.

The following is an example where the **ALL** keyword is used on the *right\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /** recompile */
      l.id, l.sub_id, l.other_id, l.name, l.filter
from
      left_tbl as l
      left outer join all right_tbl as r on l.id = r.id and l.sub_id =
r.sub_id
where
```

```

        l.filter = 6
order by
        l.name;

```

The join with the *right\_tbl* table was not eliminated.

Query plan:

```

temp(order by)
  subplan: idx-join (left outer join)
    outer: sscan
      class: l node[0]
      sargs: term[2]
      cost: 6 card 1
    inner: iscan
      class: r node[1]
      index: pk_right_tbl_id_sub_id term[0]
AND term[1] (covers)
      cost: 1 card 100
      cost: 9 card 1
  sort: 4 asc
  cost: 15 card 1

```

Query stmt:

```

select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l left outer join all right_tbl r on l.sub_id=r.sub_id and
l.id=r.id where l.filter=?:0 order by 4

```

| filter | id | sub_id | other_id | name   |
|--------|----|--------|----------|--------|
| 6'     | 1  | 60     | 600      | 'Left- |
| 106'   | 2  | 60     | 600      | 'Left- |
| 206'   | 3  | 60     | 600      | 'Left- |

|------|----|----|-----|--------|
| 806' | 9  | 60 | 600 | 'Left- |
|      |    | 6  |     |        |
| 906' | 10 | 60 | 600 | 'Left- |
|      |    | 6  |     |        |

The following is an example where the **ONLY** keyword is used on both the *left\_tbl* table and the *right\_tbl* table.

```
/* current_user: public */
set optimization level 513;

select /** recompile */
      l.id, l.sub_id, l.other_id, l.name, l.filter
from
      only left_tbl as l
      left outer join only right_tbl as r on l.id = r.id and l.sub_id
= r.sub_id
where
      l.filter = 6
order by
      l.name;
```

The join with the *right\_tbl* table was eliminated.

Query plan:

```
temp(order by)
  subplan: sscan
            class: l node[0]
            sargs: term[0]
            cost: 6 card 1
    sort: 4 asc
    cost: 13 card 1
```

Query stmt:

```
select l.id, l.sub_id, l.other_id, l.[name], l.filter from left_tbl
l where l.filter= ?::0 order by 4
```

| filter | id | sub_id | other_id | name   |

806'     10      60      600 'Left-
906'

```

## View Merging Optimization

**View Merging** is an optimization for reducing overhead that occur during the processing of view or inline view. When a query includes a view, there is an overhead of creating a temporary table for that view. And it's impossible to perform index scan on temporary tables, leading to performance degradation. But, by using **View Merging** to merge the view with table in main query, performance can be improved because index scan is available.

Like *Query 1* below, which use inline views, make it easier to understand the intent of the query.

```

/* Query 1 */
SELECT *
FROM (SELECT * FROM athlete WHERE nation_code = 'USA') a,
     (SELECT * FROM record WHERE medal = 'G') b
WHERE a.code = b.athlete_code;

```

If the query is executed without **View Merging** optimization, the join is performed with the temporary results of executing each of the inline views *a* and *b*. Temporary results cannot use indexes, resulting in performance degradation.

```

/* Query 2 */
SELECT *
FROM athlete a, record b
WHERE a.code = b.athlete_code
AND a.nation_code = 'USA'
AND b.medal = 'G';

```

When **View Merging** optimization is performed, *Query 1* is transformed into *Query 2*.

In the following cases, **View Merging** is not performed:

1. Using **NO\_MERGE** hint on a view.
2. The view includes a **CONNECT BY** clause.
3. The view includes a **DISTINCT** clause.
4. The view is **CTE** (Common Table Expressions).
5. Using **OUTER JOIN** with a view.
6. The view using aggregate or analytic functions.
7. Using **ROWNUM**, **LIMIT**, or **GROUPBY\_NUM()**, **INST\_NUM()**, **ORDERBY\_NUM()**.
8. The view using **Correlated Subquery**.
9. The view includes methods.
10. The view includes **RANDOM()**, **DRANDOM()**, **SYS\_GUID()**.

The following is an example that uses **NO\_MERGE** hint on a view.

```
SELECT *
FROM (SELECT /*+ NO_MERGE*/ * FROM athlete WHERE nation_code =
'USA') a,
(SELECT /*+ NO_MERGE*/ * FROM record WHERE medal = 'G') b
WHERE a.code = b.athlete_code;
```

If the **NO\_MERGE** hint is used on a view, **View Merging** is not performed.

The following is an example that includes the **CONNECT BY** clause.

```
-- Creating a tree table and then inserting data
CREATE TABLE tree(id INT, mgrid INT, name VARCHAR(32), birthyear
INT);

INSERT INTO tree VALUES (1,NULL,'Kim', 1963);
INSERT INTO tree VALUES (2,NULL,'Moy', 1958);
INSERT INTO tree VALUES (3,1,'Jonas', 1976);
INSERT INTO tree VALUES (4,1,'Smith', 1974);
INSERT INTO tree VALUES (5,2,'Verma', 1973);
INSERT INTO tree VALUES (6,2,'Foster', 1972);
INSERT INTO tree VALUES (7,6,'Brown', 1981);

-- Executing a hierarchical query with CONNECT BY clause
SELECT *
```

```
FROM (SELECT * FROM tree WHERE birthyear = 1973) t
CONNECT BY PRIOR t.id=t.mgrid;
```

Due to the use of the **CONNECT BY** in the above query, **View Merging** cannot be performed.

The following is an example where a view includes the **DISTINCT** clause.

```
SELECT * FROM (SELECT DISTINCT host_year FROM record) T;
```

Due to the **DISTINCT** clause used within the view in the above query, **View Merging** cannot be performed.

The following is an example that the view is **CTE** (Common Table Expressions).

```
WITH cte AS (SELECT * FROM athlete WHERE gender = 'M')
SELECT * FROM cte WHERE cte.nation_code = 'USA';
```

When using **CTE** as above, **View Merging** optimization cannot be performed.

The following is an example performing an **OUTER JOIN** with a view.

```
SELECT *
FROM athlete a
LEFT OUTER JOIN (SELECT * FROM record WHERE host_year = 2020) b
ON a.code = b.athlete_code;
```

In cases where an **OUTER JOIN** is performed as above, **View Merging** cannot be performed.

The following is an example using aggregate or analytic functions.

```
SELECT *
FROM (SELECT AVG(host_year) FROM record WHERE medal = 'G') a;
```

When using aggregate or analytic functions in views as above, **View Merging** optimization cannot be performed.

The following is an example using **ROWNUM**, **LIMIT** or **GROUPBY\_NUM()**, **INST\_NUM()**, **ORDERBY\_NUM()**.

```
SELECT *
FROM (SELECT gender, rownum FROM athlete WHERE rownum < 15) a
WHERE gender = 'M';
```

When using **ROWNUM**, **LIMIT** or **GROUPBY\_NUM()**, **INST\_NUM()**, **ORDERBY\_NUM()** in views as above, **View Merging** optimization cannot be performed. However, when **ROWNUM** is used for partial range processing, **View Merging** is performed even if **ROWNUM** exists. This is the case when the following two conditions are satisfied.

1. The **WHERE** clause includes only predicates involving **ROWNUM**
2. There is only one subquery in the **FROM** clause

```
--csql> ;plan detail
SELECT *
FROM (SELECT name, rownum rn
      FROM (SELECT name FROM athlete WHERE nation_code = 'KOR') a
      WHERE rownum < 15) b
WHERE rn > 5;
```

Query stmt:

```
select b.[name], (rownum) from athlete b where ((rownum)> ?:0 and
(rownum)< ?:1 ) and (b.nation_code= ?:2 )
```

The following is an example using **Correlated Subquery**.

```
SELECT COUNT(*)
FROM athlete a,
(SELECT * FROM record r WHERE a.code = r.athlete_code) b;
```

When using **Correlated Subquery** as above, **View Merging** optimization cannot be performed.

The following is an example where a view includes **RANDOM()**, **DRANDOM()**, **SYS\_GUID()**.

```
SELECT *
FROM (SELECT RANDOM (), code FROM athlete WHERE nation_code =
'USA') a,
(SELECT SYS_GUID (), athlete_code FROM record WHERE medal =
'G') b
WHERE a.code = b.athlete_code;
```

When using **RANDOM()**, **DRANDOM()**, **SYS\_GUID()** in views as above, **View Merging** optimization cannot be performed.

If **View Merging** optimization cannot be performed, **CUBRID** optimizes the **SELECT-LIST** item of the subquery. The following example shows how the **SELECT-LIST** of the subquery is optimized.

```
--csql> ;plan detail
SELECT /**+ recompile */ aa.host_year, aa.rn
FROM (select host_year,
      (select name from event where code = a.event_code)
event_name,
      (select name from athlete where code = a.athlete_code)
athlete_name,
      rownum rn
from game a
where medal = 'G') aa
WHERE host_year = '2004';
```

Query stmt:

```
select aa.host_year, aa.rn from (select a.host_year, (rownum) as
[rn] from game a where a.medal= ?:1 ) aa (host_year, rn) where
aa.host_year= ?:0
```

## Predicate Push

**Predicate Push** is an optimization that pushes the predicate of the main query into the view.

By applying **Predicate Push** to the subquery, the amount of data queried in the subquery is reduced.

For instance, when performing a join using the join condition  $a.code = r.athlete\_code$  as in the query below, if the external predicate can be pushed into the query block, the amount of data to be joined can be reduced.

```
SELECT a.name, r.score
FROM (SELECT name, nation_code, code, count(*) cnt FROM athlete
GROUP BY name, nation_code) a, record r
WHERE a.code = r.athlete_code
AND a.nation_code = 'KOR';
```

There are no predicates in the inline-view of the query above. If the query rewrite doesn't work, the *athlete* table would have been fully scanned, creating a temporary result, joined, and filtering with the condition  $a.nation\_code = 'KOR'$ .

However, if the query is rewritten as follows by using **Predicate Push**, it can be optimized to reduce the amount of data being queried.

```
SELECT a.name, r.score
FROM (SELECT name, nation_code, code, count(*) cnt FROM athlete
```

```
WHERE nation_code = 'KOR' GROUP BY name, nation_code ) a, record r
WHERE a.code = r.athlete_code;
```

The following example shows how **Predicate Push** works in a situation where there are multiple subqueries.

```
--csql> ;plan detail
SELECT a.host_year
FROM (select distinct host_year, event_code, athlete_code from game
where host_year = 2004) a,
     (select distinct host_year, event_code, athlete_code from game
where event_code = 20021) b
WHERE a.host_year = b.host_year
AND a.event_code = b.event_code
AND a.athlete_code = b.athlete_code;
```

Query stmt:

```
select a.host_year
  from (select distinct game.host_year, game.event_code,
game.athlete_code from game game where game.host_year=?:0 and
game.event_code=20021) a (host_year, event_code, athlete_code),
     (select distinct game.host_year, game.event_code,
game.athlete_code from game game where game.event_code=?:1 and
game.host_year=2004) b (host_year, event_code, athlete_code)
 where a.athlete_code=b.athlete_code and a.host_year=b.host_year and
a.event_code=b.event_code
```

The predicates **game.event\_code=20021** and **game.host\_year=2004** are added to each subquery according to the join condition of the main query.

In the following cases, **Predicate Push** is not performed:

1. Using **NO\_PUSH\_PRED** hint on main query.
2. Contains **CONNECT BY** on main query.
3. Using aggregate or analytic functions on view.
4. Using **ROWNUM**, **LIMIT**, or **GROUPBY\_NUM()**, **INST\_NUM()**, **ORDERBY\_NUM()** on view.
5. Using **Correlated Subquery**.
6. Using subqueries in predicates.
7. The view includes methods.

8. When the predicate to be pushed or the target for **Predicate Push** within the view uses **RANDOM (), DRANDOM (), SYS\_GUID ()**.
9. When performing an **OUTER JOIN** and either the predicate to be pushed or the target for **Predicate Push** within the view uses:
  - Predicates written in the **ON** clause.
  - Using **NULL** transformation functions. This includes **COALESCE (), NVL (), NVL2 (), DECODE (), IF (), IFNULL (), CONCAT\_WS ()**.
  - **IS NULL ,CASE** statements are also not targets for **Predicate Push**.

#### Note

**NULL** transformation function includes the following functions:

- **COALESCE ()**
- **NVL ()**
- **NVL2 ()**
- **DECODE ()**
- **IF ()**
- **IFNULL ()**
- **CONCAT\_WS ()**

Furthermore, **IS NULL ,CASE** statements are also not targets for **Predicate Push**.

The following is an example that uses **NO\_PUSH\_PRED** hint on main query.

```
SELECT /*+ NO_PUSH_PRED*/ a.name, r.score
FROM (SELECT name, nation_code, code, count(*) cnt FROM athlete
GROUP BY name, nation_code) a, record r
WHERE a.code = r.athlete_code
AND a.nation_code = 'KOR';
```

If the **NO\_PUSH\_PRED** hint is used on main query, **Predicate Push** is not performed.

The following is an example that performs an **OUTER JOIN** with the predicate to be pushed in the **ON** clause condition.

```
SELECT a.name, r.score
FROM (SELECT * FROM athlete WHERE gender = 'M') a
  LEFT OUTER JOIN record r ON a.code = r.athlete_code AND
a.nation_code = 'KOR';
```

In this case, *a.nation\_code* = 'KOR' exists in the **ON** clause during the **LEFT OUTER JOIN**. Such a predicate within the **ON** clause is not a target for **Predicate Push**.

The following is an example that performs an **OUTER JOIN** where either the predicate to be pushed or the target for **Predicate Push** within the view uses the **NULL** transformation function.

```
SELECT a.name, r.score
FROM athlete a
  LEFT OUTER JOIN (SELECT * FROM record WHERE medal = 'G') r
ON a.code = r.athlete_code
WHERE NVL(r.score, '0') = '0';
```

When performing an **OUTER JOIN** and either the predicate to be pushed or the target for **Predicate Push** within the view uses a **NULL** transformation function, it's not a target for **Predicate Push**.

## Subquery unnest

**Subquery unnest** improves performance by converting the filtering method, which executes the subquery in the **WHERE** clause repeatedly, into a join method that guarantees the same result. Subqueries in the **WHERE** clause can have different characteristics depending on the operator. Subqueries with operators like **IN** or **EXISTS**, which can return multiple rows, are the main targets for optimization. **CUBRID** partially supports this optimization only for the **IN** operator.

The following example shows converting an **IN** operator into a join query.

```
--csql> set optimization level 513;
SELECT game_date
FROM game
WHERE (host_year,event_code,athlete_code) IN (select
host_year,event_code,athlete_code
                                           from game
                                           where nation_code =
'KOR' and medal = 'G');
```

Query plan:

```
idx-join (inner join)
  outer: sscan
    class: av1861 node[1]
```

```

            cost:  1 card 25
    inner: iscan
            class: game node[0]
            index: pk_game_host_year_event_code_athlete_code
term[0] AND term[1] AND term[2]
            cost:  3 card 8653
    cost:  17 card 1

```

Query stmt:

```

select game.game_date from game game, (select distinct
game.host_year, game.event_code, game.athlete_code from game game
where game.medal=?:0 and game.nation_code=?:1 ) av1861 (av_1,
av_2, av_3) where game.host_year=av1861.av_1 and
game.event_code=av1861.av_2 and game.athlete_code=av1861.av_3

```

#### Note

Starting from CUBRID 11.0, subqueries that retrieve multiple columns are allowed in the arguments of the **IN** operator.

## Transitive predicate

**Transitive predicate** improves query performance by adding conditional clauses that can be logically constructed.

The following example shows that the **b.col1 = 3** predicate is added with **Transitive predicate** optimization.

```

CREATE TABLE t1 (col1 int, col2 int, col3 int);
CREATE TABLE t2 (col1 int, col2 int, col3 int);

--csql> ;plan detail
SELECT /** recompile */ *
FROM t1 a, t2 b
WHERE a.col1 = b.col1
AND a.col1 = 3;

```

Query stmt:

```

select a.col1, a.col2, a.col3, b.col1, b.col2, b.col3 from t1 a, t2
b where b.col1=?:0 and a.col1=?:1 and a.col1=b.col1

```

## QUERY CACHE

The **QUERY\_CACHE** hint can be used to enhance the performance for the query which is executed repeatedly. The query is cached in dedicated memory area and its results are also cached at the separated disk space. The hint is applied to SELECT query only; however, for the following cases, the hint is not applicable to the query and the hint is meaningless:

- a system time or date related attribute in the query as below ex) SELECT SYSDATE, ADDDATE(SYSDATE,INTERVAL -24 HOUR), ADDDATE(SYSDATE, -1);
- a SERIAL related attribute is in the query
- a column-path related attribute is in the query
- a method is in the query
- a stored procedure or a stored function is in the query
- a system tables like dual, \_db\_attribute, and so on, is in the query
- a system function like sys\_guid() is in the query

When the hint is set and a new SELECT query is processed, the query cache is looked up if the query appears in the query cache. The queries are considered identical in case they use the same query text and the same bind values under the same database. If the cached query is not found, the query will be processed and then cached newly with its result. If the query is found from the cache, the results will be fetched from the cached area. AT the CSQL, we can measure the enhancement easily to execute the query repeatedly using the COUNT function as below example. The query and its results will be cached at the first appearance, so the response time is slower than the next same query. The second query's result is fetched from the cached area, so the response time is much faster than the prior same query's one.

```
csql> SELECT /*+ QUERY_CACHE */ count(*) FROM game;
```

```
=== <Result of SELECT Command in Line 1> ===
```

```
count(*)
=====
8653
```

```
1 row selected. (0.107082 sec) Committed.
```

```
1 command(s) successfully processed.
```

```
csql> SELECT /*+ QUERY_CACHE */ count(*) FROM game;
```

```
=== <Result of SELECT Command in Line 1> ===
```

```
count(*)
```

```
=====
      8653

1 row selected. (0.003932 sec) Committed.

1 command(s) successfully processed.
```

The user can check the query to be cached or not by putting the session command `;info qcache'` in CSQL as follows:

```
csql> ;info qcache

LIST_CACHE {
  n_hts 1010
  n_entries 1  n_pages 1
  lookup_counter 1
  hit_counter 1
  miss_counter 0
  full_counter 0
}

list_hts[0] 0x6a74d10
HTABLE NAME = list file cache (DB_VALUE list), SIZE = 211, REHASH_AT
= 147,
NENTRIES = 1, NPREALLOC = 0, NCOLLISIONS = 0

HASH AT 0
LIST_CACHE_ENTRY (0x6c46d18) {
  param_values = [ ]
  list_id = { type_list { 1 integer/1 } tuple_cnt 1 page_cnt 1
first_vpid { 65 32766 } last_vpid { 65 32766 } lasttpl_len 24
query_id 2
  temp_vfid { 64 32766 } }
  uncommitted_marker = false
  tran_isolation = 4
  tran_index_array = [ ]
  last_ta_idx = 0
  query_string = select /*+ QUERY_CACHE */ count(*) from [game]
[game]?193="en_US";194="en_US";249="Asia/Seoul";user=0|833|1
  time_created = 11/23/20 16:07:12.779703
  time_last_used = 11/23/20 16:07:22.772330
  ref_count = 1
  deletion_marker = false
}
```

The cached query is shown as **query\_string** in the middle of the result screen. **n\_entries** and **n\_pages** represent the number of cached queries and the number of pages in the cached results, respectively. **n\_entries** is limited by the value of the configuration parameter **max\_QUERY\_CACHE\_entries**, and **n\_pages** is limited by the value of the configuration parameter

**QUERY\_CACHE\_size\_in\_pages.** If **n\_entries** or **n\_pages** overflow, some candidates among the cache entries are selected and uncached. The number of candidates is approximately 20% of the **max\_QUERY\_CACHE\_entries** value and the **QUERY\_CACHE\_size\_in\_pages** value.

Since version 11.4, subqueries can also be cached, and the subqueries that can be cached are as follows.

1) CTE query When the QUERY\_CACHE hint is specified in a non-recursive query included in the WITH clause

```
WITH
  of_drones AS (SELECT /*+ QUERY_CACHE */ item, 'drones' FROM
products WHERE parent_id = 1),
  of_cars AS (SELECT /*+ QUERY_CACHE */ item, 'cars' FROM products
WHERE parent_id = 5)
SELECT * FROM of_drones UNION ALL SELECT * FROM of_cars ORDER BY 1;
```

When the QUERY\_CACHE hint is specified in a recursive query included in the WITH clause and no other CTE is referenced.

```
WITH
  RECURSIVE cars (id, parent_id, item, price) AS (
    SELECT /*+ QUERY_CACHE */ id, parent_id, item,
price
    FROM products WHERE item LIKE 'Car%'
  UNION ALL
    SELECT /*+ QUERY_CACHE */ p.id, p.parent_id,
p.item, p.price
    FROM products p
  INNER JOIN cars rec_cars ON p.parent_id =
rec_cars.id)
SELECT item, price FROM cars ORDER BY 1;
```

In the UNION query above, the first query is cached, but the second query is not cached because it references another table.

1. When the QUERY\_CACHE hint is specified in a subquery that does not refer to another table

```
SELECT h.host_year, (SELECT /*+ QUERY_CACHE */ host_nation FROM
olympic o WHERE o.host_year > 1994 limit 1) AS host_nation,
h.event_code, h.score, h.unit
FROM history h;

SELECT name, capital, list(SELECT /*+ QUERY_CACHE */ host_city FROM
olympic WHERE host_nation like 'K%') AS host_cities
FROM nation;
```

However, if another table is referenced within a subquery as shown below, the query is not cached even if the `QUERY_CACHE` hint is specified.

```
SELECT h.host_year, (SELECT /** QUERY_CACHE */ host_nation FROM
olympic o WHERE o.host_year=h.host_year) AS host_nation,
h.event_code, h.score, h.unit
FROM history h;

SELECT name, capital, list(SELECT /** QUERY_CACHE */ host_city FROM
olympic WHERE host_nation = name) AS host_cities
FROM nation;
```

The cached query is shown as **query\_string** in the middle of the result screen. Each of the **n\_entries** and **n\_pages** represents the number of cached queries and the number of pages in the cached results. The **n\_entries** is limited to the value of configuration parameter **max\_query\_cache\_entries** and the **n\_pages** is limited to the value of **query\_cache\_size\_in\_pages**. If the **n\_entries** is overflowed or the **n\_pages** is overflowed, some victims among the cache entries are selected and they are uncached. The number of victims is about 20% of **max\_query\_cache\_entries** value and of the **query\_cache\_size\_in\_pages** value.

When executing a query using **query profiling**, profiling information for the uncorrelated subquery cache is displayed as sub-information of the subquery to which the uncorrelated subquery cache is applied.

The following is an example of subquery cache profiling information displayed when executing a subquery.

```
SELECT name, capital, list (
    SELECT /** QUERY_CACHE */ host_city
    FROM olympic
    WHERE host_nation like 'K%'
) AS host_cities
FROM nation;

Trace Statistics:
  SELECT (time: 13, fetch: 2584, fetch_time: 0, ioread: 0)
    SCAN (table: public.nation), (heap time: 2, fetch: 864, ioread:
0, readrows: 215, rows: 215)
    SUBQUERY (uncorrelated)
      SELECT (time: 0, fetch: 0, fetch_time: 0, ioread: 0)
        RESULT CACHE (reference count: 1)
```

The description of the profiling items for the uncorrelated subquery cache is as follows:

- **reference count**: The number of references to the cache referenced by the subquery.

## SUBQUERY CACHE (correlated)

Subquery cache optimization can enhance the performance of queries including correlated subqueries by caching each subquery's results in private memory space per subquery. This optimization is enabled by default. To disable it during query execution, use the `NO_SUBQUERY_CACHE` hint on the target subquery.

When the correlated subquery is in the `SELECT` clause, subquery cache is enabled. The processing mechanism of the cache is as follows: If the column values of the search conditions of the re-executed correlated subquery are the same, the cached results are used instead of executing the subquery. If the cached value cannot be found in the subquery cache, after executing the subquery, the retrieved column value and results are stored in the subquery cache.

When executing a query using **query profiling**, the profile results for the subquery cache are displayed as part of the profile for correlated subqueries.

The following example displays subquery cache profiling information, when performing a correlated subquery.

```
csql> SELECT /*+ RECOMPILE NO_MERGE */
      (SELECT t1_pk FROM t1 b WHERE b.t1_pk = a.c3)
FROM t1 a
WHERE a.c2 >= 1;

Trace Statistics:
  SELECT (time: 108, fetch: 103639, fetch_time: 13, ioread: 0)
    SCAN (table: dba.t1), (heap time: 70, fetch: 100384, ioread: 0,
readrows: 100000, rows: 99000)
    SUBQUERY (correlated)
      SELECT (time: 4, fetch: 2970, fetch_time: 0, ioread: 0)
        SCAN (index: dba.t1.pk_t1), (btree time: 2, fetch: 1980,
ioread: 0, readkeys: 990, filteredkeys: 0, rows: 990, covered: true)
        SUBQUERY_CACHE (hit: 98010, miss: 990, size: 269384, status:
enabled)
```

Descriptions for each item are as follows:

- **hit:** The number of retrieves from the cache without executing the query.
- **miss:** The number of times the result of a query execution is stored into the cache (the number of times a query result is not found in the cache).
- **size:** The memory size used by the subquery cache.
- **status:** The activation status of the subquery cache at the end of executing the query.

If the **size** exceeds the set value during query execution, the subquery cache is disabled and the **status** in the SQL trace information is output as disabled. Additionally, if the **hit** ratio is less than

90%, even when the memory size of the subquery cache does not exceed the set value, the cache may be disabled during query execution because the cache miss rate is considered high.

### **Note**

The **hit** ratio is calculated as follows:

$$\text{hit ratio} = \frac{\text{hit}}{\text{hit} + \text{miss}}$$

The following example contains queries that count the results of a correlated subquery that is executed repeatedly to check for performance improvements depending on whether subquery caching is used. The following query creates data to perform the example queries.

```
# Prepare data
csql> DROP TABLE IF EXISTS t1;

csql> CREATE TABLE t1 AS
    SELECT
        ROWNUM AS t1_pk,
        MOD(ROWNUM, 10) AS c1,
        MOD(ROWNUM, 100) AS c2,
        MOD(ROWNUM, 1000) AS c3
    FROM
        db_class a, db_class b, db_class c, db_class d,
        db_class e, db_class f
    LIMIT 100000;

csql> ALTER TABLE t1 ADD CONSTRAINT PRIMARY KEY pk_t1 (t1_pk);

csql> CREATE TABLE t2 AS
    SELECT
        ROWNUM as c1,
        1 as c2,
        TO_CHAR(ROWNUM * 1000, '0999') as code
    FROM
        db_class a, db_class b
    LIMIT 10;

csql> update statistics on t1 with fullscan;

csql> ;trace on
```

Query #1 is executed using subquery cache optimization, while Query #2 is executed without subquery cache optimization by using the NO\_SUBQUERY\_CACHE hint. A comparison of the results from the two queries reveals that subquery cache optimization improves response performance.

## Query #1

## Query #2

```

csql> SELECT COUNT(*)
      FROM (
            SELECT /**
RECOMPILE NO_MERGE */
            (SELECT
t1_pk FROM t1 b WHERE b.t1_pk
= a.c3)
            FROM t1 a
            WHERE a.c2 >= 1
            );

=== <Result of SELECT Command
in Line 2> ===

              count(*)
=====
              99000

1 row selected. (0.128251 sec)
Committed. (0.000010 sec)

1 command(s) successfully
processed.

```

```

csql> SELECT COUNT(*)
      FROM (
            SELECT /**
RECOMPILE NO_MERGE */
            (SELECT /
** NO_SUBQUERY_CACHE */ t1_pk
FROM t1 b WHERE b.t1_pk =
a.c3)
            FROM t1 a
            WHERE a.c2 >= 1
            );

=== <Result of SELECT Command
in Line 2> ===

              count(*)
=====
              99000

1 row selected. (0.626199
sec) Committed. (0.000011 sec)

1 command(s) successfully
processed.

```

Subquery cache optimization does not work in the following scenarios:

- When the correlated subquery contains another correlated subquery. (However, subquery cache optimization is performed for the innermost correlated subquery that does not contain other correlated subqueries.)
- When the subquery is not scalar subquery.
- When the subquery includes a CONNECT BY clause.
- When the subquery includes OID-related features.
- When the subquery includes the **NO\_SUBQUERY\_CACHE** hint.
- When the subquery cache memory size exceeds the configured size (default: 2MB).
- When the subquery contains functions that produce different results with each execution, such as random() or sys\_guid().

The following example shows that subquery caching is enabled only for the innermost correlated subquery and disabled for the outer correlated subquery.

```
csql> SELECT /**+ recompile */
      (
        SELECT
          (
            SELECT c.code
            FROM t2 c
            WHERE c.c1 = b.c1
          )
        FROM t1 b
        WHERE b.t1_pk = a.c1
      ) s
FROM t1 a
WHERE a.c3 = 1;

Trace Statistics:
  SELECT (time: 56, fetch: 100785, fetch_time: 10, ioread: 0)
    SCAN (table: dba.t1), (heap time: 55, fetch: 100384, ioread:
0, readrows: 100000, rows: 100)
    SUBQUERY (correlated)
      SELECT (time: 0, fetch: 401, fetch_time: 0, ioread: 0)
        SCAN (index: dba.t1.pk_t1), (btree time: 0, fetch: 300,
ioread: 0, readkeys: 100, filteredkeys: 0, rows: 100) (lookup time:
0, rows: 100)
        SUBQUERY (correlated)
          SELECT (time: 0, fetch: 1, fetch_time: 0, ioread: 0)
            SCAN (table: dba.t2), (heap time: 0, fetch: 1,
ioread: 0, readrows: 10, rows: 1)
            SUBQUERY_CACHE (hit: 99, miss: 1, size: 150704,
status: enabled)
```

The following example shows that subquery cache optimization is disabled when the correlated subquery includes random() functions, which yield different results with each execution.

```
csql> WITH cte_1 AS
      (SELECT
        DISTINCT (SELECT random(1) FROM t2 b WHERE b.c1 = a.c1
AND b.c2 = 1) v
        FROM t1 a
        WHERE a.c2 = 1
      ) SELECT count(*) FROM cte_1;

Trace Statistics:
  SELECT (time: 65, fetch: 101384, fetch_time: 9, ioread: 0)
    SCAN (temp time: 0, fetch: 0, ioread: 0, readrows: 1000,
rows: 1000)
    SUBQUERY (uncorrelated)
```

```

CTE (non_recursive_part)
  SELECT (time: 65, fetch: 101384, fetch_time: 9, ioread:
0)
    SCAN (table: dba.t1), (heap time: 59, fetch: 100384,
ioread: 0, readrows: 100000, rows: 1000)
    ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
    SUBQUERY (correlated)
      SELECT (time: 4, fetch: 1000, fetch_time: 0, ioread:
0)
        SCAN (table: dba.t2), (heap time: 3, fetch: 1000,
ioread: 0, readrows: 10000, rows: 1000)

```

## MEMOIZE

The **MEMOIZE** optimization caches the inner table's scan results per join key value in a nested loop join, enhancing the performance of joins in which the same join key values repeat. If the join key value read from the outer table is already in the cache, the inner table scan and predicate evaluation are skipped and the cached results are used; otherwise, the inner table is scanned and the results are stored in the cache.

The MEMOIZE optimization is applied automatically at query execution time; there is no dedicated syntax or hint. To disable this optimization, set the `memoize_memory_limit` parameter to **0**.

The MEMOIZE optimization is applied to a scan that satisfies all of the following conditions.

- The scan is the inner table scan of a nested loop join. It is not applied to the outer table, nor to hash joins or sort merge joins.
- Join key values — column values of the outer table — can be found in the join conditions. It is not applied to cross joins, which have no join condition.
- The scan is a read that requires no row locks. It is not applied to the target search of an **UPDATE** or **DELETE** statement, or to a **SELECT ... FOR UPDATE** query.

In addition, it is not applied in some cases where reusing cached results is unsafe, such as when the inner table has a collection type (**SET**, **MULTISET**, **LIST**) column or when a system class is queried.

If the memory used by the cache exceeds the value set in `memoize_memory_limit`, or if the **hit** ratio is below 50% once join key lookups exceed 1,000, the cache is judged to cost more than it saves and is released immediately; query execution then continues by scanning the inner table without the cache. The query does not fail, and no error or warning is raised.

### Note

The **hit** ratio is calculated as follows.

$$\text{hit ratio} = \frac{\text{hit}}{\text{hit} + \text{miss}}$$

When executing a query using **query profiling**, the profiling information for the MEMOIZE cache is displayed as part of the profile for the scan to which the MEMOIZE optimization is applied.

The following queries prepare the data used by the example queries. Only 100 values appear repeatedly in the *customer\_id* column of the *orders* table.

```
CREATE TABLE customers (id INT PRIMARY KEY, grade INT);

INSERT INTO customers
SELECT ROWNUM, MOD(ROWNUM, 5)
FROM db_class a, db_class b
LIMIT 100;

CREATE TABLE orders (id INT PRIMARY KEY, customer_id INT, amount
INT);

INSERT INTO orders
SELECT ROWNUM, MOD(ROWNUM, 100) + 1, MOD(ROWNUM, 1000)
FROM db_class a, db_class b, db_class c, db_class d
LIMIT 1000000;

UPDATE STATISTICS ON customers, orders WITH FULLSCAN;
```

The following example displays MEMOIZE profiling information when performing a nested loop join. The example query uses the **ORDERED** and **USE\_NL** hints to induce a nested loop join, and the **NO\_PARALLEL\_SCAN** hint to exclude the effects of parallel scans.

```
csql> ;trace on

SELECT /*+ RECOMPILE ORDERED USE_NL NO_PARALLEL_SCAN */ SUM(o.amount)
FROM orders o INNER JOIN customers c ON c.id = o.customer_id
WHERE c.grade = 1;
```

```
Trace Statistics:
  SELECT (time: 491, fetch: 5132, fetch_time: 1, ioread: 0)
    SCAN (table: dba.orders), (heap time: 198, fetch: 4931, ioread:
0, readrows: 1000000, rows: 1000000)
      SCAN (index: dba.customers.pk_customers_id), (btree time: 0,
fetch: 200, ioread: 0, readkeys: 100, filteredkeys: 100, rows: 100)
(lookup time: 0, rows: 20)
```

```
MEMOIZE (time: 184, hit: 999900, miss: 100, size: 18KB,
enabled: true)
```

The index scan on the *customers* table was performed only for the first lookup of each of the 100 join key values (**miss**: 100), and the remaining 999,900 lookups were served from the cache (**hit**: 999900).

The description of the profiling items for the MEMOIZE cache is as follows.

- **time**: The cumulative time spent on cache lookups and stores, in milliseconds.
- **hit**: The number of join key lookups that used cached results instead of scanning the inner table.
- **miss**: The number of join key lookups that scanned the inner table because the join key was not found in the cache.
- **size**: The amount of memory used by the cache.
- **enabled**: Whether the cache is still enabled when the query ends.

#### Note

The **MEMOIZE** item is displayed only when **hit** is 1 or greater. The absence of a **MEMOIZE** item in the profiling results does not mean that the MEMOIZE optimization was not attempted.

#### Note

**hit** and **miss** count join key lookups, not result rows.

When combined with **parallel execution**, a separate cache is created for each worker thread, and the profiling information displays the sum of the workers' statistics. In this case, **enabled** is displayed as false if the cache has been released in any worker.

Query #1 was executed using the MEMOIZE optimization, and Query #2 was executed with the MEMOIZE optimization disabled by setting **memoize\_memory\_limit** to 0. Comparing the results of the two queries shows that using the MEMOIZE optimization improves the response time.

## Query #1

```

csql> SELECT /*+ RECOMPILE
ORDERED USE_NL
NO_PARALLEL_SCAN */
SUM(o.amount)
      FROM orders o INNER
JOIN customers c ON c.id =
o.customer_id
      WHERE c.grade = 1;

=== <Result of SELECT Command
in Line 2> ===

      sum(o.amount)
=====
      99500000

1 row selected. (0.407000 sec)
Committed. (0.000000 sec)

```

## Query #2

```

csql> SET SYSTEM PARAMETERS
'memoize_memory_limit=0';

csql> SELECT /*+ RECOMPILE
ORDERED USE_NL
NO_PARALLEL_SCAN */
SUM(o.amount)
      FROM orders o INNER
JOIN customers c ON c.id =
o.customer_id
      WHERE c.grade = 1;

=== <Result of SELECT Command
in Line 3> ===

      sum(o.amount)
=====
      99500000

1 row selected. (1.407000
sec) Committed. (0.000000 sec)

```

## Parallel Execution

### Parallel Execution

CUBRID provides parallel query execution capabilities to efficiently process large amounts of data. Parallel query execution divides a single query into multiple work units, which are then processed by multiple worker threads simultaneously, dramatically reducing response time.

### Overview

Parallel queries provide the following key features:

- **Parallel Scan:** Multiple worker threads divide and scan the input data (heap, temporary list, or index), improving large input scanning performance. Three scan flavors are supported:
  - **Parallel Heap Scan:** Heap pages of a table are partitioned by **sector** and scanned in parallel.

- **Parallel List Scan:** A temporary result list (list file) that has spilled to disk is partitioned by **sector** and scanned in parallel.
- **Parallel Index Scan:** Workers cooperate through a shared cursor to walk the leaf pages of a B+tree index from left to right (or right to left).
- **Parallel Subquery Execution:** Independent subqueries (uncorrelated subqueries) are processed simultaneously by individual workers, improving query response time.
- **Parallel Hash Join:** Parallelizes both the build and probe phases, improving response time during hash join operations.
- **Parallel Sort:** Divides data to be sorted among multiple worker threads, sorts in parallel, then merges the results, improving sort response time.

## Configuration

Parallel query execution can be controlled through system parameters and SQL hints.

- Setting the **parallelism** parameter to 2 or higher enables the optimizer to determine parallel query execution during query processing.
- Use the **PARALLEL** ( *degree* ) hint to explicitly specify the degree of parallelism for each query. *degree* is the number of workers to use and must be an integer value of 0 or higher. A value of **0** or **1** disables parallel execution; a value of **2 or higher** takes precedence over the parallelism parameter setting. A value larger than the number of system CPU cores is lowered to the core count.
- The **max\_parallel\_workers** parameter sets the maximum number of parallel worker threads that can be executed simultaneously across the entire server (default: 100).
- The **NO\_PARALLEL\_SCAN** hint disables every parallel scan flavor (heap, list, and index) within the query block. When used together with the **PARALLEL** hint, **NO\_PARALLEL\_SCAN** takes precedence.
- Parallel hash join and parallel subquery execution can be disabled with the **NO\_PARALLEL\_HASH\_JOIN** and **NO\_PARALLEL\_SUBQUERY** hints, respectively. See the corresponding sections for details.

### Note

The **max\_parallel\_workers** and **parallelism** parameters are set to default values of 100 and 4 respectively, so you can use parallel queries without additional configuration. However, parallel query execution is disabled entirely when the system has 2 or fewer CPU cores.

**Note**

Under parallel execution, the order of result rows can change from run to run depending on the order in which workers finish. Specify an ORDER BY clause whenever the result order matters.

## Parallel Scan

Parallel Scan splits a single scan input across multiple worker threads that process it concurrently. CUBRID supports parallel scan over three input kinds, all sharing the same parallel execution framework:

- **Heap**: heap pages of a table — pre-partitioned across workers by **sector**
- **List**: pages of a temporary (on-disk) result list file — pre-partitioned across workers by **sector**
- **Index**: leaf pages of a B+tree index — workers cooperate through a shared **cursor**, walking left to right (or right to left)

Each worker thread independently scans its assigned region while evaluating filter predicates, and the processed results are passed to the main thread through a result queue and integrated into the final result.

**Note**

The actual degree of parallelism is automatically optimized by throughput rules within the user-configured upper limit. For more details, see [Parallel Query Throughput Rules](#).

## Common Constraints

Regardless of the scan flavor, parallel scan is not applied and falls back to single-threaded execution if any of the following conditions hold:

- Statements that do not support concurrent processing
  - Stored procedures (JavaSP, PL/CSQL) or Serial usage
  - References to session variables
  - Recursive CTE or Connect By clauses

- CUBRID object DBMS specific features
- Operations requiring exclusive lock (X-LOCK) acquisition
  - SELECT ... FOR UPDATE clause
  - Use of the incr() function
  - update, delete, merge statements
- The scan is not the first (driving) table in a JOIN
- Scans inside a correlated subquery. Scans inside an uncorrelated subquery can still be parallelized.
- The scan is the direct outer/inner input of a sort-merge join (applies to every scan flavor)
- The **NO\_PARALLEL\_SCAN** hint is specified

Each scan flavor has additional, flavor-specific constraints. See the corresponding subsections below.

```
-- Examples where parallel scan is not applied

-- Disabled by hint (covers every scan flavor)
SELECT /*+ NO_PARALLEL_SCAN */ *
FROM large_table;

-- SELECT FOR UPDATE
SELECT /*+ PARALLEL(4) */ *
FROM large_table
WHERE id <= 10
FOR UPDATE;

-- Using session variables
SET @user_id = 123;
SELECT /*+ PARALLEL(4) */ *
FROM orders
WHERE cust_id = @user_id;

-- Using SERIAL
SELECT /*+ PARALLEL(4) */ id, order_seq.NEXT_VALUE
FROM large_table
WHERE id <= 3;
```

## Parallel Heap Scan

Parallel Heap Scan statically partitions the heap pages of a table by sector and lets workers scan their partitions concurrently. It can yield a large speedup over single-threaded heap scan, especially when selectivity is low (typically 0.05 or less).

Heap scan has no additional flavor-specific restrictions beyond the [common constraints](#) listed above.

```
-- Parallel heap scan
SELECT /** PARALLEL(4) */ id, category
FROM large_table
WHERE status = 'active';

-- Parallel heap scan over a partitioned table
SELECT /** PARALLEL(4) */ *
FROM sales_partitioned
WHERE sale_date BETWEEN '2024-01-01' AND '2024-12-31';

-- INSERT SELECT (bulk copy)
INSERT INTO archive_orders
SELECT /** PARALLEL(4) */ *
FROM orders
WHERE amount < 100;
```

### Note

For a partitioned table, parallelization is decided per partition, and the activation condition ([Parallel Query Throughput Rules](#)) is also evaluated against each partition's own page count. A partition below the activation condition is scanned single-threaded.

## Parallel List Scan

Parallel List Scan statically partitions a temporary on-disk result list (list file) — produced by a subquery, derived table, or other intermediate operator — across workers by **sector**, and each worker reads its share concurrently. The partitioning mechanism itself is identical to parallel heap scan; the only difference is that the input is a temporary file rather than a table heap. It is effective when an upper operator must rescan a large intermediate result.

### Additional list-scan constraints

Parallel list scan is not applied — and falls back to a single-threaded list scan — if any of the following hold:

- The temporary list resides only in the in-memory buffer and has not spilled to a disk temp file (no sectors to partition — small lists fall back to single-threaded execution automatically).
- The upper operator consumes results in row-by-row mode (a query shape that admits neither mergeable list nor BUILDVALUE; see [Result Collection Modes](#)).
- A ROWNUM or LIMIT predicate is attached to the list scan.
- The list scan sits inside the auxiliary input subtree (subquery, CTE, etc.) of a sort-merge join.

```
-- Typical pattern that benefits from parallel list scan:  
-- the temporary result list of a derived table on which  
-- View Merging is not performed is  
-- re-aggregated by the outer query.  
SELECT /*+ PARALLEL(4) */ COUNT(*)  
FROM (SELECT DISTINCT id, pad FROM large_table) t;
```

#### Note

A derived table that is a simple projection is merged into the outer query by the **View Merging** optimization, so no temporary result list is created in the first place. A temporary result list is created for a derived table on which **View Merging** cannot be performed because it contains **DISTINCT**, **GROUP BY**, **UNION**, and the like; the **NO\_MERGE** hint can also be used to block **View Merging** and force the list to be created. Rescanning a hash join's input list from an upper operator is another typical target of parallel list scan. For more details on **View Merging**, see [View Merging Optimization](#).

## Parallel Index Scan

Parallel Index Scan lets multiple workers cooperatively walk the leaf pages of a B+tree index through a shared cursor. The vertical descent (root → leaf entry) is performed serially by the main thread; the subsequent leaf traversal, OID fetching, and predicate evaluation are parallelized across workers. Each worker grabs one leaf page, processes its keys independently, and only briefly synchronizes to obtain the next leaf.

### Additional index-scan constraints

Parallel index scan is not applied — and falls back to a single-threaded index scan — if any of the following hold:

- The scan uses an index-driven traversal optimization that changes how the tree is entered or walked:
  - ISS (Index Skip Scan)
  - ILS (Index Loose Scan)
  - KEYLIMIT clause
  - ORDERBY\_SKIP / GROUPBY\_SKIP family optimizations (replacing ORDER BY / GROUP BY with the index order)
  - MIN/MAX single-key scan (min\_max scan)
- ROWNUM is used in a form that cannot be recomputed per worker, or an analytic-function SKIP SORT / LIMIT optimization is applied.
- The upper operator consumes results in row-by-row mode (a query shape that admits neither mergeable list nor BUILDVALUE; see [Result Collection Modes](#)).
- The index scan sits inside the auxiliary input subtree (subquery, CTE, etc.) of a sort-merge join.

```
-- Typical case where parallel index scan applies
-- (covering index scan over a wide range)
CREATE INDEX idx_large_id_pad ON large_table(id, pad);

SELECT /*+ PARALLEL(4) */ COUNT(pad)
FROM large_table
WHERE id BETWEEN 1 AND 900000 USING INDEX idx_large_id_pad;

-- Parallel index scan is NOT applied
-- (KEYLIMIT clause forces single-threaded index scan)
SELECT /*+ PARALLEL(4) */ id, category
FROM large_table
WHERE id BETWEEN 1 AND 900000 USING INDEX idx_large_id_pad KEYLIMIT
100;
```

#### Note

Because the tree descent is serial on the main thread and the leaf traversal is cooperative, parallel index scan pays off when the index has enough leaf pages. On small indexes the

synchronization cost can outweigh the speedup; the throughput rules ([Parallel Query Throughput Rules](#)) guard against this.

### Note

For an index scan to be parallelized automatically without the **PARALLEL** hint, the optimizer additionally requires both of the following.

- The selectivity of every key range predicate must be derivable from **histogram statistics**. If the target table has no histogram statistics, the optimizer never chooses parallel index scan. Statistics can be refreshed with the **UPDATE STATISTICS** statement.
- The product of the selectivity and the number of index pages must reach a threshold (32 pages by default).

The **PARALLEL** hint bypasses these optimizer conditions, but the scan still runs single-threaded if the measured number of index pages does not meet the activation condition ([Parallel Query Throughput Rules](#)).

## Performance Considerations

Parallel scan delivers the largest gains in the following cases:

- Large inputs (tables, lists, indexes) — the more pages, the better
- Low selectivity ( $\approx 0.05$  or less) for heap and index scans
- Sufficient CPU cores are available
- CPU processing — not disk I/O — is the bottleneck

Conversely, performance can regress in these cases:

- The input has only a small number of pages
- A single-threaded index scan is already fast enough (e.g., short range / point lookup)
- System resources (CPU, memory) are scarce

When using parallel queries, set the `max_parallel_workers` parameter so that workers do not contend excessively for system resources. A value close to the number of physical CPU cores is usually a good starting point.

## Result Collection Modes

Once parallel scan is enabled, the way the main thread collects worker results depends on the query shape and is one of the three modes below. The mode appears as the **gather** field in the SQL trace.

- **mergeable list**: each worker builds its own temporary result list and the main thread uses those lists directly without merging. This has the lowest synchronization cost and is usually the fastest mode.
- **buildvalue**: each worker computes a partial aggregate and the main thread combines the partials into the final aggregate. Used for simple aggregate queries (see [BUILDVALUE Optimization](#)).
- **row-by-row**: the main thread receives one row at a time. Applies when neither of the other two modes can be used. It has the broadest applicability but the highest synchronization cost.

### Note

The row-by-row mode is observed **only with parallel heap scan**. Parallel list scan and parallel index scan fall back to single-threaded execution for query shapes that would require row-by-row (see the additional constraints in their respective sections), so `gather: row by row` only appears in heap-scan traces.

## When mergeable list is not chosen

Mergeable list is replaced by another mode (buildvalue or row-by-row) if any of the following hold:

- The scan carries predicates that cannot be evaluated while scanning (deferred to an upper operator).
- The select-list contains a stored procedure (JavaSP or PL/CSQL).
- ROWNUM or LIMIT is used in a form that cannot be recomputed per worker.
- The scan does not output any table column directly (e.g., a query selecting only constants).
- `result_cache` is enabled.

### Note

A top-N query combining ORDER BY with LIMIT can also run in parallel with mergeable list. In that case each worker keeps its own top N while scanning, and **topnsort: true** appears in the

parallel processing details of the trace. When GROUP BY is combined, the workers perform partial hash aggregation and the **GROUPBY** entry of the trace shows **hash: partial**.

## BUILDVALUE Optimization

When a query computes aggregate functions without GROUP BY and every aggregate function it uses is on the supported list, parallel scan applies the **BUILDVALUE optimization**. In this mode, each worker computes a partial aggregate over its scanned region and ships it to the main thread, which then combines the partials into the final result. Because workers exchange the smallest possible amount of data, this is the fastest mode for aggregate queries.

### Supported aggregate functions

The BUILDVALUE optimization applies to queries using the following aggregate functions. The SELECT list may also combine these aggregate functions in arithmetic expressions.

- **COUNT(\*), COUNT(column), COUNT(DISTINCT column)**
- **MIN, MAX**
- **SUM, AVG**
- **STDDEV, STDDEV\_POP, STDDEV\_SAMP**
- **VARIANCE, VAR\_POP, VAR\_SAMP**
- **BIT\_AND, BIT\_OR, BIT\_XOR**
- **GROUP\_CONCAT, JSON\_ARRAYAGG, JSON\_OBJECTAGG**
- **MEDIAN, PERCENTILE\_CONT, PERCENTILE\_DISC**
- **CUME\_DIST, PERCENT\_RANK**

### Conditions

In addition to using only the supported aggregate functions, all of the following must hold:

- The query has no GROUP BY clause.
- The query does not use ROWNUM.

### Scope

The BUILDVALUE optimization is independent of the scan flavor and can be applied to:

- Parallel heap scan

- Parallel list scan
- Parallel index scan

## Examples

```
-- COUNT family
SELECT /** PARALLEL(8) */ COUNT(*)
FROM large_table
WHERE status = 'active';

SELECT /** PARALLEL(8) */ COUNT(DISTINCT customer_id)
FROM orders;

-- Arithmetic aggregates (heap, list, or index scan)
SELECT /** PARALLEL(8) */ SUM(amount), AVG(amount), MAX(amount)
FROM orders
WHERE order_date > '2024-01-01';

-- Variance / standard deviation
SELECT /** PARALLEL(8) */ STDDEV(price), VARIANCE(price)
FROM products;

-- UPDATE STATISTICS internally benefits from BUILDVALUE
  optimization as well
UPDATE STATISTICS ON large_table WITH FULLSCAN;
```

### Note

If any unsupported aggregate function is included or **GROUP BY** is combined, the **BUILDVALUE** optimization is not applied and the query is processed in the mergeable list or row-by-row mode instead.

## Scan SQL Trace

When parallel scan is performed, parallel processing details are added to the **SQL trace** output.

```
csql> ;trace on

SELECT /** PARALLEL(4) RECOMPILE */ id, category
FROM large_table
WHERE status = 'active';
```

```
Trace Statistics:
  SELECT (time: 110, fetch: 19717, fetch_time: 15, ioread: 2101)
    SCAN (table: dba.large_table), (heap time: 110, fetch: 19714,
ioread: 2100, readrows: 1000000, rows: 1000000)
      (parallel workers: 4, heap time: 108..110, readrows:
248704..252416, rows: 248704..252416, gather: mergeable list)
```

The parallel scan trace fields are:

- **parallel workers**: number of worker threads used.
- **heap time / temp time / index time**: per-worker scan time range (min..max, milliseconds). The label is **heap time** for heap scan, **temp time** for list scan (the input is a temporary list file), and **index time** for index scan.
- **readrows**: per-worker range of rows read (min..max).
- **rows**: per-worker range of rows produced (min..max).
- **gather**: how worker results were collected.
  - **mergeable list**: per-worker lists are used directly without merging.
  - **buildvalue**: per-worker partial aggregates are combined (replaces the legacy `count` label).
  - **row by row**: rows are collected one at a time (heap scan only).

When **gather** shows **mergeable list** or **buildvalue**, the query took the lowest-synchronization path.

#### Note

Per-worker times and row counts appear as min..max ranges. Ideally all workers do similar amounts of work; a wide range hints at uneven data distribution or system resource contention.

### BUILDVALUE optimization trace example

When BUILDVALUE optimization is applied, **gather: buildvalue** is shown.

```
csql> ;trace on

SELECT /*+ PARALLEL(4) RECOMPILE */ COUNT(*)
FROM large_table
WHERE status = 'active';
```

```
Trace Statistics:
  SELECT (time: 86, fetch: 17249, fetch_time: 93, ioread: 13377)
    SCAN (table: dba.large_table), (heap time: 86, fetch: 17246,
ioread: 13377, readrows: 1000000, rows: 1000000)
      (parallel workers: 4, heap time: 81..86, readrows:
248704..252416, rows: 248704..252416, gather: buildvalue)
```

### Parallel index scan trace example

The parallel processing details of a parallel index scan report **index time** along with the per-worker ranges of **readkeys** (keys read) and **filteredkeys** (keys passing the key filter). A covering index scan additionally shows **covered: true**.

```
csql> ;trace on

SELECT /** PARALLEL(4) RECOMPILE */ COUNT(pad)
FROM large_table
WHERE id BETWEEN 1 AND 900000 USING INDEX idx_large_id_pad;
```

```
Trace Statistics:
  SELECT (time: 136, fetch: 13247, fetch_time: 77, ioread: 13239)
    SCAN (index: dba.large_table.idx_large_id_pad), (btree time:
136, fetch: 13244, ioread: 13239, readkeys: 900003, filteredkeys:
900000, rows: 900000, covered: true)
      (parallel workers: 4, index time: 136..136, readkeys:
224557..225285, filteredkeys: 224556..225284, rows: 224556..225284,
covered: true, gather: buildvalue)
```

For a non-covering index scan, the parallel processing details are followed by data-page lookup statistics of the form (**lookup time: min..max, rows: min..max**).

```
csql> ;trace on

SELECT /** PARALLEL(4) RECOMPILE */ category
FROM large_table
WHERE id BETWEEN 1 AND 900000 USING INDEX idx_large_id_pad;
```

```
Trace Statistics:
  SELECT (time: 330, fetch: 915916, fetch_time: 244, ioread: 129)
    SCAN (index: dba.large_table.idx_large_id_pad), (btree time:
330, fetch: 915913, ioread: 129, readkeys: 900002, filteredkeys:
900000, rows: 900000) (lookup time: 0, rows: 900000)
      (parallel workers: 4, index time: 330..330, readkeys:
```

```
223469..227732, filteredkeys: 223468..227732, rows: 223468..227732,
gather: mergeable list) (lookup time: 0..0, rows: 223468..227732)
```

## Parallel Subquery Execution

Parallel Subquery Execution is a feature that improves query performance by using multiple worker threads to simultaneously execute subqueries that can run independently.

### Subquery Execution Overview

Since subqueries can be executed independently of other subqueries, when there are multiple subqueries, executing them in parallel can reduce overall query response time. Each subquery is executed in an independent worker thread, and when all subqueries are completed, the results are merged to generate the final result.

Parallel execution of subqueries is possible if the **parallelism** parameter is set to 2 or higher, or if the degree of parallelism is specified to 2 or higher using the **PARALLEL** (*degree*) hint.

The **NO\_PARALLEL\_SUBQUERY** hint can be used to disable parallel execution of subqueries. When used together with the **PARALLEL** hint, the **NO\_PARALLEL\_SUBQUERY** hint takes precedence.

### Execution Conditions

Parallel execution of subqueries is possible when all of the following conditions are met:

- The **max\_parallel\_workers** parameter is set to 2 or higher, and available worker threads exist
- The **parallelism** parameter is set to 2 or higher, or a **PARALLEL** (2) or higher hint is specified
- The subquery is directly connected to the top-level query (top-level XASL)
- The **NO\_PARALLEL\_SUBQUERY** hint is not used

```
-- parallelism parameter setting (cubrid.conf)
-- parallelism=4

-- Subquery parallel execution example
SELECT *
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);
```

```
-- Example using hint
SELECT /** PARALLEL(4) */ *
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);
```

## Cases Not Applied

Parallel execution of subqueries is not applied if any of the following conditions apply:

- The subquery is not directly connected to the top-level query (such as subqueries inside nested subqueries)
- CTE (Common Table Expression) recursive part exists or there are references between CTEs
- References between subqueries exist due to derived tables (inline views), etc.
- Object DBMS features are used (such as path expressions, etc.)
- **JSON\_TABLE** or SET type table scans are included
- The subquery condition clause contains stored procedures
- When it is a correlated subquery

```
-- Examples where parallel execution is not applied

-- Using NO_PARALLEL_SUBQUERY hint
SELECT /** NO_PARALLEL_SUBQUERY */ *
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);

-- When there are references between CTEs
WITH cte1 AS (
    SELECT * FROM table1
),
cte2 AS (
    SELECT * FROM cte1 WHERE id > 100 -- references cte1
)
SELECT * FROM cte2;
```

```
-- Using JSON_TABLE
SELECT *
FROM orders,
JSON_TABLE(json_column, '$[*]' COLUMNS(id INT PATH '$.id')) AS jt
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);

-- When stored procedure is included in condition clause
SELECT *
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE check_region_sp(region)
= 1
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);
```

## Subquery Performance Considerations

Parallel execution of subqueries has significant performance improvements in the following cases:

- When multiple independent subqueries exist
- When each subquery's execution time is sufficiently long
- When sufficient CPU cores are available

On the other hand, performance may degrade in the following cases:

- When subquery execution time is very short (parallel processing overhead may be greater)
- When only one subquery exists
- When system resources (CPU, memory) are insufficient
- When `max_parallel_workers` setting is inappropriate

## Related Parameters

To effectively use parallel execution of subqueries, the following parameters should be set appropriately:

- `max_parallel_workers`: Maximum number of parallel workers across the server

- **parallelism**: Default degree of parallelism

```
-- cubrid.conf configuration example
max_parallel_workers=16
parallelism=4
```

## Subquery Trace Information

When parallel execution of subqueries is performed, parallel processing details are additionally output in the **SQL trace** results.

```
csql> ;trace on

SELECT /*+ PARALLEL(4) RECOMPILE */ *
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);
```

```
Trace Statistics:

```

The description of subquery parallel execution SQL trace output items is as follows:

- **SUBQUERY (uncorrelated)**: Indicates subquery execution

- **parallel workers:** Number of worker threads used for parallel execution
- **time:** Time spent on parallel execution (milliseconds)
- Each subquery is displayed as an independent SELECT, and execution statistics for each are output

In the above example, 2 subqueries (customers table query, products table query) were executed in parallel using 2 worker threads.

## Parallel Hash Join

Parallel Hash Join improves join response time by parallelizing the build and probe phases of a hash join across multiple worker threads. A hash join first loads both inputs into temporary result lists, builds a hash table from one input (build), and searches it with the other input (probe). Parallel hash join takes one of the following two forms depending on the input sizes.

- **Partitioned parallel:** both inputs are split into multiple partitions by the join key (SPLIT), and workers run the per-partition build and probe concurrently. Used when the build input is large enough to require partitioning.
- **Parallel probe:** when the build input is small enough to build the hash table in memory at once, the build runs single-threaded and only the probe input is divided among workers.

## Activation conditions

- The larger of the two input lists must satisfy the activation condition ([Parallel Query Throughput Rules](#)) in page count. Below it, the hash join runs single-threaded even with the **PARALLEL** hint.
- When the **NO\_PARALLEL\_HASH\_JOIN** hint is specified, the hash join is not parallelized. The hash join itself is kept; only its parallelization is disabled. See [NO\\_PARALLEL\\_HASH\\_JOIN](#) for details.

## Hash Join Trace

When a hash join is performed, a **HASHJOIN** tree is printed in the [SQL trace](#) output. The tree shows per-phase statistics for partitioning (**SPLIT**), build (**BUILD**), and probe (**PROBE**), and this tree structure is always printed for a hash join regardless of parallelism. When parallel hash join is applied, a **parallel workers** field is added to the **HASHJOIN** entry, and the per-partition parallel phase is shown as a **PARALLEL** entry.

```
csql> ;trace on
```

```
SELECT /*+ RECOMPILE PARALLEL(4) USE_HASH */ COUNT(*)
FROM orders o JOIN large_table t ON o.order_id = t.id;
```

```

Trace Statistics:
  SELECT (time: 915, fetch: 76794, fetch_time: 134, ioread: 497)
    SCAN (temp time: 28, fetch: 2465, ioread: 142, readrows:

              (parallel workers: 4, heap time: 300..354,
readrows: 248704..252416, rows: 248704..252416, gather: mergeable
list)

```

The parallelism-related fields of the hash join trace are:

- **parallel workers** on **HASHJOIN**: number of worker threads used by the hash join. If absent, the hash join ran single-threaded.
- **SPLIT**: the phase that splits both inputs into partitions by the join key. **partitions** is the number of partitions created.
- **PARALLEL**: the phase in which workers run per-partition build and probe concurrently. The **time** of the **BUILD** and **PROBE** entries below it is reported as a per-worker range (min..max).
- **SUBQUERY (uncorrelated)**: the phase that loads the two join inputs into temporary result lists. Loading the inputs is itself subject to parallel subquery execution and parallel scan.

The following example disables parallelization with the **NO\_PARALLEL\_HASH\_JOIN** hint. The **HASHJOIN** entry has no **parallel workers** field and **BUILD/PROBE** run single-threaded without a **PARALLEL** entry, while the scans loading the join inputs can still run in parallel independently.

```
csql> ;trace on
```

```
SELECT /*+ RECOMPILE PARALLEL(4) USE_HASH NO_PARALLEL_HASH_JOIN */
COUNT(*)
FROM orders o JOIN large_table t ON o.order_id = t.id;
```

Trace Statistics:

```
SELECT (time: 1716, fetch: 74720, fetch_time: 398, ioread: 16587)
  SCAN (temp time: 52, fetch: 2465, ioread: 1346, readrows:
1000000, rows: 1000000)
    (parallel workers: 4, temp time: 46..52, readrows:

ioread: 1, readrows: 100, rows: 100)

```

## Parallel Sort

Parallel Sort improves sort response time by distributing the sort input among multiple worker threads, letting each sort its share, and merging the results. Parallel sort can be applied to the following sort operations.

- File sort (filesort) of an ORDER BY clause
- Partitioning/sorting for analytic functions
- The sort of a GROUP BY to which hash aggregation cannot be applied (e.g., when a DISTINCT aggregate function is included)
- The internal sort for DISTINCT deduplication

## Activation conditions

- The page count of the sort input must satisfy the activation condition ([Parallel Query Throughput Rules](#)).

- If the input has no more rows than the degree of parallelism, the sort runs single-threaded.

#### Note

A top-N query combining ORDER BY with LIMIT does not go through a separate parallel sort phase; it is parallelized by the parallel scan workers each keeping their own top N while scanning. In the trace, **topnsort: true** appears in the scan's parallel processing details and the **ORDERBY** phase performs only the final merge.

#### Note

When a GROUP BY query is eligible for hash aggregation, the workers perform partial hash aggregation instead of parallelizing the sort, and the **GROUPBY** entry of the trace shows **hash: partial**. When hash aggregation is disabled with the **NO\_HASH\_AGGREGATE** hint, the GROUP BY sort is not parallelized.

#### Note

Parallel sort uses per-worker temporary sort space, so temporary volume usage can be higher than with a single-threaded sort.

## Sort Trace

When a parallel sort is performed, parallel processing details showing the per-worker ranges of elapsed time, page count, and I/O reads are additionally printed under the corresponding sort entry (**ORDERBY**, **GROUPBY**, or **ANALYTIC**).

```
csql> ;trace on
```

```
SELECT /*+ PARALLEL(4) RECOMPILE */ id, category, pad
FROM large_table
ORDER BY category;
```

#### Trace Statistics:

```
SELECT (time: 3563, fetch: 49462, fetch_time: 235, ioread: 14)
SCAN (table: dba.large_table), (heap time: 628, fetch: 49418,
ioread: 10, readrows: 1000000, rows: 1000000)
(parallel workers: 4, heap time: 497..628, readrows:
```

```
248704..252416, rows: 248704..252416, gather: mergeable list)
  ORDERBY (time: 2934, sort: true, page: 0, ioread: 4)
    (parallel workers: 4, time: 2732..2916, page:
6440..11364, ioread: 46952..58793)
```

The trace fields of parallel sort are:

- **parallel workers:** number of worker threads used for the sort
- **time:** per-worker sort time range (min..max, milliseconds)
- **page, ioread:** per-worker ranges (min..max) of pages used and I/O reads issued during the sort

The following example shows an analytic function whose sort was parallelized.

```
csql> ;trace on
```

```
SELECT /*+ PARALLEL(4) RECOMPILE */ order_id, amount,
      SUM(amount) OVER (PARTITION BY cust_id ORDER BY order_id)
FROM orders;
```

Trace Statistics:

```
SELECT (time: 1458, fetch: 1059149, fetch_time: 353, ioread: 50971)
  SCAN (table: dba.orders), (heap time: 139, fetch: 19880, ioread:
9910, readrows: 1000000, rows: 1000000)
    (parallel workers: 4, heap time: 135..139, readrows:
245632..252096, rows: 245632..252096, gather: mergeable list)
  ANALYTIC #1 (time: 1317, sort: true, page: 10561, ioread: 33612,
rows: 1000000)
    (parallel workers: 4, time: 64..70, page: 3656..4066,
ioread: 4..5)
```

The following example shows a GROUP BY whose sort was parallelized because a DISTINCT aggregate function makes hash aggregation inapplicable.

```
csql> ;trace on
```

```
SELECT /*+ PARALLEL(4) RECOMPILE */ cust_id, COUNT(DISTINCT amount)
FROM orders
GROUP BY cust_id;
```

Trace Statistics:

```
SELECT (time: 848, fetch: 984969, fetch_time: 114, ioread: 1742)
  SCAN (table: dba.orders), (heap time: 99, fetch: 14846, ioread:
34, readrows: 1000000, rows: 1000000)
    (parallel workers: 4, heap time: 96..99, readrows:
```

```
245632..252096, rows: 245632..252096, gather: mergeable list)
  GROUPBY (time: 749, hash: false, sort: true, page: 129, ioread:
3, readrows: 1000000, rows: 50000)
    (parallel workers: 4, time: 49..57, page: 2470..2759,
ioread: 4..90)
```

## Parallel Query Throughput Rules

### Throughput Rules Overview

While parallel query execution dramatically reduces query response time, it also consumes significant server resources (CPU, memory, I/O, etc.). If a small number of queries excessively occupy server resources through parallel execution, the performance of other queries may degrade. To prevent this, CUBRID applies **throughput rules** to selectively allow parallel execution only for queries with significant parallel execution benefits.

The actual degree of parallelism for each parallel operation is determined by the following factors:

- Throughput rules based on the size of the input (table, list, or index)
- Values explicitly specified by **PARALLEL** hints
- Upper limit set by the **parallelism** parameter
- Global worker pool size set by the **max\_parallel\_workers** parameter

The degree of parallelism calculated by throughput rules cannot exceed the **parallelism** parameter value. The degree of parallelism specified by hints can exceed the **parallelism** parameter value but cannot exceed the maximum value (the smaller of 32 or the number of system cores).

### Scan Throughput Rules

The degree of parallelism for parallel heap scan and parallel list scan is determined by the same rule based on the page count of the scan input (the table's heap page count for heap scan, the temporary list page count for list scan). Index scan follows a separate rule (see below).

#### Activation Condition

- Activated when the input has 2,048 or more pages (approximately 32 MB when **db\_page\_size** is 16K).
- If this condition is not met, parallel scan is not activated even if the **PARALLEL** hint is present.

## Degree Determination

The degree of parallelism is determined according to the page count as follows:

| Number of Pages | Throughput | Throughput Rule Calculation |
|-----------------|------------|-----------------------------|
| 2,048           | 32 MB      | 2                           |
| 4,096           | 64 MB      | 3                           |
| 8,192           | 128 MB     | 4                           |
| 16,384          | 256 MB     | 5                           |
| 32,768          | 512 MB     | 6                           |
| 65,536          | 1.0 GB     | 7                           |
| 131,072         | 2.0 GB     | 8                           |
| 262,144         | 4.0 GB     | 9                           |
| 524,288         | 8.0 GB     | 10                          |
| 1,048,576       | 16.0 GB    | 11                          |
| 2,097,152       | 32.0 GB    | 12                          |
| 4,194,304       | 64.0 GB    | 13                          |
| 8,388,608       | 128.0 GB   | 14                          |

Starting from 2,048 pages, the degree of parallelism calculated by the throughput rule increases by 1 each time the page count doubles from the previous threshold.

The degree of parallelism determined by throughput rules cannot exceed the **parallelism** parameter value:

- **MIN (throughput rule calculation, parallelism parameter value)**

For example, when parallelism=4 (default):

- Page count 2,048 → throughput rule calculates 2 →  $\text{MIN}(2, 4) = 2$  applied
- Page count 65,536 → throughput rule calculates 7 →  $\text{MIN}(7, 4) = 4$  applied (cannot exceed parallelism)

#### **Note**

Even when the degree of parallelism is explicitly specified using the **PARALLEL** hint, the activation condition (2,048 or more pages) still applies. After activation, the hint value takes precedence in determining the degree of parallelism.

### **Index scan throughput rule**

The automatic degree of parallelism for parallel index scan is computed by the optimizer from **selectivity × index page count**. The scan becomes a candidate when this value is 32 or more; the degree starts at 2 and increases by 1 each time the value doubles from 32, and it cannot exceed the **parallelism** parameter value. The **PARALLEL** hint bypasses this optimizer computation, but the activation condition that the measured index page count must be 2,048 or more still applies.

### **Example**

```
-- Create table and insert data
CREATE TABLE large_table (id INT PRIMARY KEY, category INT, status
VARCHAR(10), pad VARCHAR(200));

INSERT INTO large_table
SELECT ROWNUM, MOD(ROWNUM, 100),
CASE WHEN MOD(ROWNUM, 2) = 0 THEN 'active' ELSE 'closed' END,
LPAD('x', 200, 'x')
FROM db_class a, db_class b, db_class c, db_class d
LIMIT 1000000;

UPDATE STATISTICS ON large_table WITH FULLSCAN;

-- Check table statistics (SHOW HEAP CAPACITY OF large_table)
-- Num_pages: 17245 (approximately 269MB when db_page_size is 16K)
-- Num_recs: 1000000

-- When the parallelism parameter is set to 4
```

```
-- Page count 17245 -> throughput rule calculates 5 -> MIN(5, 4) = 4
applied
SELECT COUNT(*) FROM large_table WHERE status = 'active';

-- Explicit specification with hint (the hint value wins once the
activation condition is met)
SELECT /*+ PARALLEL(8) */ COUNT(*) FROM large_table WHERE status =
'active';
```

## Hash Join Throughput Rules

The degree of parallelism for parallel hash join is computed from the page count of the **larger** of the two input lists, by the same rule as for scans (activation at 2,048 pages, degree +1 per doubling of the page count, capped by **parallelism**).

- The computed degree of parallelism cannot exceed the number of partitions.
- Below the activation condition, the hash join runs single-threaded even with the **PARALLEL** hint.

## Sort Throughput Rules

The degree of parallelism for parallel sort is computed from the page count of the sort input list, by the same rule as for scans (activation at 2,048 pages, degree +1 per doubling of the page count, capped by **parallelism**).

- If the input has no more rows than the computed degree of parallelism, the sort runs single-threaded.
- Below the activation condition, the sort runs single-threaded even with the **PARALLEL** hint.

## Subquery Throughput Rules

Parallel execution of subqueries is activated when multiple subqueries have an independent structure where they do not reference each other's results.

- The degree of parallelism for subquery parallel execution is fixed at 2. For example, even if there are 4 independent subqueries within a query, the system allocates 2 parallel workers for processing.
- Whether each subquery is executed in parallel is determined by the “throughput rules”.
- When multiple independent subqueries exist, the effect of parallel execution is significant

```
-- Parallel subquery execution example
-- When parallelism=4, 2 subqueries are executed in parallel
SELECT *
```

```
FROM orders
WHERE customer_id IN (
    SELECT customer_id FROM customers WHERE region = 'Asia'
)
AND product_id IN (
    SELECT product_id FROM products WHERE category = 'Electronics'
);
```

## Worker Thread Pool Management

If the parallel thread pool is insufficient, only some operations may be performed in parallel, or parallel execution may not be performed at all.

- Set the maximum thread count for the global parallel processing worker pool with the `max_parallel_workers` parameter
- Each parallel operation reserves the required number of parallel workers from the parallel worker pool before execution, and returns them after task completion
- If the pool cannot grant the full request due to contention, the operation runs in parallel with only the workers actually reserved; if no worker is reserved, it runs single-threaded
- The sum of the degrees of parallelism used in the entire query can exceed the `parallelism` parameter value, but cannot exceed the `max_parallel_workers` value

```
-- cubrid.conf configuration example
max_parallel_workers=100 # Global worker pool size
parallelism=4           # Upper limit for single parallel operation
```

## Throughput Performance Considerations

Optimization through parallel query throughput rules:

- Prevents unnecessary parallel execution on small inputs to reduce overhead
- Automatically adjusts the degree of parallelism proportional to input size
- Prevents system resource contention due to excessive parallel execution
- Concentrates parallel resources on queries with significant benefits

Recommended Settings:

- **max\_parallel\_workers**: Set considering the number of simultaneously executable parallel queries and the average degree of parallelism for each query

- **parallelism**: Set considering the number of physical cores in the system (usually 4~8 is appropriate)
- In environments with many large tables, set **max\_parallel\_workers** value high
- In environments with many small tables, using default values is recommended

## Partitioning

Partitioning is a method by which a table is divided into multiple independent physical units called partitions. In CUBRID, each partition is a table implemented as a subclass of the partitioned table. Each partition holds a subset of the partitioned table data defined by a **Partitioning key** and a partitioning method. Users can access data stored in partitions by executing statements on the partitioned table. This means that users can partition tables without modifying statements or code that is used to access these tables (benefiting from the advantages of partitioning almost without modifying the user application).

Partitioning can enhance manageability, performance and availability. Some advantages of partitioning a table are:

- Improved management of large capacity tables
- Improved performance by narrowing the range of access when retrieving data
- Improved performance and decreased physical loads by distributing disk I/O
- Decreased possibility of data corruption and improved availability by partitioning a table into multiple chunks
- Optimized storage cost

Partitioned data is auto-managed by CUBRID. **INSERT** and **UPDATE** statements executed on partitioned tables perform an additional step during execution to identify the partition in which a tuple must be placed. During **UPDATE** statement execution, CUBRID identifies situations in which the modified tuple should be moved to another partition and performs this operation keeping the partitioning definition consistent. Inserting tuples for which there is no valid partition will return an error.

When executing **SELECT** statements, CUBRID applies a procedure called **Partition Pruning** to narrow the search space to only those partitions for which the search predicates will produce results. Pruning (eliminating) most of the partitions during a **SELECT** statement greatly improves performance.

Table partitioning is most effective when applied to large tables. Exactly what a “large” table means is dependent on the user application and on the way in which the table is used in queries.

Which is the best partitioning method ([range](#), [list](#) or [hash](#)) for a table, also depends on how the table is used in queries and how data will be distributed between partitions. Even though partitioned tables can be used just like normal tables, there are some [Notes on Partitioning](#) which should be taken into consideration.

## Partitioning

### Partitioning key

The partitioning key is an expression which is used by the partitioning method to distribute data across defined partitions. The following data types are supported for the partitioning key:

- **CHAR**
- **VARCHAR**
- **SMALLINT**
- **INT**
- **BIGINT**
- **DATE**
- **TIME**
- **TIMESTAMP**
- **DATETIME**

The following restrictions apply to the partitioning key:

- The partitioning key must use exactly one column from the partitioned table.
- [Aggregate functions](#), [analytic functions](#), [logical operators](#) and [comparison operators](#) are not allowed in the partitioning key expression.
- The following functions and expressions are not allowed in the partitioning key expression:
  - [CASE](#)
  - `CHARSET()`
  - `CHR()`
  - `COALESCE()`

- `SERIAL_CURRENT_VALUE()`
  - `SERIAL_NEXT_VALUE()`
  - `DECODE()`
  - `DECR()`
  - `INCR()`
  - `DRAND()`
  - `DRANDOM()`
  - `GREATEST()`
  - `LEAST()`
  - `IF()`
  - `IFNULL()`
  - `INSTR()`
  - `NVL()`
  - `NVL2()`
  - `ROWNUM`
  - `INST_NUM()`
  - `USER`
  - `PRIOR`
  - `WIDTH_BUCKET()`
- The partitioning key needs to be present in the key of each unique index (including primary keys). For more information on this aspect, please see [here](#).
  - The partitioning expression's length must not exceed 1024 bytes.

## Range Partitioning

Range partitioning is a partitioning method in which a table is partitioned using a user specified range of values of the partitioning key for each partition. Ranges are defined as continuous non-overlapping intervals. This partitioning method is most useful when table data can be divided into range intervals (e.g. order placement date for an orders table or age intervals for a user's

table). Range partitioning is the most versatile partitioning method in terms of **Partition Pruning** because almost all search predicates can be used to identify matching ranges.

Tables can be partitioned by range by using the **PARTITION BY RANGE** clause in **CREATE** or **ALTER** statements.

```
CREATE TABLE [schema_name.]table_name (
    ...
)
PARTITION BY RANGE ( <partitioning_key> ) (
    PARTITION partition_name VALUES LESS THAN ( <range_value> )
[COMMENT 'comment_string'] ,
    PARTITION partition_name VALUES LESS THAN ( <range_value> )
[COMMENT 'comment_string'] ,
    ...
)

ALTER TABLE [schema_name.]table_name
PARTITION BY RANGE ( <partitioning_key> ) (
    PARTITION partition_name VALUES LESS THAN ( <range_value> )
[COMMENT 'comment_string'] ,
    PARTITION partition_name VALUES LESS THAN ( <range_value> )
[COMMENT 'comment_string'] ,
    ...
)
```

- *partitioning\_key* : specifies the **Partitioning key**.
- *partition\_name* : specifies the partition name.
- *range\_value* : specifies the upper limit of the partitioning key value. All tuples for which the evaluation of partitioning key is less than (but not equal to) the *range\_value* will be stored in this partition.
- *comment\_string*: specifies a comment for each partition.

The following example shows how to create the *participant2* table which holds countries participating at the Olympics and partition this table into partitions holding participants before year 2000(*before\_2000* partition) and participants before year 2008(*before\_2008* partition):

```
CREATE TABLE participant2 (
    host_year INT,
    nation CHAR(3),
    gold INT,
    silver INT,
    bronze INT
)
PARTITION BY RANGE (host_year) (
```

```

PARTITION before_2000 VALUES LESS THAN (2000),
PARTITION before_2008 VALUES LESS THAN (2008)
);

```

When creating partitions, CUBRID sorts the user supplied range values from smallest to largest and creates the non-overlapping intervals from the sorted list. In the above example, the created range intervals are  $[-\text{inf}, 2000)$  and  $[2000, 2008)$ . The identifier **MAXVALUE** can be used to specify an infinite upper limit for a partition.

```

ALTER TABLE participant2 ADD PARTITION (
  PARTITION before_2012 VALUES LESS THAN (2012),
  PARTITION last_one VALUES LESS THAN MAXVALUE
);

```

When inserting a tuple into a range-partitioned table, CUBRID identifies the range to which the tuple belongs by evaluating the partitioning key. If the partitioning key value is **NULL**, the data is stored in the partition with the smallest specified range value. If there is no range which would accept the partitioning key value, CUBRID returns an error. CUBRID also returns an error when updating a tuple if the new value of the partitioning key does not belong to any of the defined ranges.

The below is an example to add a comment for each partition.

```

CREATE TABLE tbl (a int, b int) PARTITION BY RANGE(a) (
  PARTITION less_1000 VALUES LESS THAN (1000) COMMENT 'less 1000
comment',
  PARTITION less_2000 VALUES LESS THAN (2000) COMMENT 'less 2000
comment'
);

ALTER TABLE tbl PARTITION BY RANGE(a) (
  PARTITION less_1000 VALUES LESS THAN (1000) COMMENT 'new
partition comment');

```

To see a partition comment, refer to [COMMENT of Partition](#).

## Hash Partitioning

Hash partitioning is a partitioning method which is used to distribute data across a specified number of partition. This partitioning method is useful when table data contains values for which ranges or lists would be meaningless (for example, a keywords table or an users table for which user\_id is the most interesting value). If the values for the partitioning key are evenly distributed across the table data, hash-partitioning technique divides table data evenly between the defined partitions. For hash partitioning, [Partition Pruning](#) can only be applied on equality predicates (e.g.

predicates using **=** and **IN** expressions), making hash partitioning useful only if most of the queries specify such a predicate for the partitioning key.

Tables can be partitioned by hash by using the **PARTITION BY HASH** clause in **CREATE** or **ALTER** statements:

```
CREATE TABLE [schema_name.]table_name (  
    ...  
)  
PARTITION BY HASH ( <partitioning_key> )  
PARTITIONS ( number_of_partitions )  
  
ALTER TABLE [schema_name.]table_name  
PARTITION BY HASH ( <partitioning_key> )  
PARTITIONS ( number_of_partitions )
```

- *partitioning\_key* : Specifies the **Partitioning key**.
- *number\_of\_partitions* : Specifies the number of partitions to be created.

The following example shows how to create the *nation2* table with country *code* and country names, and define 4 hash partitions based on code values. Only the number of partitions, not the name, is defined in hash partitioning.

```
CREATE TABLE nation2 (  
    code CHAR (3),  
    name VARCHAR (50)  
)  
PARTITION BY HASH (code) PARTITIONS 4;
```

When a value is inserted into a hash-partitioned table, the partition to store the data is determined by the hash value of the partitioning key. If the partitioning key value is **NULL**, the data is stored in the first partition.

## List Partitioning

List partitioning is a partitioning method in which a table is divided into partitions according to user specified list of values for the partitioning key. The lists of values for partitions must be disjoint sets. This partitioning method is useful when table data can be divided into lists of possible values which have a certain meaning (e.g. department id for an employees table or country code for a user's table). As for hash partitioning, **Partition Pruning** for list partitioned tables can only be applied on equality predicates (e.g. predicates using **=** and **IN** expressions).

Tables can be partitioned by list by using the **PARTITION BY LIST** clause in **CREATE** or **ALTER** statements:

```

CREATE TABLE [schema_name.]table_name (
    ...
)
PARTITION BY LIST ( <partitioning_key> ) (
    PARTITION partition_name VALUES IN ( <values_list> ) [COMMENT
'comment_string'],
    PARTITION partition_name VALUES IN ( <values_list> ) [COMMENT
'comment_string'],
    ...
)

ALTER TABLE [schema_name.]table_name
PARTITION BY LIST ( <partitioning_key> ) (
    PARTITION partition_name VALUES IN ( <values_list> ) [COMMENT
'comment_string'],
    PARTITION partition_name VALUES IN ( <values_list> ) [COMMENT
'comment_string'],
    ...
)

```

- *partitioning\_key*: specifies the **Partitioning key**.
- *partition\_name*: specifies the partition name.
- *value\_list*: specifies the list of values for the partitioning key.
- *comment\_string*: specifies a comment for each partition.

The following example shows how to create the *athlete2* table with athlete names and sport events, and define list partitions based on event values.

```

CREATE TABLE athlete2 (name VARCHAR (40), event VARCHAR (30))
PARTITION BY LIST (event) (
    PARTITION event1 VALUES IN ('Swimming', 'Athletics'),
    PARTITION event2 VALUES IN ('Judo', 'Taekwondo', 'Boxing'),
    PARTITION event3 VALUES IN ('Football', 'Basketball', 'Baseball')
);

```

When inserting a tuple into a list-partitioned table, the value of the partitioning key must belong to one of the value lists defined for partitions. For this partitioning model, CUBRID does not automatically assign a partition for **NULL** values of the partitioning key. To be able to store **NULL** values into a list-partitioned table, a partition which includes the **NULL** value in the values list must be created:

```

CREATE TABLE athlete2 (name VARCHAR (40), event VARCHAR (30))
PARTITION BY LIST (event) (
    PARTITION event1 VALUES IN ('Swimming', 'Athletics' ),

```

```

PARTITION event2 VALUES IN ('Judo', 'Taekwondo', 'Boxing'),
PARTITION event3 VALUES IN ('Football', 'Basketball',
'Baseball', NULL)
);

```

The below is examples of adding comments for each partition.

```

CREATE TABLE athlete2 (name VARCHAR (40), event VARCHAR (30))
PARTITION BY LIST (event) (
    PARTITION event1 VALUES IN ('Swimming', 'Athletics') COMMENT
    'G1',
    PARTITION event2 VALUES IN ('Judo', 'Taekwondo', 'Boxing')
COMMENT 'G2',
    PARTITION event3 VALUES IN ('Football', 'Basketball',
'Baseball') COMMENT 'G3');

CREATE TABLE athlete3 (name VARCHAR (40), event VARCHAR (30));
ALTER TABLE athlete3 PARTITION BY LIST (event) (
    PARTITION event1 VALUES IN ('Handball', 'Volleyball', 'Tennis')
COMMENT 'G1');

```

## COMMENT of Partition

A partition's comment can be written only for the range partition and the list partition. You cannot write the comment about the hash partition. The partition comment can be shown by running this syntax.

```

SHOW CREATE TABLE [schema_name.]table_name;
SELECT class_name, partition_name, COMMENT FROM db_partition WHERE
class_name ='table_name';

```

Or you can use CSQL interpreter by running ;sc command.

```

$ csql -u dba demodb

csql> ;sc tbl

```

## Partition Pruning

Partition pruning is an optimization technique used when accessing a partitioned table to minimize the scope of partitions to be processed. By excluding partitions that are guaranteed not to contain records satisfying the predicate, disk I/O and scan costs are reduced, leading to improved query performance.

Partition pruning is not performed at the query compilation stage. Instead, it is performed at the open stage of query execution by evaluating the partition key predicate. Consequently, the applicability of partition pruning may vary even for the same query statement, depending on the bound values included in the partition key predicate.

Whether partition pruning was performed is not displayed in the query execution plan. Instead, it can be verified through the query profiling output after query execution. For more details on query profiling, see [Query Profiling](#).

#### Note

In versions older than CUBRID 9.0, partition pruning was performed at the query compilation stage. Starting with CUBRID 9.0, it is performed at the open stage of query execution.

### Supported Comparison Operators for Partition Pruning by Partitioning Method

| Partitioning Method | Equality Predicate | Range Predicate     |
|---------------------|--------------------|---------------------|
| Range Partitioning  | =, IN              | <, ≤, >, ≥, BETWEEN |
| List Partitioning   | =, IN              | Not supported       |
| Hash Partitioning   | =, IN              | Not supported       |

### Cases Where Partition Pruning Is Not Performed

- If the partition key predicate included in the **WHERE** clause differs from the expression defined as the partitioning key, or if the order of arguments does not match even when the expression is identical.
- If comparison operators not supported for partition pruning by the partitioning method are used.
- If the value of the partition key predicate cannot be determined at the open stage of query execution.

### Accessing Specific Partitions Directly

```
... FROM [<schema_name>.]<partition_table_name>__p__<partition_name>
[AS <alias_name>] ...

... FROM [<schema_name>.]<partition_table_name> PARTITION
(<partition_name>) [AS <alias_name>] ...
```

Individual partitions can be accessed by using the **PARTITION** clause or by specifying partition names directly. This method is available even if a partition key predicate is not included in the **WHERE** clause or partition pruning is not performed. In such cases, the executor handles the partition as a non-partitioned table, allowing the application of certain optimization techniques that are otherwise restricted for partitioned tables.

However, caution is required because the access scope is fixed to the designated partition. Records satisfying the predicate are excluded from retrieval even if they exist in other partitions, potentially resulting in incorrect results.

A target partition can also be specified in **INSERT** and **UPDATE** statements. Be aware that an error occurs if the record to be processed does not meet the mapping criteria of the specified partition, potentially resulting in a statement failure. In particular, explicitly specifying a partition for **INSERT** statements is not recommended because it provides no additional performance advantage.

Directly accessing a partition prevents the utilization of the operational benefits provided by partitioned tables. Accessing data at the table level ensures that applications do not require modification even if the partition configuration changes, allowing the system to maintain long-term flexibility. Because explicit partition specification eliminates this flexibility, we recommend accessing data through the partitioned table unless there is a particular requirement.

For details on optimization techniques otherwise restricted for partitioned tables, see [Restrictions on Partitioned Tables](#).

#### Example 1. Verifying Partition Pruning via Query Profiling

In this example, we explore whether partition pruning is applied by checking the query profiling output.

In the following query, a partitioning key predicate is included in the **WHERE** clause, and it is identical to the expression defined in the **CREATE TABLE** statement. Additionally, partition pruning can be applied because range partitioning supports pruning for range predicates. However, its application cannot be verified through the execution plan alone because partition pruning is determined at the open stage of query execution.

```
drop table if exists olympic_range;

create table olympic_range
partition by range (host_year) (
    partition before_1920 values less than (1920),
```

```

    partition before_1940 values less than (1940),
    partition before_1960 values less than (1960),
    partition before_1980 values less than (1980),
    partition before_2000 values less than (2000),
    partition latest values less than maxvalue
  )
as (select * from olympic);

create index i_olympic_range_host_nation on olympic_range
(host_nation);

update statistics on olympic_range;

```

```

set optimization level 513;
set trace on;

select /** recompile */
  o.host_year, o.host_nation, o.host_city, o.mascot
from
  olympic_range as o
where
  o.host_year > 1990
  and o.host_nation = 'USA';

```

```

Join graph segments (f indicates final):
seg[0]: [0]
seg[1]: host_year[0] (f)
seg[2]: host_nation[0] (f)
seg[3]: host_city[0] (f)
seg[4]: mascot[0] (f)
Join graph nodes:
node[0]: public.olympic_range o(25/6) (sargs 0 1) (loc 0)
Join graph terms:
term[0]: o.host_nation='USA' (sel 0.0555556) (sarg term) (not-join
eligible) (indexable host_nation[0]) (loc 0)
term[1]: o.host_year range (1990 gt_inf max) (sel 0.1) (rank 2)
(sarg term) (not-join eligible) (loc 0)

```

Query plan:

```

iscan
  class: o node[0]
  index: i_olympic_range_host_nation term[0]
  sargs: term[1]
  cost: 3 card 1

```

Query stmt:

```
select o.host_year, o.host_nation, o.host_city, o.mascot from
olympic_range o where (o.host_year> ?:0 ) and o.host_nation= ?:1
```

| host_year | host_nation | host_city | mascot |
|-----------|-------------|-----------|--------|
| =====     | =====       | =====     | =====  |
| =====     | =====       | =====     | =====  |
| 1996      | 'USA'       | 'Atlanta' | 'Izzy' |

Upon checking the profiling output after query execution, we can observe that scans for individual partitions are displayed as **PARTITION** entries under the **SCAN** entry. The **SCAN** entry displays scan information for the entire partitioned table, while each **PARTITION** entry shows scan information for its respective partition. Any partition that does not appear as a **PARTITION** entry has been excluded from the scan target.

In this example, only the `before_2000` and `latest` partitions were scanned because they satisfy the `o.host_year > 1990` predicate. All other partitions were successfully excluded from the scan target.

```
show trace;
```

Query Plan:

```
INDEX SCAN (o.i_olympic_range_host_nation) (key range:
o.host_nation= ?:1 )
```

```
rewritten query: select o.host_year, o.host_nation, o.host_city,
o.mascot from [public.olympic_range] o where (o.host_year> ?:0 ) and
o.host_nation= ?:1
```

Trace Statistics:

```
SELECT (time: 0, fetch: 10, fetch_time: 0, ioread: 0)
SCAN (index: public.olympic_range.i_olympic_range_host_nation),
(btrees time: 0, fetch: 6, ioread: 0, readkeys: 1, filteredkeys: 1,
rows: 2) (lookup time: 0, rows: 1)
PARTITION (index:
public.olympic_range__p__before_2000.i_olympic_range_host_nation),
(btrees time: 0, fetch: 4, ioread: 0, readkeys: 1, filteredkeys: 1,
rows: 2) (lookup time: 0, rows: 1)
PARTITION (index:

time: 0, fetch: 2, ioread: 0, readkeys: 0, filteredkeys: 0, rows: 0)
(lookup time: 0, rows: 0)
```

In the following query, partition pruning is not applied because no partitioning key predicate is included in the **WHERE** clause.

```

set trace on;

select /* recompile */
      o.host_year, o.host_nation, o.host_city, o.mascot
from
      olympic_range as o
where
      o.opening_date > '1990-12-31'
      and o.host_nation = 'USA';

show trace;

```

| host_year | host_nation | host_city | mascot |
|-----------|-------------|-----------|--------|
| 1996      | 'USA'       | 'Atlanta' | 'Izzy' |

Upon checking the profiling output after query execution, we can observe that scans for all partitions are displayed as **PARTITION** entries under the **SCAN** entry because partition pruning was not applied.

```

Trace Statistics:
  SELECT (time: 1, fetch: 24, fetch_time: 1, ioread: 0)
    SCAN (index: public.olympic_range.i_olympic_range_host_nation),

```

### Example 2. Partition Pruning for Arithmetic Expression Partition Keys

In this example, we explore whether partition pruning is applied to a partition key defined by an arithmetic expression, focusing on two cases: using the identical expression in the **WHERE** clause, and reordering the arguments within that expression.

In the following query, a partitioning key predicate using an arithmetic expression is included in the **WHERE** clause, and it is identical to the expression defined in the **CREATE TABLE** statement. Additionally, partition pruning can be applied because range partitioning supports pruning for range predicates.

```
drop table if exists olympic_arith_range;

create table olympic_arith_range
partition by range (host_year + 5) (
    partition before_1925 values less than (1925),
    partition before_1945 values less than (1945),
    partition before_1965 values less than (1965),
    partition before_1985 values less than (1985),
    partition before_2005 values less than (2005),
    partition latest values less than maxvalue
)
as (select * from olympic);

update statistics on olympic_arith_range;
```

```
set trace on;

select /*+ recompile */
    o.host_year, o.host_nation, o.host_city, o.mascot
from
    olympic_arith_range as o
where
    o.host_year + 5 between 1975 and 1995
order by
    o.host_year;

show trace;
```

| host_year | host_nation | host_city  | mascot  |
|-----------|-------------|------------|---------|
| 1972      | 'Germany'   | 'Munich'   | 'Waldi' |
| 1976      | 'Canada'    | 'Montreal' | 'Amik'  |

|      |         |               |          |
|------|---------|---------------|----------|
| 1980 | 'USSR'  | 'Moscow'      | 'Misha'  |
| 1984 | 'USA'   | 'Los Angeles' | 'Sam'    |
| 1988 | 'Korea' | 'Seoul'       | 'HODORI' |

Upon checking the profiling output after query execution, we can observe that only the `before_1985` and `before_2005` partitions were scanned because they satisfy the `o.host_year + 5 between 1975 and 1995` predicate. All other partitions were successfully excluded from the scan target.

```
Trace Statistics:
  SELECT (time: 4, fetch: 4, fetch_time: 0, ioread: 0)
    SCAN (table: public.olympic_arith_range), (heap time: 0, fetch:
2, ioread: 0, readrows: 10, rows: 5)
      PARTITION (table:
public.olympic_arith_range__p__before_1985), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 2)
        PARTITION (table:
public.olympic_arith_range__p__before_2005), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 3)
          ORDERBY (time: 4, sort: true, page: 0, ioread: 0)
```

Even if the arithmetic expression has an identical structure, partition pruning cannot be applied because the order of the arguments does not match.

```
set trace on;

select /*+ recompile */
  o.host_year, o.host_nation, o.host_city, o.mascot
from
  olympic_arith_range as o
where
  5 + o.host_year between 1975 and 1995
order by
  o.host_year;

show trace;
```

| host_year | host_nation | host_city     | mascot   |
|-----------|-------------|---------------|----------|
| =====     |             |               |          |
| =====     |             |               |          |
| 1972      | 'Germany'   | 'Munich'      | 'Waldi'  |
| 1976      | 'Canada'    | 'Montreal'    | 'Amik'   |
| 1980      | 'USSR'      | 'Moscow'      | 'Misha'  |
| 1984      | 'USA'       | 'Los Angeles' | 'Sam'    |
| 1988      | 'Korea'     | 'Seoul'       | 'HODORI' |

Upon checking the profiling output after query execution, we can observe that scans for all partitions are displayed as **PARTITION** entries under the **SCAN** entry because partition pruning was not applied.

```
Trace Statistics:
  SELECT (time: 0, fetch: 12, fetch_time: 0, ioread: 0)
    SCAN (table: public.olympic_arith_range), (heap time: 0, fetch:
6, ioread: 0, readrows: 25, rows: 5)
      PARTITION (table:
public.olympic_arith_range__p__before_1925), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 0)
        PARTITION (table:
public.olympic_arith_range__p__before_1945), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 0)
          PARTITION (table:
public.olympic_arith_range__p__before_1965), (heap time: 0, fetch:
1, ioread: 0, readrows: 3, rows: 0)
            PARTITION (table:
public.olympic_arith_range__p__before_1985), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 2)
              PARTITION (table:
public.olympic_arith_range__p__before_2005), (heap time: 0, fetch:
1, ioread: 0, readrows: 5, rows: 3)
                PARTITION (table: public.olympic_arith_range__p__latest),
(heap time: 0, fetch: 1, ioread: 0, readrows: 2, rows: 0)
      ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
```

### Example 3. Partition Pruning for Functional Expression Partition Keys

In this example, we explore whether partition pruning is applied to a partition key defined by a functional expression, focusing on two cases: using the identical expression in the **WHERE** clause, and using only the source column without the functional expression.

In the following query, a partitioning key predicate using a functional expression is included in the **WHERE** clause, and it is identical to the expression defined in the **CREATE TABLE** statement. Additionally, partition pruning can be applied because range partitioning supports pruning for range predicates.

```
drop table if exists olympic_func_range;

create table olympic_func_range
partition by range (YEAR (opening_date)) (
  partition before_1920 values less than (1920),
  partition before_1940 values less than (1940),
  partition before_1960 values less than (1960),
  partition before_1980 values less than (1980),
  partition before_2000 values less than (2000),
  partition latest values less than maxvalue
```

```
)
as (select * from olympic);

update statistics on olympic_func_range;
```

```
set trace on;

select /** recompile */
    YEAR (o.opening_date) as opening_year, o.host_nation,
o.host_city, o.mascot
from
    olympic_func_range as o
where
    YEAR (o.opening_date) between 1970 and 1990
order by
    opening_year;

show trace;
```

| opening_year | host_nation | host_city     | mascot   |
|--------------|-------------|---------------|----------|
| 1972         | 'Germany'   | 'Munich'      | 'Waldi'  |
| 1976         | 'Canada'    | 'Montreal'    | 'Amik'   |
| 1980         | 'USSR'      | 'Moscow'      | 'Misha'  |
| 1984         | 'USA'       | 'Los Angeles' | 'Sam'    |
| 1988         | 'Korea'     | 'Seoul'       | 'HODORI' |

Upon checking the profiling output after query execution, we can observe that only the `before_1980` and `before_2000` partitions were scanned because they satisfy the `YEAR (o.opening_date) between 1970 and 1990` predicate. All other partitions were successfully excluded from the scan target.

```
Trace Statistics:
  SELECT (time: 0, fetch: 4, fetch_time: 0, ioread: 0)
    SCAN (table: public.olympic_func_range), (heap time: 0, fetch:
2, ioread: 0, readrows: 10, rows: 5)
      PARTITION (table:
public.olympic_func_range__p__before_1980), (heap time: 0, fetch: 1,
ioread: 0, readrows: 5, rows: 2)
        PARTITION (table:
public.olympic_func_range__p__before_2000), (heap time: 0, fetch: 1,
ioread: 0, readrows: 5, rows: 3)
          ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
```

Partition pruning can be applied even if the source column is used instead of the functional expression, because the functional expression defined as the partition key guarantees the same sort order as the source column.

```
set trace on;

select /*+ recompile */
  YEAR(o.opening_date) as opening_year, o.host_nation,
  o.host_city, o.mascot
from
  olympic_func_range as o
where
  o.opening_date between '1970-01-01' and '1990-12-31'
order by
  opening_year;

show trace;
```

| opening_year | host_nation | host_city     | mascot   |
|--------------|-------------|---------------|----------|
| 1972         | 'Germany'   | 'Munich'      | 'Waldi'  |
| 1976         | 'Canada'    | 'Montreal'    | 'Amik'   |
| 1980         | 'USSR'      | 'Moscow'      | 'Misha'  |
| 1984         | 'USA'       | 'Los Angeles' | 'Sam'    |
| 1988         | 'Korea'     | 'Seoul'       | 'HODORI' |

Upon checking the profiling output after query execution, we can observe that partition pruning was applied because the **YEAR** function guarantees the same sort order as the source column, even though the functional expression defining the partition key was not directly included in the **WHERE** clause.

```
Trace Statistics:
  SELECT (time: 0, fetch: 4, fetch_time: 0, ioread: 0)
    SCAN (table: public.olympic_func_range), (heap time: 0, fetch:
2, ioread: 0, readrows: 10, rows: 5)
      PARTITION (table:
public.olympic_func_range__p__before_1980), (heap time: 0, fetch: 1,
ioread: 0, readrows: 5, rows: 2)
        PARTITION (table:
public.olympic_func_range__p__before_2000), (heap time: 0, fetch: 1,
ioread: 0, readrows: 5, rows: 3)
          ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
```

we can observe that only the `before_1980` and `before_2000` partitions were scanned because `o.opening_date` guarantees the same sort order as `YEAR(o.opening_date)`, even though `o.opening_date`

is included. These partitions satisfy the `YEAR(o.opening_date) between YEAR('1970-01-01') and YEAR('1990-12-31')` predicate. All other partitions were successfully excluded from the scan target.

#### Example 4. Partition Pruning for List Partitioning

In this example, we explore whether partition pruning is applied to a table created using list partitioning, focusing on two cases: using an equality predicate in the **WHERE** clause, and using a range predicate.

In the following query, a partitioning key predicate is included in the **WHERE** clause, and it is identical to the expression defined in the **CREATE TABLE** statement. Additionally, partition pruning can be applied because list partitioning supports pruning for equality predicates.

```
drop table if exists participant_list;

create table participant_list
partition by list (host_year) (
    partition p1988 values IN (1988),
    partition p1992 values IN (1992),
    partition p1996 values IN (1996),
    partition p2000 values IN (2000),
    partition p2004 values IN (2004)
)
as (select * from participant);

update statistics on participant_list;
```

```
set trace on;

select /*+ recompile */
    p.host_year, p.nation_code, p.gold
from
    participant_list as p
where
    p.host_year in (1988, 1996)
    and p.gold > 40
order by
    p.host_year, p.gold, p.nation_code;

show trace;
```

| host_year | nation_code | gold |
|-----------|-------------|------|
| 1988      | 'URS'       | 55   |
| 1996      | 'USA'       | 44   |

Upon checking the profiling output after query execution, we can observe that only the `p1988` and `p1996` partitions were scanned because they satisfy the `p.host_year in (1988, 1996)` predicate. All other partitions were successfully excluded from the scan target.

```
Trace Statistics:
  SELECT (time: 1, fetch: 4, fetch_time: 0, ioread: 0)
    SCAN (table: public.participant_list), (heap time: 1, fetch: 2,
ioread: 0, readrows: 352, rows: 2)
      PARTITION (table: public.participant_list__p__p1988),
(heap time: 1, fetch: 1, ioread: 0, readrows: 156, rows: 1)
      PARTITION (table: public.participant_list__p__p1996),
(heap time: 0, fetch: 1, ioread: 0, readrows: 196, rows: 1)
    ORDERBY (time: 0, sort: true, page: 0, ioread: 0)
```

Partition pruning is not applied when non-equality predicates, such as range predicates, are used because list partitioning supports pruning only for equality predicates.

```
set trace on;

select /*+ recompile */
  p.host_year, p.nation_code, p.gold
from
  participant_list as p
where
  p.host_year < 1996
  and p.gold > 40
order by
  p.host_year;

show trace;
```

| host_year | nation_code | gold |
|-----------|-------------|------|
| 1988      | 'URS'       | 55   |
| 1992      | 'EUN'       | 45   |

Upon checking the profiling output after query execution, we can observe that scans for all partitions are displayed as **PARTITION** entries under the **SCAN** entry because partition pruning was not applied.

Based on the values of each partition, the `p1996`, `p2000`, and `p2004` partitions appear to be targets for exclusion from the scan. However, specific partitions cannot be excluded from the scan target by a range predicate because list partitioning is not structured to arrange values in a sorted order.

```

Trace Statistics:
  SELECT (time: 1, fetch: 10, fetch_time: 0, ioread: 0)
    SCAN (table: public.participant_list), (heap time: 0, fetch: 5,
ioread: 0, readrows: 916, rows: 2)
      PARTITION (table: public.participant_list__p__p1988),
(heap time: 0, fetch: 1, ioread: 0, readrows: 156, rows: 1)
      PARTITION (table: public.participant_list__p__p1992),
(heap time: 0, fetch: 1, ioread: 0, readrows: 165, rows: 1)
      PARTITION (table: public.participant_list__p__p1996),
(heap time: 0, fetch: 1, ioread: 0, readrows: 196, rows: 0)
      PARTITION (table: public.participant_list__p__p2000),
(heap time: 0, fetch: 1, ioread: 0, readrows: 197, rows: 0)
      PARTITION (table: public.participant_list__p__p2004),
(heap time: 0, fetch: 1, ioread: 0, readrows: 202, rows: 0)
    ORDERBY (time: 0, sort: true, page: 0, ioread: 0)

```

#### Example 5. Partition Pruning for Hash Partitioning

In this example, we explore whether partition pruning is applied to a table created using hash partitioning, focusing on two cases: using an equality predicate in the **WHERE** clause, and using an inequality predicate.

In the following query, a partitioning key predicate is included in the **WHERE** clause, and it is identical to the expression defined in the **CREATE TABLE** statement. Additionally, partition pruning can be applied because hash partitioning supports pruning for equality predicates.

```

drop table if exists stadium_hash;

create table stadium_hash
partition by hash (nation_code) partitions 4
as (select * from stadium);

update statistics on stadium_hash;

```

```

set trace on;

select /*+ recompile */
  s.nation_code, s.name, s.seats
from
  stadium_hash as s
where
  s.nation_code = 'KOR'
  and s.seats >= 100000
order by
  s.name;

show trace;

```

| nation_code | name                    | seats  |
|-------------|-------------------------|--------|
| 'KOR'       | 'Seoul Olympic Stadium' | 100000 |

Upon checking the profiling output after query execution, we can observe that only the `p2` partition was scanned because it satisfies the `s.nation_code = 'KOR'` predicate. All other partitions were successfully excluded from the scan target.

```
Trace Statistics:
  SELECT (time: 0, fetch: 2, fetch_time: 0, ioread: 0)
    SCAN (table: public.stadium_hash), (heap time: 0, fetch: 1,
ioread: 0, readrows: 32, rows: 1)
      PARTITION (table: public.stadium_hash__p__p2), (heap
time: 0, fetch: 1, ioread: 0, readrows: 32, rows: 1)
```

Partition pruning is not applied when non-equality predicates, such as inequality predicates, are used because hash partitioning supports pruning only for equality predicates.

```
set trace on;

select /*+ recompile */
  s.nation_code, s.name, s.seats
from
  stadium_hash as s
where
  s.nation_code != 'KOR'
  and s.seats > 100000
order by
  s.name;

show trace;
```

| nation_code | name              | seats  |
|-------------|-------------------|--------|
| 'AUS'       | 'Olympic Stadium' | 115600 |

Upon checking the profiling output after query execution, we can observe that scans for all partitions are displayed as **PARTITION** entries under the **SCAN** entry because partition pruning was not applied.

In the previous query, only the `p2` partition was scanned because it satisfies the `s.nation_code = 'KOR'` predicate. Although the `p2` partition might appear to be a candidate for exclusion under an inequality predicate, the `p2` partition cannot be excluded because records satisfying the `s.nation_code ≠ 'KOR'` predicate may be included in that partition.

```

Trace Statistics:
  SELECT (time: 0, fetch: 8, fetch_time: 0, ioread: 0)
    SCAN (table: public.stadium_hash), (heap time: 0, fetch: 4,
ioread: 0, readrows: 141, rows: 1)
      PARTITION (table: public.stadium_hash__p__p0), (heap
time: 0, fetch: 1, ioread: 0, readrows: 27, rows: 0)
      PARTITION (table: public.stadium_hash__p__p1), (heap
time: 0, fetch: 1, ioread: 0, readrows: 53, rows: 0)
      PARTITION (table: public.stadium_hash__p__p2), (heap
time: 0, fetch: 1, ioread: 0, readrows: 32, rows: 0)
      PARTITION (table: public.stadium_hash__p__p3), (heap
time: 0, fetch: 1, ioread: 0, readrows: 29, rows: 1)

```

#### Example 6. Partition Pruning in Joins

In this example, we explore whether partition pruning is applied when a partitioned table is used as a driven table in a join query.

In the following query, hints are used to fix the join order so that the partitioned table is used as the driven table. Accordingly, the join predicate is expected to be utilized as a partitioning key predicate. However, partition pruning is determined by analyzing values identifiable at the open stage of query execution. Therefore, partition pruning is not applied to join predicates where column values are bound during join execution because those values are not determinable at the open stage of query execution.

```

drop table if exists olympic_range;

create table olympic_range
partition by range (host_year) (
  partition before_1920 values less than (1920),
  partition before_1940 values less than (1940),
  partition before_1960 values less than (1960),
  partition before_1980 values less than (1980),
  partition before_2000 values less than (2000),
  partition latest values less than maxvalue
)
as (select * from olympic);

update statistics on olympic_range;

```

```

set trace on;

select /*+ recompile ordered */
  p.host_year, p.nation_code, p.gold,
  o.host_nation, o.slogan
from
  participant as p

```

```

    inner join olympic_range as o on p.host_year = o.host_year
  where
    p.host_year in (1988, 2004)
    and p.gold > 40
  order by
    p.host_year, p.gold, p.nation_code;

show trace;

```

```

      host_year  nation_code      gold
host_nation      slogan
=====
=====
      1988    'URS'              55
'Korea'          'Harmony and progress'

```

Upon checking the profiling output after query execution, we can observe that scans for all partitions are displayed as **PARTITION** entries under the **SCAN** entry because partition pruning was not applied.

```

Trace Statistics:
  SELECT (time: 1, fetch: 2204, fetch_time: 0, ioread: 0)
    SCAN (index:
public.participant.pk_participant_host_year_nation_code), (btree
time: 1, fetch: 2172, ioread: 0, readkeys: 2154, filteredkeys: 2148,
rows: 2148) (lookup time: 1, rows: 6)
      SCAN (table: public.olympic_range), (heap time: 0, fetch: 31,
ioread: 0, readrows: 25, rows: 1)
        PARTITION (table:
public.olympic_range__p__before_1920), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 0)
          PARTITION (table:
public.olympic_range__p__before_1940), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 0)
            PARTITION (table:
public.olympic_range__p__before_1960), (heap time: 0, fetch: 4,
ioread: 0, readrows: 3, rows: 0)
              PARTITION (table:
public.olympic_range__p__before_1980), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 0)
                PARTITION (table:
public.olympic_range__p__before_2000), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 1)
                  PARTITION (table: public.olympic_range__p__latest),
(heap time: 0, fetch: 3, ioread: 0, readrows: 2, rows: 0)
                    MEMOIZE (time: 0, hit: 0, miss: 1, size: 0KB, enabled: true)

```

Partition pruning can be applied even when a partitioned table is used as the driven table in a join query because it is applicable if a partitioning key predicate with an identifiable value is included in the **WHERE** clause at the open stage of query execution.

```
set trace on;

select /*+ recompile ordered */
  p.host_year, p.nation_code, p.gold,
  o.host_nation, o.slogan
from
  participant as p
  inner join olympic_range as o on p.host_year = o.host_year
where
  o.host_year in (1988, 2004)
  and p.gold > 40
order by
  p.host_year, p.gold, p.nation_code;

show trace;
```

```
      host_year  nation_code          gold
host_nation      slogan
=====
=====
      1988   'URS'                  55
'Korea'          'Harmony and progress'
```

Upon checking the profiling output after query execution, we can observe that only the `before_2000` and `latest` partitions were scanned because they satisfy the `o.host_year in (1988, 2004)` predicate. All other partitions were successfully excluded from the scan target.

```
Trace Statistics:
  SELECT (time: 1, fetch: 1845, fetch_time: 1, ioread: 0)
    SCAN (table: public.participant), (heap time: 1, fetch: 1838,
ioread: 0, readrows: 1832, rows: 6)
      SCAN (table: public.olympic_range), (heap time: 0, fetch: 6,
ioread: 0, readrows: 21, rows: 1)
        PARTITION (table:
public.olympic_range__p__before_2000), (heap time: 0, fetch: 3,
ioread: 0, readrows: 15, rows: 1)
          PARTITION (table: public.olympic_range__p__latest),
(heap time: 0, fetch: 3, ioread: 0, readrows: 6, rows: 0)
            MEMOIZE (time: 0, hit: 0, miss: 3, size: 0KB, enabled: true)
```

Partition pruning is applicable even when a bind variable is used in a partitioning key predicate because the bound value is identifiable at the open stage of query execution.

```

set trace on;

prepare q from '
  select /*+ ordered */
    p.host_year, p.nation_code, p.gold,
    o.host_nation, o.slogan
  from
    participant as p
    inner join olympic_range as o on p.host_year = o.host_year
  where
    o.host_year = year (to_date (?, 'YYYY-MM-DD'))
    and p.gold > 40
  order by
    p.host_year, p.gold, p.nation_code;
';

execute q using '1988-01-01';

show trace;

```

| host_year   | nation_code            | gold |
|-------------|------------------------|------|
| host_nation | slogan                 |      |
| =====       |                        |      |
| =====       |                        |      |
| 1988        | 'URS'                  | 55   |
| 'Korea'     | 'Harmony and progress' |      |

Upon checking the profiling output after query execution, we can observe that only the `before_2000` partition was scanned because it satisfies the `o.host_year = year (to_date ('1988-01-01', 'YYYY-MM-DD'))` predicate. All other partitions were successfully excluded from the scan target.

```

Trace Statistics:
  SELECT (time: 1, fetch: 165, fetch_time: 0, ioread: 0)
    SCAN (index:
public.participant.pk_participant_host_year_nation_code), (btree
time: 1, fetch: 158, ioread: 0, readkeys: 157, filteredkeys: 156,
rows: 156) (lookup time: 1, rows: 1)
      SCAN (table: public.olympic_range), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 1)
        PARTITION (table:
public.olympic_range__p__before_2000), (heap time: 0, fetch: 6,
ioread: 0, readrows: 5, rows: 1)

```

In this example, we explore how to directly query a specific partition using the **PARTITION** clause, separate from partition pruning. Through this, we explore whether optimization techniques that were inapplicable to the partitioned table are applicable to the partition.

In the following query, the **SKIP ORDER BY** is not applied because it targets the partitioned table, even though the **ORDER BY** and **LIMIT** clauses are included and an appropriate index exists.

```
drop table if exists olympic_range;

create table olympic_range
partition by range (host_year) (
    partition before_1920 values less than (1920),
    partition before_1940 values less than (1940),
    partition before_1960 values less than (1960),
    partition before_1980 values less than (1980),
    partition before_2000 values less than (2000),
    partition latest values less than maxvalue
)
as (select * from olympic);

create index i_olympic_range_host_year on olympic_range (host_year);

update statistics on olympic_range;
```

```
set optimization level 513;
set trace on;

select /** recompile */
    o.host_year, o.host_nation, o.host_city, o.mascot
from
    olympic_range as o
where
    o.host_year > 2000
order by
    o.host_year desc
limit 1;

show trace;
```

```
Join graph segments (f indicates final):

## Partitioning Management

Partitioned tables can be managed using partition specific clauses of the **ALTER** statement. CUBRID allows several actions to be performed on partitions:

1. Modifying a partitioned table into a regular table.
2. Partitions reorganization.
3. Adding partitions to an already partitioned table.
4. Dropping partitions.
5. Promote partitions to regular tables.

## Modifying a Partitioned Table into a Regular Table

Changing a partitioned table into a regular table can be done using the **REMOVE PARTITIONING** clause of the **ALTER** statement:

```
ALTER [TABLE | CLASS] [schema_name.]table_name REMOVE PARTITIONING
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to be altered.

When removing partitioning, CUBRID moves all data from partitions into the partitioned table. This is a costly operation and should be carefully planned.

## Partition Reorganization

Partition reorganization is a process through which a partition can be divided into smaller partitions or a group of partitions can be merged into a single partition. For this purpose, CUBRID implements the **REORGANIZE PARTITION** clause of the **ALTER** statement:

```
ALTER [TABLE | CLASS] [schema_name.]table_name
REORGANIZE PARTITION <alter_partition_name_comma_list>
INTO "(" <partition_definition_comma_list> ")"

partition_definition_comma_list ::=
PARTITION partition_name VALUES LESS THAN "(" <range_value> ")", ...
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to be redefined.
- *alter\_partition\_name\_comma\_list* : Specifies the partition to be redefined(current partitions). Multiple partitions are separated by commas (,).
- *partition\_definition\_comma\_list* : Specifies the redefined partitions(new partitions). Multiple partitions are separated by commas (,).

This clause applies only to range and list partitioning. Since data distribution in hash-partitioning method is semantically different, hash-partitioned tables only allow adding and dropping partitions. See [Hash Partitioning Reorganization](#) for details.

The following example shows how to reorganize the *before\_2000* partition of the *participant2* table into the *before\_1996* and *before\_2000* partitions.

```
ALTER TABLE participant2
REORGANIZE PARTITION before_2000 INTO (
  PARTITION before_1996 VALUES LESS THAN (1996),
```

```
PARTITION before_2000 VALUES LESS THAN (2000)
);
```

The following example shows how to merge the two partitions defined in the above example back into a single *before\_2000* partition.

```
ALTER TABLE participant2
REORGANIZE PARTITION before_1996, before_2000 INTO (
    PARTITION before_2000 VALUES LESS THAN (2000)
);
```

The following example shows how to reorganize partitions defined on the *athlete2*, dividing the *event2* partition into *event2\_1* (Judo) and *event2\_2* (Taekwondo, Boxing).

```
ALTER TABLE athlete2
REORGANIZE PARTITION event2 INTO (
    PARTITION event2_1 VALUES IN ('Judo'),
    PARTITION event2_2 VALUES IN ('Taekwondo', 'Boxing')
);
```

The following example shows how to combine the *event2\_1* and *event2\_2* partitions back into a single *event2* partition.

```
ALTER TABLE athlete2
REORGANIZE PARTITION event2_1, event2_2 INTO (
    PARTITION event2 VALUES IN ('Judo', 'Taekwondo', 'Boxing')
);
```

#### Note

- In a range-partitioned table, only adjacent partitions can be reorganized.
- During partition reorganization, CUBRID moves data between partitions in order to reflect the new partitioning schema. Depending on the size of the reorganized partitions, this might be a time consuming operations and should be carefully planned.
- The **REORGANIZE PARTITION** clause cannot be used to change the partitioning method. For example, a range-partitioned table cannot be changed into a hash-partitioned one.
- There must be at least one partition remaining after deleting partitions.

## Adding Partitions

Partitions can be added to a partitioned table by using the *ADD PARTITION* clause of the *ALTER* statement.

```
ALTER [TABLE | CLASS] [schema_name.]table_name
ADD PARTITION "(" <partition_definitions_comma_list> ")"
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to which partitions are added.
- *partition\_definitions\_comma\_list* : Specifies the partitions to be added. Multiple partitions are separated by commas (,).

The following example shows how to add the *before\_2012* and *last\_one* partitions to the *participant2* table.

```
ALTER TABLE participant2 ADD PARTITION (
  PARTITION before_2012 VALUES LESS THAN (2012),
  PARTITION last_one VALUES LESS THAN MAXVALUE
);
```

### Note

- For range-partitioned tables, range values for added partitions must be greater than the largest range value of the existing partitions.
- For range-partitioned tables, if the upper limit of the range of one of the existing partitions is specified by **MAXVALUE**, **ADD PARTITION** clause will always return an error (the **REORGANIZE PARTITION** clause should be used instead).
- The *ADD PARTITION* clause can only be used on already partitioned tables.
- This clause has different semantics when executed on hash-partitioned tables. See [Hash Partitioning Reorganization](#) for details.

## Dropping Partitions

Partitions can be dropped from a partitioned table by using the **DROP PARTITION** clause of the **ALTER** statement.

```
ALTER [TABLE | CLASS] [schema_name.]table_name  
DROP PARTITION partition_name_list
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the partitioned table.
- *<partition\_name\_list>* : Specifies the names of the partitions to be dropped, separated by comma(,).

The following example shows how to drop the *before\_2000* partition in the *participant2* table.

```
ALTER TABLE participant2 DROP PARTITION before_2000;
```

#### Note

- When dropping a partition, all stored data in the partition is deleted. If you want to change the partitioning of a table without losing data, use the **ALTER TABLE ... REORGANIZE PARTITION** statement.
- The number of rows deleted is not returned when a partition is dropped. If you want to delete the data, but want to maintain the table and partitions, use the **DELETE** statement.

This statement is not allowed on hash-partitioned tables. To drop partitions of a hash-partitioned table, use the hash partitioning specific *alter clauses*.

## Hash Partitioning Reorganization

Because data distribution among partitions in a hash-partitioned table is controlled internally by CUBRID, hash-partitioning reorganization behaves differently for hash-partitioned tables than for list or range partitioned tables. CUBRID allows the number of partitions defined on a hash-partitioned table to be increased or reduced. When modifying the number of partitions of a hash-partitioned table, no data is lost. However, because the domain of the hashing function is modified, table data has to be redistributed between the new partitions in order to maintain hash-partitioning consistency.

The number of partitions defined on a hash-partitioned table can be reduced using the **COALESCE PARTITION** clause of the **ALTER** statement.

```
ALTER [TABLE | CLASS] [schema_name.]table_name  
COALESCE PARTITION number_of_shrinking_partitions
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to be redefined.
- *number\_of\_shrinking\_partitions* : Specifies the number of partitions to be deleted.

The following example shows how to decrease the number of partitions in the **nation2** table from 4 to 3.

```
ALTER TABLE nation2 COALESCE PARTITION 1;
```

The number of partitions defined on a hash partitioned table can be increased using the **ADD PARTITION** clause of the **ALTER** statement.

```
ALTER [TABLE | CLASS] [schema_name.]table_name  
ADD PARTITION PARTITIONS number
```

- *schema\_name*: Specifies the schema name of the table. If omitted, the schema name of the current session is used.
- *table\_name* : Specifies the name of the table to be redefined.
- *number* : Specifies the number of partitions to be added.

The following example shows how to add 3 partitions to the **nation2**.

```
ALTER TABLE nation2 ADD PARTITION PARTITIONS 3;
```

## Partition Promotion

The **PROMOTE** clause of the **ALTER** statement promotes a partition of a partitioned table to a regular table. This feature is useful when a certain partition contains historic data which is almost never used. By promoting the partition to a regular table, performance on the partitioned table is increased and the data removed from this table (contained in the promoted partition) can still be accessed. Promoting a partition is an irreversible process, promoted partitions cannot be added back to the partitioned table.

The partition **PROMOTE** statement is allowed only on range and list-partitioned tables. Since users do not control how data is distributed among hash partitions, promoting such a partition does not make sense.

When the partition is promoted to a standalone table, this table inherits the data and ordinary indexes only. The following constraints are not available on the promoted partition:

- Primary Key
- Foreign key
- Unique index
- **AUTO\_INCREMENT** attribute and serial
- Triggers
- Methods
- Inheritance relationship (super-class and sub-class)

The syntax for promoting partitions is:

```
ALTER TABLE [schema_name.]table_name PROMOTE PARTITION
<partition_name_list>
```

- *partition\_name\_list*: The user defined names of partitions to promote separated by comma(,)

The following example creates a partitioned table, inserts some tuples into it and then promotes two of its partitions:

```
CREATE TABLE t (i INT) PARTITION BY LIST (i) (
    PARTITION p0 VALUES IN (1, 2),
    PARTITION p1 VALUES IN (3, 4),
    PARTITION p2 VALUES IN (5, 6)
);

INSERT INTO t VALUES(1), (2), (3), (4), (5), (6);
```

Schema and data of table *t* are shown below.

```
csql> ;schema t
=== <Help: Schema of a Class> ===
...
<Partitions>
    PARTITION BY LIST ([i])
    PARTITION p0 VALUES IN (1, 2)
```

```

PARTITION p1 VALUES IN (3, 4)
PARTITION p2 VALUES IN (5, 6)

csql> SELECT * FROM t;

=== <Result of SELECT Command in Line 1> ===
      i
=====
      1
      2
      3
      4
      5
      6

```

The following statement promotes partitions *p0* and *p2*:

```
ALTER TABLE t PROMOTE PARTITION p0, p2;
```

After promotion, table *t* has only one partition (*p1*) and contains the following data.

```

csql> ;schema t
=== <Help: Schema of a Class> ===
<Class Name>
      t
...
<Partitions>
      PARTITION BY LIST ([i])
      PARTITION p1 VALUES IN (3, 4)

csql> SELECT * FROM t;

=== <Result of SELECT Command in Line 1> ===
      i
=====
      3
      4

```

## Indexes on Partitioned Tables

All indexes created on a partitioning table are local indexes. With local indexes, data for each partition is stored in a separate(local) index. This increases concurrency on a partitioned table's indexes, since transactions access data from different partitions also do different, local, indexes.

In order to ensure local unique indexes, the following restriction must be satisfied when creating unique indexes on partitions:

- The partitioning key must be part of the primary key's and the all the unique indexes' definition.

If this is not satisfied, CUBRID will return an error:

```
csql> CREATE TABLE t(i INT , j INT) PARTITION BY HASH (i) PARTITIONS 4;
```

```
Execute OK. (0.142929 sec) Committed.
```

```
1 command(s) successfully processed.
```

```
csql> ALTER TABLE t ADD PRIMARY KEY (i);
```

```
Execute OK. (0.123776 sec) Committed.
```

```
1 command(s) successfully processed.
```

```
csql> CREATE UNIQUE INDEX idx2 ON t(j);
```

```
In the command from line 1,
```

```
ERROR: Partition key attributes must be present in the index key.
```

```
0 command(s) successfully processed.
```

It is important to understand the benefits of local indexes. In a global index scan, for each partition that was not pruned a separate index scan would have been performed. This leads to poorer performance than scanning local indexes because data from other partitions is fetched from disk and then discarded (it belongs to another partition than the one being scanned at the moment). **INSERT** statements also show better performance on local indexes since these indexes are smaller.

## Notes on Partitioning

Partitioned tables normally behave like regular tables. However there are some notes that should be taken into consideration in order to fully benefit from partitioning a table.

## Statistics on Partitioning Tables

Since CUBRID 9.0, the clause **ANALYZE PARTITION** of the **ALTER** statement has been deprecated. Since partition pruning happens during query execution, this statement will not produce any useful results. Since 9.0, CUBRID keeps separated statistics on each partition. The statistics on the partitioned table are computed as a mean value of the statistics of the table partitions. This is done to optimize the usual case in which, for a query, all partitions are pruned except one.

## Restrictions on Partitioned Tables

The following restrictions apply to partitioned tables:

- The maximum number of partitions which can be defined on a table is 1,024.
- Partitions cannot be a part of the inheritance chain. Classes cannot inherit a partition and partitions cannot inherit other classes than the partitioned class (which it inherits by default).
- The following query optimizations are not performed on partitioned tables:
  - ORDER BY skip (for details, see [Optimizing ORDER BY Clause](#))
  - GROUP BY skip (for details, see [Optimizing GROUP BY Clause](#))
  - Multi-key range optimization (for details, see [Multiple Key Ranges Optimization](#))
  - INDEX JOIN

## Partitioning Key and Charset, Collation

Partitioning keys and partition definition must have the same character set. The following query will return an error:

```
CREATE TABLE t (c CHAR(50) COLLATE utf8_bin)
PARTITION BY LIST (c) (
    PARTITION p0 VALUES IN (_utf8'x'),
    PARTITION p1 VALUES IN (_iso88591'y')
);
```

```
ERROR: Invalid codeset '_iso88591' for partition value. Expecting
'_utf8' codeset.
```

CUBRID uses the collation defined on the table when performing comparisons on the partitioning key. The following example will return an error because, for utf8\_en\_ci collation 'test' equals 'TEST'.

```
CREATE TABLE tbl (str STRING) COLLATE utf8_en_ci
PARTITION BY LIST (str) (
    PARTITION p0 VALUES IN ('test'),
    PARTITION p1 VALUES IN ('TEST')
);
```

```
ERROR: Partition definition is duplicated. 'p1'
```

## Globalization

Globalization includes internationalization and localization. Internationalization can be applied to various languages and regions. Localization fits the language and culture in a specific area as appending the language-specific components. CUBRID supports multilingual collations including Europe and Asia to facilitate the localization.

If you want to know overall information about character data setting, see [Configuration Guide for Characters](#).

If you want to know about charset, collation and locale, see [An Overview of Globalization](#).

For timezone type and related functions, see [Date/Time Types with Timezone](#). For timezone related system parameters, see [Timezone Parameter](#). If you want to update a timezone information as a new one, timezone library should be recompiled; for details, see [Compiling Timezone Library](#).

If you want to apply the wanted locale to the database, you have to set the locale firstly, then create the database. Regarding this setting, see [Locale Setting](#).

If you want to change the collation or charset specified on the database, specify [COLLATE modifier](#) or [CHARSET modifier](#) to the column, table, expression, and specify [COLLATE modifier](#) or [Charset Introducer](#) to the string literal. Regarding this setting, see [Collation](#).

The functions or operators related to strings can work differently by charset and collation. Regarding this, see [Operations Requiring Collation and Charset](#).

## An Overview of Globalization

### Character data

Character data (strings) may be stored with VARCHAR(STRING), CHAR, ENUM, and they support charset and collation.

Charset(character set, codeset) controls how characters are stored (on any type of storage) as bytes, or how a series of bytes forms a character. CUBRID supports ISO-8859-1, UTF-8 and EUC-KR charsets. For UTF-8, we support only the Unicode characters up to codepoint 10FFFF (encoded on up to four bytes). For instance, the character “Ç” is encoded in codeset ISO-8859-1 using a single byte (C7), in UTF-8 is encoded with 2 bytes (C3 88), while in EUC-KR this character is not available.

Collation decides how strings compare. Most often, users require case insensitive and case sensitive comparisons. For instance, the strings “ABC” and “abc” are equal in a case insensitive

collation, while in a case sensitive collation, they are not, and depending on other collation settings, the relationship can be “ABC” < “abc” , or “ABC” > “abc”.

Collation means more than comparing character casing. Collation decides the relationship between two strings (greater, lower, equal), is used in string matching (LIKE), or computing boundaries in index scan.

In CUBRID, a collation implies a charset. For instance, collations “utf8\_en\_ci” and “iso88591\_en\_ci” perform case insensitive compare, but operate on different charsets. Although for ASCII range, in these particular cases the results are similar, the collation with “utf8\_en\_ci” is slower, since it needs to work on variable number of bytes (UTF-8 encoding).

- “‘a’ COLLATE iso88591\_en\_ci” indicates “\_iso88591‘a’ COLLATE iso88591\_en\_ci”.
- “‘a’ COLLATE utf8\_en\_ci” indicates “\_utf8‘a’ COLLATE utf8\_en\_ci”.

All string data types support precision. Special care is required with fixed characters(CHAR). The values of this types are padded to fill up the precision. For instance, inserting “abc” into a CHAR(5) column, will result in storing “abc ” (2 padding spaces are added). Space (ASCII 32 decimal, Unicode 0020) is the padding character for most charsets. But, for EUC-KR charset, the padding consists of one character which is stored with two bytes (A1 A1).

## Related Terms

- **Character set:** A group of encoded symbols (giving a specific number to a certain symbol)
- **Collation:** A set of rules for comparison of characters in the character set and for sorting data
- **Locale:** A set of parameters that defines any special variant preferences such as number format, calendar format (month and day in characters), date/time format, and collation depending on the operator’s language and country. Locale defines the linguistic localization. Character set of locale defines how the month in characters and other data are encoded. A locale identifier consists of at least a language identifier and a region identifier, and it is expressed as language[\_territory][.codeset] (For example, Australian English using UTF-8 encoding is written as en\_AU.UTF-8).
- **Unicode normalization:** The specification by the Unicode character encoding standard where some sequences of code points represent essentially the same character. CUBRID uses Normalization Form C (NFC: codepoint is decomposed and then composed) for input and Normalization Form D (NFD: codepoint is composed and then decomposed) for output. However, CUBRID does not apply the canonical equivalence rule as an exception.

For example, canonical equivalence is applied in general NFC rule so codepoint 212A (Kelvin K) is converted to codepoint 4B (ASCII code uppercase K). Since CUBRID does not perform the

conversion by using the canonical equivalence rule to make normalization algorithm quicker and easier, it does not perform reverse-conversion, too.

- **Canonical equivalence:** A basic equivalence between characters or sequences of characters, which cannot be visually distinguished when they are correctly rendered. For example, let's see 'Å' ('A' with an angstrom). 'Å' (Unicode U + 212B) and Latin 'A' (Unicode U + 00C5) have same A and different codepoints, however, the decomposed result is 'A' and U+030A, so it is canonical equivalence.
- **Compatibility equivalence:** A weaker equivalence between characters or sequences of characters that represent the same abstract character. For example, let's see number '2' (Unicode U + 0032) and superscript '²'(Unicode U + 00B2). '²' is a different format of number '2', however, it is visually distinguished and has a different meaning, so it is not canonical equivalence. When normalizing '2²' with NFC, '2²' is maintained since it uses canonical equivalence. However, with NFKC, '²' is decomposed to '2' which is compatibility equivalence and then it can be recomposed to '22'. Unicode normalization of CUBRID does not apply the compatibility equivalence rule.

For explanation on Unicode normalization, see [Unicode Normalization](#). For more details, see <http://unicode.org/reports/tr15/>.

The default value of the system parameter related to Unicode normalization is `unicode_input_normalization=no` and `unicode_output_normalization=no`. For a more detailed description on parameters, see [Statement/Type-Related Parameters](#).

## Locale Attributes

Locale is defined by following attributes.

- **Charset (codeset):** How bytes are interpreted into single characters (Unicode codepoints)
- **Collations:** Among all collations defined in locale of [LDML\(Unicode Locale Data Markup Language\)](#) file, the last one is the default collation. Locale data may contain several collations.
- **Alphabet (casing rules):** One locale data may have up to 2 alphabets, one for identifier and one for user data. One locale data can have two types of alphabets.
- **Calendar:** Names of weekdays, months, day periods (AM/PM)
- **Numbering settings:** Symbols for digit grouping
- **Text conversion data:** For CSQL conversion. Option.
- **Unicode normalization data:** Data converted by normalizing several characters with the same shape into one based on a specified rule. After normalization, characters with the same shape will have the same code value even though the locale is different. Each locale can activate/deactivate the normalization functionality.

**Note**

Generally, locale supports a variety of character sets. However, CUBRID locale supports both ISO and UTF-8 character sets for English and Korean. The other operator-defined locales using the LDML file support the UTF-8 character set only.

## Collation Properties

A collation is an assembly of information which defines an order for characters and strings. In CUBRID, collation has the following properties.

- **Strength:** This is a measure of how “different” basic comparable items (characters) are. This affects selectivity. In LDML files, collation strength is configurable and has four levels. For example a Case insensitive collation should be set with level = “secondary” (2) or “primary” (1).
- Whether it supports or not **expansions** and **contractions**

Each column has a collation, so when applying `LOWER()`, `UPPER()` functions the casing rules of locale which defines the collation’s default language is used.

Depending on collation properties some CUBRID optimizations may be disabled for some collations:

- **LIKE** rewrite: is disabled for collations which maps several different character to the same weight (case insensitive collations for example) and for collations with expansions.
- Covering index scan: disabled for collations which maps several different character to the same weight (see [Covering Index](#)).

For more information, see [Collation settings impacting CUBRID features](#).

## Collation Naming Rules

The collation name in CUBRID follows the conversion:

```
<charset>_<lang specific>_<desc1>_<desc2>_...
```

- <charset>: The full charset name as used by CUBRID. iso88591, utf8, euckr.

- <lang specific>: a region/language specific. The language code is expected as two characters; en, de, es, fr, it, ja, km, ko, tr, vi, zh, ro. “gen” if it does not address a specific language, but a more general sorting rule.
- <desc1>\_<desc2>\_...: They have the following meaning. Most of them apply only to LDML collations.
  - ci: case insensitive In LDML, can be obtained using the settings: strength=“secondary” caseLevel=“off” caseFirst=“off”.
  - cs: case sensitive; By default all collations are case sensitive. In LDML, can be obtained using at least: strength=“tertiary”.
  - bin: it means that the sorting order under such collation is almost the same with the order of codepoints; If memory (byte) comparison is used, then almost the same result is obtained. Space character and EUC double-byte padding character are always sorted as zero in “bin” collation. No collations with such setting are currently configured in LDML (they are already available as built-in), but a similar one can be obtained using the maximum setting strength=“quaternary” or strength=“identical”.
  - ai: accent insensitive; this means that ‘Á’ is sorted the same as ‘A’. Due to particularities of the UCA based algorithms, an accent insensitive collation is also a case insensitive collation. In LDML, can be obtained using: strength=“primary”.
  - uca: this signals a UCA based collation; this is used only to differentiate such collations from similar built-in variants. All LDML collations are based on UCA, but in order to keep shorter names only two collations ( ‘utf8\_ko\_cs\_uca’ , ‘utf8\_tr\_cs\_uca’ ) have this description in their names, in order to differentiate them from ‘utf8\_ko\_cs’ and ‘utf8\_tr\_cs’ collations.
  - exp: this collations use a full-word matching/compare algorithm, contrary to the rest of collations which use character-by-character compare. This collation uses a more complex algorithm, with multiple passes which is much slower, but may prove useful for alphabetical sorts. In LDML, the **Expansion** needs to be explicit by adding CUBRIDExpansions=“use”.
  - ab: accent backwards; it is particularity of French-Canadian sorting, where level 2 of UCA (used to store accents weights) is compared from end of string towards the beginning. This collation setting can be used only when :ref`expansion` setting is also activated. The “backwards” setting allows for the following sorting:
    - Normal Accent Ordering: cote < coté < côte < côté
    - Backward Accent Ordering: cote < côte < coté < côté
  - cbm: contraction boundary match; it is a particularity of collations with **Expansion** and **Contraction** and refers to how it behaves at string matching when a **Contraction** is found. Suppose the collation has defined the **Contraction** “ch”; then normally, the pattern “bac” will not match the string “bachxxx” But when the collation is configured to allow “matching the

characters starting a contraction”, the above matching will return a positive. Only one collation is configured in this manner - ‘utf8\_ja\_exp\_cbm’ - Japanese sorting requires a lot of contractions.

The collation names are not dynamically generated. They are user defined (configured in LDML), and should reflect the settings of the collation.

The name of collation influences the internal numeric id of the collation. For instance, in CUBRID only 256 collations are allowed, and the numeric IDs are assigned as:

- 0 -31: built-in collations (for these collations the name and id are hard-coded)
- 32 - 46: LDML collations having “gen” as “language” part
- 47 - 255: the rest of LDML collations

If you want to include all locales into the database which CUBRID provide, first, copy cubrid\_locales.all.txt of \$CUBRID/conf directory into cubrid\_locales.txt and next, run make\_locale script(in extension, Linux is .sh, Windows is .bat). For more details on make\_locale script, see [Step 2: Compiling Locale](#).

If you want to include the newly added locale information into the existing database, run “cubrid synccolldb <dbname>”. For more information, see [Synchronization of Database Collations with System Collations](#).

If you include all locales defined in LDML files, CUBRID has the following collations.

#### CUBRID Collation

| Collation      | Locale for casing | Character range                         |
|----------------|-------------------|-----------------------------------------|
| iso88591_bin   | en_US - English   | ASCII + ISO88591 (C0-FE, except D7, F7) |
| iso88591_en_cs | en_US - English   | ASCII + ISO88591 (C0-FE, except D7, F7) |
| iso88591_en_ci | en_US - English   | ASCII + ISO88591 (C0-FE, except D7, F7) |
| utf8_bin       | en_US - English   | ASCII                                   |

| Collation         | Locale for casing                                                         | Character range                              |
|-------------------|---------------------------------------------------------------------------|----------------------------------------------|
| euckr_bin         | ko_KR - Korean, same as<br>en_US - English                                | ASCII                                        |
| utf8_en_cs        | en_US - English                                                           | ASCII                                        |
| utf8_en_ci        | en_US - English                                                           | ASCII                                        |
| utf8_tr_cs        | tr_TR - Turkish                                                           | Turkish alphabet                             |
| utf8_ko_cs        | ko_KR - Korean, same as<br>en_US - English                                | ASCII                                        |
| utf8_gen          | de_DE - German, generic<br>Unicode casing customized<br>with German rules | All Unicode codepoints in<br>range 0000-FFFF |
| utf8_gen_ai_ci    | de_DE - German, generic<br>Unicode casing customized<br>with German rules | All Unicode codepoints in<br>range 0000-FFFF |
| utf8_gen_ci       | de_DE - German, generic<br>Unicode casing customized<br>with German rules | All Unicode codepoints in<br>range 0000-FFFF |
| utf8_de_exp_ai_ci | de_DE - German, generic<br>Unicode casing customized<br>with German rules | All Unicode codepoints in<br>range 0000-FFFF |
| utf8_de_exp       | de_DE - German, generic<br>Unicode casing customized<br>with German rules | All Unicode codepoints in<br>range 0000-FFFF |

| Collation       | Locale for casing                                                     | Character range                           |
|-----------------|-----------------------------------------------------------------------|-------------------------------------------|
| utf8_ro_cs      | ro_RO - Romanian, same as generic Unicode casing                      | All Unicode codepoints in range 0000-FFFF |
| utf8_es_cs      | es_ES - Spanish, same as generic Unicode casing                       | All Unicode codepoints in range 0000-FFFF |
| utf8_fr_exp_ab  | fr_FR - French, same as generic Unicode casing                        | All Unicode codepoints in range 0000-FFFF |
| utf8_ja_exp     | ja_JP - Japanese, same as generic Unicode casing                      | All Unicode codepoints in range 0000-FFFF |
| utf8_ja_exp_cbm | ja_JP - Japanese, same as generic Unicode casing                      | All Unicode codepoints in range 0000-FFFF |
| utf8_km_exp     | km_KH - Cambodian, same as generic Unicode casing                     | All Unicode codepoints in range 0000-FFFF |
| utf8_ko_cs_uca  | ko_KR - Korean, same as generic Unicode casing                        | All Unicode codepoints in range 0000-FFFF |
| utf8_tr_cs_uca  | tr_TR - Turkish, generic Unicode casing customized with Turkish rules | All Unicode codepoints in range 0000-FFFF |
| utf8_vi_cs      | vi_VN - Vietnamese, same as generic Unicode casing                    | All Unicode codepoints in range 0000-FFFF |
| binary          | none (invariant to casing operations)                                 | any byte value (zero is null-terminator)  |

The Turkish casing rules changes the casing for character i,İ,ı. The German casing rules changes the casing for ß.

On the above collations, 9 collations like iso88591\_bin, iso88591\_en\_cs, iso88591\_en\_ci, utf8\_bin, euckr\_bin, utf8\_en\_cs, utf8\_en\_ci, utf8\_tr\_cs and utf8\_ko\_cs, are built in the CUBRID before running make\_locale script.

If a collation is included in more than one locale (.ldml) file, the locale for casing (default locale of collation) is the locale in which it is first included. The order of loading is the locales order from \$CUBRID/conf/cubrid\_locales.txt. The above locale casing for collations utf8\_gen, utf8\_gen\_ci, utf8\_gen\_ai\_ci, assumes the default order (alphabetical) in cubrid\_locales.txt, so the default locale for all generic LDML collations is de\_DE (German).

## Files For Locale Setting

CUBRID uses following directories and files to set the locales.

- **\$CUBRID/conf/cubrid\_locales.txt** file: A configuration file containing the list of locales to be supported
- **\$CUBRID/conf/cubrid\_locales.all.txt** file: A configuration file template with the same structure as **cubrid\_locales.txt**. Contains the entire list of all the locales that the current version of CUBRID is capable of supporting without any efforts from the end user's side.
- **\$CUBRID/locales/data** directory: This contains files required to generate locale data.
- **\$CUBRID/locales/loclib** directory: contains a C header file, **locale\_lib\_common.h** and OS dependent makefile which are used in the process of creating / generating locales shared libraries.
- **\$CUBRID/locales/data/ducet.txt** file: Text file containing default universal collation information (codepoints, contractions and expansions, to be more specific) and their weights, as standardized by The Unicode Consortium, which is the starting point for the creation of collations. For more information, see [http://unicode.org/reports/tr10/#Default\\_Unicode\\_Collation\\_Element\\_Table](http://unicode.org/reports/tr10/#Default_Unicode_Collation_Element_Table).
- **\$CUBRID/locales/data/unicodedata.txt** file: Text file containing information about each Unicode codepoint regarding casing, decomposition, normalization etc. CUBRID uses this to determine casing. For more information, see <https://docs.python.org/3/library/unicodedata.html>.
- **\$CUBRID/locales/data/ldml** directory: common\_collations.xml and XML files, name with the convention cubrid\_<locale\_name>.xml. common\_collations.xml file contains shared collation information in all locale files, and each cubrid\_<locale\_name>.xml file contains a locale information for the supported language.
- **\$CUBRID/locales/data/codepages** directory: contains codepage console conversion for single byte codepages(8859-1.txt , 8859-15.txt, 8859-9.txt) and codepage console conversion for double byte codepages(CP1258.txt , CP923.txt, CP936.txt , CP949.txt).

- **\$CUBRID/bin/make\_locale.sh** file or **%CUBRID%\bin\make\_locale.bat** file: A script file used to generate shared libraries for locale data
- **\$CUBRID/lib** directory: Shared libraries for generated locales will be stored here.

## Locale Setting

When you want to use a charset and collation of a specific language, the charset should be identical with a database which will be created newly. Supported CUBRID charsets are ISO-8859-1, EUC-KR and UTF-8 and the charset to be used is specified when creating a database.

For example, when you created a database with a locale ko\_KR.utf8, you can use collations starting with “utf8\_” like utf8\_ja\_exp. However, if you set the locale as ko\_KR.euckr, you cannot use all collations which are related with other charset(see [CUBRID Collation](#)).

The following is an example which used utf8\_ja\_exp after creating a database with en\_US.utf8.

1. cd \$CUBRID/conf
2. cp cubrid\_locales.all.txt cubrid\_locales.txt
3. make\_locale.sh -t64 # 64 bit locale library creation
4. cubrid createdb testdb en\_US.utf8
5. cubrid server start testdb
6. csql -u dba testdb
7. run below query on csql

```
SET NAMES utf8;
CREATE TABLE t1 (i1 INT , s1 VARCHAR(20) COLLATE utf8_ja_exp, a
INT, b VARCHAR(20) COLLATE utf8_ja_exp);
INSERT INTO t1 VALUES (1, 'いイ基盤', 1, 'いイ 繭');
```

For more details, see the following.

### Step 1: Selecting a Locale

Configure locales to use on **\$CUBRID/conf/cubrid\_locales.txt**. You can select all or some of locales which are supported.

CUBRID supports locales as follows: en\_US, de\_DE, es\_ES, fr\_FR, it\_IT, ja\_JP, km\_KH, ko\_KR, tr\_TR, vi\_VN, zh\_CN, ro\_RO.

The language and country for each locale are shown in the following table.

| Locale Name | Language - Country   |
|-------------|----------------------|
| en_US       | English - U.S.A.     |
| de_DE       | German - Germany     |
| es_ES       | Spanish - Spain      |
| fr_FR       | French - France      |
| it_IT       | Italian - Italy      |
| ja_JP       | Japanese - Japan     |
| km_KH       | Khmer - Cambodia     |
| ko_KR       | Korean - Korea       |
| tr_TR       | Turkish - Turkey     |
| vi_VN       | Vietnamese - Vietnam |
| zh_CN       | Chinese - China      |
| ro_RO       | Romanian - Romania   |

#### Note

The LDML files for the supported locales are named `cubrid_<locale_name>.xml` and they can be found in the **\$CUBRID/locales/data/ldml** directory. If only a subset of these locales are to be supported by CUBRID, one must make sure their corresponding LDML files are present in

the **\$CUBRID/locales/data/ldml** folder. A locale cannot be used by CUBRID, unless it has an entry in **cubrid\_locales.txt** file and it has a corresponding cubrid\_<locale\_name>.xml.

Locale libraries are generated according to the contents of **\$CUBRID/conf/cubrid\_locales.txt** configuration file. This file contains the language codes of the wanted locales (all user defined locales are generated with UTF-8 charset). Also, in this file can be configured the file paths for each locale LDML file and libraries can be optionally configured.

```
<lang_name>  <LDML file>
<lib file>
ko_KR        /home/CUBRID/locales/data/ldml/cubrid_ko_KR.xml    /
home/CUBRID/lib/libcubrid_ko_KR.so
```

By default, the LDML files are found in **\$CUBRID/locales/data/ldml** and the locale libraries in **\$CUBRID/lib**; the filenames for LDML are formatted like: cubrid\_<lang\_name>.ldml.

The filenames for libraries: libcubrid\_<lang\_name>.dll (.so for Linux).

## Step 2: Compiling Locale

Once the requirements described above are met, the locales can be compiled.

Regarding the embedded locales in CUBRID, they can be used without compiling user locale library, so they can be used by skipping the step 2. But there are differences between the embedded locale and the library locale. Regarding this, see [Built-in Locale and Library Locale](#).

To compile the locale libraries, one must use the **make\_locale** (.bat for Windows and .sh for Linux) utility script from command console. The file is delivered in **\$CUBRID/bin** folder so it should be resolved by **\$PATH** environment variable. Here **\$CUBRID**, **\$PATH** are the environment variables of Linux, **%CUBRID%**, **%PATH%** are the environment variables of Windows.

### Note

To run a **make\_locale** script in Windows, it requires Visual C++ 2005, 2008 or 2010.

Usage can be displayed by running **make\_locale.sh -h**. (**make\_locale /h** in Windows.)

```
make_locale.sh [options] [locale]

options ::= [-t 32|64 ] [-m debug|release]
```

```
locale ::= [de_DE|es_ES|fr_FR|it_IT|ja_JP|km_KH|ko_KR|tr_TR|vi_VN|
zh_CN|ro_RO]
```

- *options*

- **-t**: Selects 32bit or 64bit (default value: **64**).
- **-m**: Selects release or debug. In general, release is selected (default value: release). The debug mode is provided for developers who would like to write the locale library themselves. Selects release or debug. In general, release is selected (default value: release). The debug mode is provided for developers who would like to write the locale library themselves.
- *locale*: The locale name of the library to build. If *locale* is not specified, the build includes data from all configured locales. In this case, library file is stored in **\$CUBRID/lib** directory with the name of **libcubrid\_all\_locales.so** (.dll for Windows).

To create user defined locale shared libraries, two choices are available:

- Creating a single lib with all locales to be supported.

```
make_locale.sh -t64                                # Build and pack all
locales (64/release)
```

- Creating one lib for each locale to be supported.

```
make_locale.sh -t 64 -m release ko_KR
```

The first choice is recommended. In this scenario, some data may be shared among locales. If you choose the first one, a lib supporting all locales has less than 15 MB; in the second one, consider for each locale library from 1 MB to more than 5 MB. Also the first one is recommended because it has no runtime overhead during restarting the servers when you choose the second one.

### Warning

#### Limitations and Rules

- Do not change the contents of **\$CUBRID/conf/cubrid\_locales.txt** after locales generation; once the locales libraries are generated, the contents of **\$CUBRID/conf/cubrid\_locales.txt** should not be changed (order of languages within the file must also be preserved). During locale compiling, the generic collation uses the first one as default locale; changing the order may cause different results with casing for such collation (utf8\_gen\_\*).

- Do not change the contents for **\$CUBRID/locales/data/\*.txt** files.

### Note

#### Procedure of Executing **make\_locale.sh(.bat)** Script

The processing in **make\_locale.sh(.bat)** script

1. Reads the **.ldml** file corresponding to a language, along with some other installed common data files like **\$CUBRID/locales/data/ducet.txt**, **\$CUBRID/locales/data/unicodedata.txt**, and **\$CUBRID/locales/data/codepages/\*.txt**
2. After processing of raw data, it writes in a temporary **\$CUBRID/locales/loclib/locale.c** file C constants values and arrays consisting of locales data.
3. The temporary file **locale.c** is passed to the platform compiler to build a **.dll/.so** file. This step assumes that the machines has an installed C/C++ compiler and linker. Currently, only the MS Visual Studio for Windows and gcc for Linux compilers are supported.
4. Temporary files are removed.

### Step 3: Setting CUBRID to Use a Specific Locale

Only one locale can be selected as the default locale when you create DB.

In addition to the possibility of specifying a default locale, one can override the default calendar settings with the calendar settings from another locale, using the **intl\_date\_lang** system parameter.

- The locale will be in the format: **<locale\_name>.[utf8 | iso]** (e.g. tr\_TR.utf8, en\_EN.ISO, ko\_KR.utf8)
- **intl\_date\_lang**: **<locale\_name>**. The possible values for **<locale\_name>** are listed on [Step 1: Selecting a Locale](#).

### Note

#### Setting the Month/Day in Characters, AM/PM, and Number Format

For the function that inputs and outputs the day/time, you can set the month/day in characters, AM/PM, and number format by the locale in the **intl\_date\_lang** system parameter.

Also for the function that converts a string to numbers or the numbers to a string, you can set the string format by the locale in **intl\_number\_lang** system parameter.

## Built-in Locale and Library Locale

Regarding the embedded locales in CUBRID, they can be used without compiling user locale library, so they can be used by skipping the step 2. But there are two differences between the embedded locale and the library locale.

- Embedded(built-in) locale(and collation) are not aware of Unicode data. For instance, casing (lower, upper) of (Ă, ă) is not available in embedded locales. The LDML locales provide data for Unicode codepoints up to 65535.
- Also, the embedded collations deal only with ASCII range, or in case of 'utf8\_tr\_cs' - only ASCII and letters from Turkish alphabet. Embedded UTF-8 locales are not Unicode compatible, while compiled (LDML) locales are.

Currently, the built-in locales which can be set during creating DB are as follows:

- en\_US.iso88591
- en\_US.utf8
- ko\_KR.utf8
- ko\_KR.euckr
- ko\_KR.iso88591: Will have Romanized Korean names for month, day names.
- tr\_TR.utf8
- tr\_TR.iso88591: Will have Romanized Turkish names for month, day names.

The order stated above is important; if no charset is defined while creating DB, the charset is the charset of the locale shown first. For example, if the locale is set as ko\_KR(e.g. cubrid createdb testdb ko\_KR), the charset is specified as ko\_KR.utf8, the first locale among the ko\_KR in the above list. Locales of the other languages except the built-in locales should end with **.utf8**. For example, specify the locale as de\_DE.utf8 for German.

The names of month and day for ko\_KR.iso88591 and tr\_TR.iso88591 should be Romanized. For example, “일요일” for Korean (Sunday in English) is Romanized to “Iryoil”. Providing ISO-8859-1 characters only is required. For more information, see [The Month/Day in Korean and Turkish Characters for ISO-8859-1 Charset](#).

## The Month/Day in Korean and Turkish Characters for ISO-8859-1 Charset

In Korean or Turkish which have charset UTF-8 or in Korean which have charset EUC-KR, the month/day in characters and AM/PM are encoded according to the country. However, for ISO-8859-1 charset, if the month/day in characters and AM/PM in Korean or Turkish is used as its original encoding, an unexpected behavior may occur in the server process because of its complex expression. Therefore, the name should be Romanized. The default charset of CUBRID is ISO-8859-1 and the charset can be used for Korean and Turkish. The Romanized output format is as follows:

### Day in Characters

| Day in Characters<br>Short Format | Long/<br>Short | Long/Short<br>Korean | Romanized | Long/Short<br>Turkish | Romanized |
|-----------------------------------|----------------|----------------------|-----------|-----------------------|-----------|
| Sunday / Sun                      |                | Iryoil / Il          |           | Pazar / Pz            |           |
| Monday / Mon                      |                | Woryoil / Wol        |           | Pazartesi / Pt        |           |
| Tuesday / Tue                     |                | Hwayoil / Hwa        |           | Sali / Sa             |           |
| Wednesday / Wed                   |                | Suyoil / Su          |           | Carsamba / Ca         |           |
| Thursday / Thu                    |                | Mogyoil / Mok        |           | Persembе / Pe         |           |
| Friday / Fri                      |                | Geumyoil / Geum      |           | Cuma / Cu             |           |
| Saturday / Sat                    |                | Toyoil / To          |           | Cumartesi / Ct        |           |

### Month in Characters

| Month in Characters<br>Short Format | Long/<br>Short | Long/Short<br>Korean (Not Classified) | Romanized | Long/Short<br>Turkish | Romanized |
|-------------------------------------|----------------|---------------------------------------|-----------|-----------------------|-----------|
| January / Jan                       |                | 1wol                                  |           | Ocak / Ock            |           |

| Month in Characters Long/<br>Short Format | Long/Short<br>Korean (Not Classified) | Romanized<br>Long/Short<br>Turkish |
|-------------------------------------------|---------------------------------------|------------------------------------|
| February / Feb                            | 2wol                                  | Subat / Sbt                        |
| March / Mar                               | 3wol                                  | Mart / Mrt                         |
| April / Apr                               | 4wol                                  | Nisan / Nsn                        |

### AM/PM in Characters

| AM/PM in Characters Long/<br>Short Format | Romanized in Korean | Romanized in Turkish |
|-------------------------------------------|---------------------|----------------------|
| AM                                        | ojeon               | AM                   |

| AM/PM in Characters Long/<br>Short Format | Romanized in Korean | Romanized in Turkish |
|-------------------------------------------|---------------------|----------------------|
| PM                                        | ohu                 | PM                   |

#### Step 4: Creating a Database with the Selected Locale Setting

When issuing the command “**cubrid createdb** <db\_name> <locale\_name.charset>”, a database will be created using the settings in the variables described above.

Once the database is created a locale setting which was given to the database cannot be changed. The charset and locale name are stored in “**db\_root**” system catalog table.

#### Step 5 (optional): Manually Verifying the Locale File

The contents of locales libraries may be displayed in human readable form using the **dumplocale** CUBRID utility. Execute **cubrid dumplocale -h** to output the usage. The used syntax is as follows.

```
cubrid dumplocale [options] [language-string]

options ::= -i|--input-file <shared_lib>
           -d|--calendar
           -n|--numeric
           {-a |--alphabet={l|lower|u|upper|both}}
           -c|--codepoint-order
           -w|--weight-order
           {-s|--start-value} <starting_codepoint>
           {-e|--end-value} <ending_codepoint>
           -k
           -z

language-string ::= de_DE|es_ES|fr_FR|it_IT|ja_JP|km_KH|ko_KR|tr_TR|
vi_VN|zh_CN|ro_RO
```

- **dumplocale**: A command which dumps the contents of locale shared library previously generated using LDML input file.
- *language-string*: One of de\_DE, es\_ES, fr\_FR, it\_IT, ja\_JP, km\_KH, ko\_KR, tr\_TR, vi\_VN, zh\_CN and ro\_RO. Configures the locale language to dump the locale shared library. If it's not set, all languages which are configured on **cubrid\_locales.txt** are given.

The following are [options] for **cubrid dumplocale**.

**-i, --input-file=FILE**

The name of the locale shared library file (< *shared\_lib*>) created previously. It includes the directory path.

**-d, --calendar**

Dumps the calendar and date/time data. Default value: No

**-n, --numeric**

Dumps the number data. Default value: No

**-a, --alphabet=l|lower|u|upper|both**

Dumps the alphabet and case data. Default value: No

**--identifier-alphabet=l|lower|u|upper**

Dumps the alphabet and case data for the identifier. Default value: No

**-c, --codepoint-order**

Dumps the collation data sorted by the codepoint value. Default value: No (displayed data: cp, char, weight, next-cp, char and weight)

**-w, --weight-order**

Dumps the collation data sorted by the weight value. Default value: No (displayed data: weight, cp, char)

**-s, --start-value=CODEPOINT**

Specifies the dump scope. Starting codepoint for **-a, --identifier-alphabet, -c, -w** options. Default value: 0

**-e, --end-value=CODEPOINT**

Specifies the dump scope. Ending codepoint for **-a, --identifier-alphabet, -c, -w** options. Default value: Max value read from the locale shared library.

**-k, --console-conversion**

Dumps the data of console conversion. Default value: No

**-z, --normalization**

Dumps the normalization data. Default value: No

The following example shows how to dump the calendar, number formatting, alphabet and case data, alphabet and case data for the identifier, collation sorting based on the codepoint order, collation sorting based on the weight, and the data in ko\_KR locale into ko\_KR\_dump.txt by normalizing:

```
% cubrid dumplocale -d -n -a both -c -w -z ko_KR > ko_KR_dump.txt
```

It is highly recommended to redirect the console output to a file, as it can be very big data, and seeking information could prove to be difficult.

## Step 6: Starting CUBRID-Related Processes

All CUBRID-related processes should be started in an identical environmental setting. The CUBRID server, the broker, CAS, and CSQL should use the locale binary file of an identical version. Also CUBRID HA should use the same setting. For example, in the CUBRID HA, master server, slave server and replica server should use the same environmental variable setting.

There is no check on the compatibility of the locale used by server and CAS (client) process, so the user should make sure the LDML files used are the same.

Locale library loading is one of the first steps in CUBRID start-up. Locale (collation) information is required for initializing databases structures (indexes depends on collation). This process is performed by each CUBRID process which requires locale information: server, CAS, CSQL, createdb, copydb, unload, load DB.

The process of loading a locale library is as follows.

- If no lib path is provided, CUBRID will try to load `$CUBRID/lib/libcubrid_<lang_name>.so` file; if this file is not found, then CUBRID assumes all locales are found in a single library: **`$CUBRID/lib/libcubrid_all_locales.so`**.
- If suitable locale library cannot be found or any other error occurs during loading, the CUBRID process stops.
- If collations between the database and the locale library are different, the CUBRID process cannot start. To include the newly changed collations of the locale library, firstly synchronize the database collation with the system collation by running **`cubrid synccolldb`** command. Next, update from the existing database to the wanted collations of schemas and data. For more details, see [Synchronization of Database Collations with System Collations](#).

## Synchronization of Database Collations with System Collations

CUBRID's normal operation requires that the system collation and the database collation must be the same. The system locale means that the locale which include built-in locales and library locales created through `cubrid_locales.txt` (see [Locale Setting](#)), and it includes the system collation information. The database collation information is stored on the **`_db_collation`** system catalog table.

**`cubrid synccolldb`** utility checks if the database collation is the same with the system collation, and synchronize into the system collation if they are different. However, note that this utility doesn't transform the data itself stored on the database.

This utility can be used when the existing database collation should be changed after the system locale is changed. However, there are operations which the user have to do manually.

The user should do this operations before the synchronization. These operations can be done by running CSQL with `cubrid_synccolldb_<database_name>.sql` file, which is created by **cubrid synccolldb -c**.

- Change collation using ALTER TABLE .. MODIFY statement.
- Remove any views, indexes, triggers or partitions containing the collation.

Run synchronization with **cubrid synccolldb**. After then, do the following operations.

- Recreate views, indexes, triggers, or partitions
- Update application statements to use new collations

This utility should work only in offline mode.

**synccolldb** syntax is as follows.

```
cubrid synccolldb [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **synccolldb**: A command to synchronize collations of a database with collations from the system(according to contents of locales libraries and `$CUBRID/conf/cubrid_locales.txt`).
- *database\_name*: A database name to be synchronized with collations from the system.

If [options] is omitted, **synccolldb** checks the collation differences between the system and the database, synchronize the database collation with the system collation, and create the `cubrid_synccolldb_<database_name>.sql` file including the queries of objects to be dropped before the synchronization.

The following are [options] which are used on **cubrid synccolldb**.

#### **-c, --check-only**

This option prints out the collation information which is different between the database collation and the system collation.

#### **-f, --force-only**

This option doesn't ask when updating the database collation with the system collation.

The following shows that how it works when the system collation and the database collation are different.

Firstly, make locale library about ko\_KR locale.

```
$ echo ko_KR > $CUBRID/conf/cubrid_locales.txt
$ make_locale.sh -t 64
```

Next, create the database.

```
$ cubrid createdb --db-volume-size=20M --log-volume-size=20M xdb
en_US
```

Create a schema. At this time, specify the needed collation in each table.

```
$ csql -S -u dba xdb -i in.sql
```

```
CREATE TABLE dept(depname STRING PRIMARY KEY) COLLATE utf8_ko_cs_uca;
CREATE TABLE emp(eid INT PRIMARY KEY, depname STRING,address STRING)
COLLATE utf8_ko_cs_uca;
ALTER TABLE emp ADD CONSTRAINT FOREIGN KEY (depname) REFERENCES
dept(depname);
```

Change the locale setting of the system. If you do not any values on **cubrid\_locales.txt**, the database consider that only built-in locales exist

```
$ echo "" > $CUBRID/conf/cubrid_locales.txt
```

Check the difference between system and database by running **cubrid synccolldb -c** command.

```
$ cubrid synccolldb -c xdb

-----
Collation 'utf8_ko_cs_uca' (Id: 133) not found in database or
changed in new system configuration.
-----
Collation 'utf8_gen_ci' (Id: 44) not found in database or changed in
new system configuration.
-----
Collation 'utf8_gen_ai_ci' (Id: 37) not found in database or changed
in new system configuration.
-----
Collation 'utf8_gen' (Id: 32) not found in database or changed in
new system configuration.
-----
```

```
-----
There are 4 collations in database which are not configured or are
changed compared to system collations.
Synchronization of system collation into database is required.
Run 'cubrid synccolldb -f xdb'
```

If the indexes exist, firstly you should remove the indexes, and change the collation of each table, then recreate the indexes directly. The process to remove indexes and change the collation of tables can be executed by using `cubrid_synccolldb_xdb.sql` file which was created by **synccolldb** command. On the below example, a foreign key is the index which you should recreate.

```
$ cat cubrid_synccolldb_xdb.sql

ALTER TABLE [dept] COLLATE utf8_bin;
ALTER TABLE [emp] COLLATE utf8_bin;
ALTER TABLE [emp] DROP FOREIGN KEY [fk_emp_depname];
ALTER TABLE [dept] MODIFY [depname] VARCHAR(1073741823) COLLATE
utf8_bin;
ALTER TABLE [emp] MODIFY [address] VARCHAR(1073741823) COLLATE
utf8_bin;
ALTER TABLE [emp] MODIFY [depname] VARCHAR(1073741823) COLLATE
utf8_bin;

$ csql -S -u dba -i cubrid_synccolldb_xdb.sql xdb
```

Removing the obsolete collations by executing the above `cubrid_synccolldb_xdb.sql` script file must be performed before forcing the synchronization of system collations into database.

Run **cubrid synccolldb** command. If the option is omitted, the message is shown to ask to run this command or not; if the **-f** option is given, the synchronization is run without checking message.

```
$ cubrid synccolldb xdb
Updating system collations may cause corruption of database.
Continue (y/n) ?
Contents of '_db_collation' system table was updated with new system
collations.
```

Recreate the dropped foreign key.

```
$ csql -S -u dba xdb

ALTER TABLE emp ADD CONSTRAINT FOREIGN KEY fk_emp_depname(depname)
REFERENCES dept(depname);
```

**Note**

In CUBRID, collations are identified by the ID number on the CUBRID server, and its range is from 0 to 255. LDML file is compiled with shared library, which offers the mapping information between the ID and the collation(name, attribute).

- The system collation is the collation which is loaded from the locale library, by the CUBRID server and the CAS module.
- The database collation is the collation which is stored into the **\_db\_collation** system table.

## Collation

A collation is an assembly of information which defines an order for characters and strings. One common type of collation is called alphabetization.

If not explicitly set otherwise at column creation, the charset and collation of columns are charset and collation of table. The charset and collation are taken (in order in is found first) from the client. If the result of an expression is a character data type, gets the collation and charset by the collation inference with the operands of the expression.

**Note**

In CUBRID, collations are supported for a number of languages, including European and Asian. In addition to the different alphabets, some of these languages may require the definition of expansions or contractions for some characters or character groups. Most of these aspects have been put together by the Unicode Consortium into The Unicode Standard (up to version 6.1.0 in 2012). Most of the information is stored in the DUCET file <http://www.unicode.org/Public/UCA/latest/allkeys.txt> which contains all characters required by most languages.

Most of the codepoints represented in DUCET, are in range 0 - FFFF, but codepoints beyond this range are included. However, CUBRID will ignore the latest ones, and use only the codepoints in range 0 - FFFF (or a lower value, if configured).

Each codepoint in DUCET has one or more 'collation elements' attached to it. A collation element is a set of four numeric values, representing weights for 4 levels of comparison. Weight values are in range 0 - FFFF.

In DUCET, a character is represented on a single line, in the form:

```
< codepoint_or_multiple_codepoints > ; [.W1.W2.W3.W4][.....]....
# < readable text explanation of the symbol/character >
```

A Korean character kiyeok is represented as follows:

```
1100 ; [.313B.0020.0002.1100] # HANGUL CHOSEONG KIYEOK
```

For example, 1100 is a codepoint, [.313B.0020.0002.1100] is one collation element, 313B is the weight of Level 1, 0020 is the weight of Level 2, 0002 is the weight of Level 3, and 1100 is the weight of Level 4.

Expansion support, defined as a functional property, means supporting the interpretation of a composed character as a pair of the same characters which it's made of. A rather obvious example is interpreting the character "æ" in the same way as the two character string "ae". This is an expansion. In DUCET, expansions are represented by using more than one collation element for a codepoint or contraction. By default, CUBRID has expansions disabled. Handling collations with expansions requires when comparing two strings several passes (up to the collation strength/level).

## Charset and Collation of Column

Charset and Collation apply to string data types: **VARCHAR (STRING)**, **CHAR** and **ENUM**. By default, all string data types inherit the default database collation and character set, but CUBRID supports two modifiers which affect collation and character set.

## Charset

Character set may be specified as character string literal or as non-quoted identifier. Supported character sets:

- ISO-8859-1
- UTF-8 (with maximum 4 bytes per characters, which means it supports codepoints from 0 to 0x10FFFF)
- EUC-KR (the support for this character set is only for backward compatibility reasons, its usage is not recommended)

**Note**

Previous versions of CUBRID 9.0 supported EUC-KR characters when ISO-8859-1 charset (the single one available) was set. From CUBRID 9.0 Beta, this is no longer available. EUC-KR characters should be used only with EUC-KR charset.

## String Check

By default, all input data is assumed to be in the server character specified when creating DB. This may be overridden by **SET NAMES** or charset introducer (or **COLLATE** string literal modifier) (For more information, see [Charset and Collation of String Literals](#)).

Invalid data may lead to undefined behavior or even crashes if string checking is disabled (by default is disabled). This can be enabled by **intl\_check\_input\_string** system parameter. However, if you are sure that only valid data is input, you can obtain better performance by disabling string check. Only UTF-8 and EUC-KR text data is checked for valid encodings. Since ISO-8859-1 is single byte encoding and all byte values are valid, there is no checking on this charset.

## Charset Conversion

When **collation** / **charset** modifiers or normal collation inference requires it, character conversion may occur. Conversions are not reversible. Generally, charset conversion is character transcoding (the bytes representing a character in one charset are replaced with other bytes representing the same character but in the destination charset).

With any conversion, losses may occur. If a character from source charset cannot be encoded in destination charset, it is replaced with a '?' character. This also applies to conversions from binary charset to any other charset. The widest character support is with UTF-8 charset, and since it encodes Unicode, one expects that all character can be encoded. However, during conversion from ISO-8859-1 to UTF-8 some "losses" occur: bytes range 80-A0 are not valid ISO-8859-1 characters but may appear in strings. After conversion to UTF-8 these characters are replaced with '?'.

Rules for conversion of values from one charset to another:

| Source<br>Destination | \ | Binary    | ISO-8859-1                               | UTF-8                                      | EUC-KR                                     |
|-----------------------|---|-----------|------------------------------------------|--------------------------------------------|--------------------------------------------|
| Binary                |   | No change | No change The<br>byte size<br>unchanged. | No change.<br>Validation per<br>character. | No change.<br>Validation per<br>character. |

| Source<br>Destination \ | Binary                                                          | ISO-8859-1                                                          | UTF-8                                                                   | EUC-KR                                                              |
|-------------------------|-----------------------------------------------------------------|---------------------------------------------------------------------|-------------------------------------------------------------------------|---------------------------------------------------------------------|
|                         |                                                                 | Character length unchanged.                                         | Invalid char replace with '?'                                           | Invalid char replace with '?'                                       |
| ISO-8859-1              | No change                                                       | No change                                                           | Byte conversion. The byte size increases. No loss of useful characters. | Byte conversion. Byte size increase. No loss of useful characters.  |
| UTF-8                   | No change. The byte size unchanged. Character length increases. | Byte conversion. Byte size may decrease. Expect loss of characters. | No change                                                               | Byte conversion. Byte size may decrease. Expect loss of characters. |
| EUC-KR                  | No change. The byte size unchanged. Character length increases  | Byte conversion. Byte size may decrease. Expect loss of characters  | Byte conversion. Byte size may increase. No loss of useful characters.  | No change                                                           |

#### Note

Previous versions of CUBRID 9.x didn't supported binary charset. The ISO-8859-1 charset had the role of existing binary charset. Conversions from UTF-8 and EUC-KR charsets to ISO-8859-1 were performed by reinterpreting the byte content of source, not by character translation.

## Collation

Collation may be specified as character string literal or as non-quoted identifier.

The following is a query(`SELECT * FROM db_collation WHERE is_builtin='Yes'`) on the **db\_collation** system table.

```

coll_id  coll_name      charset_name  is_builtin
has_expansions  contractions  uca_strength
=====
=====
0        'iso88591_bin'    'iso88591'    'Yes'
'No'      0              'Not applicable'
1        'utf8_bin'       'utf8'        'Yes'
'No'      0              'Not applicable'
2        'iso88591_en_cs' 'iso88591'    'Yes'
'No'      0              'Not applicable'
3        'iso88591_en_ci' 'iso88591'    'Yes'
'No'      0              'Not applicable'
4        'utf8_en_cs'     'utf8'        'Yes'
'No'      0              'Not applicable'
5        'utf8_en_ci'     'utf8'        'Yes'
'No'      0              'Not applicable'
6        'utf8_tr_cs'     'utf8'        'Yes'
'No'      0              'Not applicable'
7        'utf8_ko_cs'     'utf8'        'Yes'
'No'      0              'Not applicable'
8        'euckr_bin'     'euckr'       'Yes'
'No'      0              'Not applicable'
9        'binary'        'binary'      'Yes'
'No'      0              'Not applicable'

```

Built-in collations are available without requiring additional user locale libraries.

Each **collation** has an associated **charset**. For this reason, it is not allowed to set incompatible pair to **character** set and **collation**.

When **COLLATE** modifier is specified without **CHARSET** modifier, then the default charset of collation is set. When **CHARSET** modifier is specified without **COLLATE** modifier, then the default collation is set. The default collation for character sets are the bin collation:

- ISO-8859-1: iso88591\_bin
- UTF-8: utf8\_bin
- EUC-KR: euckr\_bin
- Binary: binary

Binary is the name of both the collation and its associated charset.

For more information on how to determine the collation among the expression parameters (operands) with different collations (and charsets), see [How to Determine Collation among Columns with Different Collation](#).

## CHARSET and COLLATE modifier

CUBRID supports two modifiers which affect collation and character set without following the default database collation and character set.

- **CHARACTER\_SET** (alias **CHARSET**) changes the columns character set
- **COLLATE** changes the collation

```
<data_type> ::= <column_type> [<charset_modifier_clause>]  
[<collation_modifier_clause>]  
  
<charset_modifier_clause> ::= {CHARACTER_SET | CHARSET}  
{<char_string_literal> | <identifier> }  
  
<collation_modifier_clause> ::= {COLLATE } {<char_string_literal> |  
<identifier> }
```

The following example shows how to set the charset of the **VARCHAR** type column to UTF-8

```
CREATE TABLE t1 (s1 VARCHAR (100) CHARSET utf8);
```

The following example shows how to change the name of column s1 to c1 and the type to CHAR(10) with the collation of utf8\_en\_cs (the charset is the default charset of the collation, UTF-8).

```
ALTER TABLE t1 CHANGE s1 c1 CHAR(10) COLLATE utf8_en_cs;
```

The value of the c1 column is changed to the VARCHAR(5) type whose collation is iso88591\_en\_ci. It is performed by using the collation iso88591\_en\_ci for the type of column selected first or by using sorting.

```
SELECT CAST (c1 as VARCHAR(5) COLLATE 'iso88591_en_ci') FROM t1  
ORDER BY 1;
```

The following query (same sorting) is similar to the above but the output column result is the original value.

```
SELECT c1 FROM t1 ORDER BY CAST (c1 as VARCHAR(5) COLLATE
iso88591_en_ci);
```

## How to Determine Collation among Columns with Different Collation

```
CREATE TABLE t (
    s1 STRING COLLATE utf8_en_cs,
    s2 STRING COLLATE utf8_tr_cs
);

-- insert values into both columns

SELECT s1, s2 FROM t WHERE s1 > s2;
```

```
ERROR: '>' requires arguments with compatible collations.
```

In the above example, column *s1* and column *s2* have different collations. Comparing *s1* with *s2* means comparing the strings to determine which column value is “larger” among the records on the table *t*. In this case, an error will occur because the comparison between the collation *utf8\_en\_cs* and the collation *utf8\_tr\_cs* cannot be done.

The rules to determine the types of arguments for an expression are also applied to the rules to determine the collations.

1. A common collation and a character set are determined by considering all arguments of an expression.
2. If an argument has a different collation (and a character set) with a common collation (and a character set) decided in No. 1, it is changed into the common collation (and a character set).
3. To change the collation, `CAST()` operator can be used.

Collation coercibility is used to determine the result collation of comparison expression. It expresses how easily the collation can be converted to the collation of the opposite argument. High collation coercibility when comparing two operands of an expression means that the collation can be easily converted to the collation of the opposite argument. That is, an argument with high collation coercibility can be changed to the collation of an argument with lower collation coercibility.

When an expression has various arguments with different collation, a common collation is computed based on each arguments collation and coercibility. The rules for collation inference are:

1. Arguments with higher coercibility are coerced (or casted) to collation of arguments with lower coercibility.
2. When arguments have different collation but same coercibility, the expression's collation cannot be resolved and an error is returned. However, when comparing two operands of which collation coercibility level is 11(session variable, host variable) and charset is the same, one of their collation is changed as non-bin collation if one of them is bin collation(utf8\_bin, iso88591\_bin, euckr\_bin). See [Converting Collation of Session Variable and/or Host Variable](#).

Below table shows the collation coercibility about arguments of the expression

| Collation Coercibility | Arguments of the Expression(Operands)                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| -1                     | As an expression which has arguments with only host variables, this coercibility cannot be determined before the execution step. |
| 0                      | Operand having <b>COLLATE</b> modifier                                                                                           |
| 1                      | <b>Columns</b> with non-binary and non-bin collation                                                                             |
| 2                      | <b>Columns</b> with binary collation and binary charset                                                                          |
| 3                      | <b>Columns</b> with bin collation (iso88591_bin, utf8_bin, euckr_bin)                                                            |
| 4                      | <b>SELECT values, Expression</b> With non-binary and non-bin collation                                                           |
| 5                      | <b>SELECT values, Expression</b> With binary collation and binary charset                                                        |

| Collation Coercibility | Arguments of the Expression(Operands)                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 6                      | <b>SELECT values, Expression</b> With bin collation (iso88591_bin, utf8_bin, euckr_bin)                                            |
| 7                      | <b>Special functions</b> ( <code>SYSTEM_USER()</code> , <code>DATABASE()</code> , <code>SCHEMA()</code> , <code>VERSION()</code> ) |
| 8                      | <b>Constants(string literals)</b> With non-binary and non-bin collation                                                            |
| 9                      | <b>Constants(string literals)</b> With binary collation and binary charset                                                         |
| 10                     | <b>Constants(string literals)</b> With bin collation (iso88591_bin, utf8_bin, euckr_bin)                                           |
| 11                     | host variables, session variables                                                                                                  |

#### Note

In 9.x versions, the binary collation was not available. The iso85891\_bin collation had the role of existing binary collation. Since version 10.0, the coercibility of columns with iso88591\_bin was demoted from 2 to 3, that of expressions with iso88591\_bin from 5 to 6, and of constants with iso88591\_bin from 9 to 10.

Regarding an expression which has arguments with only host variables, (e.g. UPPER(?) as the below) this coercibility can be determined on the execution step. That is, the coercibility like this expression cannot be determined on the parsing step; therefore, COERCIBILITY function returns -1.

```
SET NAMES utf8
PREPARE st FROM 'SELECT COLLATION(UPPER(?)) col1,
COERCIBILITY(UPPER(?)) col2';
EXECUTE st USING 'a', 'a';
```

| col1       | col2 |
|------------|------|
| =====      |      |
| 'utf8_bin' | -1   |

For expressions having all arguments with coercibility 11 and with different collations, the common collation is resolved at run-time (this is an exception from the coercibility value-based rule for inference which would require to raise an error).

```
PREPARE st1 FROM 'SELECT INSERT(?,2,2,?)';
EXECUTE st1 USING _utf8'abcd', _binary'ef';
```

```
insert( ?:0 , 2, 2,  ?:1 )
=====
'aefd'
```

The following shows converting two parameters with different collation to one collation.

#### • Converting into the Wanted Collation

The **SELECT** statement, failing to execute in the above example, is successfully executed by specifying a collation on one column by using the **CAST** operator as shown in the following query; then the two operands have the same collation.

```
SELECT s1, s2 FROM t WHERE s1 > CAST (s2 AS STRING COLLATE
utf8_en_cs);
```

Also, by **CAST** s2 to bin collation, the collation coercibility of CAST (6) is higher than coercibility of s1 (1).

```
SELECT s1, s2 FROM t WHERE s1 > CAST (s2 AS STRING COLLATE
utf8_bin);
```

In the following query, the second operand “CAST (s2 AS STRING COLLATE utf8\_tr\_cs)” is a sub-expression. The sub-expression has higher coercibility than the column (s1) so “CAST (s2 AS STRING COLLATE utf8\_tr\_cs)” is converted to the collation of s1.

```
SELECT s1, s2 FROM t WHERE s1 > CAST (s2 AS STRING COLLATE
utf8_tr_cs);
```

Any expression has higher coercibility than any column. So “CONCAT (s2,)” is converted to the collation of s1 in the following query and the query is successfully performed.

```
SELECT s1, s2 FROM t WHERE s1 > CONCAT (s2, '');
```

#### · Converting Collation of Constant and Column

In the following case, comparison is made by using the collation of s1.

```
SELECT s1, s2 FROM t WHERE s1 > 'abc';
```

#### · When a Column is Created with Bin Collation

```
CREATE TABLE t (  
    s1 STRING COLLATE utf8_en_cs,  
    s2 STRING COLLATE utf8_bin  
);  
SELECT s1, s2 FROM t WHERE s1 > s2;
```

In this case, s2 column's coercibility is 6(bin collation) and s2 can be “fully convertible” to the collation of s1. utf8\_en\_cs is used.

```
CREATE TABLE t (  
    s1 STRING COLLATE utf8_en_cs,  
    s2 STRING COLLATE iso88591_bin  
);  
SELECT s1, s2 FROM t WHERE s1 > s2;
```

In this case, utf8\_en\_cs is used as collation, too. However, some overhead occurs to convert the charset to UTF-8 since s2 is the ISO charset.

In the following query, the charset is not converted (UTF-8 byte data in s2 is easily reinterpreted to the ISO-8859-1 charset) but character comparison is made by using the iso88591\_en\_cs collation.

```
CREATE TABLE t (  
    s1 STRING COLLATE iso88591_en_cs,  
    s2 STRING COLLATE utf8_bin  
);  
SELECT s1, s2 FROM t WHERE s1 > s2;
```

#### · Converting Collation of Sub-Expression and Column

```
CREATE TABLE t (  
    s1 STRING COLLATE utf8_en_cs,  
    s2 STRING COLLATE utf8_tr_cs
```

```
);
SELECT s1, s2 FROM t WHERE s1 > s2 + 'abc';
```

In this case, the second operand is the expression, so the collation of s1 is used.

In the following example, an error occurs. An error occurs because '+' operation is tried for s2 and s3 where the collation is different.

```
CREATE TABLE t (
  s1 STRING COLLATE utf8_en_cs,
  s2 STRING COLLATE utf8_tr_cs,
  s3 STRING COLLATE utf8_en_ci
);

SELECT s1, s2 FROM t WHERE s1 > s2 + s3;
```

```
ERROR: '+' requires arguments with compatible collations.
```

In the following example, the collation of s2 and s3 is utf8\_tr\_cs. Therefore, the collation of '+' expression is utf8\_tr\_cs, too. Expressions have higher coercibility than columns. Therefore, comparison operation is made by using the utf8\_en\_cs collation.

```
CREATE TABLE t (
  s1 STRING COLLATE utf8_en_cs,
  s2 STRING COLLATE utf8_tr_cs,
  s3 STRING COLLATE utf8_tr_cs
);

SELECT s1, s2 FROM t WHERE s1 > s2 + s3;
```

#### • Converting Collation of Number, Date

Number or date constant which is convertible into string during operation always coercible into the other string's collation.

#### • Converting Collation of Session Variable and/or Host Variable

When comparing the two operands of which collation coercibility level is 11(session variable, host variable) and charset is the same, one of their collation is changed as non-bin collation.

```
SET NAMES utf8;
SET @v1='a';
PREPARE stmt FROM 'SELECT COERCIBILITY(?), COERCIBILITY(@v1),
COLLATION(?), COLLATION(@v1), ? = @v1';
```

```
SET NAMES utf8 COLLATE utf8_en_ci;
EXECUTE stmt USING 'A', 'A', 'A';
```

When comparing @v1 and 'A', @v1's collation will be changed as utf8\_en\_ci, non-bin collation; therefore, @v1's value and 'A' will be the same and the result of "? = @v1" will be 1 as below.

```
coercibility( ?:0 )   coercibility(@v1)   collation( ?:1 )
collation(@v1)       ?:2 =@v1
=====
=====
'utf8_bin'           11                   11  'utf8_en_ci'
                        1
```

```
SET NAMES utf8 COLLATE utf8_en_cs;
EXECUTE stmt USING 'A', 'A', 'A';
```

When comparing @v1 and 'A', @v1's collation will be changed as utf8\_en\_cs, non-bin collation; therefore, @v1's value and 'A' will be different and "? = @v1"s result will be 0 as below.

```
coercibility( ?:0 )   coercibility(@v1)   collation( ?:1 )
collation(@v1)       ?:2 =@v1
=====
=====
'utf8_bin'           11                   11  'utf8_en_cs'
                        0
```

However, if collations of @v1 and 'A' are different as below and the two collations are different, an error occurs.

```
DEALLOCATE PREPARE stmt;
SET NAMES utf8 COLLATE utf8_en_ci;
SET @v1='a';
PREPARE stmt FROM 'SELECT COERCIBILITY(?), COERCIBILITY(@v1),
COLLATION(?), COLLATION(@v1), ? = @v1';
SET NAMES utf8 COLLATE utf8_en_cs;
EXECUTE stmt USING 'A', 'A', 'A';
```

```
ERROR: Context requires compatible collations.
```

## Charset and Collation of an ENUM type column

Charset and Collation of an ENUM type column follow the locale specified when creating DB.

For example, create the below table after creating DB with en\_US.iso88591.

```
CREATE TABLE tbl (e ENUM (_utf8'a', _utf8'b'));
```

a column 'e' of the above table has ISO88591 charset and iso88591\_bin collation even if the charset of the element is defined as UTF8. If the user want to apply the other charset or collation, it should be specified to the column of the table.

Below is an example to specify the collation about the column of the table.

```
CREATE TABLE t (e ENUM (_utf8'a', _utf8'b') COLLATE utf8_bin);  
CREATE TABLE t (e ENUM (_utf8'a', _utf8'b')) COLLATE utf8_bin;
```

## Charset and Collation of Tables

The charset and the collation can be specified after the table creation syntax.

```
CREATE TABLE table_name (<column_list>) [CHARSET charset_name]  
[COLLATE collation_name]
```

If the charset and the collation of a column are omitted, the charset and the collation of a table is used. If the charset and the collation of a table are omitted, the charset and the collation of a system is used.

The following shows how to specify the collation on the table.

```
CREATE TABLE tbl(  
    i1 INTEGER,  
    s STRING  
) CHARSET utf8 COLLATE utf8_en_cs;
```

If the charset of a column is specified and the collation of a table is specified, the collation of this column is specified as the default collation(<collation\_name>\_bin) about this column's charset.

```
CREATE TABLE tbl (col STRING CHARSET utf8) COLLATE utf8_en_ci;
```

On the above query, the collation of the column col becomes utf8\_bin, the default collation about this column.

```

csql> ;sc tbl

<Class Name>

tbl                                COLLATE utf8_en_ci

<Attributes>

col                                CHARACTER VARYING(1073741823) COLLATE utf8_bin

```

## Charset and Collation of String Literals

The charset and the collation of a string literal are determined based on the following priority.

1. **Charset Introducer** introducer or **COLLATE modifier** of string literal
2. The charset and the collation defined by the **SET NAMES Statement**
3. System charset and collation(Default collation by the locale specified when creating DB)

## SET NAMES Statement

The **SET NAMES** statement changes the default client charset and the collation. Therefore, all sentences in the client which has executed the statement have the specified charset and collation. The syntax is as follows.

```
SET NAMES [ charset_name ] [ COLLATE collation_name]
```

- *charset\_name*: Valid charset name is iso88591, utf8, euckr and binary.
- *collation\_name*: Collation setting can be omitted and all available collations can be set. The collation should be compatible with the charset; otherwise, an error occurs. To find the available collation names, look up the **db\_collation** catalog VIEW (see [Charset and Collation of Column](#)).

Specifying a collation with **SET NAMES** statement is the same as specifying a system parameter **intl\_collation**. Therefore, the following two statements are the same behavior.

```

SET NAMES utf8;
SET SYSTEM PARAMETERS 'intl_collation=utf8_bin';

```

The following example shows how to create the string literal with the default charset and collation.

```
SELECT 'a';
```

The following example shows how to create the string literal with the utf8 charset and utf8\_bin collation(the default collation is the bin collation of the charset)

```
SET NAMES utf8;  
SELECT 'a';
```

## Charset Introducer

In front of the constant string, the charset introducer and the **COLLATE** modifier can be positioned. The charset introducer is the charset name starting with a underscore (\_), coming before the constant string. The syntax to specify the **CHARSET** introducer and the **COLLATE** modifier for a string is as follows.

```
[charset_introducer]'constant-string' [ COLLATE collation_name ]
```

- *charset\_introducer*: a charset name starting with an underscore (\_), can be omitted. One of \_utf8, \_iso88591, \_euckr and \_binary can be entered.
- *constant-string*: a constant string value.
- *collation\_name*: the name of a collation, which can be used in the system, can be omitted.

The default charset and collation of the constant string is determined based on the current database connected (the **SET NAMES** statement executed last or the default value).

- When the string charset introducer is specified and the **COLLATE** modifier is omitted, the collation is:
  - if the charset introducer is the same as client charset (from a previous SET NAMES), then the client collation is applied.
  - if the charset introducer does not match the client charset, then the bin collation(one of euckr\_bin, iso88591\_bin and utf8\_bin) corresponding to charset introducer is applied.
- When the charset introducer is omitted and the **COLLATE** modifier is specified, the character is determined based on collation.

The following example shows how to specify the charset introducer and the **COLLATE** modifier.

```
SELECT 'cubrid';  
SELECT _utf8'cubrid';  
SELECT _utf8'cubrid' COLLATE utf8_en_cs;
```

The following example shows how to create the string literal with utf8 charset and utf8\_en\_cs collation. The **COLLATE** modifier of **SELECT** statement overrides the collation specified by **SET NAMES** syntax.

```
SET NAMES utf8 COLLATE utf8_en_ci;  
SELECT 'a' COLLATE utf8_en_cs;
```

## Charset and Collation of Expressions

The charset and collation of expression's result are inferred from charset and collation of arguments in the expression. Collation inference in CUBRID is based on coercibility. For more information, see [How to Determine Collation among Columns with Different Collation](#).

All string matching function(LIKE, REPLACE, INSTR, POSITION, LOCATE, SUBSTRING\_INDEX, FIND\_IN\_SET, etc) and comparison operators(<, >, =, etc) take collation into account.

## Charset and Collation of System Data

The system charset is taken from the locale specified when creating DB. The system collation is always the bin collation (< charset>\_bin) of system charset. CUBRID supports three charset(iso88591, euckr, utf8), and accordingly three system collations(iso88591\_bin, euckr\_bin, utf8\_bin).

## Impact of Charset Specified When Creating DB

The locale specified when creating DB affects the following.

- Character supported in identifiers and casing rules (called “alphabet”)
- Default locale for date - string conversion functions
- Default locale for number - string conversion functions
- Console conversion in CSQL

## Casing and identifiers

In CUBRID, identifiers are cases insensitive. Tables, columns, session variables, triggers, stored procedures are stored in lower case. Authentication identifiers (user and group names) are stored in upper case.

The ISO-8859-1 charset contains only 255 characters, so the primitives are able to use built-in data. Also the EUC-KR charset, from which only the ASCII compatible characters are considered for casing (and are handled in the code), is built-in.

The UTF-8 charset is a special case: There are built-in variants of UTF-8 locales (like en\_US.utf8, tr\_TR.utf8 and ko\_KR.utf8) and LDML locales.

The built-in variant implement only the characters specific to the locale (ASCII characters for en\_US.utf8 and ko\_KR.utf8, ASCII + Turkish glyphs [1] for tr\_TR.utf8). This means that while all UTF-8 characters encoded on maximum 4 bytes are still supported and accepted as identifiers, most of them are not handled as letters, and treated as any normal Unicode character by casing primitives. For instance, character “È” (Unicode codepoint 00C8) is allowed, but an identifier containing it will not be normalized to “è” (lower case).

```
CREATE TABLE ÈABC;
```

Therefore, after running above query, it will have a table name with “Èabc” into the system table, **\_db\_class**.

Using a LDML locale (built-in variants can also be overridden with a LDML variant), extends the supported Unicode characters up to codepoint FFFF. For instance, if the locale is set by es\_ES.utf8 when creating DB and the corresponding locale library is loaded, the previous statement will create a table with the name “èabc”.

As previously mentioned, a set of casing rules and supported characters (letters) forms an “alphabet” in CUBRID (this is actually a tag in LDML). Some locales, like tr\_TR and de\_DE have specific casing rules: - in Turkish: lower(‘İ’)=‘ı’ (dot-less lower i); upper(‘ı’) = ‘İ’ (capital I with dot). - in German: upper(‘ß’)=‘SS’ (two capital S letters).

Because of this, such locales have two sets of alphabets: one which applies to system data (identifiers) and one which applies to user data. The alphabet applying to user data include the special rules, while the system (identifiers) alphabet do not, thus making the system alphabets compatible between locales. This is required to avoid issues with identifiers (like in Turkish, where casing of the group name “public” results in errors -> “PUBLiC” != “PUBLIC”).

It also provides a compatibility between databases with different locales (should be able to export - import schema and data).

## String literal input and output

String literals data may be entered to CUBRID by various ways:

- API interface (CCI)
- language dependent interface - JDBC, Perl driver, etc.
- CSQL - command line from console or input file

When receiving character data through drivers, CUBRID cannot be aware of the charset of those strings. All text data contained between quotes (string literals) are handled by CUBRID as raw bytes; the charset meta-information must be provided by client. CUBRID provides a way for the client to instruct it about which type of encoding is using for its character data. This is done with the SET NAMES statement or with charset introducer.

## Text Conversion for CSQL

Text console conversion works in CSQL console interface. Most locales have associated character set (or codepage in Windows) which make it easy to write non-ASCII characters from console. For example in LDML for tr\_TR.utf8 locale, there is a line:

```
<consoleconversion type="ISO88599" windows_codepage="28599"  
linux_charset="iso88599,ISO_8859-9,ISO8859-9,ISO-8859-9">
```

If the user set its console in one of the above settings (chcp 28599 in Windows, or export LANG=tr\_TR.iso88599 in Linux), CUBRID assumes all input is encoded in ISO-8859-9 charset, and converts all data to UTF-8. Also when printing results, CUBRID performs the reverse conversion (from UTF-8 to ISO-8859-9). In Linux, to prevent this transform, using UTF-8(ex: export LANG=tr\_TR.utf8) directly is recommended.

The setting is optional in the sense that the XML tag is not required in LDML locale file. For example, the locale km\_KH.utf8 does not have an associated codepage.

## Example for configuring French language and inputting French characters

Enable fr\_FR in cubrid\_locales.txt, compile the locales(see [Locale Setting](#)) and set fr\_FR.utf8 when you create DB.

In Linux:

- Set console to receive UTF-8; set LANG=fr\_FR.utf8 or en\_US.utf8 (any locale with UTF-8). This setting will allow to input any UTF-8 character (not only French specific)
- or, set console to receive ISO-8859-15; set LANG=fr\_FR.iso885915; in LDML <consoleconversion> tag, set linux\_charset="iso885915". This will receive only ISO-8859-15 characters which will be converted by CSQL to UTF-8 encoding.

In Windows:

- Set windows codepage to 28605 (chcp 28605 in a command prompt); in LDML <consoleconversion> tag, set windows\_codepage="28605". Codepage 28605 is the corresponding for ISO-8859-15 charset.

### Example for configuring Romanian and inputting Romanian characters

Enable ro\_RO in cubrid\_locales.txt, compile the locales(see [Locale Setting](#)) and set ro\_RO.utf8 when you create DB.

In Linux:

- Set console to receive UTF-8; set LANG=ro\_RO.utf8 or en\_US.utf8 (any locale with UTF-8). This setting will allow to input any UTF-8 character (not only Romanian specific)
- or, set console to receive ISO-8859-2; set LANG=ro\_RO.iso88592; in LDML <consoleconversion> tag, set linux\_charset="iso88592". This will receive only ISO-8859-15 characters which will be converted by CSQL to UTF-8 encoding.

In Windows:

- Set windows codepage to 1250 (chcp 1250 in a command prompt); in LDML <consoleconversion> tag, set windows\_codepage="1250". Codepage 1250 is the corresponding for ISO-8859-2 charset. Codepage 1250 contains characters specific to some Central and Eastern European languages, including Romanian. Please note that characters outside codepage 1250 will not be properly displayed.

To use special characters which exist on Romanian alphabet(e.g. "S" and "T" with cedilla below), the Romanian legacy keyboard setting of "Control Panel" on Windows is required.

- ISO8859-2 contains some characters which codepage 1250 does not have, so you cannot input or output all characters of ISO8859-2 with CSQL.

At input, the console conversion process takes all input (including statements) and performs the conversion (only if it is required - if it contains characters that needs conversion). At output (printing results, error messages), CSQL is more selective and does not convert all texts. For instance, printing of numeric values is not filtered through console conversion (since number text contains only ASCII characters).

### Unicode Normalization

Glyphs [1] can be written in various forms using Unicode characters/codepoints. Most known are the decomposed and composed forms. For instance, the glyph 'Ä' is written in composed form with a single codepoint: 00C4, in UTF-8 these has two bytes: C3 84. In (fully) decomposed form, it written with two codepoints: 0041 ('A') and 0308 (COMBINING DIAERESIS), and in UTF-8 is encode

using 3 bytes: 41 CC 88. Most text editors are able to handle both forms, so both encodings will appear as the same glyph: 'Ä'. Internally, CUBRID “knows” to work only with “fully composed” text.

For clients working with “fully decomposed” text, CUBRID can be configured to convert such text to “fully composed” and serve them back as “fully decomposed”. Normalization is not a locale specific feature, it does not depend on locale.

**unicode\_input\_normalization** system parameter controls the composition at system level. For more details, see [unicode\\_input\\_normalization](#).

The main use case is with both enabled (**unicode\_input\_normalization**, **unicode\_output\_normalization**): this ensures that a string from a client knowing only decomposed Unicode is still properly handled by CUBRID. A second use case is with **unicode\_input\_normalization** = yes and **unicode\_output\_normalization** = no, for a client able to handle both types of Unicode writing.

## Contraction and Expansion of Collation

CUBRID supports contraction and expansion for collation. Contraction and expansion are available for UTF-8 charset collation. You can see the contraction and expansion of collation in the collation setting in the LDML file. Using contraction and expansion affects the size of locale data (shared library) and server performance.

### Contraction

A contraction is a sequence consisting of two or more codepoints, considered a single letter in sorting. For example, in the traditional Spanish sorting order, “ch” is considered a single letter. All words that begin with “ch” sort after all other words beginning with “c”, but before words starting with “d”. Other examples of contractions are “ch” in Czech, which sorts after “h”, and “lj” and “nj” in Croatian and Latin Serbian, which sort after “l” and “n” respectively. See <https://unicode-org.github.io/icu/userguide/collation/concepts> for additional information. There are also some contractions defined in <http://www.unicode.org/Public/UCA/latest/allkeys.txt> DUCET.

Contractions are supported in both collation variants: with expansions and without expansions. Contractions support requires changes in a significant number of key areas. It also involves storing a contraction table inside the collation data. The handling of contractions is controlled by LDML parameters **DUCETContractions="ignore/use"** **TailoringContractions="ignore/use"** in <settings> tag of collation definition. The first one controls if contractions in DUCET file are loaded into collation, the second one controls if contractions defined by rules in LDML are ignore or not (easier way then adding-deleting all rules introducing contractions).

## Expansion

Expansions refer to codepoints which have more than one collation element. Enabling expansions in CUBRID radically changes the collation's behavior as described below. The `CUBRIDExpansions="use"` parameter controls the this behavior.

### Collation without Expansion

In a collation without expansions, each codepoint is treated independently. Based on the strength of the collation, the alphabet may or may not be fully sorted. A collation algorithm will sort the codepoints by comparing the weights in a set of levels, and then will generate a single value, representing the weight of the codepoint. String comparison will be rather straight-forward. Comparing two strings in an expansion-free collation means comparing codepoint by codepoint using the computed weight values.

### Collation with Expansion

In a collation with expansions, some composed characters (codepoints) are to be interpreted as an ordered list of other characters (codepoints). For example, 'æ' might require to be interpreted the same way as 'ae', or 'ä' as "ae" or "aa". In DUCET, the collation element list of 'æ' will be the concatenation of collation element lists of both 'a' and 'e', in this order. Deciding a particular order for the codepoints is no longer possible, and neither is computing new weight values for each character/codepoint.

In a collation with expansions, string comparison is done by concatenating the collation elements for the codepoints/contractions in two lists (for the two strings) and then comparing the weights in those lists for each level.

### Example 1

The purpose of these examples is to show that under different collation settings (with or without expansion support), string comparison might yield different results.

Here there are the lines from DUCET which correspond to a subset of codepoints to be used for comparisons in the examples below.

```
0041 ; [.15A3.0020.0008.0041] # LATIN CAPITAL LETTER A
0052 ; [.1770.0020.0008.0052] # LATIN CAPITAL LETTER R
0061 ; [.15A3.0020.0002.0061] # LATIN SMALL LETTER A
0072 ; [.1770.0020.0002.0072] # LATIN SMALL LETTER R
00C4 ; [.15A3.0020.0008.0041][.0000.0047.0002.0308] #
LATIN CAPITAL LETTER A WITH DIAERESIS;
00E4 ; [.15A3.0020.0002.0061][.0000.0047.0002.0308] #
LATIN SMALL LETTER A WITH DIAERESIS;
```

Three types of settings for the collation will be illustrated:

- Primary strength, no casing (level 1 only)
- Secondary strength, no casing (levels 1 and 2)
- Tertiary strength, uppercase first (levels 1, 2 and 3)

From now on, sorting of the strings “Ar” and “Är” will be attempted.

### Collation without Expansions Support

When expansions are disabled, each codepoint is reassigning a new single valued weight. Based on the algorithms described above the weights for A, Ä, R and their lowercase correspondents, the order of the codepoints for these characters, for each collation settings example above, will be as follows.

- Primary strength:  $A = \text{Ä} < R = r$
- Secondary strength:  $A < \text{Ä} < R = r$
- Tertiary strength:  $A < \text{Ä} < R < r$

The sort order for the chosen strings is easy to decide, since there are computed weights for each codepoint.

- Primary strength: “Ar” = “Är”
- Secondary strength: “Ar” < “Är”
- Tertiary strength: “Ar” < “Är”

### Collation with Expansions

The sorting order is changed for collation with expansion. Based on DUCET, the concatenated lists of collation elements for the strings from our samples are provided below:

```
Ar [ .15A3.0020.0008.0041][.1770.0020.0002.0072]
Är [ .15A3.0020.0008.0041][.0000.0047.0002.0308][.
1770.0020.0002.0072]
```

It is rather obvious that on the first pass, for level 1 weights, 0x15A3 will be compared with 0x15A3. In the second iteration, the 0x0000 weight will be skipped, and 0x1770 will be compared with 0x1770. Since the strings are declared identical so far, the comparison will continue on the level 2 weights, first comparing 0x0020 with 0x0020, then 0x0020 with 0x0047,

yielding “Ar” < “Är”. The example above was meant to show how strings comparison is done when using a collation with expansion support.

Let us change the collation settings, and show how one may obtain a different order for the same strings when using a collation for German, where “Ä” is supposed to be interpreted as the character group “AE”. The codepoints and collation elements of the characters involved in this example are as follows.

```
0041 ; [.15A3.0020.0008.0041] # LATIN CAPITAL
LETTER A
0045 ; [.15FF.0020.0008.0045] # LATIN CAPITAL
LETTER E
0072 ; [.1770.0020.0002.0072] # LATIN SMALL
LETTER R
00C4 ; [.15A3.0020.0008.0041][.15FF.
0020.0008.0045] # LATIN CAPITAL LETTER A WITH
DIAERESIS; EXPANSION
```

When comparing the strings “Är” and “Ar”, the algorithm for string comparison when using a collation with expansion support will involve comparing the simulated concatenation of collation element lists for the characters in the two strings.

```
Ar [.15A3.0020.0008.0041][.1770.0020.0002.0072]
Är [.15A3.0020.0008.0041][.15FF.0020.0008.0045][.
1770.0020.0002.0072]
```

On the first pass, when comparing level 1 weights, 0x15A3 will be compared with 0x15A3, then 0x1770 with 0x15FF, where a difference is found. This comparison yields “Ar” > “Är”, a result completely different than the one for the previous example.

## Example 2

In Canadian French sorting by the collation with expansion, accent is compared from end of string towards the beginning.

- Normal Accent Ordering: cote < coté < côte < côté
- Backward Accent Ordering: cote < côte < coté < côté

## Operations Requiring Collation and Charset

### Charset

Charset information is required for functions which use character primitives. There are exceptions: `OCTET_LENGTH()` and `BIT_LENGTH()` do not require charset internally to return the length in bytes and bits. However, for the same glyph (character symbol) stored in different charset, they return different values:

```
CREATE TABLE t (s_iso STRING CHARSET iso88591, s_utf8 STRING CHARSET utf8);
SET NAMES iso88591;
INSERT INTO t VALUES ('È', 'È');

-- the first returns 1, while the second does 2
SELECT OCTET_LENGTH(s_iso), OCTET_LENGTH(s_utf8) FROM t;
```

The previous example should be run from console (or a client) with ISO-8859-1 charset.

### Collation

Collation is required in functions and operators which involves a comparison between two strings or matching two strings. These includes functions like: `STRCMP()`, `POSITION()`, LIKE condition, and operators (`<=`, `>=`, etc.). Also clauses like ORDER BY, GROUP BY and aggregates(`MIN()`, `MAX()`, `GROUP_CONCAT()`) use collation.

Also, collation is considered in `UPPER()` and `LOWER()` functions, in the following manner:

- Each collation has a default (parent) locale.
- UPPER and LOWER functions are performed using the user alphabet of the default locale of the collation.

For most collations, the default locale is obvious (is embedded in the name):

- utf8\_tr\_cs → tr\_TR.utf8
- iso88591\_en\_ci → en\_US (ISO-8859-1 charset)

The bin collations have the following default locales:

- iso88591\_bin → en\_US (ISO-8859-1 charset)
- utf8\_bin (en\_US.utf8 - built-in locale - and handles ASCII characters only)
- euckr\_bin (ko\_KR.euckr - built-in locale - and handles ASCII characters only)

There are some generic collations available in LDML. These collations have as default locale, the locale in which they are first found. The order of loading is the locales order from **\$CUBRID/conf/cubrid\_locales.txt**. Assuming the default order (alphabetical), the default locale for all generic LDML collations is de\_DE (German).

## Charset conversion

For the three charsets supported by CUBRID the conversion rules are:

- General rules is that character transcoding occurs (representation of bytes is changed to the destination charset) - precision is kept, while byte size may change (for variable character data). When changing charset of a column with fixed precision (ALTER..CHANGE), the size in bytes always changes (size = precision x charset multiplier).
- Exceptions are: utf8 and euckr to iso88591 - the precision is kept and data can be truncated.

The following is an example that you run queries by changing the charset as utf8 in the database that the locale specified when creating DB is en\_US(iso88591).

```
SET NAMES utf8;  
CREATE TABLE t1(col1 CHAR(1));  
INSERT INTO t1 VALUES ('Ç');
```

When you run above queries, the data of col1 is truncated because 'Ç' is two bytes character and col1's size is one byte. The charset of database is iso88591, and the charset of input data is utf8; it converts utf8 to iso88591.

## Collation settings impacting CUBRID features

### LIKE Conditional Optimization

The **LIKE** conditional expression compares patterns between string data, and returns TRUE if a string whose pattern matches the search word is found.

As already proven above, when using a "collation without expansion support", each codepoint will receive a single integer value, representing its weight in the comparison process. This weight value is computed based on collation settings (strength, casing etc.). Due to the fact that characters can always be regarded as single entities, trying to match a string with a pattern using the **LIKE** predicate is equivalent to checking if the string can be found in a certain range of strings. For example in order to process a predicate such as "s LIKE 'abc%' ", CUBRID will first rewrite it as a range restriction for the string "s". "s LIKE 'abc%'" means that "s" must start with the string "abc". In terms of string comparison, this is equivalent, in expansion-free collations, with "s"

being greater than “abc”, but smaller than its successor (using the English alphabet, the successor of “abc” would be “abd”).

```
s LIKE 'abc%' → s ≥ 'abc' AND s < 'abd' (if using strictly the English alphabet)
```

This way, the actual interpretation of **LIKE** is replaced with simple comparisons, but “Collations with expansion support” behave differently.

To compare strings when using such a collation means comparing the concatenated lists of collation elements for each codepoint or expansion, level by level. For more information about comparing strings on the collation with expansion, see [Expansion](#).

If the **LIKE** predicate rewrite method is kept the same as in a collation with no expansion support as above example, the comparison result can be wrong. To ensure the right query result, the **LIKE** predicate rewrite method is ran differently as the below example. That is, the **LIKE** predicate is added as a filter to exclude the wrong data which can be added in a collation with expansion.

```
s LIKE 'abc%' → s ≥ 'abc' AND s < 'abd' and s LIKE 'abc%' (if using strictly the English alphabet)
```

## Index Covering

Covering index scan is query optimization, in which if all values in query can be computed using only the values found in the index, without requiring additional row lookup in heap file. For more information, see [Covering Index](#).

In the collation without casing, for two strings values, ‘abc’ and ‘ABC’, only one value is stored in the index (this is either ‘abc’ or ‘ABC’ depending which one was inserted first). As a result, the incorrect result may happen when at least two different strings produce the same sort key in a given collation. For this reason, for all UTF-8 collations with strength level less than 4 (quaternary), the index covering query optimization is disabled.

This is controlled by strength=“tertiary/quaternary” in <strength> tag of collation definition in LDML. It should be considered to set this level as maximum strength, because the quaternary strength level requires not only more memory space and bigger size of the shared library file, but also string-comparison time.

For more information about collations, see [Collation](#).

## Summary of CUBRID Features for Each Collation

| <b>Collation</b>  | <b>LIKE condition kept after rewrite to range</b> | <b>Allows index covering</b> |
|-------------------|---------------------------------------------------|------------------------------|
| iso88591_bin      | No                                                | Yes                          |
| iso88591_en_cs    | No                                                | Yes                          |
| iso88591_en_ci    | Yes                                               | No                           |
| utf8_bin          | No                                                | Yes                          |
| euckr_bin         | No                                                | Yes                          |
| utf8_en_cs        | No                                                | Yes                          |
| utf8_en_ci        | Yes                                               | No                           |
| utf8_tr_cs        | No                                                | Yes                          |
| utf8_ko_cs        | No                                                | Yes                          |
| utf8_gen          | No                                                | Yes                          |
| utf8_gen_ai_ci    | Yes                                               | No                           |
| utf8_gen_ci       | Yes                                               | No                           |
| utf8_de_exp_ai_ci | Yes                                               | No                           |
| utf8_de_exp       | Yes                                               | No                           |

| <b>Collation</b> | <b>LIKE condition kept after<br/>rewrite to range</b> | <b>Allows index covering</b> |
|------------------|-------------------------------------------------------|------------------------------|
| utf8_ro_cs       | No                                                    | Yes                          |
| utf8_es_cs       | No                                                    | Yes                          |
| utf8_fr_exp_ab   | Yes                                                   | No                           |
| utf8_ja_exp      | Yes                                                   | No                           |
| utf8_ja_exp_cbm  | Yes                                                   | No                           |
| utf8_km_exp      | Yes                                                   | No                           |
| utf8_ko_cs_uca   | No                                                    | Yes                          |
| utf8_tr_cs_uca   | No                                                    | Yes                          |
| utf8_vi_cs       | No                                                    | Yes                          |
| binary           | No                                                    | Yes                          |

## Viewing Collation Information

To view the collation information, use `CHARSET()`, `COLLATION()` and `COERCIBILITY()` functions.

The information of the database collation can be shown on db\_collation system view or **SHOW COLLATION**.

## Using i18n characters with JDBC

CUBRID JDBC stores string type values received from server using String and CUBRIDBinaryString objects. String objects uses UTF-16 internally to store each character. It should be used to store any string DB value except those having binary charset. CUBRIDBinaryString uses byte array and

should be used to store database string values of binary charset. The data buffer of each string value received from server is accompanied by the charset of the value from server. The charset is either the charset of column or expression's result or system charset for any other string without correspondent in database.

#### Note

In previous versions, the connection charset was used to instantiate JDBC String objects from database values.

Create table with one column having UTF-8 charset and the other of binary charset:

```
CREATE TABLE t1(col1 VARCHAR(10) CHARSET utf8, col2 VARCHAR(10)
CHARSET binary);
```

Insert one row (the second column has random value bytes):

```
Connection conn = getConn(null);
PreparedStatement st = conn.prepareStatement("insert into t1
values( ?, ? )");
byte[] b = new byte[] {(byte)161, (byte)224};
CUBRIDBinaryString cbs = new CUBRIDBinaryString(b);
String utf8_str = new String("abc");
st.setObject(1, utf8_str);
st.setObject(2, cbs);
st.executeUpdate();
```

Query the table and show contents (for binary string - we display a hex dump, for other charsets - the String value):

```
ResultSet rs = null;
Statement stmt = null;
rs = stmt.executeQuery("select col1, col2 from t1;");
ResultSetMetaData rsmd = null;
rsmd = rs.getMetaData();
int numberOfColumn = rsmd.getColumnCount();
while (rs.next()) {
    for (int j = 1; j <= numberOfColumn; j++) {
        String columnTypeName = rsmd.getColumnTypeName(j);
        int columnType = rsmd.getColumnType(j);
        if (((CUBRIDResultSetMetaData)
rsmd).getColumnCharset(j).equals("BINARY")) {
            // database string with binary charset
            Object res;
```

```

byte[] byte_array = ((CUBRIDBinaryString)
res).getBytes();
res = rs.getObject(j);
System.out.println(res.toString());
} else {
// database string with any other charset
String res;
res = rs.getString(j);
System.out.print(res);
}
}
}

```

## Timezone Setting

Timezone can be set by system parameters; a **timezone** parameter which is set on a session, and a **server\_timezone** parameter which is set on a database server. For details, see [Timezone Parameter](#).

A **timezone** parameter is a parameter about a session. This setting value can be kept by session unit.

```
SET SYSTEM PARAMETERS 'timezone=Asia/Seoul';
```

If this value is not set, it follows **server\_timezone**'s setting as default.

A **server\_timezone** parameter is a parameter about a database server.

```
SET SYSTEM PARAMETERS 'server_timezone=Asia/Seoul';
```

If this value is not set, it follows OS's setting.

To use timezone information, timezone type should be used. For details, see [Date/Time Types with Timezone](#).

When timezone is set by a region name, it requires a separate timezone library. To use an updated library which has a changed timezone information, not an installed timezone information, timezone library should be compiled after timezone information is changed.

The following is an example to compile a timezone library after updating a timezone information through IANA (<http://www.iana.org/time-zones>).

For details, see the following description.

## Compiling Timezone Library

To use a timezone by specifying a timezone region name, timezone library is required. This is provided as default when CUBRID is installed. By the way, to update a timezone region information as a latest one, timezone library should be compiled after updating a recent code which can be downloaded in IANA (<http://www.iana.org/time-zones>).

The following is a process to update timezone library as a recent one.

At first, stop cubrid service and operate the following process.

### Windows

1. Download the recent data from <http://www.iana.org/time-zones>.

Download the linked file in “Latest version”’s “Time Zone Data”.

2. Decompress the compressed file to **%CUBRID%/timezones/tzdata** directory.
3. Run **%CUBRID%/bin/make\_tz.bat**.

**libcubrid\_timezones.dll** is created at the **%CUBRID%/lib** directory.

```
make_tz.bat
```

#### Note

To run **make\_locale** script in Windows, one of Visual C++ 2005, 2008 or 2010 should be installed.

### Linux

1. Download the recent data from <http://www.iana.org/time-zones>.

Download the linked file in “Latest version”’s “Time Zone Data”.

2. Decompress the compressed file to **\$CUBRID/timezones/tzdata** directory.
3. Run **make\_tz.sh**.

**libcubrid\_timezones.so** is created at the **\$CUBRID/lib** directory.

```
make_tz.sh
```

## Timezone library and database compatibility

The timezone library built by CUBRID includes an MD5 checksum of the timezone data it contains. This hash is stored in all databases which are created with that library, into column **timezone\_checksum** of **db\_root** system table. If timezone library is changed (recompiled with newer timezone data) and the checksum changes, the CUBRID server, nor any other CUBRID tool cannot be started with existing databases. To avoid such incompatibility, one option is to use **extend** argument of the **make\_tz** tool. When this option is provided, the **timezone\_checksum** value of database is also changed with the new MD5 checksum of the new timezone library. The extend feature should be used when you decide to use a different version of timezone library from the IANA site. It does two things:

- It generates a new library by merging the old timezone data with the new timezone data. After the merge, all the timezone regions that aren't present in the new timezone database are kept in order to ensure backward compatibility with the data in the database tables.
- The second thing that it does is to update the timezone data in the tables in the situation when backward compatibility could not be ensured in the first phase when the new timezone library was generated. This situation can occur when an offset rule or a daylight saving rule changes.

When you run **make\_tz** with the extend option all the databases in your database directory file (**databases.txt**) are updated together with the MD5 checksum. There are some corner cases:

- There is the situation when multiple users share the same **CUBRID** installation and an extend is done by one of them. If that user doesn't have access rights on the files that contain the databases of the other users, those databases will not be updated. After that, if a different user for whom the update wasn't made will try to do an extend on his or her databases, he or she will not be able to do this because the checksum of the library will be different from the one in his or her databases.
- Also, if the **CUBRID\_DATABASES** environment variable has a different value for some users, they will have different **databases.txt** files. In this situation, currently, the update of all the databases at once will not be possible.

There would be two solutions for this with the current implementation:

- Each user grants access to the folders that contain his or her databases and also the **CUBRID\_DATABASES** variable must have the same value.
- If this is not possible, then we can do the following for each user except the last one:
  - Backup the current timezone library and the **databases.txt** file
  - Delete from the **databases.txt** file all the databases except for the ones of the current user
  - Run the extend

- Restore the **databases.txt** file and the timezone library

For the last user the single difference is that only the **databases.txt** file should be backed up and restored.

In Linux:

```
make_tz.sh -g extend
```

In Windows:

```
make_tz.bat /extend
```

### Usage of timezone data types with JDBC

JDBC CUBRID driver is completely dependent on CUBRID server for timezone information. Although, Java and CUBRID uses the same primary source of information for timezone (IANA), the names of regions and timezone information should be considered as incompatible.

All CUBRID data types having timezone are mapped to **CUBRIDTimestamptz** Java objects.

Using JDBC to insert value with timezone:

```
String datetime = "2000-01-01 01:02:03.123";
String timezone = "Europe/Kiev";
CUBRIDTimestamptz dt_tz =
CUBRIDTimestamptz.valueOf(datetime, false, timezone);
PreparedStatement pstmt = conn.prepareStatement("insert
into t values(?)");
pstmt.setObject(1, ts);
pstmt.executeUpdate();
```

Using JDBC to retrieve value with timezone:

```
String sql = "select * from tz";
Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery(sql);
CUBRIDTimestamptz object1 = (CUBRIDTimestamptz)
rs.getObject(1);
System.out.println("object: " + object1.toString());
```

Internally, CUBRID JDBC stores the date/time parts of **CUBRIDTimestamptz** object into a 'long' value (inheritant through Date object) which holds the number of milliseconds elapsed since 1st January 1970 (Unix epoch). The internal encoding is performed in UTC time reference, which is

different from Timestamp objects which uses local timezone. For this reason, a **CUBRIDTimestamptz** object created with the same timezone as Java local timezone will not hold the same internal epoch value. In order to provide the Unix epoch, the **getUnixTime()** method may be used:

```
String datetime = "2000-01-01 01:02:03.123";
String timezone = "Asia/Seoul";
CUBRIDTimestamptz dt_tz =
CUBRIDTimestamptz.valueOf(datetime, false, timezone);
System.out.println("dt_tz.getTime: " + dt_tz.getTime());
System.out.println("dt_tz.getUnixTime: " +
dt_tz.getUnixTime ());
```

## Configuration Guide for Characters

Database designers should take into account character data properties when designing the database structure. The following is the summarized guide when configuring aspects related to CUBRID character data.

### Locale

- By default, en\_US gives best performance. If you have a plan to use only English, this is recommended.
- Using UTF-8 locale will increase storage requirement of fixed char(CHAR) by 4 times; using EUC-KR increases storage 3 times.
- If user string literals have different charset and collation from system, query strings will grow as the string literals are decorated with them.
- If localized (non-ASCII) characters will be used for identifiers, then use an .utf8 locale
- Once established the UTF-8 charset for DB, it is best to use a LDML locale (this ensures that identifier names containing most Unicode characters are correctly cased) than a system locale.
- Setting a locale affects also conversion functions(intl\_date\_lang, intl\_number\_lang).
- When you set the locale during creating DB, there should be no concern on charset and collation of string-literals or user tables columns; all of them can be changed at run-time (with **CAST()** in queries) or ALTER .. CHANGE for a permanent change.

## CHAR and VARCHAR

- Generally, use VARCHAR if there are large variations in actual number of characters in user data.
- CHAR type is fixed length type. Therefore, Even if you store only English character in CHAR type, it requires 4 bytes storage in UTF-8 and 3 bytes in EUC-KR.
- The precision of columns refers to the number of characters (glyphs).
- After choosing precision, charset and collation should be set according to most used scenarios.

## Choosing Charset

- Even if your text contains non-ASCII character, use utf8 or euckr charsets only if application requires character counting, inserting, replacing.
- For CHAR data, the main concern should be storage requirement (4x or utf8, 3x for euckr).
- For both CHAR and VARCHAR data, there is some overhead when inserting/updating data: counting the precision (number of characters) of each instance is more consuming for non-ISO charsets.
- In queries, charset of expressions may be converted using `CAST()` operator.

## Choosing Collation

- If no collation dependent operations are performed (string searching, sorting, comparisons, casing), than choose bin collation for that charset or binary collation
- Collation may be easily overridden using `CAST()` operator, and `COLLATE modifier` (in 9.1 version) if charset is unchanged between original charset of expression and the new collation.
- Collation controls also the casing rules of strings
- Collations with expansions are slower, but are more flexible and they perform whole-word sorting

## Normalization

- If your client applications send text data to CUBRID in decomposed form, then configure **unicode\_input\_normalization** = yes, so that CUBRID re-composes it and handles it in composed form

- If your client “knows” to handle data only in decomposed form, then set **unicode\_output\_normalization** = yes, so that CUBRID always sends in decomposed form.
- If the client “knows” both forms, then leave **unicode\_output\_normalization** = no

## CAST vs COLLATE

- When building statements, the `CAST()` operator is more costly than `COLLATE modifier` (even more when charset conversion occurs).
- `COLLATE modifier` does not add an additional execution operator; using `COLLATE modifier` should enhance execution speed over using `CAST()` operator.
- `COLLATE modifier` can be used only when charset is not changed

## Remark

- Query plans printing: collation is not displayed in plans for results with late binding.
- Only the Unicode code-points in range 0000-FFFF (Basic Multilingual Plan) are normalized.
- Some locales use space character as separator for digit grouping (thousands, millions, ..). Space is allowed but not working properly in some cases of localized conversion from string to number.

### Note

- In 9.2 or lower version, user defined variable cannot be changed into the different collation from the system collation. For example, “set @v1='a' collate utf8\_en\_cs;” syntax cannot be executed when the system collation is iso88591.
- In 9.3 or higher version, the above constraint no more exists.

## Guide for Adding Locales and Collations

Most new locales and/or collations can be added by user simply by adding (or changing) a new (existing) LDML file. The LDML files format used by CUBRID are derived from generic Unicode Locale Data Markup Language (<http://www.unicode.org/reports/tr35/>). The tags and attributes which are specific only to CUBRID can be easily identified (they contain a “cubrid” into the naming).

The best approach to add a new locale is to copy existing LDML file and tweak various setting until desired results are obtained. The filename must be formatted like `cubrid_<language>.xml` and be placed in the folder **\$CUBRID/locales/data/ldml**. The `<language>` part should be a ASCII string (normally five characters) in IETF format ([https://en.wikipedia.org/wiki/BCP\\_47](https://en.wikipedia.org/wiki/BCP_47)). After creating the LDML file, the `<language>` part string must be added into CUBRID configuration file **\$CUBRID/conf/cubrid\_locales.txt**. Note that the order in this file is the order of generating (compiling) locale library and loading locales at start-up.

The **make\_locale** script must be used to compile the new added locale and add its data into the CUBRID locales library (locale in **\$CUBRID/lib/**).

The LDML file is expected in UTF-8 encoding, and it is not possible to add more than one locale into the same LDML file.

Adding a new locale in LDML file requires:

- to specify calendar information (CUBRID date formats, name of months and week days in various forms, names for AM/PM day periods). CUBRID supports only Gregorian calendar (generic LDML specifies other calendar types which are not supported by CUBRID).
- to specify number settings (digit grouping symbols)
- providing an alphabet (set of rules for how letters are upper-cased and lower-cased)
  - optionally, some collations can be added
  - also optionally, console conversion rules for Windows CSQL application can be defined

## LDML Calendar Information

- The first part consists in providing default CUBRID formats for **DATE**, **DATETIME**, **TIME**, **TIMESTAMP**, **DATETIME WITH TIME ZONE** and **TIMESTAMP WITH TIME ZONE** data type conversion to/from string. This formats are used by functions `TO_DATE()`, `TO_TIME()`, `TO_DATETIME()`, `TO_TIMESTAMP()`, `TO_CHAR()`, `TO_DATETIME_TZ()`, `TO_TIMESTAMP_TZ()`. The formats elements allowed depend on data type and are the ones used for `TO_CHAR()` function (**Date/Time Format 1**). Only ASCII characters are allowed in the format strings. The allowed size are 30 bytes (characters) for **DATE** and **TIME** formats, 48 characters for **DATETIME** and **TIMESTAMP** formats and 70 characters for **DATETIME WITH TIME ZONE** and **TIMESTAMP WITH TIME ZONE**.
- The `<months>` requires to specify the names for months in both long form and abbreviated form. The allowed size are 15 (or 60 bytes) for abbreviated form and 25 characters (or 100 bytes) for normal form.

- The <days> requires week day names in both long and abbreviated form. The allowed size are 10 characters (or 40 bytes) for abbreviated form and 15 characters (or 60 bytes) for full day name.
  - The <dayperiods> sub-tree requires to define the string for AM/PM format variants (according to type attribute). The allowed size is 10 characters (or 40 bytes).

The months and week-days names (in both long and abbreviated form) must be specified in Camel case format (first letter upper case, the rest in lower case). CUBRID checks only the maximum allowed size in bytes; the size in characters is computed only for full-width UTF-8 characters (4 bytes), so it would be possible to set a month name having 100 ASCII-only characters (the 25 characters limit is when each character from month name is encoded on 4 bytes in UTF-8).

## LDML Numbers information

- The <symbols> tag defines the characters used as symbols for splitting decimal part from integer part in numbers and for grouping the digits. CUBRID expects only ASCII characters for these symbols. Empty of space character is not allowed. CUBRID performs grouping for 3 digits.

## LDML Alphabet

These allow to define casing rules for alphabet of the locale. The 'CUBRIDAlphabetMode' attribute defines the primary source of data for characters. Normally, this should be set to "UNICODEDATAFILE", values which instructs CUBRID to use the Unicode data file (**\$CUBRID/locales/data/unicodedata.txt**).

This file must not be modified, any customization on certain characters should be done in LDML file. If such value is configured, all Unicode characters up to codepoint 65535 are loaded with casing information. The other allowed value for *CUBRIDAlphabetMode* is "ASCII" which will lead to only ASCII character can be lower case, upper case or case-insensitive compare in matching functions.

This does not affect CUBRID's ability to support all UTF-8 4 bytes encoded Unicode characters, it just limits the casing ability for characters not included.

The casing rules are optional and apply on top of the primary source of character information (UNICODEDATAFILE or ASCII).

CUBRID allows to define upper casing rules (<u> tag) and lower casing rules (<l> tag). Each of upper and lower casing rules set consists for pairs of source-destination (<s> = source, <d> = destination). For instance, the following defines a rule that each character "A" is lower cased to "aa" (two character "a").

```
<l>  
  <s>A</s>  
  <d>aa</d>  
</l>
```

## LDML Console Conversion

In Windows, the console does not support UTF-8 encoding, so CUBRID allows to translate characters from their UTF-8 encoding to a desired encoding. After configuring console conversion for a locale, the user must set prior to starting CSQL application the codepage of the console using 'chcp' command (the codepage argument must match the 'windows\_codepage' attribute in LDML). Conversion will work bidirectionally (input and output in CSQL), but is only limited to Unicode characters which can be converted in the configured codepage.

The <consoleconversion> element is optional and allows to instruct CSQL how to print (in which character encoding) the text in interactive command. The 'type' attribute defines the conversion scheme. The allowed values are:

- ISO: is a generic scheme in which the destination codepage is a single byte charset
- ISO88591: is a predefined single byte scheme for ISO-8859-1 charset (the 'file' attribute is not required, is ignored)
- ISO88599: is a predefined single byte scheme for ISO-8859-9 charset (also the 'file' attribute is not required)
- DBCS: Double Byte Code-Set; it is a generic scheme in which the destination codepage is a double byte charset

The 'windows\_codepage' is the value for Windows codepage which CUBRID automatically activates console conversion. The 'linux\_charset' is corresponding value for charset part in **LANG** environment variable from UNIX system. It is recommended to use native CUBRID charset in Linux console.

The 'file' attribute is required only for "ISO" and "DBCS" values of 'type' attribute and is the file containing the translation information (**`$CUBRID/locales/data/codepages/`**).

## LDML Collation

Configuring a collation is the most complex task for adding LDML locale in CUBRID. Only collation having UTF-8 codeset can be configured. CUBRID allows to configure most constructs specified by UCA - Unicode Collation Algorithm (<http://www.unicode.org/reports/tr10/>) including contractions and expansions, but the properties for the collation are mostly controlled via the 'settings' attribute.

A LDML file can contain multiple collations. Collations can be included from external file using the 'include' tag. The 'validSubLocales' attribute of 'collations' tag is a filter allowing to control locale compilation when external collations (from external files) are included. Its values can be either a list of locales or "\*" in which case the collations in sub-tree are added in all locales from which the file is included.

One collation is defined using the 'collation' tag and its sub-tree. The 'type' attribute indicates the name for the collation as it will be added in CUBRID. The 'settings' tag defines the properties of the collation:

- 'id' is the (internal) numeric identifier used by CUBRID. It is integer value in range (32 - 255) and is optional, but is strongly recommended that an explicit unassigned values is set. Please see [Collation Naming Rules](#).
- 'strength' is a measure of how strings compare. See [Collation Properties](#). The allowed values are :
  - "quaternary": different graphic symbols of the same character compare differently, but different Unicode codepoints may compare equal.
  - "tertiary": graphic symbols of the same character are equal, case-sensitive collation.
  - "secondary": case insensitive collation, characters with accents compare different
  - "primary": accents are ignored, all characters compare as the base character.
- 'caseLevel': special setting to enable case sensitive compare for collations having strength < tertiary. Valid values are "on" or "off".
- 'caseFirst': order of casing. Valid values are "lower", "upper" and "off". The "upper" values means upper case letters are ordered before the corresponding lower case letter.
- 'CUBRIDMaxWeights': it is the number of codepoints (or last codepoint + 1) which are customized in the collation. Maximum value is 65536. Increasing this value increases the size of collation data.
- 'DUCETContractions': valid values are "use" or "ignore". When "use" - enable CUBRID to use in the collation the contractions defined by DUCET file (\$CUBRID/locales/data/ducet.txt) or ignoring them.
- 'TailoringContractions': same as previous but refers to the contractions defined or derived from explicit collation rules. Enabling contractions leads to a more complex collation (slower string compares).
- 'CUBRIDExpansions': allowed values are "use" or "ignore" (default) and refers to usage of collation expansions from both the DUCET file and tailoring rules; This has the most influence on collation properties. Enabling it will result in a compare with multiple passes (up to

collation strength) when comparing strings. Also it greatly increases collation data, with the benefit of obtaining a more “natural” sort order. See [Expansion](#).

- ‘backwards’: “on” or “off”: used to obtain “french” order by performing an end-to-start compare on secondary level (for accents). It has effect only when ‘CUBRIDExpansions’ are enabled.
- ‘MatchContractionBoundary’: “true” or “false”. This is used in collation having expansions and contractions to configure behavior at string matching when a contraction is found.

The main data for a collation is loaded from the DUCET file. After this step, the collation may be customized using “tailoring rules”. These are the “<rules>” (LDML) and “<cubridrules>” (CUBRID specific).

The ‘cubridrules’ tag is optional and can be used to explicitly set weight values for a codepoint or a range of codepoints. The cubridrules apply after loading the primary collation data from DUCET file and before applying the UCA rules (from ‘<rules>’ tag). Each of these rule is enclosed in ‘<set>’ tag. If the rule refers to only one Unicode codepoint, then a ‘<scp>’ tag is provided which contains the hexadecimal value of codepoint.

All available CUBRID collations contain this cubrid-rule:

```
<cubridrules>
  <set>
    <scp>20</scp>
    <w>[0.0.0.0]</w>
  </set>
</cubridrules>
```

This rule says that weight values (UCA defines four weight values per collation element) of the codepoints starting with 20 (which is ASCII space character) are all set to zero. Since there is no ‘<ecp>’ tag, the only codepoint affected is 20. In CUBRID, space character compares as zero. The allowed tags inside of a ‘<set>’ rule are:

- ‘<cp>’: rule to set the weights for single codepoint.
- ‘<ch>’: rule to set the weights for single character. Similar to previous one, but instead of codepoint it expects a Unicode character (in UTF-8 encoding).
- ‘<scp>’: rule to set the weights for a range of codepoints. This is the starting codepoint.
- ‘<sch>’: rule to set the weights for a range of characters. This is the starting character. In this context, the order of characters is given by their Unicode codepoints.
- ‘<ecp>’: end codepoint for a range rule.
- ‘<ech>’: end character for a range rule.

- ‘<w>’: weight values to set (single value). The weight values are expected in hexadecimal. Each collation element has four values which are delimited by point and enclosed by square brackets([]). There can be up to 10 collation elements.
- ‘<wr>’: starting weight values to set for a range. Optionally, there is ‘step’ attribute of this tag, which sets the increasing step after each codepoint. By default the step is [0001.0000.0000.0000], which means that after setting the first weight values for the starting codepoint, one value is added to primary level weight and set to the next codepoint in range, and the process is repeated until end codepoint.

Examples:

```
<cupridrules>
  <set>                                <!-- Rule 1 -->
    <scp>0</scp>
    <ecp>20</ecp>
    <w>[0.0.0.0]</w>
  </set>

  <set>                                <!-- Rule 2 -->
    <scp>30</scp>
    <ecp>39</ecp>
    <wr step="[1.0.0.0][1.0.0.0]">[30.0.0.0][30.0.0.0]</
wr>
  </set>

</cupridrules>
```

The Rule 1, sets for codepoints ranging from 0 to 20 (including) the weight values 0. The Rule 2, sets for codepoints ranging from 30 to 39 (which are the digits), a set of two collation elements with increasing weights; In this example, codepoint 39 (character “9”) will have the weights with two collation elements [39.0.0.0][39.0.0.0].

The ‘<rules>’ tag is also optional but is according to LDML and UCA specifications. The meanings of sub-ordinates tags are :

- ‘<reset>’: anchor collation element. It defines the reference to which subsequent rules (up to next <reset>) are tailored. It can be a single characters or multiple characters in which case is either a contraction or an expansion. By default, all the tailoring rules after the anchor are sort “after” (element from first rule is after the anchor, element from second rule sorts after element in first rule); if the optional attribute “before” is present, then only the first rule after the <reset> sorts before the anchor, while the second and the following rules resumes the normal “after” sort (element in second rule sorts after element in first rule).
- ‘<p>’: the character comes after (or before, if the anchor had the *before* attribute) the previously tailored one at primary level.

- ‘<s>’: the character comes after (or before, if the anchor had the *before* attribute) the previously tailored one at secondary level.
- ‘<t>’: the character comes after (or before, if the anchor had the *before* attribute) the previously tailored one at tertiary level.
- ‘<i>’: the character sorts identically to previous one
- ‘<pc>’, ‘<sc>’, ‘<tc>’, ‘<ic>’: same as ‘<p>’, ‘<s>’, ‘<t>’, ‘<i>’ but applies to a range of characters
- ‘<x>’: specifies the expansion character
- ‘<extend>’: specifies the second character of expansion.
- ‘<context>’: specifies the context in which a rule applies. A variant to specify contractions and expansions.

For more information on UCA tailoring with LDML rules see <http://www.unicode.org/reports/tr35/tr35-collation.html>.

#### Footnotes

[1] (1,2)

glyph: an element for the shape of a character; a graphic symbol which indicates a shape or a form for a character. Because a glyph specifies the shape which is shown, several glyphs about one character can exist.

## Transaction and Lock

This chapter covers issues relating to concurrency and restore, as well as how to commit or rollback transactions.

In multi-user environment, controlling access and update is essential to protect database integrity and ensure that a user’s transaction will have accurate and consistent data. Without appropriate control, data could be updated incorrectly in the wrong order.

To control parallel operations on the same data, data must be locked during transaction, and unacceptable access to the data by another transaction must be blocked until the end of the transaction. In addition, any updates to a certain class must not be seen by other users before they are committed. If updates are not committed, all queries entered after the last commit or rollback of the update can be invalidated.

CUBRID uses Multiversion Concurrency Control to optimize data access. Data being modified is not overwritten, old data is instead marked as deleted and a newer version is added elsewhere. Other transactions can continue to read the old version without locking it. Each transaction sees

its own snapshot of the database that is defined at the start of transaction or statement execution. Furthermore, the snapshot is only affected by own changes and remains consistent throughout the execution.

All examples introduced here were executed by `csql`.

## Database Transaction

A database transaction groups CUBRID queries into a unit of consistency (for ensuring valid results in multi-user environment) and restore (for making the results of committed transactions permanent and ensuring that the aborted transactions are canceled in the database despite any failure, such as system failure). A transaction is a collection of one or more queries that access and update the database.

CUBRID allows multiple users to access the database simultaneously and manages accesses and updates to prevent inconsistency of the database. For example, if data is updated by one user, the changes made by this transaction are not seen to other users or the database until the updates are committed. This principle is important because the transaction can be rolled back without being committed.

You can delay permanent updates to the database until you are confident of the transaction result. Also, you can remove (**ROLLBACK**) all updates in the database if an unsatisfactory result or failure occurs in the application or computer system during the transaction. The end of the transaction is determined by the **COMMIT WORK** or **ROLLBACK WORK** statement. The **COMMIT WORK** statement makes all updates permanent while the **ROLLBACK WORK** statement cancels all updates entered in the transaction.

## Transaction Commit

Updates that occurred in the database are not permanently stored until the **COMMIT WORK** statement is executed. “Permanently stored” means that storing the updates in the disk is completed; The **WORK** keyword can be omitted. In addition, other users of the database cannot see the updates until they are permanently applied. For example, when a new row is inserted into a class, only the user who inserted the row can access it until the database transaction is committed.

All locks obtained by the transaction are released after the transaction is committed.

```
COMMIT [WORK];
```

```
-- ;autocommit off  
-- AUTOCOMMIT IS OFF
```

```
SELECT name, seats
FROM stadium WHERE code IN (30138, 30139, 30140);
```

| name                           | seats |
|--------------------------------|-------|
| 'Athens Olympic Tennis Centre' | 3200  |
| 'Goudi Olympic Hall'           | 5000  |
| 'Vouliagmeni Olympic Centre'   | 3400  |

The following **UPDATE** statement changes three column values of seats from the stadium. To compare the results, check the current values and names before the update is done. Since csql runs in an autocommit mode by default, the following example is executed after setting the autocommit mode to off.

```
UPDATE stadium
SET seats = seats + 1000
WHERE code IN (30138, 30139, 30140);

SELECT name, seats FROM stadium WHERE code in (30138, 30139, 30140);
```

| name                           | seats |
|--------------------------------|-------|
| 'Athens Olympic Tennis Centre' | 4200  |
| 'Goudi Olympic Hall'           | 6000  |
| 'Vouliagmeni Olympic Centre'   | 4400  |

If the update is properly done, the changes can be permanently fixed. In this time, use the **COMMIT WORK** as below:

```
COMMIT [WORK];
```

#### Note

In CUBRID, an auto-commit mode is set by default for transaction management.

An auto-commit mode is a mode that commits or rolls back all SQL statements. The transaction is committed automatically if the SQL is executed successfully, or is rolled back automatically if an error occurs. Such auto commit modes are supported in any interfaces.

In CCI, PHP, ODBC and OLE DB interfaces, you can configure auto-commit mode by using **CCI\_DEFAULT\_AUTOCOMMIT** upon startup of an application. If configuration on broker parameter

is omitted, the default value is set to **ON**. To change auto-commit mode, use the following functions by interface: **cci\_set\_autocommit** () for CCI interface and **cubrid\_set\_autocommit** () for PHP interface.

For session command (**;Autocommit**) which enables auto-commit configuration in CSQL Interpreter, see [Session Commands](#).

## Transaction Rollback

The **ROLLBACK WORK** statement removes all updates to the database since the last transaction. The **WORK** keyword can be omitted. By using this statement, you can cancel incorrect or unnecessary updates before they are permanently applied to the database. All locks obtained during the transaction are released.

```
ROLLBACK [WORK];
```

The following example shows two commands that modify the definition and the row of the same table.

```
-- csql> ;autocommit off
CREATE TABLE code2 (
    s_name CHAR(1),
    f_name VARCHAR(10)
);
COMMIT;

ALTER TABLE code2 DROP s_name;
INSERT INTO code2 (s_name, f_name) VALUES ('D','Diamond');
```

```
ERROR: s_name is not defined.
```

The **INSERT** statement fails because the *s\_name* column has been dropped in the definition of *code*. The data intended to be entered to the *code* table is correct, but the *s\_name* column is wrongly removed. At this point, you can use the **ROLLBACK WORK** statement to restore the original definition of the *code* table.

```
ROLLBACK WORK;
```

Later, remove the *s\_name* column by entering the **ALTER TABLE** again and modify the **INSERT** statement. The **INSERT** command must be entered again because the transaction has been aborted. If the database update has been done as intended, commit the transaction to make the changes permanent.

```
ALTER TABLE code2 DROP s_name;  
INSERT INTO code2 (f_name) VALUES ('Diamond');  
  
COMMIT WORK;
```

## Savepoint and Partial Rollback

A savepoint is established during the transaction so that database changes made by the transaction are rolled back to the specified savepoint. Such operation is called a partial rollback. In a partial rollback, database operations (insert, update, delete, etc.) after the savepoint are rolled back, and transaction operations before it are not rolled back. The transaction can proceed with other operations after the partial rollback is executed. Or the transaction can be terminated with the **COMMIT WORK** or **ROLLBACK WORK** statement. Note that the savepoint does not commit the changes made by the transaction.

A savepoint can be created at a certain point of the transaction, and multiple savepoints can be used for a certain point. If a partial rollback is executed to a savepoint before the specified savepoint or the transaction is terminated with the **COMMIT WORK** or **ROLLBACK WORK** statement, the specified savepoint is removed. The partial rollback after the specified savepoint can be performed multiple times.

Savepoints are useful because intermediate steps can be created and named to control long and complicated utilities. For example, if you use a savepoint during the update operation, you don't need to perform all statements again when you made a mistake.

```
SAVEPOINT <mark>;  
  
<mark> :  
- a SQL identifier  
- a host variable (starting with :)
```

If you make *mark* all the same value when you specify multiple savepoints in a single transaction, only the latest savepoint appears in the partial rollback. The previous savepoints remain hidden until the rollback to the latest savepoint is performed and then appears when the latest savepoint disappears after being used.

```
ROLLBACK [WORK] [TO [SAVEPOINT] <mark>];  
  
<mark>:  
- a SQL identifier  
- a host variable (starting with :)
```

Previously, the **ROLLBACK WORK** statement canceled all database changes added since the latest transaction. The **ROLLBACK WORK** statement is also used for the partial rollback that rolls back the transaction changes after the specified savepoint.

If *mark* value is not given, the transaction terminates canceling all changes including all savepoints created in the transaction. If *mark* value is given, changes after the specified savepoint are canceled and the ones before it are remained.

The below example shows how to rollback a part of a transaction. Firstly, specify savepoints *SP1*, *SP2*.

```
-- csql> ;autocommit off

CREATE TABLE athlete2 (name VARCHAR(40), gender CHAR(1), nation_code
CHAR(3), event VARCHAR(30));
INSERT INTO athlete2(name, gender, nation_code, event)
VALUES ('Lim Kye-Sook', 'W', 'KOR', 'Hockey');
SAVEPOINT SP1;

SELECT * FROM athlete2;
INSERT INTO athlete2(name, gender, nation_code, event)
VALUES ('Lim Jin-Suk', 'M', 'KOR', 'Handball');

SELECT * FROM athlete2;
SAVEPOINT SP2;

RENAME TABLE athlete2 AS sportsman;
SELECT * FROM sportsman;
ROLLBACK WORK TO SP2;
```

In the example above, the name change of the *athlete2* table is rolled back by the partial rollback. The following example shows how to execute the query with the original name and examining the result.

```
SELECT * FROM athlete2;
DELETE FROM athlete2 WHERE name = 'Lim Jin-Suk';
SELECT * FROM athlete2;
ROLLBACK WORK TO SP2;
```

In the example above, deleting 'Lim Jin-Suk' is discarded by rollback work to *SP2* command. The following example shows how to roll back to *SP1*.

```
SELECT * FROM athlete2;
ROLLBACK WORK TO SP1;
SELECT * FROM athlete2;
COMMIT WORK;
```

## Cursor Holdability

Cursor holdability is when an application holds the record set of the **SELECT** query result to fetch the next record even after performing an explicit commit or an automatic commit. In each application, cursor holdability can be specified as Connection level or Statement level. If it is not specified, the cursor is held by default. Therefore, **HOLD\_CURSORS\_OVER\_COMMIT** is the default setting.

The following code shows how to set cursor holdability in JDBC:

```
// set cursor holdability at the connection level
conn.setHoldability(ResultSet.HOLD_CURSORS_OVER_COMMIT);

// set cursor holdability at the statement level which can override
the connection
PreparedStatement pstmt = conn.prepareStatement(sql,
                                                ResultSet.TYPE_SCROLL_SENSITIVE,
                                                ResultSet.CONCUR_UPDATABLE,
                                                ResultSet.HOLD_CURSORS_OVER_COMMIT);
```

To set cursor holdability to close the cursor when a transaction is committed, set **ResultSet.CLOSE\_CURSORS\_AT\_COMMIT**, instead of **ResultSet.HOLD\_CURSORS\_OVER\_COMMIT**, in the above example.

The default setting for applications that were developed based on CCI is to hold the cursor. If the cursor is set to 'not to hold a cursor' at connection level and you want to hold the cursor, define the **CCI\_PREPARE\_HOLDABLE** flag while preparing a query. The default setting for CCI drivers (PHP, PDO, ODBC, OLE DB, ADO.NET, Perl, Python, Ruby) is to hold the cursor. To check whether a driver supports the cursor holdability setting, refer to the **PREPARE** function of the driver.

### Note

- Note that versions lower than CUBRID 9.0 do not support cursor holdability. The default setting of those versions is to close all cursors at commit.
- CUBRID currently does not support `ResultSet.HOLD_CURSORS_OVER_COMMIT` in `java.sql.XAConnection` interface.

## Cursor-related Operation at Transaction Commit

When a transaction is committed, all statements and result sets that are closed are released even if you have set cursor holdability. After that, when the result sets are used for another transaction, some or all of the result sets should be closed as required.

When a transaction is rolled back, all result sets are closed. This means that all result sets held in the previous transaction are closed because you have set cursor holdability.

```
rs1 = stmt.executeQuery(sql1);
conn.commit();
rs2 = stmt.executeQuery(sql2);
conn.rollback(); // result sets rs1 and rs2 are closed and it will
                not be available to use them.
```

### When the Result Sets are Closed

The result sets that hold the cursor are closed in the following cases:

- Driver closes the result set, i.e. `rs.close()`
- Driver closes the statement, i.e. `stmt.close()`
- Driver disconnects the connection.
- Transaction aborts, for instance, application explicitly calls `rollback()`, auto rollback due to a query failure under auto-commit mode.

### Relationship with CAS

When the connection between an application and the CAS is closed, all result sets are automatically closed even if you have set cursor holdability in the application. The setting value of **KEEP\_CONNECTION**, the broker parameter, affects cursor holdability of the result set.

- `KEEP_CONNECTION = ON`: Cursor holdability is not affected.
- `KEEP_CONNECTION = AUTO`: The CAS cannot be restarted while the result set with cursor holdability is open.

#### Warning

Usage of memory will increase in the status of result set opened. Thus, you should close the result set after completion.

#### Note

Note that CUBRID versions lower than 9.0 do not support cursor holdability and the cursor is automatically closed when a transaction is committed. Therefore, the recordset of the **SELECT** query result is not kept.

## Database Concurrency

If there are multiple users with read and write authorization to a database, possibility exists that more than one user will access the database simultaneously. Controlling access and update in multi-user environment is essential to protect database integrity and ensure that users and transactions should have accurate and consistent data. Without appropriate control, data could be updated incorrectly in the wrong order.

The transaction must ensure database concurrency, and each transaction must guarantee appropriate results. When multiple transactions are being executed at once, an event in transaction *T1* should not affect an event in transaction *T2*. This means isolation. Transaction isolation level is the degree to which a transaction is separated from all other concurrent transactions. The higher isolation level means the lower interference from other transactions. The lower isolation level means the higher the concurrency. A database determines whether which lock is applied to tables and records based on these isolation levels. Therefore, can control the level of consistency and concurrency specific to a service by setting appropriate isolation level.

The read operations that allow interference between transactions with isolation levels are as follows:

- **Dirty read** : A transaction *T2* can read *D'* before a transaction *T1* updates data *D* to *D'* and commits it.
- **Non-repeatable read** : A transaction *T1* can read changed value, if a transaction *T2* updates or deletes data and commits while data is retrieved in the transaction *T1* multiple times.
- **Phantom read** : A transaction *T1* can read *E*, if a transaction *T2* inserts new record *E* and commits while data is retrieved in the transaction *T1* multiple times.

Based on these interferences, the SQL standard defines four levels of transaction isolation:

- **READ UNCOMMITTED** allows dirty read, unrepeatable read and phantom read.
- **READ COMMITTED** does not allow dirty read but allows unrepeatable read and phantom read.
- **REPEATABLE READ** does not allow dirty read and unrepeatable read but allows phantom read.
- **SERIALIZABLE** does not allow interrupts between transactions when doing read operation.

### Isolation Levels Provided by CUBRID

On the below table, the number wrapped with parenthesis right after the isolation level name is a number which can be used instead of the isolation level name when setting an isolation level.

You can set an isolation level by using the **SET TRANSACTION ISOLATION LEVEL** statement or system parameters provided by CUBRID. For details, see [Concurrency/Lock-Related Parameters](#).

(O: YES, X: NO)

| CUBRID<br>Isolation Level<br>(isolation_level<br>) | DIRTY READ | UNREPEATABLE<br>READ | PHANTOM READ | Schema<br>Changes of the<br>Table Being<br>Retrieved |
|----------------------------------------------------|------------|----------------------|--------------|------------------------------------------------------|
| <b>SERIALIZABLE</b><br>Isolation Level (6)         | X          | X                    | X            | X                                                    |
| <b>REPEATABLE<br/>READ</b> Isolation<br>Level (5)  | X          | X                    | X            | X                                                    |
| <b>READ<br/>COMMITTED</b><br>Isolation Level (4)   | X          | O                    | O            | X                                                    |

The default value of CUBRID isolation level is **READ COMMITTED Isolation Level**.

## Multiversion Concurrency Control

CUBRID previous versions managed isolation levels using the well known two phase locking protocol. In this protocol, a transaction obtains a shared lock before it reads an object, and an exclusive lock before it updates the object so that conflicting operations are not executed simultaneously. If transaction *T1* requires a lock, the system checks if the requested lock conflicts with the existing one. If it does, transaction *T1* enters a standby state and delays the lock. If another transaction *T2* releases the lock, transaction *T1* resumes and obtains it. Once the lock is released, the transaction do not require any new locks.

CUBRID 10.0 replaced the two phase locking protocol with a Multiversion Concurrency Control (MVCC) protocol. Unlike two phase locking, MVCC does not block readers to access objects being modified by concurrent transactions. MVCC duplicates rows, creating multiple versions on each update. Never blocking readers is important for workloads involving mostly value reads from the

database, commonly used in read-world scenarios. Exclusive locks are still required before updating objects.

MVCC is also known for providing point in time consistent view of the database and for being particularly adept at implementing true **snapshot isolation** with less performance costs than other methods of concurrency.

### Versioning, visibility and snapshot

MVCC maintains multiple versions for each database row. Each version is marked by its inserter and deleter with MVCCID's - unique identifiers for writer transactions. These markers are useful to identify the author of a change and to place the change on a timeline.

When a transaction *T1* inserts a new row, it creates its first version and sets its unique identifier *MVCCID1* as insert id. The MVCCID is stored as meta-data in record header:

| OTHER META-DATA | MVCCID1 | RECORD DATA |
|-----------------|---------|-------------|
|-----------------|---------|-------------|

Until *T1* commits, other transactions should not see this row. The MVCCID helps identifying the authors of database changes and place them on a time line, so others can know if the change is valid or not. In this case, anyone checking this row find the *MVCCID1*, find out that the owner is still active, hence the row must be (still) invisible.

After *T1* commits, a new transaction *T2* finds the row and decides to remove it. *T2* does not remove this version, allowing others to access it, instead it gets an exclusive lock, to prevent others from changing it, and marks the version as deleted. It adds another MVCCID so others can identify the deleter:

| OTHER META-DATA | MVCCID1 | MVCCID2 | RECORD DATA |
|-----------------|---------|---------|-------------|
|-----------------|---------|---------|-------------|

If *T2* decides instead to update one of the record values, it must update the row to a new version and store the old version in log. The new row consists of new data, transaction MVCCID as insert MVCCID and the address of log entry storing previous version. The row representations looks like this:

HEAP file contains a single row identified by an OID:

| OTHER META-DATA | MVCCID_INS1 | PREV_VERSION_LSA1 | RECORD DATA |
|-----------------|-------------|-------------------|-------------|
|-----------------|-------------|-------------------|-------------|

LOG file has a chain of log entries, the undo part of each log entry contains the original heap record before modification:

|                     |            |       |             |                   |             |
|---------------------|------------|-------|-------------|-------------------|-------------|
| LOG ENTRY META-DATA | OTHER DATA | META- | MVCCID_INS2 | PREV_VERSION_LSA2 | RECORD DATA |
|---------------------|------------|-------|-------------|-------------------|-------------|

|                     |            |       |             |      |             |
|---------------------|------------|-------|-------------|------|-------------|
| LOG ENTRY META-DATA | OTHER DATA | META- | MVCCID_INS3 | NULL | RECORD DATA |
|---------------------|------------|-------|-------------|------|-------------|

Other transactions may need to walk the log chain of previous version LSA of multiple log record until one record satisfies the visibility condition, determined by the values of insert and delete MVCCID of each record.

#### Note

- Previous version used the heap (another OID) to store the old and new version of the updated rows. In fact, old version was the the row which remained unchanged, which was appended with and OID link to the new version. Both new version and old version were located in the heap.

Currently, only *T2* can see the updated row, while other transactions will access the row version contained on the log page and accessible through the LSA obtained from heap row. The property of a version to be seen or not to be seen by running transactions is called **visibility**. The visibility property is relative to each transaction, some can consider it true, whereas others can consider it false.

A transaction *T3* that starts after *T2* executes row update, but before *T2* commits, will not be able to see its new version, not even after *T2* commits. The visibility of one version towards *T3* depends on the state of its inserter and deleter when *T3* started and preserves its status for the lifetime of *T3*.

As a matter of fact, the visibility of all versions in database towards on transaction does not depend on the changes that occur after transaction is started. Moreover, any new version added is also ignored. Consequently, the set of all visible versions in the database remains unchanged and form the snapshot of the transaction. Hence, **snapshot isolation** is provided by MVCC and it is a guarantee that all read queries made in a transaction see a consistent view of the database.

In CUBRID 10.0, **snapshot** is a filter of all invalid MVCCID's. An MVCCID is invalid if it is not committed before the snapshot is taken. To avoid updating the snapshot filter whenever a new transaction starts, the snapshot is defined using two border MVCCID's: the lowest active MVCCID and the highest committed MVCCID. Only a list of active MVCCID values between the border is saved. Any transaction starting after snapshot is guaranteed to have an MVCCID bigger than

highest committed and is automatically considered invalid. Any MVCCID below lowest active must be committed and is automatically considered valid.

The snapshot filter algorithm that decides a version visibility queries the MVCCID markers used for insert and delete. The snapshot starts by checking the *last version* stored in heap and, based on result, it can either fetch version from heap, fetch older version from log or can ignore row:

| Insert MVCCID   | Previous version LSA | Delete MVCCID       | Snapshot test result                                                                                  |
|-----------------|----------------------|---------------------|-------------------------------------------------------------------------------------------------------|
| Not visible     | NULL                 | None or not visible | Version is too <i>new</i> and is not visible<br>Row has no previous version, so it is ignored         |
|                 | LSA                  | None or not visible | Version is too <i>new</i> and is not visible<br>Row has previous version and snapshot must check it   |
| None or visible | LSA or NULL          | None or not visible | Version is visible and its data is fetched<br>It does not matter if row has previous versions         |
|                 |                      | Visible             | Version is too old, was deleted and is not visible<br>It does not matter if row has previous versions |

If version is too new, but it has a previous version stored in log, the same checks are repeated on previous version. The checks stop when no previous versions are found (the entire row chain is too new for this transaction), or when a visible version is found.

Let's see how snapshot works (**REPEATABLE READ** isolation will be used to keep same snapshot during entire transaction):

**Example 1: Inserting a new row****session 1**

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> set transaction
isolation level REPEATABLE
READ;

Isolation level set to:
REPEATABLE READ
```

**session 2**

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> set transaction
isolation level REPEATABLE
READ;

Isolation level set to:
REPEATABLE READ
```

```
csql> CREATE TABLE
tbl(host_year integer,
nation_code char(3));
csql> COMMIT WORK;
```

```
-- insert a row without
committing
csql> INSERT INTO tbl VALUES
(2008, 'AUS');
```

```
-- current transaction sees
its own changes
```

```
csql> SELECT * FROM tbl;
```

```
      host_year  nation_code
=====
====
          2008    'AUS'
```

```
-- this snapshot should not
see uncommitted row
csql> SELECT * FROM tbl;
```

## session 1

## session 2

There **are no** results.

```
csql> COMMIT WORK;
```

```
-- even though inserter did
commit, this snapshot still
can't see the row
```

```
csql> SELECT * FROM tbl;
```

There **are no** results.

```
-- commit to start a new
transaction with a new
snapshot
```

```
csql> COMMIT WORK;
```

```
-- the new snapshot should
see committed row
```

```
csql> SELECT * FROM tbl;
```

```
      host_year  nation_code
=====
=====
      2008      'AUS'
```

## Example 2: Deleting a row

## session 1

## session 2

```
csql> ;autocommit off
```

```
AUTOCOMMIT IS OFF
```

```
csql> set transaction
isolation level REPEATABLE
```

```
csql> ;autocommit off
```

```
AUTOCOMMIT IS OFF
```

```
csql> set transaction
isolation level REPEATABLE
```

## session 1

```
READ;
```

```
Isolation level set to:
REPEATABLE READ
```

## session 2

```
READ;
```

```
Isolation level set to:
REPEATABLE READ
```

```
csql> CREATE TABLE
tbl(host_year integer,
nation_code char(3));
csql> INSERT INTO tbl VALUES
(2008, 'AUS');
csql> COMMIT WORK;
```

```
-- delete the row without
committing
csql> DELETE FROM tbl WHERE
nation_code = 'AUS';

-- this transaction sees its
own changes
csql> SELECT * FROM tbl;
```

There **are no** results.

```
-- delete was not committed,
so the row is visible to this
snapshot
csql> SELECT * FROM tbl;

      host_year  nation_code
=====
=====
          2008    'AUS'
```

## session 1

## session 2

```
csql> COMMIT WORK;
```

```
-- delete was committed, but
the row is still visible to
this snapshot
csql> SELECT * FROM tbl;

      host_year  nation_code
=====
=====
          2008    'AUS'
```

```
-- commit to start a new
transaction with a new
snapshot
csql> COMMIT WORK;

-- the new snapshot can no
longer see deleted row
csql> SELECT * FROM tbl;

There are no results.
```

## Example 3: Updating a row

## session 1

## session 2

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> set transaction
isolation level REPEATABLE
READ;
```

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> set transaction
isolation level REPEATABLE
READ;
```

## session 1

Isolation level set to:  
REPEATABLE READ

## session 2

Isolation level set to:  
REPEATABLE READ

```
csql> CREATE TABLE
tbl(host_year integer,
nation_code char(3));
csql> INSERT INTO tbl VALUES
(2008, 'AUS');
csql> COMMIT WORK;
```

```
-- delete the row without
committing
csql> UPDATE tbl SET host_year
= 2012 WHERE nation_code =
'AUS';
```

```
-- this transaction sees new
version, host_year = 2012
csql> SELECT * FROM tbl;
```

```
      host_year  nation_code
=====
====
          2012   'AUS'
```

```
-- update was not committed,
so this snapshot sees old
version
```

```
csql> SELECT * FROM tbl;
```

```
      host_year  nation_code
=====
====
          2008   'AUS'
```

session 1

session 2

```
csql> COMMIT WORK;
```

```
-- update was committed, but
-- this snapshot still sees old
-- version
csql> SELECT * FROM tbl;

      host_year  nation_code
=====
=====
      2008      'AUS'
```

```
-- commit to start a new
-- transaction with a new
-- snapshot
csql> COMMIT WORK;
```

```
-- the new snapshot can see
-- new version, host_year = 2012
csql> SELECT * FROM tbl;

      host_year  nation_code
=====
=====
      2012      'AUS'
```

#### Example 4: Different versions can be visible to different transactions

session 1

session 2

session 3

```
csql> ;autocommit
off
```

```
AUTOCOMMIT IS OFF
```

```
csql> set
transaction
```

```
csql> ;autocommit
off
```

```
AUTOCOMMIT IS OFF
```

```

                2012
'AUS'
```

## VACUUM

Creating new versions for each update and keeping old versions on delete could lead to unlimited database size growth, definitely a major issue for a database. Therefore, a clean up system is necessary, to remove obsolete data and reclaim the occupied space for reuse.

Each row version goes through same stages:

1. newly inserted, not committed, visible only to its inserter.
2. committed, invisible to preceding transactions, visible to future transactions.
3. deleted, not committed, visible to other transactions, invisible to the deleter.
4. committed, still visible to preceding transactions, invisible to future transactions.
5. invisible to all active transactions.
6. removed from database.

The role of the clean up system is to get versions from stage 5 to 6. This system is called **VACUUM** in CUBRID.

**VACUUM** system was developed with the guidance of three principles:

- **VACUUM** must be correct and complete. **VACUUM** should never remove data still visible to some and it should not miss any obsolete data.
- **VACUUM** must be discreet. Since clean-up process changes database content, there may be some interference in the activity of live transactions, but it must be kept to the minimum possible.
- **VACUUM** must be fast and efficient. If **VACUUM** is too slow and if it starts lagging, the database state can deteriorate, thus the overall performance can be affected.

With these principles in mind, **VACUUM** implementation uses existing recovery logging, because:

- The address is kept among recovery data for both heap and index changes. This allows **VACUUM** go directly to target, rather than scanning the database.
- Processing log data rarely interferes with the work of active workers.

Log recovery was adapted to **VACUUM** needs by adding MVCCID information to logged data. **VACUUM** can decide based on MVCCID if the log entry is ready to be processed. MVCCID's that are still visible to active transactions cannot be processed. In due time, each MVCCID becomes old enough and all changes using the MVCCID become invisible.

Each transaction keeps the oldest MVCCID it considers active. The oldest MVCCID considered active by all running transactions is determined by the smallest oldest MVCCID of all transactions. Anything below this value is invisible and **VACUUM** can clean.

## VACUUM Parallel Execution

According to the third principle of **VACUUM** it must be fast and it should not fall behind active workers. It is obvious that one thread cannot handle all the **VACUUM** works if system workload is heavy, thus it had to be parallelized.

To achieve parallelization, the log data was split into fixed size blocks. Each block generates one vacuum job, when the time is right (the most recent MVCCID can be vacuumed, which means all logged operations in the block can be vacuumed). Vacuum jobs are picked up by multiple **VACUUM Workers** that clean the database based on relevant log entries found in the log block. The tracking of log blocks and generating vacuum jobs is done by the **VACUUM Master**.

## VACUUM Data

Aggregated data on log blocks is stored in vacuum data file. Since the vacuum job generated by an operations occurs later in time, the data must be saved until the job can be executed, and it must also be persistent even if the server crashes. No operation is allowed to leak and not be

vacuumed. If the server crashes, some jobs may be executed twice, which is preferable to not being executed at all.

After a job has been successfully executed, the aggregated data on the processed log block is removed.

Aggregated log block data is not added directly to vacuum data. A latch-free buffer is used to avoid synchronizing active working threads (which generate the log blocks and their aggregated data) with the vacuum system. **VACUUM Master** wakes up periodically, dumps everything in buffer to vacuum data, removes data already process and generates new jobs (if available).

## VACUUM jobs

Vacuum job execution steps:

1. **Log pre-fetch.** Vacuum master or workers pre-fetch log pages to be processed by the job.
2. **Repeat for each log record:**
  1. **Read** log record.
  2. **Check dropped file.** If the log record points to dropped file, proceed to next log record.
  3. **Execute index vacuum and collect heap OID's**
    - If log record belongs to index, execute vacuum immediately.
    - If log record belongs to heap, collect OID to be vacuumed later.
1. **Execute heap vacuum** based on collected OID's.
2. **Complete job.** Mark the job as completed in vacuum data.

Several measures were taken to ease log page reading and to optimize vacuum execution.

## Tracking dropped files

When a transaction drops a table or an index, it usually locks the affected table(s) and prevents others from accessing it. Opposed to active workers, **VACUUM** Workers are not allowed to use locking system, for two reasons: interference with active workers must be kept to the minimum,

and **VACUUM** system is never supposed to stop as long as it has data to clean. Moreover, **VACUUM** is not allowed to skip any data that needs cleaning. This has two consequences:

1. **VACUUM** doesn't stop from cleaning a file belonging to a dropped table or a dropped index until the dropper commits. Even if a transaction drops a table, its file is not immediately destroyed and it can still be accessed. The actual destruction is postponed until after commit.
2. Before the actual file destruction, **VACUUM** system must be notified. The dropper sends a notification to **VACUUM** system and then waits for the confirmation. **VACUUM** works on very short iterations and it checks for new dropped files frequently, so the dropper doesn't have to wait for a long time.

After a file is dropped, **VACUUM** will ignore all found log entries that belong to the file. The file identifier, paired with an MVCCID that marks the moment of drop, is stored in a persistent file until **VACUUM** decides it is safe to remove it (the decision is based on the smallest MVCCID not yet vacuumed).

## Lock Protocol

In the two-phase locking protocol, a transaction obtains a shared lock before it reads an object, and an exclusive lock before it updates the object so that conflicting operations are not executed simultaneously. The MVCC locking protocol, which is now used by CUBRID, does not require shared locks before reading rows (however intent shared lock on table object is still used to read its rows). If transaction *T1* requires a lock, CUBRID checks if the requested lock conflicts with the existing one. If it does, transaction *T1* enters a standby state and delays the lock. If another transaction *T2* releases the lock, transaction *T1* resumes and obtains it. Once the lock is released, the transaction do not acquire any new locks.

## Granularity Locking

CUBRID uses a granularity locking protocol to decrease the number of locks. In the granularity locking protocol, a database can be modelled as a hierarchy of lockable units: row lock, table lock and database lock. Coarser locks have more granular locks.

If the locking granularities overlap, effects of a finer granularity are propagated in order to prevent conflicts. That is, if a shared lock is required on an instance of a table, an intent shared lock will be set on the table. If an exclusive lock is required on an instance of a table, an intent exclusive lock will be set on the table. An intent shared lock on a table means that a shared lock can be set on an instance of the table. An intent exclusive lock on a table means that a shared/exclusive lock can be set on an instance of the table. That is, if an intent shared lock on a table is allowed in one transaction, another transaction cannot obtain an exclusive lock on the table (for example, to add a new column). However, the second transaction may obtain a shared lock on the table. If an intent exclusive lock on the table is allowed in one transaction, another transaction

cannot obtain a shared lock on the table (for example, a query on an instance of the tables cannot be executed because it is being changed).

A mechanism called lock escalation is used to limit the number of locks being managed. If a transaction has more than a certain number of locks (a number which can be changed by the **lock\_escalation** system parameter), the system begins to require locks at the next higher level of granularity. This escalates the locks to a coarser level of granularity. CUBRID performs lock escalation when no transactions have a higher level of granularity in order to avoid a deadlock caused by lock conversion.

## Lock Mode Types And Compatibility

CUBRID determines the lock mode depending on the type of operation to be performed by the transaction, and determines whether or not to share the lock depending on the mode of the lock preoccupied by another transaction. Such decisions concerning the lock are made by the system automatically. Manual assignment by the user is not allowed. To check the lock information of CUBRID, use the **cubrid lockdb** *db\_name* command. For details, see [lockdb](#).

### • Shared lock (shared lock, S\_LOCK, no longer used with MVCC protocol)

This lock is obtained before the read operation is executed on the object.

It can be obtained by multiple transactions for the same object. At this time, transaction *T2* and *T3* can perform the read operation on the object concurrently, but not the update operation.

#### Note

- Shared locks are rarely used in CUBRID 10.0, because of MVCC. It is still used, mostly in internal database operations, to protect rows or index keys from being modified.

### • Exclusive lock (exclusive lock, X\_LOCK)

This lock is obtained before the update operation is executed on the object.

It can only be obtained by one transaction. Transaction *T1* obtains the exclusive lock first before it performs the update operation on a certain object *X*, and does not release it until transaction *T1* is committed even after the update operation is completed. Therefore, transaction *T2* and *T3* cannot perform the read operation as well on *X* before transaction *T1* releases the exclusive lock.

### • Intent lock

This lock is set inherently in a higher-level object than a certain object to protect the lock on the object of a certain level.

For example, when a shared lock is requested for a certain row, prevent a situation from occurring in which the table is locked by another transaction by setting the intent shared lock as well on the table at the higher level in hierarchy. Therefore, the intent lock is not set on rows at the lowest level, but is set on higher-level objects. The types of intent locks are as follows:

- **Intent shared lock (IS\_LOCK)**

If the intent shared lock is set on the table, which is the higher-level object, as a result of the shared lock set on a certain row, another transaction cannot perform operations such as changing the schema of the table (e.g. adding a column or changing the table name) or updating all rows. However updating some rows or viewing all rows is allowed.

- **Intent exclusive lock (IX\_LOCK)**

If the intent exclusive lock is set on the table, which is the higher-level object, as a result of the exclusive lock set on a certain row, another transaction cannot perform operations such as changing the schema of the table, updating or viewing all rows. However updating some rows is allowed.

- **Shared with intent exclusive lock(SIX\_LOCK)**

This lock is set on the higher-level object inherently to protect the shared lock set on all objects at the lower hierarchical level and the intent exclusive lock on some object at the lower hierarchical level.

Once the shared intent exclusive lock is set on a table, another transaction cannot change the schema of the table, update all/some rows or view all rows. However, viewing some rows is allowed.

- **Schema Lock**

A schema lock is acquired when executing DDL work.

- **Schema stability lock, SCH\_S\_LOCK**

This lock is acquired during compiling a query and it guarantees that the schema which is included in this query is not changed.

- **Schema modification lock, SCH\_M\_LOCK**

This lock is acquired during running DDL(**ALTER/CREATE/DROP**) and it protects that other transactions access the modified schema.

Some DDL operations like **ALTER, CREATE INDEX** do not acquire **SCH\_M\_LOCK** directly. For example, CUBRID operates type checking about filtering expression when you create a filtered

index; during this term, the lock which is kept to the target table is **SCH\_S\_LOCK** like other type checking operations. The lock is then upgraded to **SIX\_LOCK** (other transactions are prevented from modifying target table rows, but they can continue reading them), and finally **SCH\_M\_LOCK** is requested to change the table schema. The method has a strength to increase the concurrency by allowing other transaction's operation during DDL operation's compilation and execution.

However, it also has a weakness not to avoid a deadlock when DDL operations are operated at the same table at the same time. A deadlock case by loading indexes is as follows.

**T1**

**T2**

```
CREATE INDEX i_t_i on t(i)
WHERE i > 0;
```

```
CREATE INDEX i_t_j on t(j)
WHERE j > 0;
```

SCH\_S\_LOCK during checking types of "i > 0" case.

SCH\_S\_LOCK during checking types of "j > 0" case."j > 0"

SIX\_LOCK during index loading.

requesting SIX\_LOCK but waiting T1's SIX\_LOCK is released

requesting SCH\_M\_LOCK but waiting T2's SCH\_S\_LOCK is released

## • Special Locks

**CUBRID 10.2** introduces a new type of locks, which are used in a few special cases of internal operations.

### ◦ Bulk Update Lock, BU\_LOCK

This lock is designed for inserting large amounts of data into the database. As of **CUBRID 10.2**, this lock is exclusively used during the **loaddb** process while loading rows into a table.

**BU\_LOCK** is compatible with itself and **SCH\_S\_LOCK**; as a result this ensures that no other **SELECT/DML/DDL** statements are allowed on the same table. However, multiple **loaddb** may load rows into a table. The **BU\_LOCK** holder doesn't require row locks.

### Note

This is a summarized description about locking.

- There are row(instance) and schema(class) about objects of locking targets. The locks grouped by the type of objects they're used:
  - row locks: **S\_LOCK**, **X\_LOCK**
  - intention/schema locks: **IX\_LOCK**, **IS\_LOCK**, **SIX\_LOCK**, **SCH\_S\_LOCK**, **SCH\_M\_LOCK**
  - special locks: **BU\_LOCK**
- All types of locks affect each other.

The following table briefly shows the lock compatibility between the locks described above. Compatibility means that the lock requester can obtain a lock while the lock holder is keeping the lock obtained for a certain object.

### Lock Compatibility

- **NULL**: The status that any lock exists.

(O: TRUE, X: FALSE)

|                |       | Lock holder |       |    |   |    |    |     |   |       |
|----------------|-------|-------------|-------|----|---|----|----|-----|---|-------|
|                |       | NULL        | SCH-S | IS | S | IX | BU | SIX | X | SCH-M |
| Lock requester | NULL  | O           | O     | O  | O | O  | O  | O   | O | O     |
|                | SCH-S | O           | O     | O  | O | O  | O  | O   | O | X     |
|                | IS    | O           | O     | O  | O | O  | X  | O   | X | X     |

|              |   |   |   |   |   |   |   |   |   |

### Examples using locks

For next few examples, REPEATABLE READ(5) isolation level will be used. READ COMMITTED has different rules for updating rows and will be presented in next section (reference here). The examples will make use of lockdb utility to show existing locks.

**Locking example:** For next example REPEATABLE READ(5) isolation will be used and it will prove that read and write on same row are not blocked. Also conflicting updates will be tried, where the second updater is blocked. When transaction T1 commits, T2 is unblocked but update is not permitted because of isolation level restrictions. If T1 would rollback, then T2 can proceed with its update.

| T1                                                                                    | T2                                                                                    | Description                        |
|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|------------------------------------|
| <pre>csql&gt; ;au off csql&gt; SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;</pre> | <pre>csql&gt; ;au off csql&gt; SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;</pre> | AUTOCOMMIT OFF and REPEATABLE READ |

| T1                                                                                                                                                | T2 | Description |
|---------------------------------------------------------------------------------------------------------------------------------------------------|----|-------------|
| <pre> csql&gt; CREATE TABLE tbl(a INT PRIMARY KEY, b INT);  csql&gt; INSERT INTO tbl VALUES (10, 30), (30, 50), (50, 70); csql&gt; COMMIT; </pre> |    |             |

```

csql> UPDATE tbl
SET a = 90 WHERE a
= 10;

```

First version of row where a = 10 is locked and updated. A new version where row has a = 90 is created and also locked.

### Locking to protect unique constraint

Two phase locking protocol in older CUBRID versions used index key locks to protect unique constraints and higher isolation restrictions. In CUBRID 10.0, key locking was removed. Isolation level restrictions are solved by MVCC snapshot, however unique constraint still needed some type of protection.

With MVCC, unique index can keep multiple versions at the same time, similarly to rows, each visible to different transactions. One is the last version, while the other versions are kept temporarily until they become invisible and can be removed by **VACUUM**. The rule to protect unique constraint is that all transactions trying to modify a key has to lock key's last existing version.

The below example uses **REPEATABLE READ** isolation to show the way locking prevents unique constraint violations.

| T1                                                                                    | T2                                                                                    | Description                               |

## Transaction Deadlock

A deadlock is a state in which two or more transactions wait at once for another transaction's lock to be released. CUBRID resolves the problem by rolling back one of the transactions because transactions in a deadlock state will hinder the work of another transaction. The transaction to be rolled back is usually the transaction which has made the least updates; it is usually the one that started more recently. As soon as a transaction is rolled back, the lock held by the transaction is released and other transactions in a deadlock are permitted to proceed.

It is impossible to predict such deadlocks, but it is recommended that you reduce the range to which lock is applied by setting the index, shortening the transaction, or setting the transaction isolation level as low in order to decrease such occurrences.

Note that if you configure the value of **error\_log\_level**, which indicates the severity level, to NOTIFICATION, information on lock is stored in error log file of server upon deadlock occurrences.

Compared to older versions, CUBRID 10.0 no longer uses index key locking to read and write in index, thus deadlock occurrences have been greatly reduced. Another reason that deadlocks do not occur as often is that reading a range in index could lock many objects with high isolation levels in previous CUBRID versions, whereas CUBRID 10.0 uses no locks.

However, deadlocks are still possible when two transaction update same objects, but in a different order.

## Example

| session 1                                                                                                           | session 2                                                                                                           |

```

## Transaction Lock Timeout

CUBRID provides the lock timeout feature, which sets the waiting time for the lock until the transaction lock setting is allowed.

If the lock is allowed within the lock timeout, CUBRID rolls back the transaction and outputs an error message when the timeout has passed. If a transaction deadlock occurs within the lock timeout, CUBRID rolls back the transaction whose waiting time is closest to the timeout.

### Setting the Lock Timeout

The system parameter **lock\_timeout** in the **\$CUBRID/conf/cubrid.conf** file or the **SET TRANSACTION** statement sets the timeout (in seconds) during which the application will wait for the lock and rolls back the transaction and outputs an error message when the specified time has passed. The default value of the **lock\_timeout** parameter is **-1**, which means the application will wait indefinitely until the transaction lock is allowed. Therefore, the user can change this value depending on the transaction pattern of the application. If the lock timeout value has been set to 0, an error message will be displayed as soon as a lock occurs.

```
SET TRANSACTION LOCK TIMEOUT timeout_spec [ ; ]
timeout_spec:
- INFINITE
- OFF
```

- `unsigned_integer`
- `variable`

- **INFINITE** : Wait indefinitely until the transaction lock is allowed. Has the same effect as setting the system parameter **lock\_timeout** to -1.
- **OFF** : Do not wait for the lock, but roll back the transaction and display an error message. Has the same effect as setting the system parameter **lock\_timeout** to 0.
- *unsigned\_integer* : Set in seconds. Wait for the transaction lock for the specified time period.
- *variable* : A variable can be specified. Wait for the transaction lock for the value stored by the variable.

### Example 1

```
vi $CUBRID/conf/cubrid.conf
...
lock_timeout = 10s
...
```

### Example 2

```
SET TRANSACTION LOCK TIMEOUT 10;
```

### Checking the Lock Timeout

You can check the lock timeout set for the current application by using the **GET TRANSACTION** statement, or store this value in a variable.

```
GET TRANSACTION LOCK TIMEOUT [ { INTO | TO } variable ] [ ; ]
```

### Example

```
GET TRANSACTION LOCK TIMEOUT;
```

Result

```
=====
1.000000e+001
```

### Checking and Handling Lock Timeout Error Message

The following message is displayed if lock timeout occurs in a transaction that has been waiting for another transaction's lock to be released.

```
Your transaction (index 2, user1@host1|9808) timed out waiting on
IX_LOCK lock on class tbl. You are waiting for
user(s) user1@host1|csql(9807), user1@host1|csql(9805) to finish.
```

- Your transaction(index 2 ...): This means that the index of the transaction that was rolled back due to timeout while waiting for the lock is 2. The transaction index is a number that is sequentially assigned when the client connects to the database server. You can also check this number by executing the **cubrid lockdb** utility.
- (... user1@host1|9808): *cub\_user* is the login ID of the client and the part after @ is the name of the host where the client was running. The part after| is the process ID (PID) of the client.
- IX\_LOCK: This means the exclusive lock set on the object to perform data update. For details, see [Lock Mode Types And Compatibility](#).
- user1@host1|csql(9807), user1@host1|csql(9805): Another transactions waiting for termination to lock **IX\_LOCK**

That is, the above lock error message can be interpreted as meaning that “Because another client is holding **X\_LOCK** on a specific row in the *participant* table, transaction 3 which running on the host *host1* waited for the lock and the timeout has passed”. If you want to check the lock information of the transaction specified in the error message, you can do so by using the **cubrid lockdb** utility to search for the OID value (ex: 0|636|34) of a specific row where the **X\_LOCK** is set currently to find the transaction ID currently holding the lock, the client program name and the process ID (PID). For details, see [lockdb](#). You can also check the transaction lock information in the CUBRID Manager.

You can organize the transactions by checking uncommitted queries through the SQL log after checking the transaction lock information in the manner described above. For information on checking the SQL log, see [Broker Logs](#).

Also, you can forcefully stop problematic transactions by using the **cubrid killtran** utility. For details, see [killtran](#).

## Transaction Isolation Level

The transaction isolation level is determined based on how much interference occurs. The higher isolation means the less interference from other transactions and more serializable. The lower isolation means the more interference from other transactions and higher level of concurrency. You can control the level of consistency and concurrency specific to a service by setting appropriate isolation level.

### Note

A transaction can be restored in all supported isolation levels because updates are not committed before the end of the transaction.

## SET TRANSACTION ISOLATION LEVEL

You can set the level of transaction isolation by using **isolation\_level** and the **SET TRANSACTION** statement in the **\$CUBRID/conf/cubrid.conf**. The level of **READ COMMITTED** is set by default, which indicates the level 4 through level 4 to 6 (levels 1 to 3 were used by older versions of CUBRID and are now obsolete). For details, see [Database Concurrency](#).

```
SET TRANSACTION ISOLATION LEVEL isolation_level_spec ;

isolation_level_spec:
    SERIALIZABLE | 6
    REPEATABLE READ | 5
    READ COMMITTED | CURSOR STABILITY | 4
```

### Example 1

```
vi $CUBRID/conf/cubrid.conf
...

isolation_level = 4
...

-- or

isolation_level = "TRAN_READ_COMMITTED"
```

### Example 2

```
SET TRANSACTION ISOLATION LEVEL 4;
-- or
SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
```

## Levels of Isolation Supported by CUBRID

| Name               | Description                                                                        |
|--------------------|------------------------------------------------------------------------------------|
| READ COMMITTED (4) | Another transaction T2 cannot update the schema of table A while transaction T1 is |

| Name                | Description                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | viewing table A. Transaction T1 may experience R read (non-repeatable read) that was updated and committed by another transaction T2 when it is repeatedly retrieving the record R. |
| REPEATABLE READ (5) | Another transaction T2 cannot update the schema of table A while transaction T1 is viewing table A.                                                                                 |
| SERIALIZABLE (6)    | Temporarily disabled - details in <b>SERIALIZABLE Isolation Level</b>                                                                                                               |

If the transaction level is changed in an application while a transaction is executed, the new level is applied to the rest of the transaction being executed. It is recommended that to modify the transaction isolation level when a transaction starts (after commit, rollback or system restart) because an isolation level which has already been set does not apply to the entire transaction, but can be changed during the transaction.

## GET TRANSACTION ISOLATION LEVEL

You can assign the current isolation level to *variable* by using the **GET TRANSACTION ISOLATION LEVEL** statement. The following is a statement that verifies the isolation level.

```
GET TRANSACTION ISOLATION LEVEL [ { INTO | TO } variable ] [ ; ]
```

```
GET TRANSACTION ISOLATION LEVEL;
```

```
Result
=====
READ COMMITTED
```

## READ COMMITTED Isolation Level

A relatively low isolation level (4). A dirty read does not occur, but non-repeatable or phantom read may. That is, transaction *T1* can read another value because insert or update by transaction *T2* is allowed while transaction *T1* is repeatedly retrieving one object.

The following are the rules of this isolation level:

- Transaction *T1* cannot read or modify the record inserted by another transaction *T2*. The record is instead ignored.
- Transaction *T1* can read the record being updated by another transaction *T2* and it sees the record's last committed version (but it cannot see uncommitted versions).
- Transaction *T1* cannot modify the record being updated by another transaction *T2*. *T1* waits for *T2* to commit and it re-evaluates record values. If the re-evaluation test is passed, *T1* modifies the record, otherwise it ignores it.
- Transaction *T1* can modify the record being viewed by another transaction *T2*.
- Transaction *T1* can update/insert record to the table being viewed by another transaction *T2*.
- Transaction *T1* cannot change the schema of the table being viewed by another transaction *T2*.
- Transaction *T1* creates a new snapshot with each executed statement, thus phantom or non-repeatable read may occur.

This isolation level follows MVCC locking protocol for an exclusive lock. A shared lock on a row is not required; however, an intent lock on a table is released when a transaction terminates to ensure repeatable read on the schema.

### Example

The following example shows that a phantom or non-repeatable read may occur because another transaction can add or update a record while one transaction is performing the object read but repeatable read for the table schema update is ensured when the transaction level of the concurrent transactions is **READ COMMITTED**.

#### session 1

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL READ COMMITTED;
```

#### session 2

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL READ
```

## session 1

```
Isolation level set to:
READ COMMITTED
```

## session 2

```
COMMITTED;
```

```
Isolation level set to:
READ COMMITTED
```

```
csql> CREATE TABLE
isol4_tbl(host_year integer,
nation_code char(3));
```

```
csql> INSERT INTO isol4_tbl
VALUES (2008, 'AUS');
```

```
csql> COMMIT;
```

```
csql> SELECT * FROM isol4_tbl;
```

```
      host_year  nation_code
=====
=====
      2008      'AUS'
```

```
csql> INSERT INTO isol4_tbl
VALUES (2004, 'AUS');
```

```
csql> INSERT INTO isol4_tbl
VALUES (2000, 'NED');
```

```
csql> COMMIT;
```

```
/* phantom read occurs
because tran 1 committed */
csql> SELECT * FROM isol4_tbl;
```

```
      host_year  nation_code
=====
=====
      2008      'AUS'
```

## session 1

## session 2

```
2004  'AUS'
2000  'NED'
```

```
csql> UPDATE isol4_tbl
csql> SET nation_code = 'KOR'
csql> WHERE host_year = 2008;
csql> COMMIT;
```

```
/* unrepeatable read occurs
because tran 1 committed */
csql> SELECT * FROM isol4_tbl;
```

```
      host_year  nation_code
=====
=====
      2008      'KOR'
      2004      'AUS'
      2000      'NED'
```

```
csql> ALTER TABLE isol4_tbl
ADD COLUMN gold INT;
```

```
/* unable to alter the table
schema until tran 2 committed
*/
```

```
/* repeatable read is ensured
while
 * tran_1 is altering table
schema
*/
```

```
csql> SELECT * FROM isol4_tbl;

      host_year  nation_code
```

## session 1

## session 2

```
=====
=====
2008 'KOR'
2004 'AUS'
2000 'NED'
```

```
csql> COMMIT;
```

/* unable to access the table
until tran_1 committed */
```

```
csql> COMMIT;
```

```
host_year  nation_code  gold
=====
=====
2008 'KOR'          NULL
2004 'AUS'          NULL
2000 'NED'          NULL
```

## READ COMMITTED UPDATE RE-EVALUATION

**READ COMMITTED** isolation treats concurrent row updates differently than higher isolation levels. In higher isolation levels, if  $T_2$  tries to modify a row already updated by concurrent transaction  $T_1$ , it is blocked until  $T_1$  commits and rollbacks, and if  $T_1$  commits,  $T_2$  aborts its statement execution, throwing serialization error. Under **READ COMMITTED** isolation, after  $T_1$  commits,  $T_2$  does not immediately abort its statement execution and re-evaluates the new version, which is not considered committed and would not violate any restrictions for this isolation. If the predicate used to select previous version is still true for the new version,  $T_2$  goes ahead and modifies the

new version. If the predicate is no longer true, T2 just ignores the record as if the predicate was never satisfied.

Example:

### session 1

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL 4;

Isolation level set to:
READ COMMITTED
```

### session 2

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL 4;

Isolation level set to:
READ COMMITTED
```

```
csql> CREATE TABLE
isol4_tbl(host_year integer,
nation_code char(3));
csql> INSERT INTO isol4_tbl
VALUES (2000, 'KOR');
csql> INSERT INTO isol4_tbl
VALUES (2004, 'USA');
csql> INSERT INTO isol4_tbl
VALUES (2004, 'GER');
csql> INSERT INTO isol4_tbl
VALUES (2008, 'GER');
csql> COMMIT;
```

```
csql> UPDATE isol4_tbl
csql> SET host_year =
host_year - 4
csql> WHERE nation_code =
'GER';

/* T1 locks and modifies
(2004, 'GER') to (2000, 'GER')
*/
/* T1 locks and modifies
```

## session 1

```
(2008, 'GER') to (2004, 'GER')
*/
```

## session 2

```
csql> UPDATE isol4_tbl
csql> SET host_year =
host_year + 4
csql> WHERE host_year >= 2004;
```

```
/* T2 snapshot will try to
modify three records:
 * (2004, 'USA'), (2004,
'GER'), (2008, 'GER')
 *
 * T2 locks and modifies
(2004, 'USA') to (2008, 'USA')
 * T2 is blocked on lock on
(2004, 'GER').
 */
```

```
csql> COMMIT;
```

```
/* T1 releases locks on
modified rows. */
```

```
/* T2 is unblocked and will
do the next steps:
 *
 * T2 finds (2004, 'GER')
has a new version (2000,
'GER')
 * that doesn't satisfy
predicate anymore.
 * T2 releases the lock on
object and ignores it.
 *
 * T2 finds (2008, 'GER')
has a new version (2004,
'GER')
```

## session 1

## session 2

```
*    that still satisfies the
predicate.
*    T2 keeps the lock and
changes row to (2008, 'GER')
*/
```

```
csql> SELECT * FROM isol4_tbl;
```

```
      host_year  nation_code
=====
=====
          2000    'KOR'
          2000    'GER'
          2008    'USA'
          2008    'GER'
```

## REPEATABLE READ Isolation Level

A relatively high isolation level (5). Dirty, non-repeatable, and phantom reads do not occur due to **snapshot isolation**. However, it's still not truly **serializable**, transaction execution cannot be defined as *if there were no other transactions running* at the same time. More complex anomalies, like write skew, that a **serializable snapshot isolation** level should not allow still occur.

In a write skew anomaly, two transactions concurrently read overlapping data sets and make disjoint updates on the overlapped data set, neither having seen the update performed by the other. In a serializable system, such anomaly would be impossible, since one transaction must occur first and the second transaction should see the update of the first transaction.

The following are the rules of this isolation level:

- Transaction *T1* cannot read or modify the record inserted by another transaction *T2*. The record is instead ignored.
- Transaction *T1* can read the record being updated by another transaction *T2* and it will see the record's last committed version.
- Transaction *T1* cannot modify the record being updated by another transaction *T2*.

- Transaction *T1* can modify the record being viewed by another transaction *T2*.
- Transaction *T1* can update/insert record to the table being viewed by another transaction *T2*.
- Transaction *T1* cannot change the schema of the table being viewed by another transaction *T2*.
- Transaction *T1* creates a unique snapshot valid throughout the entire duration of the transaction.

### Example

The following example shows that non-repeatable and phantom reads may not occur because of **snapshot isolation**. However, write skewes are possible, which means the isolation level is not **serializable**.

#### session 1

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL 5;

Isolation level set to:
REPEATABLE READ
```

#### session 2

```
csql> ;autocommit off

AUTOCOMMIT IS OFF

csql> SET TRANSACTION
ISOLATION LEVEL 5;

Isolation level set to:
REPEATABLE READ
```

```
csql> CREATE TABLE
isol5_tbl(host_year integer,
nation_code char(3));
csql> CREATE UNIQUE INDEX
isol5_u_idx
      on
isol5_tbl(nation_code,
host_year);
csql> INSERT INTO isol5_tbl
VALUES (2008, 'AUS');
csql> INSERT INTO isol5_tbl
VALUES (2004, 'AUS');

csql> COMMIT;
```

## session 1

## session 2

```
csql> SELECT * FROM isol5_tbl
WHERE nation_code='AUS';
```

| host_year | nation_code |
|-----------|-------------|
| 2004      | 'AUS'       |
| 2008      | 'AUS'       |

```
csql> INSERT INTO isol5_tbl
VALUES (2004, 'KOR');
csql> INSERT INTO isol5_tbl
VALUES (2000, 'AUS');

/* able to insert new rows */
csql> COMMIT;
```

```
csql> SELECT * FROM isol5_tbl
WHERE nation_code='AUS';
```

```
/* phantom read cannot occur
due to snapshot isolation */
```

| host_year | nation_code |
|-----------|-------------|
| 2004      | 'AUS'       |
| 2008      | 'AUS'       |

```
csql> UPDATE isol5_tbl
SET host_year = 2012
WHERE nation_code =
'AUS' and
host_year=2008;
```

```
/* able to update rows viewed
```

## session 1

```
by T2 */
csql> COMMIT;
```

## session 2

```
csql> SELECT * FROM isol5_tbl
WHERE nation_code = 'AUS';
```

```
/* non-repeatable read cannot
occur due to snapshot
isolation */
```

## SERIALIZABLE Isolation Level

CUBRID 10.0 **SERIALIZABLE** isolation level is identical to **REPEATABLE READ** isolation level. As explained in [REPEATABLE READ Isolation Level](#) section, even though **SNAPSHOT** isolation ensures non-repeatable read and phantom read anomalies do not happen, write skew anomalies are still possible. To protect against write skew, index key locks for read may be used. Alternatively, there are many works that describe complex systems to provide **SERIALIZABLE SNAPSHOT ISOLATION**, by aborting transactions with the potential of creating an isolation conflict. One such system will be provided in a future CUBRID version.

The keyword was not removed for backward compatibility reasons, but remember, it is similar to **REPEATABLE READ**.

## How to Handle Dirty Record

CUBRID flushes dirty data (or dirty record) in the client buffers to the database (server) such as the following situations. In additions to those, there can be more situations where flushes can be performed.

- Dirty data can be flushed to server when a transaction is committed.
- Some of dirty data can be flushed to server when a lot of data is loaded into the client buffers.
- Dirty data of table A can be flushed to server when the schema of table A is updated.
- Dirty data of table A can be flushed to server when the table A is retrieved (**SELECT**)
- Some of dirty data can be flushed to server when a server function is called.

## Transaction Termination and Restoration

The restore process in CUBRID makes it possible that the database is not affected even if a software or hardware error occurs. In CUBRID, all read and update commands that are made during a transaction must be atomic. This means that either all of the transaction's commands are committed to the database or none are. The concept of atomicity is extended to the set of operations that consists of a transaction. The transaction must either commit so that all effects are permanently applied to the database or roll back so that all effects are removed. To ensure transaction atomicity, CUBRID applies the effects of the committed transaction again every time an error occurs without the updates of the transaction being written to the disk. CUBRID also removes the effects of partially committed transactions in the database every time the site fails (some transactions may have not committed or applications may have requested to cancel transactions). This restore feature eases the burden for the applications of maintaining the database consistency depending on the system error. The restore process used in CUBRID is based on the undo/redo logging mechanism.

CUBRID provides an automatic restore method to maintain the transaction atomicity when a hardware or software error occurs. You do not have to take the responsibility for restore since CUBRID's restore feature always returns the database to a consistent state even when an application or computer system error occurs. For this purpose, CUBRID automatically rolls back part of committed transactions when the application fails or the user requests explicitly. For example, a system error that occurred during the execution of the **COMMIT WORK** statement must be stopped if the transaction has not committed yet (it cannot be confirmed that the user's operation has been committed). Automatic stop prevents errors causing undesired changes to the database by canceling uncommitted updates.

## Restarting Database

CUBRID uses log volumes/files and database backups to restore committed or uncommitted transactions when system or media (disk) error occurs. Logs are also used to support the user-specified rollback. A log consists of a collection of sequential files created by CUBRID. The most recent log is called the active log, and the rest are called archive logs. A log file refers to both the active and archive logs.

All updates of the database are written to the log. Actually, two copies of the updates are logged. The first one is called a before image (UNDO log) and used to restore data during execution of the user-specified **ROLLBACK WORK** statement or during media or system errors. The second copy is an after image (REDO log) and used to re-apply the updates when media or system error occurs.

When the active log is full, CUBRID copies it to an archive log to store in the disk. The archive log is needed to restore the database when a system failure occurs.

## Normal Termination or Error

CUBRID restores the database if it restarts due to a normal termination or a device error. The restore process re-applies the committed changes that have not been applied to the database and removes the uncommitted changes stored in the database. The general operation of the database resumes after the restore is completed. This restore process does not use any archive logs or database backup.

In a client/server environment, the database can restart by using the **cubrid server** utility.

## Media Error

The user's intervention is somewhat needed to restart the database after media error occurs. The first step is to restore the database by installing a backup of a known good state. In CUBRID, the most recent log file (the one after the last backup) must be installed. This specific log (archive or active) is applied to a backup copy of the database. As with normal termination, the database can restart after restoration is committed.

**Note**

To minimize the possibility of losing database updates, it is recommended to create a snapshot and store it in the backup media before it is deleted from the disk. The DBA can backup and restore the database by using the **cubrid backupdb** and **cubrid restoredb** utilities. For details on these utilities, see [backupdb](#).

## Trigger

### CREATE TRIGGER

#### Guidelines for Trigger Definition

Trigger definition provides various and powerful functionalities. Before creating a trigger, you must consider the following:

- **Does the trigger condition expression cause unexpected results (side effect)?**

You must use the SQL statements within an expectable range.

- **Does the trigger action change the table given as its event target?**

While this type of design is not forbidden in the trigger definition, it must be carefully applied, because a trigger can be created that falls into an infinite loop. When the trigger action modifies the event target table, the same trigger can be called again. If a trigger occurs in a statement that contains a **WHERE** clause, there is no side effect in the table affected by the **WHERE** clause.

- **Does the trigger cause unnecessary overhead?**

If the desired action can be expressed more effectively in the source, implement it directly in the source.

- **Is the trigger executed recursively?**

If the trigger action calls a trigger and this trigger calls the previous trigger again, a recursive loop is created in the database. If a recursive loop is created, the trigger may not be executed correctly, or the current session must be forced to terminate to break the ongoing infinite loop.

- **Is the trigger definition unique?**

A trigger defined in the same table or the one started in the same action becomes the cause of an unrecoverable error. A trigger in the same table must have a different trigger event. In addition, trigger priority must be explicitly and unambiguously defined.

## Trigger Definition

A trigger is created by defining a trigger target, condition and action to be performed in the **CREATE TRIGGER** statement. A trigger is a database object that performs a defined action when a specific event occurs in the target table.

```
CREATE TRIGGER [schema_name.]trigger_name
[ STATUS { ACTIVE | INACTIVE } ]
[ PRIORITY key ]
<event_time> <event_type> [<event_target>]
[ IF condition ]
EXECUTE [ AFTER | DEFERRED ] action
[COMMENT 'trigger_comment'];

<event_time> ::=
    BEFORE |
    AFTER |
    DEFERRED

<event_type> ::=
    INSERT |
    STATEMENT INSERT |
    UPDATE |
    STATEMENT UPDATE |
    DELETE |
    STATEMENT DELETE |
    ROLLBACK |
    COMMIT

<event_target> ::=
    ON [schema_name.]table_name |
    ON [schema_name.]table_name [ (column_name) ]

<condition> ::=
    expression

<action> ::=
    REJECT |
    INVALIDATE TRANSACTION |
    PRINT message_string |
    INSERT statement |
```

UPDATE statement |  
DELETE statement

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name*: specifies the name of the trigger to be defined.
- [ **STATUS** { **ACTIVE** | **INACTIVE** } ]: Defines the state of the trigger (if not defined, the default value is **ACTIVE**).
  - If **ACTIVE** state is specified, the trigger is executed every time the corresponding event occurs.
  - If **INACTIVE** state is specified, the trigger is not executed even when the corresponding event occurs. The state of the trigger can be modified. For details, see [ALTER TRIGGER](#) section.
- [ **PRIORITY** *key* ]: specifies a trigger priority if multiple triggers are called for an event. *key* must be a floating point value that is not negative. If the priority is not defined, the lowest priority 0 is assigned. Triggers having the same priority are executed in a random order. The priority of triggers can be modified. For details, see [ALTER TRIGGER](#) section.
- *<event\_time>*: specifies the point of time when the conditions and actions are executed. **BEFORE**, **AFTER** or **DEFERRED** can be specified. For details, see the [Event Time](#) section.
- *<event\_type>*: trigger types are divided into a user trigger and a table trigger. For details, see the [Trigger Event Type](#) section.
- *<event\_target>*: An event target is used to specify the target for the trigger to be called. For details, see the [Trigger Event Target](#) section.
- *<condition>*: specifies the trigger condition. For details, see the [Trigger Condition](#) section.
- *<action>*: specifies the trigger action. For details, see the [Trigger Action](#) section.
- *trigger\_comment*: specifies a trigger's comment.

#### Note

- **DBA** and **DBA** members can create triggers in different schemas. If a user is neither **DBA** nor **DBA** member, triggers can only be created in the schema of that user.

The following example shows how to create a trigger that rejects the update if the number of medals won is smaller than 0 when an instance of the *participant* table is updated. As shown

below, the update is rejected if you try to change the number of gold (*gold*) medals that Korea won in the 2004 Olympic Games to a negative number.

```
CREATE TRIGGER medal_trigger
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;

UPDATE participant SET gold = -5 WHERE nation_code = 'KOR'
AND host_year = 2004;
```

```
ERROR: The operation has been rejected by trigger "medal_trigger".
```

## Event Time

Specifies the point of time when trigger conditions and actions are executed. The types of event time are **BEFORE**, **AFTER** and **DEFERRED**.

- **BEFORE**: checks the condition before the event is processed.
- **AFTER**: checks the condition after the event is processed.
- **DEFERRED**: checks the condition at the end of the transaction for the event. If you specify **DEFERRED**, you cannot use **COMMIT** or **ROLLBACK** as the event type.

## Trigger Type

### User Trigger

- A trigger relevant to a specific user of the database is called a user trigger.
- A user trigger has no event target and is executed only by the owner of the trigger (the user who created the trigger).
- Event types that define a user trigger are **COMMIT** and **ROLLBACK**.

### Table Trigger

- A trigger that has a table as the event target is called a table trigger (class trigger).
- A table trigger can be seen by all users who have the **SELECT** authorization on a target table.
- Event types that define a table trigger are instance and statement events.

## Trigger Event Type

- Instance events: An event type whose unit of operation is an instance. The types of instance (record) events are as follows:
  - **INSERT**
  - **UPDATE**
  - **DELETE**
- Statement events: If you define a statement event as an event type, the trigger is called only once when the trigger starts even when there are multiple objects (instances) affected by the given statement (event). The types of statement events are as follows:
  - **STATEMENT INSERT**
  - **STATEMENT UPDATE**
  - **STATEMENT DELETE**
- Other events: **COMMIT** and **ROLLBACK** cannot be applied to individual instances.
  - **COMMIT**
  - **ROLLBACK**

The following example shows how to use an instance event. The *example* trigger is called by each instance affected by the database update. For example, if the *score* values of five instances in the *history* table are modified, the trigger is called five times.

```
CREATE TABLE update_logs(event_code INTEGER, score VARCHAR(10), dt
DATETIME);

CREATE TRIGGER example
BEFORE UPDATE ON history(score)
EXECUTE INSERT INTO update_logs VALUES (obj.event_code, obj.score,
SYSDATETIME);
```

If you want the trigger to be called only once, before the first instance of the *score* column is updated, use the **STATEMENT UPDATE** type as the following example.

The following example shows how to use a statement event. If you define a statement event, the trigger is called only once before the first instance gets updated even when there are multiple instances affected by the update.

```
CREATE TRIGGER example
BEFORE STATEMENT UPDATE ON history(score)
EXECUTE PRINT 'There was an update on history table';
```

### Note

- You must specify the event target when you define an instance or statement event as the event type.
- **COMMIT** and **ROLLBACK** cannot have an event target.

## Trigger Event Target

An event target specifies the target for the trigger to be called. The target of a trigger event can be specified as a table or column name. If a column name is specified, the trigger is called only when the specified column is affected by the event. If a column is not specified, the trigger is called when any column of the table is affected. Only **UPDATE** and **STATEMENT UPDATE** events can specify a column as the event target.

The following example shows how to specify the *score* column of the *history* table as the event target of the *example* trigger.

```
CREATE TABLE update_logs(event_code INTEGER, score VARCHAR(10), dt
DATETIME);

CREATE TRIGGER example
BEFORE UPDATE ON history(score)
EXECUTE INSERT INTO update_logs VALUES (obj.event_code, obj.score,
SYSDATETIME);
```

## Combination of Event Type and Target

A database event calling triggers is identified by the trigger event type and event target in a trigger definition. The following table shows the trigger event type and target combinations, along with the meaning of the CUBRID database event that the trigger event represents.

| Event Type      | Event Target | Corresponding Activity                                               | Database |
|-----------------|--------------|----------------------------------------------------------------------|----------|
| <b>UPDATE</b>   | Table        | Trigger is called when the UPDATE statement for a table is executed. |          |
| <b>INSERT</b>   | Table        | Trigger is called when the INSERT statement for a table is executed. |          |
| <b>DELETE</b>   | Table        | Trigger is called when the DELETE statement for a table is executed. |          |
| <b>COMMIT</b>   | None         | Trigger is called when database transaction is committed.            |          |
| <b>ROLLBACK</b> | None         | Trigger is called when database transaction is rolled back.          |          |

## Trigger Condition

You can specify whether a trigger action is to be performed by defining a condition when defining the trigger.

- If a trigger condition is specified, it can be written as an independent compound expression that evaluates to true or false. In this case, the expression can contain arithmetic and logical operators allowed in the **WHERE** clause of the **SELECT** statement. The trigger action is performed if the condition is true; if it is false, action is ignored.
- If a trigger condition is omitted, the trigger becomes an unconditional trigger, which refers to that the trigger action is performed whenever it is called.

The following example shows how to use a correlation name in an expression within a condition. If the event type is **INSERT**, **UPDATE** or **DELETE**, the expression in the condition can refer to the

correlation names **obj**, **new** or **old** to access a specific column. This example prefixes **obj** to the column name in the trigger condition to show that the *example* trigger tests the condition based on the current value of the *record* column.

```
CREATE TRIGGER example
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;
```

The following example shows how to use the **SELECT** statement in an expression within a condition. The trigger in this example uses the **SELECT** statement that contains an aggregate function **COUNT** (\*) to compare the value with a constant. The **SELECT** statement must be enclosed in parentheses and must be placed at the end of the expression.

```
CREATE TRIGGER example
BEFORE INSERT ON participant
IF 1000 > (SELECT COUNT(*) FROM participant)
EXECUTE REJECT;
```

#### Note

The expression given in the trigger condition may cause side effects on the database if a method is called while the condition is performed. A trigger condition must be constructed to avoid unexpected side effects in the database.

## Correlation Name

You can access the column values defined in the target table by using a correlation name in the trigger definition. A correlation name is the instance that is actually affected by the database operation calling the trigger. A correlation name can also be specified in a trigger condition or action.

The types of correlation names are **new**, **old** and **obj**. These correlation names can be used only in instance triggers that have an **INSERT**, **UPDATE** or **DELETE** event.

As shown in the table below, the use of correlation names is further restricted by the event time defined for the trigger condition.

|        | BEFORE | AFTER or DEFERRED |
|--------|--------|-------------------|
| INSERT | new    | obj               |
| UPDATE | obj    | obj               |
|        | new    | old (AFTER)       |
| DELETE | obj    | N/A               |

| Correlation Name | Representative Attribute Value                                                                                                                                                                                                                     |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj              | Refers to the current attribute value of an instance. This can be used to access attribute values before an instance is updated or deleted. It is also used to access attribute values after an instance has been updated or inserted.             |
| new              | Refers to the attribute value proposed by an insert or update operation. The new value can be accessed only before the instance is actually inserted or updated.                                                                                   |
| old              | <p><b>Refers to the attribute value that existed prior to the completion of an update operation. This value is maintained</b></p> <p>only while the trigger is being performed. Once the trigger is completed, the <b>old</b> values get lost.</p> |

## Trigger Action

A trigger action describes what to be performed if the trigger condition is true or omitted. If a specific point of time (**AFTER** or **DEFERRED**) is not given in the action clause, the action is executed at once as the trigger event.

The following is a list of actions that can be used for trigger definitions.

- **REJECT**: discards the operation that initiated the trigger and keeps the former state of the database, if the condition is not true. Once the operation is performed, **REJECT** is allowed only when the action time is **BEFORE** because the operation cannot be rejected. Therefore, you must not use **REJECT** if the action time is **AFTER** or **DEFERRED**.
- **INVALIDATE TRANSACTION**: allows the event operation that called the trigger, but does not allow the transaction that contains the commit to be executed. You must cancel the transaction by using the **ROLLBACK** statement if it is not valid. Such action is used to protect the database from having invalid data after a data-changing event happens.
- **PRINT**: displays trigger actions on the terminal screen in text messages, and can be used during developments or tests. The results of event operations are not rejected or discarded.
- **INSERT**: inserts one or more new instances to the table.
- **UPDATE**: updates one or more column values in the table.
- **DELETE**: deletes one or more instances from the table.

The following example shows how to define an action when a trigger is created. The *medal\_trig* trigger defines **REJECT** in its action. **REJECT** can be specified only when the action time is **BEFORE**.

```
CREATE TRIGGER medal_trig
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;
```

### Note

- Trigger may fall into an infinite loop when you use **INSERT** in an action of a trigger where an **INSERT** event is defined.
- If a trigger where an **UPDATE** event is defined runs on a partitioned table, you must be careful because the defined partition can be broken or unintended malfunction may occur. To prevent such situation, CUBRID outputs an error so that the **UPDATE** causing changes to

the running partition is not executed. Trigger may fall into an infinite loop when you use **UPDATE** in an action of a trigger where an **UPDATE** event is defined.

## Trigger's COMMENT

You can specify a trigger's comment as follows.

```
CREATE TRIGGER trg_ab BEFORE UPDATE on abc(c) EXECUTE UPDATE cube_ab
SET sumc = sumc + 1
COMMENT 'test trigger comment';
```

You can see a trigger's comment by running the below statement.

```
SELECT name, comment FROM db_trigger;
SELECT trigger_name, comment FROM db_trigger;
```

Or you can see a trigger's comment with ;sc command which displays a schema in the CSQL interpreter.

```
$ csql -u dba demodb

csql> ;sc tbl
```

To change the trigger's comment, refer to **ALTER TRIGGER** syntax on the below.

## ALTER TRIGGER

In the trigger definition, **STATUS** and **PRIORITY** options can be changed by using the **ALTER** statement. If you need to alter other parts of the trigger (event targets or conditional expressions), you must delete and then re-create the trigger.

```
ALTER TRIGGER [schema_name.]trigger_name <trigger_option> ;

<trigger_option> ::=
    STATUS { ACTIVE | INACTIVE } |
    PRIORITY key
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name*: specifies the name of the trigger to be changed.

- **STATUS { ACTIVE | INACTIVE }**: changes the status of the trigger.
- **PRIORITY** *key*: changes the priority.

The following example shows how to create the `medal_trig` trigger and then change its state to **INACTIVE** and its priority to 0.7.

```
CREATE TRIGGER medal_trig
STATUS ACTIVE
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;

ALTER TRIGGER medal_trig STATUS INACTIVE;
ALTER TRIGGER medal_trig PRIORITY 0.7;
```

#### Note

- Only one *trigger\_option* can be specified in a single **ALTER TRIGGER** statement.
- To change a table trigger, you must be the trigger owner or granted the **ALTER** authorization on the table where the trigger belongs.
- A user trigger can only be changed by its owner. For details on *trigger\_option*, see the **CREATE TRIGGER** section. The key specified together with the **PRIORITY** option must be a non-negative floating point value.

## Trigger's COMMENT

You can change a trigger's comment by running **ALTER TRIGGER** syntax as below.

```
ALTER TRIGGER [schema_name.]trigger_name [trigger_option]
[COMMENT 'comment_string'];
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name*: specifies the name of the trigger to be changed.
- *comment\_string*: specifies a trigger's comment.

If you want to change only trigger's comment, you can omit trigger options (*trigger\_option*).

For *trigger\_option*, see **ALTER TRIGGER** on the above.

```
ALTER TRIGGER trg_ab COMMENT 'new trigger comment';
```

## DROP TRIGGER

You can drop a trigger by using the **DROP TRIGGER** statement.

```
DROP TRIGGER [schema_name.]trigger_name ;
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name*: specifies the name of the trigger to be dropped.

The following example shows how to drop the medal\_trig trigger.

```
DROP TRIGGER medal_trig;
```

### Note

- A user trigger (i.e. the trigger event is **COMMIT** or **ROLLBACK**) can be seen and dropped only by the owner.
- Only one trigger can be dropped by a single **DROP TRIGGER** statement. A table trigger can be dropped by a user who has an **ALTER** authorization on the table.

## RENAME TRIGGER

You can change a trigger name by using the **TRIGGER** reserved word in the **RENAME** statement.

```
RENAME TRIGGER [schema_name.]old_trigger_name {AS | TO}  
[schema_name.]new_trigger_name ;
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used. The schema of the current trigger and the schema of the trigger to be changed must be the same.
- *old\_trigger\_name*: specifies the current name of the trigger.
- *new\_trigger\_name*: specifies the name of the trigger to be modified.

```
RENAME TRIGGER medal_trigger AS medal_trig;
```

#### Note

- A trigger name must be unique among triggers owned by the user. However, it can be the same as the table name in the database or the name of a trigger owned by another owner.
- To rename a table trigger, you must be the trigger owner or granted the **ALTER** authorization on the table where the trigger belongs. A user trigger can only be renamed by its user.

## Deferred Condition and Action

A deferred trigger action and condition can be executed later or canceled. These triggers include a **DEFERRED** time option in the event time or action clause. If the **DEFERRED** option is specified in the event time and the time is omitted before the action, the action is deferred automatically.

### Executing Deferred Condition and Action

Executes the deferred condition or action of a trigger immediately.

```
EXECUTE DEFERRED TRIGGER <trigger_identifier> ;

<trigger_identifier> ::=
    [schema_name.]trigger_name |
    ALL TRIGGERS
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name*: executes the deferred action of the trigger when a trigger name is specified.
- **ALL TRIGGERS**: executes all currently deferred actions.

## Dropping Deferred Condition and Action

Drops the deferred condition and action of a trigger.

```
DROP DEFERRED TRIGGER trigger_identifier ;

<trigger_identifier> ::=
```

```
[schema_name.]trigger_name |  
ALL TRIGGER
```

- *schema\_name*: Specifies the schema name of the trigger. If omitted, the schema name of the current session is used.
- *trigger\_name* : Cancels the deferred action of the trigger when a trigger name is specified.
- **ALL TRIGGERS** : Cancels currently deferred actions.

## Granting Trigger Authorization

Trigger authorization is not granted explicitly. Authorization on the table trigger is automatically granted to the user if the authorization is granted on the event target table described in the trigger definition. In other words, triggers that have table targets (**INSERT**, **UPDATE**, etc.) are seen by all users. User triggers (**COMMIT** and **ROLLBACK**) are seen only by the user who defined the triggers. All authorizations are automatically granted to the trigger owner.

### Note

- To define a table trigger, you must have an **ALTER** authorization on the table.
- To define a user trigger, the database must be accessed by a valid user.

## Trigger on REPLACE and INSERT ... ON DUPLICATE KEY UPDATE

When the **REPLACE** statement and **INSERT ... ON DUPLICATE KEY UPDATE** statements are executed, the trigger is executed in CUBRID, while **DELETE**, **UPDATE**, **INSERT** jobs occur internally. The following table shows the order in which the trigger is executed in CUBRID depending on the event that occurred when the **REPLACE** or **INSERT ... ON DUPLICATE KEY UPDATE** statement is executed. Both the **REPLACE** statement and the **INSERT ... ON DUPLICATE KEY UPDATE** statement do not execute triggers in the inherited class (table).

### Execution Sequence of Triggers in the REPLACE and the INSERT ... ON DUPLICATE KEY UPDATE statements

| Event                                                    | Execution Sequence of Triggers                              |
|----------------------------------------------------------|-------------------------------------------------------------|
| REPLACE When a record is deleted and new one is inserted | BEFORE DELETE > AFTER DELETE > BEFORE INSERT > AFTER INSERT |

| Event                                                                      | Execution Sequence of Triggers |
|----------------------------------------------------------------------------|--------------------------------|
| INSERT ... ON DUPLICATE KEY UPDATE When a record is updated                | BEFORE UPDATE > AFTER UPDATE   |
| REPLACE, INSERT ... ON DUPLICATE KEY UPDATE Only when a record is inserted | BEFORE INSERT > AFTER INSERT   |

The following example shows that **INSERT ... ON DUPLICATE KEY UPDATE** and **REPLACE** are executed in the *with\_trigger* table and records are inserted to the *trigger\_actions* table as a consequence of the execution.

```
CREATE TABLE with_trigger (id INT UNIQUE);
INSERT INTO with_trigger VALUES (11);

CREATE TABLE trigger_actions (val INT);

CREATE TRIGGER trig_1 BEFORE INSERT ON with_trigger EXECUTE INSERT
INTO trigger_actions VALUES (1);
CREATE TRIGGER trig_2 BEFORE UPDATE ON with_trigger EXECUTE INSERT
INTO trigger_actions VALUES (2);
CREATE TRIGGER trig_3 BEFORE DELETE ON with_trigger EXECUTE INSERT
INTO trigger_actions VALUES (3);

INSERT INTO with_trigger VALUES (11) ON DUPLICATE KEY UPDATE id=22;

SELECT * FROM trigger_actions;
```

```
      va
=====
      2
```

```
REPLACE INTO with_trigger VALUES (22);

SELECT * FROM trigger_actions;
```

```
      va
=====
      2
      3
      1
```

## Trigger Debugging

Once a trigger is defined, it is recommended to check whether it is running as intended. Sometimes the trigger takes more time than expected in processing. This means that it is adding too much overhead to the system or has fallen into a recursive loop. This section explains several ways to debug the trigger.

The following example shows a trigger that was defined to fall into a recursive *loop\_tgr* when it is called. A *loop\_tgr* trigger is somewhat artificial in its purpose; it can be used as an example of debugging trigger.

```
CREATE TRIGGER loop_tgr
BEFORE UPDATE ON participant(gold)
IF new.gold > 0
EXECUTE UPDATE participant
    SET gold = new.gold - 1
    WHERE nation_code = obj.nation_code AND host_year =
obj.host_year;
```

## Viewing Trigger Execution Log

You can view the execution log of the trigger from a terminal by using the **SET TRIGGER TRACE** statement.

```
SET TRIGGER TRACE <switch> ;

<switch> ::=
    ON |
    OFF
```

- **ON**: executes **TRACE** until the switch is set to **OFF** or the current database session terminates.
- **OFF**: stops the **TRACE**.

The following example shows how to execute the **TRACE** and the *loop\_tgr* trigger to view the trigger execution logs. To identify the trace for each condition and action executed when the trigger is called, a message is displayed on the terminal. The following message appears 15 times because the *loop\_tgr* trigger is executed until the *gold* value becomes 0.

```
SET TRIGGER TRACE ON;
UPDATE participant SET gold = 15 WHERE nation_code = 'KOR' AND
host_year = 1988;
```

```
TRACE: Evaluating condition for trigger "loop".  
TRACE: Executing action for trigger "loop".
```

## Limiting Nested Trigger

With the **MAXIMUM DEPTH** keyword of the **SET TRIGGER** statement, you can limit the number of triggers to be initiated at each step. By doing so, you can prevent a recursively called trigger from falling into an infinite loop.

```
SET TRIGGER [ MAXIMUM ] DEPTH count ;
```

- *count*: A positive integer value that specifies the number of times that a trigger can recursively start another trigger or itself. If the number of triggers reaches the maximum depth, the database request stops (aborts) and the transaction is marked as invalid. The specified **DEPTH** applies to all other triggers except the current session. The maximum value is 32.

The following example shows how to configure the maximum number of times of recursive trigger calling to 10. This applies to all triggers that start subsequently. In this example, the *gold* column value is updated to 15, so the trigger is called 16 times in total. This exceeds the currently set maximum depth and the following error message occurs.

```
SET TRIGGER MAXIMUM DEPTH 10;  
UPDATE participant SET gold = 15 WHERE nation_code = 'KOR' AND  
host_year = 1988;
```

```
ERROR: Maximum trigger depth 10 exceeded at trigger "loop_tgr".
```

### Note

When a **DEFERRED** trigger fires, its action is not executed immediately but accumulates as a deferred action until the end of the transaction, so the more deferred actions accumulate in a single transaction, the more CAS memory is used. In particular, if triggers repeatedly fire each other or a large number of **DEFERRED** triggers fire in a single transaction, the deferred actions can accumulate excessively; if the CAS memory usage then reaches **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT**, that CAS is restarted.

**MAXIMUM DEPTH** limits only the depth to which triggers fire in a nested manner, not the total number of accumulated deferred actions, so this accumulation cannot be prevented with **MAXIMUM DEPTH**. Therefore, design triggers so that the number of accumulated deferred actions does not become excessive: avoid triggers that fire each other cyclically, and do not

use **DEFERRED** triggers for operations that change a large number of rows in a single transaction.

## Trigger Example

This section covers trigger definitions in the demo database. The triggers created in the *demodb* database are not complex, but use most of the features available in CUBRID. If you want to maintain the original state of the *demodb* database when testing such triggers, you must perform a rollback after changes are made to the data.

Triggers created by the user in the own database can be as powerful as applications created by the user.

The following trigger created in the *participant* table rejects an update to the medal column (*gold*, *silver*, *bronze*) if a given value is smaller than 0. The evaluation time must be **BEFORE** because a correlation name *new* is used in the trigger condition. Although not described, the action time of this trigger is also **BEFORE**.

```
CREATE TRIGGER medal_trigger
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;
```

The trigger *medal\_trigger* starts when the number of gold (*gold*) medals of the country whose nation code is 'BLA' is updated. Since the trigger created does not allow negative numbers, the example below will not be updated.

```
UPDATE participant
SET gold = -10
WHERE nation_code = 'BLA';
```

The following trigger has the same condition as the one above except that **STATUS ACTIVE** is added. If the **STATUS** statement is omitted, the default value is **ACTIVE**. You can change **STATUS** to **INACTIVE** by using the **ALTER TRIGGER** statement.

You can specify whether or not to execute the trigger depending on the **STATUS** value.

```
CREATE TRIGGER medal_trig
STATUS ACTIVE
BEFORE UPDATE ON participant
IF new.gold < 0 OR new.silver < 0 OR new.bronze < 0
EXECUTE REJECT;
```

```
ALTER TRIGGER medal_trig
STATUS INACTIVE;
```

The following trigger shows how integrity constraint is enforced when a transaction is committed. This example is different from the previous ones, in that one trigger can have specific conditions for multiple tables.

```
CREATE TRIGGER check_null_first
BEFORE COMMIT
IF 0 < (SELECT count(*) FROM athlete WHERE gender IS NULL)
OR 0 < (SELECT count(*) FROM game WHERE nation_code IS NULL)
EXECUTE REJECT;
```

The following trigger delays the update integrity constraint check for the *record* table until the transaction is committed. Since the **DEFERRED** keyword is given as the event time, the trigger is not executed at the time.

```
CREATE TRIGGER deferred_check_on_record
DEFERRED UPDATE ON record
IF obj.score = '100'
EXECUTE INVALIDATE TRANSACTION;
```

Once completed, the update in the *record* table can be confirmed at the last point (commit or rollback) of the current transaction. The correlation name **old** cannot be used in the conditional clause of the trigger where **DEFERRED UPDATE** is used. Therefore, you cannot create a trigger as the following.

```
CREATE TABLE foo (n int);
CREATE TRIGGER foo_trigger
DEFERRED UPDATE ON foo
IF old.n = 100
EXECUTE PRINT 'foo_trigger';
```

If you try to create a trigger as shown above, an error message is displayed and the trigger fails.

```
ERROR: Error compiling condition for 'foo_trigger' : old.n is not
defined.
```

The correlation name **old** can be used only with **AFTER**.

## CUBRID DBLink

### Introduction to CUBRID DBLink

When retrieving information from a database, it is often necessary to retrieve information from an external database. In this way, if you use CUBRID DBLink to inquire information in an external database, you can access information in other databases. CUBRID DBLink provides a function to inquire information in the databases of homogeneous CUBRID and heterogeneous Oracle, MySQL and MariaDB.

It has the advantage of being able to directly inquire information from an external database. However, it is possible to set up multiple external databases, but when searching for information, it is possible to inquire information from only one other database.

CUBRID DBLink can be used in the form of a DBLINK statement specifying the server to be connected and the query to be executed in the FROM clause of SELECT and in the form of a remote table (table extension), and only remote table forms can be used in INSERT/UPDATE/DELETE/MERGE.

### CUBRID DBLink diagram

CUBRID DBLink supports DBLink between homogeneous and heterogeneous DBLinks.

### Homogeneous DBLink diagram

If you look at the configuration diagram for inquiring information of a homogeneous database, you can use CCI in Database Server to connect to homogeneous brokers and inquire information from an external database.

### Heterogeneous DBLink diagram

If you look at the configuration diagram for inquiring information in heterogeneous databases, you can inquire information in heterogeneous databases through GATEWAY. The gateway uses the ODBC (Open DataBase Connectivity) driver of the connecting database.

### GATEWAY

A gateway is a middleware that mediates between the CUBRID database and heterogeneous databases and is similar to a broker. The gateway connects to a heterogeneous database server (Oracle/MySQL/MariaDB etc), retrieves data, and delivers it to the CUBRID database server.

A cubrid system including a gateway has a multi-hierarchical structure including cub\_gateway and cub\_cas\_cgw as shown in the figure below.

### cub\_cas\_cgw

cub\_cas\_cgw (CAS Gateway) acts as a common application server used by all the application clients that request connections. cub\_cas\_cgw also acts as the database server's client and provides the connection to the database server upon the client's request. The number of cub\_cas\_cgw(s) running in the service pool can be specified in the cubrid\_broker.conf file, and this number is dynamically adjusted by cub\_gateway.

### cub\_gateway

cub\_gateway mediates the connection between the application client and the cub\_cas\_cgw. That is, when an application client requests access, the cub\_broker checks the status of the cub\_cas\_cgw through the shared memory, and then delivers the request to an accessible

cub\_cas\_cgws. It then returns the processing results of the request from the cub\_cas\_cgw to the application client.

The cub\_gateway also manages the server load by adjusting the number of cub\_cas\_cgw (s) in the service pool and monitors and manages the status of the cub\_cas\_cgw. If the cub\_gateway delivers the request to cub\_cas\_cgw but the connection to cub\_cas\_cgw 1 fails because of an abnormal termination, it sends an error message about the connection failure to the application client and restarts cub\_cas\_cgw 1. Restarted cub\_cas\_cgw 1 is now in a normal stand-by mode, and will be reconnected by a new request from a new application client.

## Shared memory

The status information of the cub\_cas\_cgw is stored in the shared memory, and the cub\_broker refers to this information to mediate the connection to the application client. With the status information stored in the shared memory, the system manager can identify which task the cub\_cas\_cgw is currently performing or which application client's request is currently being processed.

## Start GATEWAY

Enter the command below to start the GATEWAY.

```
$ cubrid gateway start
```

The following message is returned if the GATEWAY is already running.

```
$ cubrid gateway start
@ cubrid gateway start
++ cubrid gateway is running.
```

## Stopping GATEWAY

Enter the below command to stop the GATEWAY.

```
$ cubrid gateway stop
```

The following message is returned if the GATEWAY has stopped.

```
$ cubrid gateway stop
@ cubrid gateway stop
++ cubrid gateway is not running.
```

## Restarting GATEWAY

Enter the below command to restart the GATEWAY.

```
$ cubrid gateway restart
```

## Checking GATEWAY Status

**cubrid gateway status** provides various options and allows you to check the gateway status information, including the number of completed tasks for each gateway and the number of tasks waiting to be processed.

GATEWAY status is the same as broker, so refer to [Checking Broker Status](#).

```
cubrid gateway status [options] [expr]
```

## Starting the GATEWAY together when the CUBRID service starts

To have *GATEWAY* started upon startup of the CUBRID service (cubrid service start), configure *gateway* in the **service** parameter of the **cubrid.conf** file.

```
# cubrid.conf

[service]

service=server,broker,gateway,manager

...
```

## CUBRID DBLINK settings

The settings for using CUBRID DBLink are different from those of homogeneous DBLink and heterogeneous DBLink.

### Homogeneous DBLink Setting

---

If you look at the homogeneous DBlink diagram above, you need to connect to the broker in the remote database, so you need to set up the broker in the remote database. This setting is the same as the general broker setting.

## Heterogeneous DBLink Setting

To connect to a heterogeneous database (Oracle/MySQL/MariaDB), cubrid\_gateway.conf, unixODBC installation, and ODBC Driver information settings are required.

### Gateway configuration file

The parameters used in cubrid\_gateway.conf, the default gateway configuration file created when CUBRID is installed, are almost identical to the broker parameters, and some additional parameters that must be changed are included. Parameter values not included by default can be directly added/edited and used. The following is the content of the cubrid\_gateway.conf file that is provided by default during installation.

The following is the content of the cubrid\_gateway.conf file provided by default.

```
[gateway]
MASTER_SHM_ID          =50001
ADMIN_LOG_FILE         =log/gateway/cubrid_gateway.log

[%oracle_gateway]

CGW_LINK_CONNECT_URL_PROPERTY =

```

## GATEWAY Parameter

This parameter is set to use a heterogeneous database and DBLink.

The meaning of each parameter is slightly different for each heterogeneous database.

| Parameter Name | Type   | Value |
|----------------|--------|-------|
| APPL_SERVER    | string |       |

| Parameter Name             | Type   | Value |
|----------------------------|--------|-------|
| CGW_LINK_SERVER            | string |       |
| CGW_LINK_SERVER_IP         | string |       |
| CGW_LINK_SERVER_PORT       | int    |       |
| CGW_LINK_ODBC_DRIVER_NAME  | string |       |
| CGW_LINK_CONNECT_URL_PROXY | string |       |

## APPL\_SERVER

**APPL\_SERVER** is the part that sets the application server name of the gateway and must be set as CAS\_CGW.

## CGW\_LINK\_SERVER

**CGW\_LINK\_SERVER** should set the name of the heterogeneous database to be used by connecting to CAS\_CGW. Currently, supported databases are Oracle, MySQL and MariaDB.

## CGW\_LINK\_SERVER\_IP

**CGW\_LINK\_SERVER\_IP** should set the IP address of the heterogeneous database to be connected with CAS\_CGW.

### Note

- In case of Oracle, net\_service\_name of tnsnames.ora is used, so this parameter is not used.
- For details, refer to [Setting Connection Information for Connection to Oracle Database](#).

## CGW\_LINK\_SERVER\_PORT

**CGW\_LINK\_SERVER\_PORT** should set the port number of database to be connected with CAS\_CGW.

#### Note

- In case of Oracle, net\_service\_name of tnsnames.ora is used, so this parameter is not used.
- For details, refer to [Setting Connection Information for Connection to Oracle Database](#).

### **CGW\_LINK\_ODBC\_DRIVER\_NAME**

**CGW\_LINK\_ODBC\_DRIVER\_NAME** must set the ODBC Driver name provided by the heterogeneous database when connecting with CAS\_CGW.

#### Note

- In Windows, if the ODBC driver of the heterogeneous database is installed, the driver name can be checked through the ODBC data source manager.
- In Linux, the driver name must be specified directly in odbcinit.ini.
- For details, refer to :ref: *ODBC Driver Information Settings <odbcdriver-info>*.

### **CGW\_LINK\_CONNECT\_URL\_PROPERTY**

**CGW\_LINK\_CONNECT\_URL\_PROPERTY** sets the connection property used for the connection string for heterogeneous database connection.

#### Note

- Connection properties are different for each database, so refer to the site below.
- Oracle : [https://docs.oracle.com/cd/B19306\\_01/server.102/b15658/app\\_odbc.htm#UNXAR418](https://docs.oracle.com/cd/B19306_01/server.102/b15658/app_odbc.htm#UNXAR418)
- MySQL : <https://dev.mysql.com/doc/connector-odbc/en/connector-odbc-configuration-connection-parameters.html#codbc-dsn-option-flags>
- MariaDB : <https://mariadb.com/docs/connectors/mariadb-connector-odbc/mariadb-connector-odbc-guide#general-connection-parameters>

## Install unixODBC

The unixODBC Driver Manager is an open source ODBC driver manager that can be used with ODBC drivers on Linux and UNIX operating systems. To use ODBC in the gateway, unixODBC must be installed.

### Note

- In Windows, you can use Microsoft® ODBC Data Source Manager, which is installed by default.

## How to install unixODBC

```
$ wget https://www.unixodbc.org/unixODBC-2.3.9.tar.gz
$ tar xvf unixODBC-2.3.9.tar.gz
$ cd unixODBC-2.3.9
$ ./configure
$ make
$ make install
```

### Note

For instructions on how to install the unixODBC driver manager, refer to the url below.

unixODBC website: <https://www.unixodbc.org/>

## ODBC Driver information setting

After unixODBC is installed, the ODBC Driver information of the database to be connected must be registered.

ODBC Driver information is registered by directly modifying odbcinst.ini.

The following is an example of setting MySQL, Oracle and MariaDB ODBC Driver information.

```
[MySQL ODBC 8.0 Unicode Driver]
Description = MySQL ODBC driver v8.0
Driver=/usr/lib64/libmyodbc8w.so

[Oracle 11g ODBC driver]
Description = Oracle ODBC driver v11g
Driver = /home/user/oracle/instantclient/libsqora.so.19.1
```

```
[mariadb odbc 3.1.13 driver]
Description= mariadb odbc driver 3.1.13
Driver=/home/user/mariadb-odbc-3.1.13/lib64/mariadb/libmaodbc.so
```

### Note

For reference, in the example above, the driver names are “MySQL ODBC 8.0 Unicode Driver”, “Oracle 11g ODBC driver” and “mariadb odbc 3.1.13 driver” respectively.

## Oracle Setting for Dblink

### Oracle Environment Configuration

To use Oracle in Dblink, you must install and configure Oracle Instant Client, set connection information, set Oracle Database environment variables, and set gateway.

#### Install Oracle Instant Client ODBC

Download ODBC Package and Basic Package from the Oracle Instant Client download site and extract them to the same directory.

```
unzip instantclient-basic-linux.x64-19.20.0.0.0dbru.zip
unzip instantclient-odbc-linux.x64-19.20.0.0.0dbru.zip
```

Oracle Instant Client Download Site: <https://www.oracle.com/database/technologies/instant-client/downloads.html>

#### Oracle Instant Client Environment Variable Settings

```
export ORACLE_INSTANT_CLIENT=/home/user/oracle/instantclient
export PATH=$ORACLE_INSTANT_CLIENT:$PATH
export LD_LIBRARY_PATH=$ORACLE_INSTANT_CLIENT:$LD_LIBRARY_PATH
```

#### Set connection information for connection to Oracle Database

In order to connect to Oracle Database, the tnsnames.ora file containing connection information must be modified. Connection information should be written in these three items: HOST, PORT, and SERVICE\_NAME in the basic format below. For the tnsnames.ora file in which connection information is created, the directory path must be set in the TNS\_ADMIN environment variable. For how to set TNS\_ADMIN, refer to “Setting TNS\_ADMIN Environment Variable”.

Default format of the tnsnames.ora file

```
net_service_name =  
  (DESCRIPTION=  
    (ADDRESS = (PROTOCOL = TCP)(HOST = xxx.xxx.xxx.xxx)(PORT =  
1521)  
    )  
    (CONNECT_DATA =  
      (SERVICE_NAME=service_name)  
    )  
  )  
)
```

- net\_service\_name: The name of the net service for database connection, and the name used for the db\_name of the connection url.
- HOST: IP address or server name to connect to the database.
- PORT: Port required for connection. In most cases, the default port is 1521.
- SERVICE\_NAME: The name of the database to connect to.

#### Note

For reference, no error occurs even if net\_service\_name is duplicated. However, since it may be connected to a different server than the intended one, net\_service\_name must be set so that it does not overlap.

## Oracle Database Environment Variable Settings

The following environment variables must be set in the Oracle database server.

```
export ORACLE_SID=XE  
export ORACLE_BASE=/u01/app/oracle  
export ORACLE_HOME=$ORACLE_BASE/product/11.2.0/x64  
export PATH=$ORACLE_HOME/bin:$PATH
```

- ORACLE\_SID is the system identifier.
- ORACLE\_BASE is the Oracle base directory.
- ORACLE\_HOME is the path where the Oracle database is installed.

## TNS\_ADMIN environment variable setting

TNS\_ADMIN points to the directory path where the tnsnames.ora file is located. If there is a tnsnames.ora file in /home/user/myconfigs, you can settings it as follows.

```
export TNS_ADMIN=/home/user/myconfigs
```

### Configuring cubrid\_gateway.conf for Oracle

In order to connect to Oracle from the gateway, several settings are required as follows.

For details, refer to [Gateway configuration file](#).

Because the gateway uses the information in tnsnames.ora to connect to oracle, it is not necessary to write CGW\_LINK\_SERVER\_IP and CGW\_LINK\_SERVER\_PORT. Even if the corresponding information is written, the gateway does not refer to it.

```
APPL_SERVER                      =CAS_CGW
      .
      .
      .
CGW_LINK_SERVER                  =ORACLE
CGW_LINK_ODBC_DRIVER_NAME       =Oracle 19c ODBC driver
CGW_LINK_CONNECT_URL_PROPERTY =
```

## MySQL Configuration for DBLink

### MySQL Environment Configuration

#### Install MySQL ODBC Driver

MySQL Unicode ODBC Driver is required to connect to MySQL from the gateway. The following is how to install MySQL ODBC Driver.

Use the MySQL Yum repository to provide the Connector/ODBC RPM package. The MySQL Yum repository should be in your system's list of repositories, If not, select the package for your platform from the MySQL Yum repository download page ( <https://dev.mysql.com/downloads/repo/yum/> ) and download it.

Install the downloaded release package.

```
$ sudo yum install mysql80-community-release-el6-{version-  
number}.noarch.rpm
```

Update the repository using yum.

```
$ sudo yum update mysql-community-release
```

Install Connector/ODBC with the command below.

```
$ sudo yum install mysql-connector-odbc
```

For detailed installation instructions, refer to <https://dev.mysql.com/doc/connector-odbc/en/connector-odbc-installation-binary-yum.html>.

### Configuring cubrid\_gateway.conf for MySQL

In order to connect to MySQL from the gateway, several settings are required as below.

For details, refer to [gateway configuration file](#).

```
APPL_SERVER                =CAS_CGW
.
.
.
CGW_LINK_SERVER            =MYSQL
CGW_LINK_SERVER_IP        =localhost
CGW_LINK_SERVER_PORT      =3306
CGW_LINK_ODBC_DRIVER_NAME  =MySQL ODBC 8.0 Unicode Driver
CGW_LINK_CONNECT_URL_PROPERTY = "charset=utf8;PREFETCH=100;NO_CACHE=1"
```

## MariaDB Configuration for DBLink

### MariaDB Environment Configuration

#### Install MariaDB ODBC Driver

MariaDB ODBC Driver is required to connect to MariaDB from the gateway.

The following is how to install MariaDB ODBC Driver.

MariaDB Connector/ODBC package can be downloaded by selecting the version from the page below.

<https://mariadb.com/downloads/connectors/>

Extract the files from the downloaded tarball package. Then, install the driver's shared library in an appropriate location in the system. The installed driver must register driver information in `odbcinst.ini`. For settings method, refer to :ref: *ODBC Driver Information Settings* <*odbcdriver-info*>.

```
$ mariadb-connector-odbc-3.1.13-centos7-amd64.tar.gz -C mariadb-odbc-3.1.13
```

For detailed installation instructions, refer to <https://mariadb.com/docs/connectors/mariadb-connector-odbc/mariadb-connector-odbc-guide#installing-mariadb-connector-odbc-on-linux>.

### Configuring cubrid\_gateway.conf for MariaDB

In order to connect to MariaDB from the gateway, several settings are required as below.

For details, refer to [gateway configuration file](#).

```
APPL_SERVER                =CAS_CGW
.
.
.
CGW_LINK_SERVER            =MARIADB
CGW_LINK_SERVER_IP        =localhost
CGW_LINK_SERVER_PORT      =3306
CGW_LINK_ODBC_DRIVER_NAME =mariadb odbc 3.1.13 driver
```

### How to use Cubrid DBLink

If the information on brokers of CUBRID to be connected to use DBLink has been completed or gateway settings for heterogeneous databases have been completed, let's learn how to write a query statement using DBLink.

There are two ways to write DBLINK Query statement for data inquiry.

**First**, how to query information from other databases by writing DBLINK syntax in the FROM clause

The Query statement below is a Query statement that inquires the remote\_t table information of another database of IP 192.xxx.xxx.xxx.

```
SELECT * FROM DBLINK ('192.xxx.xxx.xxx:
53000:testdb:user:password:', 'SELECT col1, col2 FROM remote_t') AS
t(col1 int, col2 varchar(32));
```

#### Note

In case of Oracle, ip and port are gateway connection information among remote connection information, and net\_service\_name of tnsnames.ora must be entered in the db\_name field. If net\_service\_name is ora\_test, write as follow

```
SELECT * FROM DBLINK ('192.xxx.xxx.xxx:53000:ora_test:user:password:', 'SELECT col1, col2 FROM
remote_t') AS t(col1 int, col2 varchar(32));
```

**Second**, use the CREATE SERVER statement to protect user information (id, password) and the hassle of writing connection information every time you write a Query. If the CREATE SERVER statement is used, the Query statement becomes concise and helps to protect user information.

```
CREATE SERVER remote_srv1 ( HOST='192.xxx.xxx.xxx', PORT=53000,  
DBNAME=testdb, USER=user, PASSWORD='password');  
SELECT * FROM DBLINK (remote_srv1, 'SELECT col1 FROM remote_t') AS  
t(col1 int);
```

### Note

DBLINK can set additional connection properties in the connection URL. For detailed attribute details, refer to [CCI driver's cci\\_connect\\_with\\_url function](#)

If the DBLINK target database is configured as an HA environment, you can use the altHosts attribute to set it as shown in the example below.

```
192.168.0.1:53000:testdb:user:password::?altHosts=192.168.0.2:33000,192.168.0.3:33000
```

In the example, if the 192.168.0.1 server is an active database and cannot connect to the server, it is the setting to request a connection to the 192.168.0.2 server. As in the example above, multiple altHosts can be specified, and connections are attempted in the order listed.

For detailed DBLink SQL syntax, refer to [SELECT](#) and [SERVER DEFINITION STATEMENTS](#).

## Notice

- Synonym creation: Local synonyms can be created for remote tables and remote synonyms. In the case of DBMSs other than CUBRID, the user name or db name must be added to the original table name.

```
-- for CUBRID  
create synonym synonym_1 for t1@srv1;  
create synonym synonym_2 for remote_synonym@srv1;  
  
-- for ORACLE  
create synonym synonym_ora for user_ora.t1@srv_ora;  
  
-- for MySQL and MariaDB
```

```
create synonym synonym_my for my_db.t1@srv_mysql;
create synonym synonym_maria for maria_db.t1@srv_maria;
```

- The reserved word processing character for CUBRID is the double quotation mark ( " ") as like the following.

```
SELECT ["COLUMN"],["ADD"],["ALTER"] FROM ["TABLE"]@srv1 ;
SELECT * FROM dblink(srv1, 'select "COLUMN","ADD","ALTER" from
"TABLE" ') AS t(a varchar, b varchar, c varchar );
```

- The reserved word processing character for ORACLE is the double quotation mark ( " ") as like the following.

```
SELECT ["COLUMN"],["ADD"],["ALTER"] FROM ["TABLE"]@srv1 ;
SELECT * FROM dblink(srv1, 'select "COLUMN","ADD","ALTER" from
"TABLE" ') AS t(a varchar, b varchar, c varchar );
```

- The reserved word processing character for MySQL and MariaDB is the backquote ( ` `) as like the following.

```
SELECT [`COLUMN`,`ADD`,`ALTER`] FROM [`TABLE`]@srv1 ;
SELECT * FROM dblink(srv1, 'select `COLUMN`,`ADD`,`ALTER` from
`TABLE` ') AS t(a varchar, b varchar, c varchar );
```

## Constraints

### Common Constraints

- The charset of the remote database must be unicode (utf-8).
- The collation of remote string columns is assumed to be a binary collation (e.g., utf8\_bin). For remote string columns using a non-binary collation (e.g., case/accnt-insensitive), correct behavior is not guaranteed (unsupported), as the results may vary depending on the query.

- **Table extension style (object@server)**

- Supports only tables, views, and synonyms
- Serial, built-in functions, and stored functions are not supported.

(Example: stored function sp\_func() of remote server (server1) cannot be used in sp\_func@server1(arg1, ...) format.)

- All functions (stored functions, built-in functions including SYSDATE), serial-related functions and system constants in the SELECT query all operate locally. (If you need to execute a function or serial in a remote DB, you should use the DBLINK statement.) For example, when the select query for remote table is requested and the optimizer rewrite query as below, you look the queries in DBLINK() are only executed in the remote DB.

```
SELECT A.*, rownum rn, '' empty, null null_col, SYSDATE
FROM t1@srv1 A ;

-- rewritten query
SELECT A.id, A.parentid, A.[text], rownum, '', null, SYS_DATE -- at
local
FROM ( SELECT [_dbl].id, [_dbl].parentid, [_dbl].[text]
        FROM DBLINK( srv1 /* '192.168.1.125:33000:remotedb1:dba:*/
        ,
        'SELECT * FROM tree A') AS [_dbl](id integer, parentid
integer, [text] varchar(32)) -- at remote
    ) A (id, parentid, [text])
```

- All functions, serial-related functions, and system constants of INSERT/UPDATE/DELETE/MERGE queries are all executed on the remote server, so be careful when using built-in functions (i.e., CUBRID's built-in functions may not be supported by the remote DBMS or have different usage instructions)
- Transaction: Transactions (commit, rollback) between local DB and remote DB are not processed as one transaction. DML (INSERT/UPDATE/DELETE/MERGE) queries in the remote DB are executed as auto commits separately from transactions in the local DB. As in the example below, when performing a transaction, data is inserted into the remote DB, but no data is entered into the local DB, because doing rollback.

```
-- local input
INSERT INTO t1(a, b) VALUES (1, 'local');

-- remote input
INSERT INTO t2@srv1(a, b) VALUES (1, 'remote');

rollback;

SELECT a, b FROM t1, t2@srv1 t2 WHERE t1.a = t2.a;
there's no result
```

- TRUNCATE statement is not supported.
- CREATE TABLE ... LIKE table@server syntax is not supported (For reference, CREATE TABLE ... AS SELECT FROM table@server syntax is supported)

- DBLINK() and remote table (@server) are not allowed in the TRIGGER statement.
- predicate push: The SELECT statement written in table extension style (@server) is internally rewritten to DBLINK() by the optimizer. To improve performance, It push with conditional clauses that can be performed in the remote DB. However, if a built-in function or user-defined function in a conditional clause is used, it is excluded from pushing.
- Performance notes

#### Note

When the connect by clause, group by clause, having clause, and limit clause are used in the SELECT statement in table extension style (@server), the where condition, group by clause, having clause, and limit clause are not executed in the remote DB. After executing exclude the statement in the remote DB and sending the performed results to the local DB, performance may be slowed due to execute the statement in the local DB.

Below is an example of processing the “group by” and “count()” after transferring all data from the remote DB’s *tree* table to the local DB.

```
-- original query
SELECT A.parentid, count()
FROM tree@srv1 A
GROUP BY A.parentid ;

-- rewritten query
SELECT A.parentid, count()
FROM ( SELECT [_dbl].parentid
      FROM DBLINK( srv1 /* '192.168.1.125:33000:remotedb1:dba::'
*/ ,
              'SELECT parentid FROM tree A'
            ) AS [_dbl](parentid integer)
      ) A (parentid)
GROUP BY A.parentid
```

- The SYSDATE function used in the table extension style (@server) is performed in the local DB, so caution is required if the time between servers is different.

```
-- original query
SELECT * FROM tbl@srv1 WHERE col1 >= sysdate;

-- rewritten query
SELECT *
FROM ( SELECT col1, col2
```

```

        FROM DBLINK( srv1 /* '192.168.1.125:33000:remotedb1:dba::'
*/ ,
        'SELECT col1, col2 FROM tbl'
        ) AS [_dbl](col1 date, col2 varchar)
    ) tbl (col1, col2)
WHERE col1>= SYS_DATE

```

- When using a scalar subquery, subquery and EXIST clause with a co-related condition in the table extension style (@server), the remote query brings the whole data to the local DB every time and performs to find data corresponding to the join column. As a result, a rapid decrease in performance occurs. The example below uses T1.a as a condition for a scalar subquery, and all data as T1.a < 4 of srv1's tree table is sent to the local DB to find suitable data per executing scalar subquery, so it may degrade performance.

```

-- original query
SELECT T1.a,
       (SELECT A.text FROM tree@srv1 A WHERE A.id = T1.a )
remote_text
FROM hangul_t1 T1
WHERE T1.a < 4;

-- rewritten query
SELECT T1.a,
       (SELECT A.[text] from (select [_dbl].[text], [_dbl].id
        FROM DBLINK(srv1 /* '192.168.1.125:33000:remotedb1:dba::'
*/ ,
        'SELECT [text], id FROM tree A'
        ) AS [_dbl]([text] varchar(32), id integer)
        WHERE [_dbl].id=T1.a) A ([text], id))
FROM hangul_t1 T1
WHERE (T1.a < ? :0)

```

## CUBRID Constraints

- ENUM, BLOB, CLOB, and SET types are not supported in the select statement.
- If the system parameters of the local DB and remote DB are different, undesirable results may occur.

### Common constraints of Heterogeneous DBMS.

- The gateway must use the Unicode-only ODBC Driver of the heterogeneous remote database (Oracle/MySQL/MariaDB).

- Among ODBC types, SQL\_INTERVAL, SQL\_GUID, SQL\_BIT, SQL\_BINARY, SQL\_VARBINARY, SQL\_LONGVARBINARY, SQL\_LONGVARCHAR, and SQL\_WLONGVARCHAR are not supported types.

| ODBC SQL Type     | Oracle Data Type | MySQL Data Type | MariaDB Data Type |
|-------------------|------------------|-----------------|-------------------|
| SQL_LONGVARCHAR   | LONG, CLOB       | LONGTEXT        | LONGTEXT          |
| SQL_WLONGVARCHAR  | NCLOB            |                 |                   |
| SQL_BIT           |                  | BIT             | BIT               |
| SQL_BINARY        |                  | BINARY          | BINARY            |
| SQL_VARBINARY     | RAW              | VARBINARY       | VARBINARY         |
| SQL_LONGVARBINARY | LONG RAW         | LONG VARBINARY  | LONG VARBINARY    |
|                   | BLOB             | BLOB            | BLOB              |
|                   | BFILE            | TINYBLOB        | TINYBLOB          |
|                   |                  | MEDIUMBLOB      | MEDIUMBLOB        |
|                   |                  | LOB             | LOB               |
|                   |                  | GEOMETRY        | GEOMETRY          |
|                   |                  | POINT           | POINT             |

| ODBC SQL Type | Oracle Data Type       | MySQL Data Type    | MariaDB Type       | Data |
|---------------|------------------------|--------------------|--------------------|------|
|               |                        | POLYGON            | POLYGON            |      |
|               |                        | GEOMETRYCOLLECTION | GEOMETRYCOLLECTION |      |
|               |                        | MULTILINESTRING    | MULTILINESTRING    |      |
|               |                        | MULTIPOINT         | MULTIPOINT         |      |
|               |                        | MULTIPOLYGON       | MULTIPOLYGON       |      |
| SQL_INTERVAL  | INTERVAL YEAR TO MONTH |                    |                    |      |
|               | INTERVAL DAY TO SECOND |                    |                    |      |

- The maximum string length for one column is 16M. The table below shows the data type for each DBMS with a data length of 16M or more.

| DBMS Name | Data Type         |
|-----------|-------------------|
| Oracle    | LONG, NCLOB, CLOB |
| MySQL     | LONGTEXT          |
| MariaDB   | LONGTEXT          |

- In DML statements such as INSERT, UPDATE, DELETE, and MERGE, if the built-in functions not supported by CUBRID and are not in the form of function (parameter 1, ..., parameter N) as below, the query results error.

Example: the convert function of MySQL and MariaDB: convert('binary' using binary)

### Note

#### Oracle Constraints

- LONG, INTERVAL DAY TO SECOND, INTERVAL YEAR TO MONTH, BLOB, and CLOB types are not supported in the select statement. For more information, refer to [Unsupported Types of Common constraints of Heterogeneous DBMS](#)
- The INTERVAL DAY TO SECOND and INTERVAL YEAR TO MONTH types are not supported by Oracle ODBC. For more information, see “Using the Oracle ODBC Driver” (<https://docs.oracle.com/en/database/oracle/oracle-database/19/adfns/odbc-driver.html#GUID-3FE69BEF-F8D2-4152-9B1A-877186C47028>).
- Oracle ODBC does not support the time zone type, so when SELECTing time zone data, the time zone is calculated as a local time, converted to timestamp type, and returned.

Below is an example of converting Oracle DB's time zone data to a local time zone when querying it with ODBC. The entered time zone is “+02:00”, converted to local time zone “+09:00”, and output as “PM 08:00”.

```
-- oracle input
INSERT INTO tbl VALUES (to_timestamp_tz('2021-07-25 12:34:56
+02:00', 'yyyy-mm-dd hh24:mi:ss tzh:tzm'));

-- local
SELECT t_timestamp_timezone2 FROM tbl@server;
07:34:56.000 PM 07/25/2021

SELECT to_char(t_timestamp_timezone2, 'yyyy-mm-dd hh24:mi:ss.ff
tzh:tzm') FROM tbl@server;
2021-07-25 19:34:56.000 +09:00
```

- REPLACE syntax is not supported and an error occurs when used.
- Oracle's processing range of date and number types is larger than CUBRID's, so data that falls outside of CUBRID's type range will result in an error.

**Note**

## MySQL/MariaDB limitations

- When using cache in Mysql, the memory usage of gateway cub\_cas\_cgw increases, so it is recommended to use PREFETCH, NO\_CACHE=1.
- When performing a query that includes the repeat() function in MySQL/MariaDB, part of the string may be truncated or the string may not be read.
- LONGTEXT, BIT, BLOB, and LONGBLOB types are not supported in the select statement. For more information, refer to [Unsupported Types of Common constraints of Heterogeneous DBMS](#)

## Class Inheritance

To explain the concept of inheritance, a table is expressed as a class, a column is expressed as an attribute, and a type is expressed as a domain.

Classes in CUBRID database can have class hierarchy. Attributes and methods can be inherited through such hierarchy. As shown in the previous section, you can create a *Manager* class by inheriting attributes from an *Employee* class. The *Manager* class is called the sub class of the *Employee* class, and the *Employee* class is called the super class of the *Manager* class. Inheritance can simplify class creation by reusing the existing class hierarchy.

CUBRID allows multiple inheritances, which means that a class can inherit attributes and methods from more than one super class. However, inheritance can cause conflicts when an attribute or method of the super class is added or deleted.

Such conflict occurs in multiple inheritance if there are attributes or methods with the same name in different super classes. For example, if it is likely that a class inherits attributes of the same name and type from more than one super class, you must specify the attributes to be inherited. In such a case, if the inherited super class is deleted, a new attribute of the same name and type must be inherited from another super class. In most cases, the database system resolves such problems automatically. However, if you don't like the way that the system resolves a problem, you can resolve it manually by using the INHERIT clause.

When attributes are inherited from more than one super class, it is possible that their names are to be the same, while their domains are different. For example, two super classes may have the same attribute, whose domain is a class. In this case, a sub class automatically inherits attributes

with more specialized (a lower in the class hierarchy) domains. If such conflict occurs between basic data types (e.g. STRING or INTEGER) provided by the system, inheritance fails.

Conflicts during inheritance and their resolutions will be covered in the [Resolving Class Conflicts](#) section.

#### Note

The following cautions must be observed during inheritance:

- The class name must be unique in the database. An error occurs if you create a class that inherits another class that does not exist.
- The name of a method/attribute must be unique within a class. The name cannot contain spaces, and cannot be a reserved keyword of CUBRID. Alphabets as well as '\_', '#', '%' are allowed in the class name, but the first character cannot be '\_'. Class names are not case-sensitive. A class name will be stored in the system after being converted to lowercase characters.
- Encryption option (TDE) of the class is not inherited. For more information, see [Table Encryption \(TDE\)](#).

#### Note

A super class name can begin with the user name so that the owner of the class can be easily identified.

## Class Attribute and Method

You can create class attributes to store the aggregate property of all instances in the class. When you define a **CLASS** attribute or method, you must precede the attribute or method name with the keyword **CLASS**. Because a class attribute is associated with the class itself, not with an instances of the class, it has only one value. For example, a class attribute can be used to store the average value determined by a class method or the timestamp when the class was created. A class method is executed in the class object itself. It can be used to calculate the aggregate value for the instances of the class.

When a sub class inherits a super class, each class has a separate storage space for class attributes, so that two classes may have different values of class attribute. Therefore, the sub class does not change even when the attributes of the super class are changed.

The name of a class attribute can be the same as that of an instance attribute of the same class. Likewise, the name of a class method can be the same as that of an instance method of the same class.

## Order Rule for Inheritance

The following rules apply to inheritance. The term class is generally used to describe the inheritance relationship between classes and virtual classes in the database.

- For an object without a super class, attributes are defined in the same order as in the **CREATE** statement (an ANSI standard).
- If there is one super class, locally created attributes are placed after the super class attributes. The order of the attributes inherited from the super class follows the one defined during the super class definition. For multiple inheritance, the order of the super class attributes is determined by the order of the super classes specified during the class definition.
- If more than one super class inherits the same class, the attribute that exists in both super classes is inherited to the sub class only once. At this time, if a conflict occurs, the attribute of the first super class is inherited.
- If a name conflict occurs in more than one super class, you can inherit only the ones you want from the super class attributes by using the **INHERIT** clause in order to resolve the conflict.
- If the name of the super class attribute is changed by the alias option of the **INHERIT** clause, its position is maintained.

## INHERIT Clause

When a class is created as a sub class, the class inherits all attributes and methods of the super class. A name conflict that occurs during inheritance can be handled by either a system or a user. To resolve the name conflict directly, add the **INHERIT** clause to the **CREATE CLASS** statement.

```
CREATE CLASS
•
•
•
INHERIT resolution [{, resolution}] ;

resolution:
[column_name | method_name] OF [schema_name.]superclass_name [AS
alias]
```

In the **INHERIT** clause, specify the name of the attribute or method of the super class to inherit. With the **ALIAS** clause, you can resolve a name conflict that occurs in multiple inheritance statements by inheriting a new name.

## ADD SUPERCLASS Clause

To extend class inheritance, add a super class to a class. A relationship between two classes is created when a super class is added to an existing class. Adding a super class does not mean adding a new class.

```
ALTER CLASS
.
.
.
ADD SUPERCLASS [schema_name.]superclass_name [{,
[schema_name.]superclass_name}]
[INHERIT resolution [{, resolution}]] ;

resolution:
[column_name | method_name] OF [schema_name.]superclass_name [AS
alias]
```

Specify the name of the superclass to be added in *superclass\_name*. Attributes and methods of the super class can be inherited by using the syntax above.

Name conflicts can occur when adding a new super class. If a name conflict cannot be resolved by the database system, attributes or methods to inherit from the super class can be specified by using the **INHERIT** clause. You can use aliases to inherit all attributes or methods that cause the conflict. For details on super class name conflicts, see [Class Conflict Resolution](#).

The following example shows how to create the *female\_event* class by inheriting the *event* class included in *demodb*.

```
CREATE CLASS female_event UNDER event;
```

## DROP SUPERCLASS Clause

Deleting a super class from a class means removing the relationship between two classes. If a super class is deleted from a class, it changes inheritance relationship of the classes as well as of all their sub classes.

```
ALTER CLASS
.
.
.
DROP SUPERCLASS [schema_name.]superclass_name [{,
[schema_name.]superclass_name}]
[INHERIT resolution [{, resolution}]] ;
```

```
resolution:  
[column_name | method_name] OF [schema_name.]superclass_name [AS  
alias]
```

Specify the name of the superclass to be deleted in *superclass\_name*. For the second *class\_name*, specify the name of the super class to be deleted. If a name conflict occurs after deleting a super class, see the [Class Conflict Resolution](#) section for the resolution.

The following example shows how to inherit the *female\_event* class from the *event* class.

```
CREATE CLASS female_event UNDER event
```

The following example shows how to delete the super class *event* from the *female\_event* class. Attributes that the *female\_event* class inherited from the *event* class no longer exist.

```
ALTER CLASS female_event DROP SUPERCLASS event;
```

## Class Conflict Resolution

If you modify the schema of the database, conflicts can occur between attributes or methods of inheritance classes. Most conflicts are resolved automatically by CUBRID otherwise, you must resolve the conflict manually. Therefore, you need to examine the possibility of conflicts before modifying the schema.

Two types of conflicts can cause damage to the database schema. One is conflict with a sub class when the sub class schema is modified. The other is conflict with a super class when the super class is modified. The following are operations that may cause conflicts between classes.

- Adding an attribute
- Deleting an attribute
- Adding a super class
- Deleting a super class
- Deleting a class

If a conflict occurs as a result of the above operations, CUBRID applies a basic resolution to the sub class where the conflict occurred. Therefore, the database schema can always maintain consistent state.

## Resolution Specifier

Conflicts between the existing classes or attributes, and inheritance conflicts can occur if the database schema is modified. If the system fails to resolve a conflict automatically or if you don't like the way the system resolved the problem, you can suggest how to resolve the conflict by using the **INHERIT** clause of the **ALTER** statement (often referred to as resolution specifier).

When the system resolves the conflict automatically, basically, the existing inheritance is maintained (if any). If the previous resolution becomes invalid when the schema is modified, the system will arbitrarily select another one. Therefore, you must avoid excessive reuse of attributes or methods in the schema design stage because the way the system will resolve the conflict cannot always be predictable.

What will be discussed concerning conflicts is applied commonly to both attributes and methods.

```
ALTER [class_type] [schema_name.]class_name alter_clause
[INHERIT resolution [{, resolution }]] ;

resolution:
[column_name | method_name] OF [schema_name.]superclass_name [AS
alias]
```

## Superclass Conflict

### Adding a super class

The **INHERIT** clause of the **ALTER CLASS** statement is optional, but must be used when a conflict occurs due to class changes. You can specify more than one resolution after the **INHERIT** clause.

*superclass\_name* specifies the name of the super class that has the new attribute(column) or method to inherit when a conflict occurs. *column\_name* or *method\_name* specifies the name of the attribute or method to inherit. You can use the **AS** clause when you need to change the name of the attribute or method to inherit.

The following example shows how to create the *soccer\_stadium* class by inheriting the *event* and *stadium* classes in the *olympic* database of *demodb*. Because both *event* and *stadium* classes have the name and code attributes, you must specify the attributes to inherit using the **INHERIT** clause.

```
CREATE CLASS soccer_stadium UNDER event, stadium
INHERIT name OF stadium, code OF stadium;
```

When the two super classes (*event* and *stadium*) have the *name* attribute, if the *soccer\_stadium* class needs to inherit both attributes, it can inherit the *name* unchanged from the *stadium* class and the *name* changed from the *event* class by using the **alias** clause of the **INHERIT**.

The following example shows in which the *name* attribute of the *stadium* class is inherited as it is, and that of the *event* class is inherited as the *purpose* alias.

```
ALTER CLASS soccer_stadium
INHERIT name OF event AS purpose;
```

### Deleting a super class

A name conflict may occur again if a super class that explicitly inherited an attribute or method is dropped by using the **INHERIT**. In this case, you must specify the attribute or method to be explicitly inherited when dropping the super class.

```
CREATE CLASS a_tbl(a INT PRIMARY KEY, b INT);
CREATE CLASS b_tbl(a INT PRIMARY KEY, b INT, c INT);
CREATE CLASS c_tbl(b INT PRIMARY KEY, d INT);

CREATE CLASS a_b_c UNDER a_tbl, b_tbl, c_tbl INHERIT a OF b_tbl, b
OF b_tbl;

ALTER CLASS a_b_c
DROP SUPERCLASS b_tbl
INHERIT b OF a_tbl;
```

The above example shows how to create the *a\_b\_c* class by inheriting *a\_tbl*, *b\_tbl* and *c\_tbl* classes, and delete the *b\_tbl* class from the super class. Because *a* and *b* are explicitly inherited from the *b\_tbl* class, you must resolve their name conflicts before deleting it from the super class. However, *a* does not need to be specified explicitly because it exists only in the *a\_tbl* class except for the *b\_tbl* class to be deleted.

### Compatible Domains

If the conflicting attributes do not have compatible domains, the class hierarchy cannot be created.

For example, the class that inherits a super class with the *phone* attribute of integer type cannot have another super class with the *phone* attribute of string type. If the types of the *phone* attributes of the two super classes are both String or Integer, you can add a new super class by resolving the conflict with the **INHERIT** clause.

Compatibility is checked when inheriting an attribute with the same name, but with the different domain. In this case, the attribute that has a lower class in the class inheritance hierarchy as the domain is automatically inherited. If the domains of the attributes to inherit are compatible, the conflict must be resolved in the class where an inheritance relationship is defined.

## Sub class Conflict

Any changes in a class will be automatically propagated to all sub classes. If a problem occurs in the sub class due to the changes, CUBRID resolves the corresponding sub class conflict and then displays a message saying that the conflict has been resolved automatically by the system.

Sub class conflicts can occur due to operations such as adding a super class, or creating/deleting a method or an attribute. Any changes in a class will affect all sub classes. Since changes are automatically propagated, harmless changes can even cause side effects in sub classes.

## Adding Attributes and Methods

The simplest sub class conflict occurs when an attribute is added. A sub class conflict occurs if an attribute added to a super class has the same name as one already inherited by another super class. In such cases, CUBRID will automatically resolve the problem. That is, the added attribute will not be inherited to all sub classes that have already inherited the attribute with the same name.

The following example shows how to add an attribute to the *event* class. The super classes of the *soccer\_stadium* class are the *event* and the *stadium* classes, and the *nation\_code* attribute already exists in the *stadium* class. Therefore, a conflict occurs in the *soccer\_stadium* class if the *nation\_code* attribute is added to the *event* class. However, CUBRID resolves this conflict automatically.

```
ALTER CLASS event
ADD ATTRIBUTE nation_code CHAR(3);
```

If the *event* class is dropped from the *soccer\_stadium* super class, the *cost* attribute of the *stadium* class will be inherited automatically.

## Dropping Attributes and Methods

When an attribute is dropped from a class, any resolution specifiers which refer to the attribute by using the **INHERIT** clause are also removed. If a conflict occurs due to the deletion of an attribute, the system will determine a new inheritance hierarchy. If you don't like the inheritance hierarchy determined by the system, you can determine it by using the **INHERIT** clause of the **ALTER** statement. The following example shows such conflict.

Suppose there is a sub class that inherits attributes from three different super classes. If a name conflict occurs in all super classes and the explicitly inherited attribute is dropped, one of the remaining two attributes will be inherited automatically to resolve the problem.

The following example shows sub class conflict. Classes *B*, *C* and *D* are super classes of class *E*, and have an attribute whose name is *team* and the domain is *team\_event*. Class *E* was created with the *place* attribute inherited from class *C* as follows:

```
create class E under B, C, D
inherit place of C;
```

In this case, the inheritance hierarchy is as follows:

Suppose that you decide to delete class *C* from the super class. This drop will require changes to the inheritance hierarchy. Because the domains of the remaining classes *B* and *D* with the *game* attribute are at the same level, the system will randomly choose to inherit from one of the two classes. If you don't want the system to make a random selection, you can specify the class to inherit from by using the **INHERIT** clause when you change the class.

```
ALTER CLASS E INHERIT game OF D;
ALTER CLASS C DROP game;
```

### Note

If the domain of one *game* attribute in one super class is *event* and that of another super class is *team\_event*, *team\_event* is more specific than *event* because *team\_event* is the descendant of *event*. Therefore, a super class that has the *team\_event* attribute as a domain will be inherited; a user cannot forcefully inherit a super class that has the *event* attribute as a domain.

## Schema Invariant

Invariants of a database schema are a property of the schema that must be preserved consistently (before and after the schema change). There are four types of invariants: invariants of class hierarchy, name, inheritance and consistency.

### Invariant of class hierarchy

has a single root and defines a class hierarchy as a Directed Acyclic Graph (DAG) where all connected classes have a single direction. That is, all classes except the root have one or more super classes, and cannot become their own super classes. The root of DAG is “object,” a system-defined class.

### Invariant of name

means that all classes in the class hierarchy and all attributes in a class must have unique names. That is, attempts to create classes with the same name or to create attributes or methods with the same name in a single class are not allowed.

Invariant of name is redefined by the ‘RENAME’ qualifier. The ‘RENAME’ qualifier allows the name of an attribute or method to be changed.

### Invariant of inheritance

means that a class must inherit all attributes and methods from all super classes. This invariant can be distinguished with three qualifiers: source, conflict and domain. The names of inherited attributes and methods can be modified. For default or shared value attributes, the default or shared value can be modified. Invariant of inheritance means that such changes will be propagated to all classes that inherit these attributes and methods.

- **source qualifier**

means that if class *C* inherits sub classes of class *S*, only one of the sub class attributes (methods) inherited from class *S* can be inherited to class *C*. That is, if an attribute (method) defined in class *S* is inherited by other classes, it is in effect a single attribute (method), even though it exists in many sub classes. Therefore, if a class multiply inherits from classes that have attributes (methods) of the same source, only one appearance of the attribute (method) is inherited.

- **conflict qualifier**

means that if class *C* inherits from two or more classes that have attributes (methods) with the same name but of different sources, it can inherit more than one class. To inherit attributes (methods) with the same name, you must change their names so as not to violate the invariant of name.

## • domain qualifier

means that a domain of an inherited attribute can be converted to the domain's sub class.

## Invariant of consistency

means that the database schema must always follow the invariants of a schema and all rules except when it is being changed.

## Rule for Schema Changes

The Invariants of a Schema section has described the characteristics of schema that must be preserved all the time.

There are some methods for changing schemas, and all these methods must be able to preserve the invariants of a schema. For example, suppose that in a class which has a single super class, the relationship with the super class is to be removed. If the relationship with the super class is removed, the class becomes a direct sub class of the object class, or the removal attempt will be rejected if the user specified that the class should have at least one super class. To have some rules for selecting one of the methods for changing schemas, even though such selection seems arbitrary, will be definitely useful to users and database designers.

The following three types of rules apply: conflict-resolution rules, domain-change rule and class-hierarchy rule.

Seven conflict-resolution rules reinforce the invariant of inheritance. Most schema change rules are needed because of name conflicts. A domain-change rule reinforces a domain resolution of the invariant of inheritance. A class-hierarchy rule reinforces the invariant of class hierarchy.

## Conflict-Resolution Rules

- **Rule 1:** If an attribute (method) name of class C and an attribute name of the super class S conflict with each other (that is, their names are same), the attribute of class C is used. The attribute of S is not inherited.

If a class has one or more super classes, three aspects of the attribute (method) of each super class must be considered to determine whether the attributes are semantically equal and which attribute to inherit. The three aspects of the attribute (method) are the name, domain and source. The following table shows eight combinations of these three aspects that can happen with two super classes. In Case 1 (two different super classes have attributes with the same name, domain and source), only one of the two sub classes should be inherited because two attributes are identical. In Case 8 (two different super classes have attributes with different names, domains and sources), both classes should be inherited because two attributes are totally different ones.

| Case | Name      | Domain    | Source    |
|------|-----------|-----------|-----------|
| 1    | Same      | Same      | Same      |
| 2    | Same      | Same      | Different |
| 3    | Same      | Different | Same      |
| 4    | Same      | Different | Different |
| 5    | Different | Same      | Same      |
| 6    | Different | Same      | Different |
| 7    | Different | Different | Same      |
| 8    | Different | Different | Different |

Five cases (1, 5, 6, 7, 8) out of eight have clear meaning. Invariant of inheritance is a guideline for resolving conflicts in such cases. In other cases (2, 3, 4), it is very difficult to resolve conflicts automatically. Rules 2 and 3 can be resolutions for these conflicts.

- **Rule 2:** When two or more super classes have attributes (methods) with different sources but the same name and domain, one or more attributes (methods) can be inherited if the conflict-resolution statement is used. If the conflict-resolution statement is not used, the system will select and inherit one of the two attributes.

This rule is a guideline for resolving conflicts of Case 2 in the table above.

- **Rule 3:** If two or more super classes have attributes with different sources and domains but the same name, attributes (methods) with more detailed (lower in the inheritance hierarchy) domains are inherited. If there is no inheritance relationship between domains, schema change is not allowed.

This rule is a guideline for resolving conflicts of Case 3 and 4. If Case 3 and 4 conflict with each other, Case 3 has the priority.

- **Rule 4:** The user can make any changes except the ones in Case 3 and 4. In addition, the resolution of sub class conflicts cannot cause changes in the super class.

The philosophy of Rule 4 is that “an inheritance is a privilege that sub class has obtained from a super class, so changes in a sub class cannot affect the super class.” Rule 4 means that the name of the attribute (method) included in the super class cannot be changed to resolve conflicts between class C and super classes. Rule 4 has an exception in cases where the schema change causes conflicts in Case 3 and 4.

- For example, suppose that class A is the super class of class B, and class B has the *playing\_date* attribute of **DATE** type. If an attribute of **STRING** type named *playing\_date* is added to class A, it conflicts with the *playing\_date* attribute in class B. This is what happens in Case 4. The precise way to resolve such conflict is for the user to specify that class B must inherit the *playing\_date* attribute of class A. If a method refers to the attribute, the user of class B needs to modify the method properly so that the appropriate *playing\_date* attribute will be referenced. Schema change of class A is not allowed because the schema falls into an inconsistent state if the user of class B does not describe an explicit statement to resolve the conflict occurring from the schema change.

- **Rule 5:** If a conflict occurs due to a schema change of the super class, the original resolution is maintained as long as the change does not violate the rules. However, if the original resolution becomes invalid due to the schema change, the system will apply another resolution.

Rule 5 is for cases where a conflict is caused to a conflict-free class or where the original resolution becomes invalid.

This is the case where the name or domain of an attribute (method) is modified or a super class is deleted when the attribute (method) is added to the super class or the one inherited from the super class is deleted. The philosophy of Rule 5 coincides with that of Rule 4. That is, the user can change the class freely without considering what effects the sub class that inherits from the given class will have on the inherited attribute (method).

When you change the schema of class C, if you decide to inherit an attribute of the class due to an earlier conflict with another class, this may cause attribute (method) loss of class C. Instead, you must inherit one of the attributes (methods) that caused conflicts earlier.

The schema change of the super class can cause a conflict between the attribute (method) of the super class and the (locally declared or inherited) attribute (method) of class C. In this

case, the system resolves the conflict automatically by applying Rule 2 or 3 and may inform the user.

Rule 5 cannot be applied to cases where a new conflict occurs due to the addition or deletion of the relationship with the super class. The addition/deletion of a super class must be limited to within the class. That is, the user must provide an explicit resolution.

- **Rule 6:** Changes of attributes or methods are propagated only to sub classes without conflicts.

This rule limits the application of Rule 5 and the invariant of inheritance. Conflicts can be detected and resolved by applying Rule 2 and 3.

- **Rule 7:** Class *C* can be dropped even when an attribute of class *R* uses class *C* as a domain. In this case, the domain of the attribute that uses class *C* as a domain can be changed to *object*.

## Domain-Change Rules

- **Rule 8:** If the domain of an attribute of class *C* is changed from *D* to a super class of *D*, the new domain is less generic than the corresponding domain in the super class from which class *C* inherited the attribute. The following example explains the principle of this rule.

Suppose that in the database there are the *game* class with the *player* attribute and the *female\_game* class which inherits *game*. The domain of the *player* attribute of the *game* class is the *athlete* class, but the domain of the *player* attribute of the *female\_game* class is changed to *female\_athlete* which is a sub class of *athlete*. The following diagram shows such relationship. The domain of the *player* attribute of the *female\_game* class can be changed back to *athlete*, which is the super class of *female\_athlete*.

## Class-Hierarchy Rules

- **Rule 9:** A class without a super class becomes a direct sub class of object. The class-hierarchy rule defines characteristics of classes without super classes. If you create a class without a super class, object becomes the super class. If you delete the super class *S*, which is a unique super class of class *C*, class *C* becomes a direct sub class of object.

## Database Administration

### User Management

#### Database User

To know the user name's writing rule, see [Identifier](#).

CUBRID has two types of users by default: **DBA** and **PUBLIC**. At the initial installation of the product, no passwords are set for these users.

- All database users are automatically members of **PUBLIC**, so they inherit any authorization granted to the **PUBLIC** user. Granting authorization to **PUBLIC** means granting it to all users.
- The **DBA** user has the authorization of the database administrator. The **DBA** automatically becomes the member of all users and groups. That is, the **DBA** is granted the access for all tables. Therefore, there is no need to grant authorization explicitly to the **DBA** and **DBA** members. Each database user has a unique name. The database administrator can create multiple users simultaneously using the **cubrid createdb** utility (see [cubrid Utilities](#) for details). A database user cannot have a member who already has the same authorization. If authorization is granted to a user, all members of the user is automatically granted the same authorization.

#### Note

From version 11.3 of CUBRID, **DBA** members can also query objects of all users in the system catalog virtual class.

#### CREATE USER

You can create a user using the CREATE USER statement. The default DBA, PUBLIC user is created without a password.

```
CREATE USER user_name
[PASSWORD password]
[GROUPS user_name [{, user_name } ... ]]
```

```
[MEMBERS user_name [{, user_name } ... ]]  
[COMMENT 'comment_string'];
```

- *user\_name*: specifies the user name to create.
- *password*: specifies the user password to create.
- *comment\_string*: specifies the user comment to create.

#### Note

Only **DBA** and **DBA** members can create users using the CREATE USER statement.

The following example creates a user test\_user1 and specifies a password.

```
CREATE USER test_user1 PASSWORD 'password';
```

The following example shows how to create a user and add member to the user. By the following statement, *company* becomes a group that has *engineering*, *marketing* and *design* as its members. *marketing* becomes a group with members *smith* and *jones*, *design* becomes a group with a member *smith*, and *engineering* becomes a group with a member *brown*.

```
CREATE USER company;  
CREATE USER engineering GROUPS company;  
CREATE USER marketing GROUPS company;  
CREATE USER design GROUPS company;  
CREATE USER smith GROUPS design, marketing;  
CREATE USER jones GROUPS marketing;  
CREATE USER brown GROUPS engineering;
```

The following example shows how to create the same groups as above but use the **MEMBERS** keyword instead of **GROUPS**.

```
CREATE USER smith;  
CREATE USER brown;  
CREATE USER jones;  
CREATE USER engineering MEMBERS brown;  
CREATE USER marketing MEMBERS smith, jones;  
CREATE USER design MEMBERS smith;  
CREATE USER company MEMBERS engineering, marketing, design;
```

## User's COMMENT

The following example creates a user test\_user1 and adds a password and a comment.

```
CREATE USER test_user1 PASSWORD 'password' COMMENT 'new user';
```

You can see a comment for a user with this syntax.

```
SELECT name, comment FROM db_user;
```

To change user comment, refer to the description of the ALTER USER statement.

## ALTER USER

You can use the ALTER USER statement to change the password, members and comment of a created user.

```
ALTER USER user_name  
[PASSWORD password] |  
[ADD MEMBERS user_name [{, user_name } ... ]] |  
[DROP MEMBERS user_name [{, user_name } ... ]]  
[COMMENT 'comment_string'];
```

- *user\_name*: specifies the user name to change.
- *password*: specifies the user password to change.
- *comment\_string*: specifies the user comment to change.

### Note

**DBA** and **DBA** members can use the ALTER USER statement to change the password, members and comment of **all users**.

**General users** can change **their own** password, member and comment using the ALTER USER statement.

The following example creates a user test\_user1 and changes the password.

```
CREATE USER test_user1;  
ALTER USER test_user1 PASSWORD '1234';
```

The following example creates a user and adds members to the created user. This example does the same thing as the example in CREATE USER .. MEMBERS ..

```
CREATE USER company;  
CREATE USER engineering;  
CREATE USER marketing;  
CREATE USER design;  
CREATE USER smith;  
CREATE USER jones;  
CREATE USER brown;  
  
ALTER USER engineering ADD MEMBERS brown;  
ALTER USER marketing ADD MEMBERS smith, jones;  
ALTER USER design ADD MEMBERS smith;  
ALTER USER company ADD MEMBERS engineering, marketing, design;
```

The following example deletes the members of a created user group. The *marketing* member is deleted from the *company* group through the following sentence and the *marketing* group deletes *smith* and *jones* from the member.

```
ALTER USER company DROP MEMBERS marketing;  
ALTER USER marketing DROP MEMBERS smith, jones;
```

## User's COMMENT Change

The following example changes the comment for the created user.

```
CREATE USER test_user1 COMMENT 'new user';  
ALTER USER test_user1 COMMENT 'old user';
```

## DROP USER

You can delete a user using the DROP USER statement. Users who own objects in table, view, trigger, stored function/procedure, serial, synonym, and server cannot be dropped.

```
DROP USER user_name;
```

- *user\_name*: specifies the user name to delete.

### Note

Only **DBA** and **DBA** members can delete users using the DROP USER statement.

The following example shows how to create a user (*test\_user1*), change a password, and delete the user.

```
CREATE USER test_user1;  
ALTER USER test_user1 PASSWORD '1234';  
DROP USER test_user1;
```

## GRANT

In CUBRID, the following database objects can be granted permissions:

- **Table**
- **View**
- **Procedure**

To allow other users (groups) to access the database objects you created, you must grant them the appropriate permissions. All members of a group with granted permissions have the same permissions, so there is no need to grant permissions individually to each member. However, members of a group with the WITH GRANT OPTION permission, who are not part of the DBA or owner group, cannot grant the received permissions to other users.

Database objects created by the **PUBLIC** user are accessible to all users.

You can grant access permissions to a user using the following **GRANT** statement:

```
(1) Table and View:  
    GRANT operation [ { ,operation } ... ] ON  
    [schema_name.]object_name [ { , [schema_name.]object_name } ... ]  
    TO user [ { ,user } ... ] [ WITH GRANT OPTION ];  
  
(2) Stored Procedure and Function:
```

```
GRANT EXECUTE ON PROCEDURE [schema_name.]object_name  
TO user [ { ,user } ... ];
```

- *operation*: Specifies an operation that can be used when granting authorization. The following table shows operations.

- 1. Table and View

- **SELECT**: Allows reading the table definitions and retrieving instances. The most common type of permission.
- **INSERT**: Allows creating instances in the table.
- **UPDATE**: Allows modifying instances already existing in the table.
- **DELETE**: Allows deleting instances in the table.
- **ALTER**: Allows modifying the table definition, renaming, or deleting the table.
- **INDEX**: Allows creating indexes on columns to improve search speed.
- **EXECUTE**: Allows calling table methods or instance methods.
- **ALL PRIVILEGES**: Includes all the above-mentioned permissions.

- 1. Stored Procedure and Function

- **EXECUTE ON PROCEDURE**: Allows calling a stored procedure or function.

- *schema\_name*: Specifies the schema name of the table or virtual table. If omitted, the schema name of the current session is used.

- *table\_name*: Specifies the name of a table or virtual table to be granted.

- *user*: Specifies the name of a user (group) to be granted. Enter the login name of the database user or **PUBLIC**, a system-defined user. If **PUBLIC** is specified, all database users are granted with the permission.

- **WITH GRANT OPTION**

- The **WITH GRANT OPTION** allows the grantee of authorization to grant that same authorization to another user.
- The **EXECUTE ON PROCEDURE** permission for stored procedures and functions does not support the **WITH GRANT OPTION**.

The following example shows how to grant the **SELECT** authorization for the *olympic* table to *smith* (including his members).

```
GRANT SELECT ON olympic TO smith;
```

The following example shows how to grant the **SELECT**, **INSERT**, **UPDATE** and **DELETE** authorization on the *nation* and *athlete* tables to *brown* and *jones* (including their members).

```
GRANT SELECT, INSERT, UPDATE, DELETE ON nation, athlete TO brown,  
jones;
```

The following example shows how to grant every authorization on the *tbl1* and *tbl2* tables to all users(public).

```
CREATE TABLE tbl1 (a INT);  
CREATE TABLE tbl2 (a INT);  
GRANT ALL PRIVILEGES ON tbl1, tbl2 TO public;
```

The following **GRANT** statement example shows how to grant retrieval authorization on the *record* and *history* tables to *brown*. Using **WITH GRANT OPTION** allows *brown* to grant retrieval authorization to other users. *brown* can grant authorization to others within their own authorization.

```
GRANT SELECT ON record, history TO brown WITH GRANT OPTION;
```

#### Note

- The grantor of authorization must be the owner of all tables listed before the grant operation or have **WITH GRANT OPTION** specified.
- Before granting **SELECT**, **UPDATE**, **DELETE** and **INSERT** authorization for a virtual table, the owner of the virtual table must have **SELECT** and **GRANT** authorization for all the tables included in the query specification. The **DBA** user and the members of the **DBA** group are automatically granted all authorization for all tables.
- To execute the **TRUNCATE** statement, the **ALTER**, **INDEX**, and **DELETE** authorization is **required**.

The following example shows how to grant the permission to execute the *my\_sp* procedure to *smith*.

```
CREATE OR REPLACE PROCEDURE my_sp ()
IS
BEGIN
    DBMS_OUTPUT.put_line('grant test');
END;
GRANT EXECUTE ON PROCEDURE my_sp TO smith;
```

#### Note

- The **GRANT** statement can only grant permission to one object at a time for stored procedures and functions.
- The **EXECUTE ON PROCEDURE** operation is used for both stored procedures and functions.
- Currently, the **WITH GRANT OPTION** is not supported for granting permissions on stored procedures and functions, and will return a syntax error if used.

## REVOKE

You can revoke authorization using the **REVOKE** statement. The authorization granted to a user can be revoked at any time. If more than one type of authorization is granted to a user, all or part of the authorization can be revoked. Additionally, even if a single **GRANT** statement is used to grant authorization on multiple database objects to multiple users, selective revocation of authorization for specific users and specific database objects is possible.

If the authorization is revoked from the grantor (**WITH GRANT OPTION**), the authorization granted to the grantee by that grantor is also revoked.

The following **REVOKE** statement can be used to revoke the authorization granted to a user.

```
(1) For tables and views:
    REVOKE operation [ { ,operation } ... ] ON
[schema_name.]object_name [ { , [schema_name.]object_name } ... ]
    FROM user [ { ,user } ... ];

(2) For stored procedures and functions:
    REVOKE EXECUTE ON PROCEDURE [schema_name.]object_name
    FROM user [ { ,user } ... ];
```

- *operation*: Indicates the type of operation that can be revoked (see **GRANT** for details).

- *schema\_name*: Specifies the schema name of the database object. If omitted, the schema name of the current session is used.
- *object\_name*: Specifies the name of the database object for which the authorization is to be revoked.
- *user*: Specifies the name of the user or group from which the authorization is to be revoked.

The following example shows how to grant **SELECT**, **INSERT**, **UPDATE** and **DELETE** authorization to *smith* and *jones* so that they can perform on the *nation* and *athlete* tables.

```
GRANT SELECT, INSERT, UPDATE, DELETE ON nation, athlete TO smith,  
jones;
```

The following example shows how to execute the **REVOKE** statement; this allows *jones* to have only **SELECT** authorization. If *jones* has granted authorization to another user, the user is also allowed to execute **SELECT** only.

```
REVOKE INSERT, UPDATE, DELETE ON nation, athlete FROM jones;
```

The following example shows how to execute the **REVOKE** statement revoking all authorization that has granted to *smith*. *smith* is not allowed to execute any operations on the *nation* and *athlete* tables once this statement is executed.

```
REVOKE ALL PRIVILEGES ON nation, athlete FROM smith;
```

## ALTER ... OWNER

Database Administrator (**DBA**) or a member of the **DBA** group can change the owner of table, view, trigger, stored functions/procedures, and serial by using the following query.

```
ALTER (TABLE | CLASS | VIEW | VCLASS | TRIGGER | PROCEDURE |  
FUNCTION | SERIAL) [schema_name.]name OWNER TO user_id;
```

- *schema\_name*: Specifies the schema of the object. If omitted, the schema name of the current session is used.
- *name*: The name of schema object of which owner is to be changed
- *user\_id*: User ID

```
ALTER TABLE test_tbl OWNER TO public;
ALTER VIEW test_view OWNER TO public;
ALTER TRIGGER test_trigger OWNER TO public;
ALTER FUNCTION test_function OWNER TO public;
ALTER PROCEDURE test_procedure OWNER TO public;
ALTER SERIAL test_serial OWNER TO public;
```

### Warning

When the owner changes, privileges granted by the previous owner are transferred to the new owner. **However, privileges on the object that were previously granted to the new owner by the previous owner are automatically revoked.**

## User Authorization Management METHOD

The database administrator (**DBA**) can check and modify user authorization by calling authorization-related methods defined in **db\_user** where information about database user is stored, or **db\_root** (the system root class). The administrator can specify **db\_user** or **db\_root** depending on the method to be called, and store the return value of a method to a variable. In addition, some methods can be called only by **DBA** or members of **DBA** group.

### Note

Note that method call made by the master node is not applied to the slave node in the HA environment.

```
CALL method_definition ON CLASS auth_class [ TO variable ] [ ; ]
CALL method_definition ON variable [ ; ]
```

## login() method

As a class method of **db\_user** class, this method is used to change the users who are currently connected to the database. The name and password of a new user to connect are given as arguments, and they must be string type. If there is no password, a blank character (") can be used as the argument. **DBA** and **DBA** members can call the **login()** method without a password.

```
-- Connect as DBA user who has no password
CALL login ('dba', '') ON CLASS db_user;
```

```
-- Connect as a user_1 whose password is cubrid  
CALL login ('user_1', 'cubrid') ON CLASS db_user;
```

### **add\_user( ) method**

As a class method of **db\_user** class, this method is used to add a new user. The name and password of a new user to add are given as arguments, and they must be string type. At this time, the new user name should not duplicate any user name already registered in a database. The **add\_user( )** can be called only by **DBA** or members of **DBA** group.

```
-- Add user_2 who has no password  
CALL add_user ('user_3', '') ON CLASS db_user;  
  
-- Add user_3 who has no password, and store the return value of a  
method into an admin variable  
CALL add_user ('user_2', '') ON CLASS db_user to admin;
```

### **drop\_user( ) method**

As a class method of **db\_user** class, this method is used to drop an existing user. Only the user name to be dropped is given as an argument, and it must be a string type. However, the owner of a class cannot be dropped thus **DBA** needs to specify a new owner of the class before dropping the user. The **drop\_user( )** method can be also called only by **DBA** or members of **DBA**.

```
-- Delete user_2  
CALL drop_user ('user_2') ON CLASS db_user;
```

### **find\_user( ) method**

As a class method of **db\_user** class, this method is used to find a user who is given as an argument. The name of a user to be found is given as an argument, and the return value of the method is stored into a variable that follows 'to'. The stored value can be used in a next query execution.

```
-- Find user_2 and store it into a variable called 'admin'  
CALL find_user ('user_2') ON CLASS db_user to admin;
```

### **set\_password( ) method**

This method is an instance method that can call each user instance, and it is used to change a user's password. The new password of a specified user is given as an argument. General users other than **DBA** and **DBA** group members can only change their own passwords.

```
-- Add user_4 and store it into a variable called user_common
CALL add_user ('user_4','') ON CLASS db_user to user_common;

-- Change the password of user_4 to 'abcdef'
CALL set_password('abcdef') on user_common;
```

### change\_owner() method

As a class method of **db\_root** class, this method is used to change the owner of a class. The name of a class for which you want to change the owner, and the name of a new owner are given as arguments. The table name must be prefixed with the schema name. If omitted, the schema name of the current session is used. At this time, the class and owner that are specified as an argument must exist in a database. Otherwise, an error occurs. **change\_owner( )** can be called only by **DBA** or members of **DBA** group. The **ALTER ... OWNER** query has the same role as the method. See **ALTER ... OWNER**.

```
-- Change the owner of table_1 owned by user_1 to user_4
CALL change_owner ('user_1.table_1', 'user_4') ON CLASS db_root;
```

The following example shows a **CALL** statement that calls the **find\_user** method defined in the system table **db\_user**. It is called to determine whether the database user entered as the **find\_user** exists. The first statement calls the table method defined in the **db\_user** class. The name (**db\_user** in this case) is stored in x if the user is registered in the database. Otherwise, **NULL** is stored.

The second statement outputs the value stored in the variable x. In this query statement, the **db\_root** is a system class that can have only one record. It can be used to output the value of **sys\_date** or other registered variables. For this purpose, the **db\_root** can be replaced by another table having only one record.

```
CALL find_user('dba') ON CLASS db_user to x;
```

Result

```
=====
db_user
```

```
SELECT x FROM db_root;
```

```
x
=====
db_user
```

With **find\_user**, you can determine if the user exists in the database depending on whether the return value is **NULL** or not.

## SET

The **SET** statement is the syntax that specifies a system parameter's value or user-defined variables.

### System Parameter

You can define a value of a system parameter with SQL syntax by CSQL interpreter or a query editor of CUBRID Manager. However, be cautious that updatable parameters are limited. For the information of updatable parameters, see [cubrid.conf Configuration File and Default Parameters](#).

```
SET SYSTEM PARAMETERS 'parameter_name=value [{; name=value}...]'
```

**DEFAULT** for *value* will reset the parameter to its default value with an exception of **call\_stack\_dump\_activation\_list** parameter.

```
SET SYSTEM PARAMETERS 'lock_timeout=DEFAULT';
```

### User Variables

You can create user-defined variables in two ways. One is to use the **SET** statement and the other is to use the assignment statement of user-defined variables within SQL statements. You can delete the user-defined variables that you defined with the **DEALLOCATE** or the **DROP** statements.

The user-defined variables are also called session variables as they are used for maintaining connections within one application. The user-defined variables are used within the part of a connection session, and the user-defined variables defined by an application cannot be accessed by other applications. When an application terminates connections, all variables will be removed automatically. The user-defined variables are limited to twenty per connection session for an application. If you already have twenty user-defined variables and want to define a new user-defined variable, you must remove some variables with the **DROP VARIABLE** statement.

You can use user-defined variables in most SQL statements. If you define user-defined variables and refer to them in one statement, the sequence is not guaranteed. That is, if you refer to the variables specified in the **SELECT** list of the **HAVING**, **GROUP BY** or **ORDER BY** clause, you may not get the values in the sequence you expect. You cannot also use user-defined variables as identifiers, such as column names or table names within SQL statements

The user-defined variables are not case-sensitive. The user-defined variable type can be one of the **SHORT**, **INTEGER**, **BIGINT**, **FLOAT**, **DOUBLE**, **NUMERIC**, **CHAR**, **VARCHAR**, **BIT** and **BIT VARYING**. Other types will be converted to the **VARCHAR** type.

```
SET @v1 = 1, @v2=CAST(1 AS BIGINT), @v3 = '123', @v4 =
DATE'2010-01-01';

SELECT typeof(@v1), typeof(@v2), typeof(@v3), typeof(@v4);
```

```
      typeof(@v1)      typeof(@v2)      typeof(@v3)
typeof(@v4)
=====
=====
'integer'             'bigint'             'character (-1)'
'character varying (1073741823)'
```

The user-defined variables can be changed when you define values.

```
SET @v = 'a';
SET @v1 = 10;

SELECT @v := 1, typeof(@v1), @v1:='1', typeof(@v1);
```

```
      @v := 1      typeof(@v1)      @v1 := '1'
typeof(@v1)
=====
=====
1             'integer'             '1'
'character (-1)'
```

```
<set_statement>
: <set_statement>, <udf_assignment>
| SET <udv_assignment>
;

<udv_assignment>
: @<name> = <expression>
| @<name> := <expression>
;

{DEALLOCATE|DROP} VARIABLE <variable_name_list>
```

```
<variable_name_list>
: <variable_name_list> ',' @<name>
```

- You must define the variable names with alphanumeric characters and underscores (\_).
- When you define the variables within SQL statements, you should use the ':=’ operator.

The following example shows how to define the variable a and assign a value 1 to it.

```
SET @a = 1;
SELECT @a;
```

```
@a
=====
1
```

The following example shows how to count the number of rows in the **SELECT** statement by using the user-defined variable.

```
CREATE TABLE t (i INTEGER);
INSERT INTO t(i) VALUES(2),(4),(6),(8);

SET @a = 0;

SELECT @a := @a+1 AS row_no, i FROM t;
```

```
row_no          i
=====
1              2
2              4
3              6
4              8

4 rows selected.
```

The following example shows how to use the user-defined variable as the input of bind parameter specified in the prepared statement.

```
SET @a:=3;

PREPARE stmt FROM 'SELECT i FROM t WHERE i < ?';
EXECUTE stmt USING @a;
```

```

      i
=====
      2

```

The following example shows how to declare the user-defined variable by using the `:=` operator.

```

SELECT @a := 1, @user_defined_variable := 'user defined variable';
UPDATE t SET i = (@var := 1);

```

The following example shows how to delete the user-defined variable `a` and `user_defined_variable`.

```

DEALLOCATE VARIABLE @a, @user_defined_variable;
DROP VARIABLE @a, @user_defined_variable;

```

### Note

The user-defined variables that are defined by the **SET** statement start by connecting an application to a server and will be maintained until the application terminates the connection. The connection maintained during this period is called a session. When an application terminates the connection or when there are no requests for a certain period of time, the session will expire, and the user-defined variables will be deleted as a result. You can set the session time with the **session\_state\_timeout** parameter of **cubrid.conf**; the default value is **21600** seconds (=6 hours).

The data managed by the session includes **PREPARE** statements, the user-defined variables, the last ID inserted (**LAST\_INSERT\_ID**) and the number of rows affected by the statement that you execute at the end (**ROW\_COUNT**).

## KILL

The **KILL** statement terminates transactions with an option **TRANSACTION** or **QUERY** modifier.

```

KILL [TRANSACTION | QUERY] tran_index, ... ;

```

- **KILL TRANSACTION** is default of **KILL** statement. It is the same as **KILL** without a modifier. It terminates the connection associated with the given *tran\_index*.

- **KILL QUERY** terminates the statement that the transaction is executing.

DBA and a user of DBA group are able to terminate all the transactions of the system, while non-DBA users are only allowed to terminate their own transaction.

```
KILL TRANSACTION 1;
```

## SHOW

Contents

|                        |             |

## DESC, DESCRIBE

It shows the column information of a table, and it's like a **SHOW COLUMNS** statement. For more details, see [SHOW COLUMNS](#).

```
DESC [schema_name.]table_name;  
DESCRIBE [schema_name.]table_name;
```

## EXPLAIN

It shows the column information of a table, and it's like a **SHOW COLUMNS** statement. For more details, see [SHOW COLUMNS](#).

```
EXPLAIN [schema_name.]table_name;
```

## SHOW TABLES

It shows the list of all table names within a database. The name of the result column will be *tables\_in\_<database name>* and it will have one column. If you use the **LIKE** clause, you can search the table names matching this and if you use the **WHERE** clause, you can search table names with more general terms. **SHOW FULL TABLES** displays the *owner* column and the *table\_type* column together. The *owner* column has the owner name as a value. *table\_type* columns have **BASE TABLE** values for tables and **VIEW** for views.

```
SHOW [FULL] TABLES [LIKE 'pattern' | WHERE expr];
```

The following shows the examples of this syntax.

```
SHOW TABLES;
```

```
Tables_in_demodb
=====
'athlete'
'code'
'event'
'game'
'history'
'nation'
'olympic'
'participant'
'record'
'stadium'
```

```
SHOW FULL TABLES;
```

| Tables_in_demodb | Owner    | Table_type   |
|------------------|----------|--------------|
| 'athlete'        | 'PUBLIC' | 'BASE TABLE' |
| 'code'           | 'PUBLIC' | 'BASE TABLE' |
| 'event'          | 'PUBLIC' | 'BASE TABLE' |

|               |          |              |
|---------------|----------|--------------|
| 'game'        | 'PUBLIC' | 'BASE TABLE' |
| 'history'     | 'PUBLIC' | 'BASE TABLE' |
| 'nation'      | 'PUBLIC' | 'BASE TABLE' |
| 'olympic'     | 'PUBLIC' | 'BASE TABLE' |
| 'participant' | 'PUBLIC' | 'BASE TABLE' |
| 'record'      | 'PUBLIC' | 'BASE TABLE' |
| 'stadium'     | 'PUBLIC' | 'BASE TABLE' |

```
SHOW FULL TABLES LIKE '%c%';
```

| Tables_in_demodb | Owner    | Table_type   |
|------------------|----------|--------------|
| =====            | =====    | =====        |
| 'code'           | 'PUBLIC' | 'BASE TABLE' |
| 'olympic'        | 'PUBLIC' | 'BASE TABLE' |
| 'participant'    | 'PUBLIC' | 'BASE TABLE' |
| 'record'         | 'PUBLIC' | 'BASE TABLE' |

```
SHOW FULL TABLES WHERE table_type = 'BASE TABLE' and
TABLES_IN_demodb LIKE '%co%';
```

| Tables_in_demodb | Owner    | Table_type   |
|------------------|----------|--------------|
| =====            | =====    | =====        |
| 'code'           | 'PUBLIC' | 'BASE TABLE' |
| 'record'         | 'PUBLIC' | 'BASE TABLE' |

## SHOW COLUMNS

It shows the column information of a table. You can use the **LIKE** clause to search the column names matching it. If you use the **WHERE** clause, you can search column names with more general terms like, “General Considerations for All **SHOW** Statements.”.

```
SHOW [FULL] COLUMNS (FROM | IN) [schema_name.]table_name [LIKE
'pattern' | WHERE expr];
```

If a **FULL** keyword is used, it shows the additional information, **collation** and **comment**.

The **DESCRIBE** (abbreviated **DESC**) statement and the **EXPLAIN** statement provide the same information with **SHOW COLUMNS**, but they don't support LIKE clause or WHERE clause.

This query has the following columns:

| Column name | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Field       | VARCHAR | Column name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Type        | VARCHAR | Column data type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Null        | VARCHAR | If you can store <b>NULL</b> , the value is YES; if not, it is NO                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Key         | VARCHAR | <p><b>Whether a column has an index or not. If there is more than one key value in the given column of a table, this displays only the one that appears first in the order of PRI, UNI and MUL.</b></p> <ul style="list-style-type: none"> <li>• If the key is a space, the column doesn't have an index, it is not the first column in the multiple column index or the index is non-unique.</li> <li>• If the value is PRI, it is a primary key or the primary key of multiple columns.</li> <li>• If the value is UNI, it is a unique index. (The unique index allows multiple NULL values but you can also set a NOT NULL constraint.)</li> <li>• If the value is MUL, it is the first column</li> </ul> |

| Column name | Type    | Description                                                                                                                                                                                                                                                                    |
|-------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |         | of the non-unique index that allows the given value to be displayed in the column several times. If the column composes a composite unique index, the value will be MUL. The combination of column values can be unique but the value of each column can appear several times. |
| Default     | VARCHAR | Default value defined in the column                                                                                                                                                                                                                                            |
| Extra       | VARCHAR | Additional information available on the given column. For the column with <b>AUTO_INCREMENT</b> constraint, it shows the 'auto_increment'.                                                                                                                                     |

The following shows the examples of this syntax.

```
SHOW COLUMNS FROM athlete;
```

```

Field      Type      Null
Key        Default  Extra
=====
'code'     'INTEGER' 'NO'
'PRI'      NULL      'auto_increment'
'name'     'VARCHAR(40)' 'NO'
```

```

''          NULL          ''
'gender'    'CHAR(1)'      'YES'
''          NULL          ''
'nation_code' 'CHAR(3)'      'YES'
''          NULL          ''
'event'     'VARCHAR(30)' 'YES'
''          NULL          ''

```

```
SHOW COLUMNS FROM athlete WHERE field LIKE '%c%';
```

| Field         | Type      | Null             |
|---------------|-----------|------------------|
| Key           | Default   | Extra            |
| 'code'        | 'INTEGER' | 'NO'             |
| 'PRI'         | NULL      | 'auto_increment' |
| 'nation_code' | 'CHAR(3)' | 'YES'            |
| ''            | NULL      | ''               |

```
SHOW COLUMNS FROM athlete WHERE "type" = 'INTEGER' and "key"='PRI'
AND extra='auto_increment';
```

| Field  | Type      | Null             |
|--------|-----------|------------------|
| Key    | Default   | Extra            |
| 'code' | 'INTEGER' | 'NO'             |
| 'PRI'  | NULL      | 'auto_increment' |

```
SHOW FULL COLUMNS FROM athlete WHERE field LIKE '%c%';
```

| Field            | Type      | Collation      |
|------------------|-----------|----------------|
| Null             | Key       | Default        |
| Extra            | Comment   |                |
| 'code'           | 'INTEGER' | NULL           |
| 'NO'             | 'PRI'     | NULL           |
| 'auto_increment' | NULL      |                |
| 'nation_code'    | 'CHAR(3)' | 'iso88591_bin' |
| 'YES'            | ''        | NULL           |
| ''               | NULL      |                |

## SHOW INDEX

It shows the index information.

```
SHOW (INDEX | INDEXES | KEYS) (FROM | IN) [schema_name.]table_name;
```

This query has the following columns:

| Column name  | Type    | Description                                                                                                                                        |
|--------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Table        | VARCHAR | Table name                                                                                                                                         |
| Non_unique   | INTEGER | <b>Unique or not</b> <ul style="list-style-type: none"><li>• 0: Duplicated value is not allowed</li><li>• 1: Duplicated value is allowed</li></ul> |
| Key_name     | VARCHAR | Index name                                                                                                                                         |
| Seq_in_index | INTEGER | Serial number of the column in the index. Starts from 1.                                                                                           |
| Column_name  | VARCHAR | Column name                                                                                                                                        |
| Collation    | VARCHAR | Method of sorting columns in the index. 'A' means ascending and <b>NULL</b> means not sorted.                                                      |
| Cardinality  | INTEGER | The number of values measuring the unique values in the index. The higher the cardinality, the                                                     |

| Column name | Type    | Description                                                                                                                              |
|-------------|---------|------------------------------------------------------------------------------------------------------------------------------------------|
|             |         | more efficient the index search. This value is updated every time <b>SHOW INDEX</b> is executed. Note that this is an approximate value. |
| Sub_part    | INTEGER | The number of bytes of the indexed characters if the columns are indexed partially. <b>NULL</b> if all columns are indexed.              |
| Packed      |         | Shows how keys are packed. If they are not packed, it will be <b>NULL</b> . Currently no support.                                        |
| Null        | VARCHAR | YES if a column can include <b>NULL</b> , NO if not.                                                                                     |
| Index_type  | VARCHAR | Index to be used (currently, only the BTREE is supported.)                                                                               |
| Func        | VARCHAR | A function which is used in a function-based index                                                                                       |
| Comment     | VARCHAR | Comment to describe the index                                                                                                            |
| Visible     | VARCHAR | Shows the Visibility of an index (YES/NO)                                                                                                |

The following shows the examples of this syntax.

```
SHOW INDEX IN athlete;
```

```

## SHOW COLLATION

It lists collations supported by the database. If LIKE clause is present, it indicates which collation names to match.

```
SHOW COLLATION [LIKE 'pattern'];
```

This query has the following columns:

| Column name | Type    | Description                                                                                                 |
|-------------|---------|-------------------------------------------------------------------------------------------------------------|
| Collation   | VARCHAR | Collation name                                                                                              |
| Charset     | CHAR(1) | Charset name                                                                                                |
| Id          | INTEGER | Collation ID                                                                                                |
| Built_in    | CHAR(1) | Built-in collation or not. Built-in collations are impossible to add or remove because they are hard-coded. |
| Expansions  | CHAR(1) | Collation with expansion or not. For details, see <a href="#">Expansion</a> .                               |
| Strength    | CHAR(1) | The number of levels to be considered in comparison, and the character order can                            |

| Column name | Type | Description                                                                             |
|-------------|------|-----------------------------------------------------------------------------------------|
|             |      | be different by this number.<br>For details, see <a href="#">Collation Properties</a> . |

The following shows the examples of this syntax.

### SHOW COLLATION;

```

## SHOW TIMEZONES

It shows the timezone information which the current CUBRID supports.

```
SHOW [FULL] TIMEZONES [LIKE 'pattern'];
```

If FULL is not specified, one column which has timezone's region names is displayed. The name of this column is `timezone_region`.

If FULL is specified, four columns which have timezone information are displayed.

If LIKE clause is present, it indicates which `timezone_region` names to match.

| Column name                  | Type                     | Description          |
|------------------------------|--------------------------|----------------------|
| <code>timezone_region</code> | <code>VARCHAR(32)</code> | Timezone region name |
| <code>region_offset</code>   | <code>VARCHAR(32)</code> |                      |

| Column name      | Type        | Description                                                                               |
|------------------|-------------|-------------------------------------------------------------------------------------------|
|                  |             | Offset of timezone (daylight saving time is not considered)                               |
| dst_offset       | VARCHAR(32) | Offset of daylight saving time (applied to timezone region) which is currently considered |
| dst_abbreviation | VARCHAR(32) | An abbreviation of the daylight saving time which is currently applied for the region     |

The information listed for the second, third and fourth columns is for the current date and time.

If a timezone region doesn't have daylight saving time rules at all then the dst\_offset and dst\_abbreviation columns will contain NULL values.

If at the current date, there aren't daylight saving time rules that apply, then dst\_offset will be set to 0 and dst\_abbreviation will be the empty string.

The LIKE condition without the WHERE condition is applied on the first column. The WHERE condition may be used to filter the output.

```
SHOW TIMEZONES;
```

'WET'                  '+00:00'           '+00:00'
'WET'
'Zulu'                 '+00:00'           '+00:00'
'UTC'
```

```
SHOW FULL TIMEZONES LIKE '%Paris%';
```

```

timezone_region      region_offset      dst_offset
dst_abbreviation
=====
'Europe/Paris'      '+01:00'      '+00:00'
'CET'

```

## SHOW GRANTS

It shows the permissions associated with the database user accounts.

```
SHOW GRANTS FOR user_name;
```

The following shows the examples of this syntax.

```

CREATE TABLE testgrant (id INT);
CREATE USER user1;
GRANT INSERT,SELECT ON testgrant TO user1;

SHOW GRANTS FOR user1;

```

```

Grants for USER1
=====
'GRANT INSERT, SELECT ON dba.testgrant TO USER1'

```

## SHOW CREATE TABLE

When a table name is specified, It shows the **CREATE TABLE** statement of the table.

```
SHOW CREATE TABLE [schema_name.]table_name;
```

```
SHOW CREATE TABLE nation;
```

```

TABLE      CREATE TABLE
=====
'public.nation'      'CREATE TABLE [nation] ([code] CHARACTER(3)
NOT NULL, [name] CHARACTER VARYING(40) NOT NULL, [continent]
CHARACTER VARYING(10), [capital] CHARACTER VARYING(30), CONSTRAINT

```

```
[pk_nation_code] PRIMARY KEY ([code])) DONT_REUSE_OID, COLLATE
iso88591_bin'
```

**SHOW CREATE TABLE** statement does not display as the user's written syntax. For example, the comment that user wrote is not displayed, and table names and column names are always displayed as lower case letters.

## SHOW CREATE VIEW

It shows the corresponding **CREATE VIEW** statement if view name is specified.

```
SHOW CREATE VIEW view_name;
```

The following shows the examples of this syntax.

```
SHOW CREATE VIEW db_class;
```

| View       | Create View                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## SHOW ACCESS STATUS

**SHOW ACCESS STATUS** statement displays login information regarding database accounts. Only database's DBA account can use this statement.

```
SHOW ACCESS STATUS [LIKE 'pattern' | WHERE expr];
```

This statement displays the following columns.

| Column name      | Type        | Description                                           |
|------------------|-------------|-------------------------------------------------------|
| user_name        | VARCHAR(32) | DB user's account                                     |
| last_access_time | DATETIME    | Last time that the database user accessed             |
| last_access_host | VARCHAR(32) | Lastly accessed host                                  |
| program_name     | VARCHAR(32) | The name of client program(broker_cub_cas_1, csq1 ..) |

The following shows the result of running this statement.

```
SHOW ACCESS STATUS;
```

```

user_name last_access_time last_access_host program_name
=====
=====
'DBA' 08:19:31.000 PM 02/10/2014 127.0.0.1 'csq1'
'PUBLIC' NULL NULL NULL

```

#### Note

The above login information which **SHOW ACCESS STATUS** shows is initialized when the database is restarted, and this query is not replication in HA environment; therefore, each node shows the different result.

## SHOW EXEC STATISTICS

It shows statistics information of executing query.

- To start collecting **@collect\_exec\_stats** statistics information, configure the value of session variable **@collect\_exec\_stats** to 1; to stop, configure it to 0.
- It outputs the result of collecting statistics information.
  - The **SHOW EXEC STATISTICS** statement outputs four part of data page statistics information; data\_page\_fetches, data\_page\_dirties, data\_page\_ioreads, and data\_page\_iowrites. The result columns consist of variable column (name of statistics name) and value column (value of statistics value). Once the **SHOW EXEC STATISTICS** statement is executed, the statistics information which has been accumulated is initialized.
  - The **SHOW EXEC STATISTICS ALL** statement outputs all items of statistics information.

For details, see [statdump](#).

```
SHOW EXEC STATISTICS [ALL];
```

The following shows the examples of this syntax.

```
-- set session variable @collect_exec_stats as 1 to start collecting
the statistical information.
SET @collect_exec_stats = 1;
SELECT * FROM db_class;

-- print the statistical information of the data pages.
SHOW EXEC STATISTICS;
```

| variable             | value |
|----------------------|-------|
| 'data_page_fetches'  | 332   |
| 'data_page_dirties'  | 85    |
| 'data_page_ioreads'  | 18    |
| 'data_page_iowrites' | 28    |

```
SELECT * FROM db_index;
```

```
-- print all of the statistical information.
SHOW EXEC STATISTICS ALL;
```

## Diagnostics

The following diagnostic SHOW statements can only be used by users who are DBA or members of the DBA group.

### SHOW VOLUME HEADER

It shows the volume header of the specified volume in one row.

```
SHOW VOLUME HEADER OF volume_id;
```

This query has the following columns:

| Column name  | Type         | Description                                                           |
|--------------|--------------|-----------------------------------------------------------------------|
| Volume_id    | INT          | Volume identifier                                                     |
| Magic_symbol | VARCHAR(100) | Magic value for for a volume file                                     |
| Io_page_size | INT          | Size of DB volume                                                     |
| Purpose      | VARCHAR(32)  | Volume purposes, 'Permanent data purpose' or 'Temporary data purpose' |
| Type         | VARCHAR(32)  | Volume type, 'Permanent Volume' or 'Temporary Volume'                 |

| Column name                      | Type        | Description                              |
|----------------------------------|-------------|------------------------------------------|
| Sector_size_in_pages             | INT         | Size of sector in pages                  |
| Num_total_sectors                | INT         | Total number of sectors                  |
| Num_free_sectors                 | INT         | Number of free sectors                   |
| Num_max_sectors                  | INT         | Maximum number of sectors                |
| Hint_alloc_sector                | INT         | Hint for next sector to be allocated     |
| Sector_alloc_table_size_in_pages | INT         | Size of sector allocation table in page  |
| Sector_alloc_table_first_page    | INT         | First page of sector allocation table    |
| Page_alloc_table_size_in_pages   | INT         | Size of page allocation table in page    |
| Page_alloc_table_first_page      | INT         | First page of page allocation table      |
| Last_system_page                 | INT         | Last system page                         |
| Creation_time                    | DATETIME    | Volume creation time                     |
| Db_charset                       | INT         | Charset number of database               |
| Checkpoint_lsa                   | VARCHAR(64) | Lowest log sequence address to start the |

| Column name        | Type         | Description                                             |
|--------------------|--------------|---------------------------------------------------------|
|                    |              | recovery process of this volume                         |
| Boot_hfid          | VARCHAR(64)  | System Heap file for booting purposes and multi volumes |
| Full_name          | VARCHAR(255) | The full path of volume                                 |
| Next_volume_id     | INT          | Next volume identifier                                  |
| Next_vol_full_name | VARCHAR(255) | The full path of next volume                            |
| Remarks            | VARCHAR(64)  | Volume remarks                                          |

The following shows the examples of this syntax.

```
-- csql> ;line on
SHOW VOLUME HEADER OF 0;
```

```
<00001> Volume_id           : 0
        Magic_symbol        : 'MAGIC SYMBOL = CUBRID/'

        Num_free_sectors     : 459
        Num_max_sectors      : 512
        Hint_alloc_sector    : 0
        Sector_alloc_table_size_in_pages: 1
        Sector_alloc_table_first_page  : 1
        Last_system_page     : 1
        Creation_time         : 09:46:41.000 PM 05/23/2017
        Db_charset            : 3
        Checkpoint_lsa        : '(0|12832)'
        Boot_hfid             : '(0|41|50)'
        Full_name             : '/home1/brightest/CUBRID/'
```

```
databases/demodb/demodb'
  Next_volume_id          : -1
  Next_vol_full_name      : ''
  Remarks                 : ''
```

## SHOW LOG HEADER

It shows the header information of an active log file.

```
SHOW LOG HEADER [OF file_path];
```

If you omit **OF file\_path**, it shows the header information of a memory; if you include **OF file\_path**, it shows the header information of *file\_path*. In *file\_path*, you can input either the relative path or the absolute path of the active log file. When entering a relative path, the base path is the directory where the active log file is located.

This query has the following columns:

| Column name                | Type        | Description                                                         |
|----------------------------|-------------|---------------------------------------------------------------------|
| Volume_id                  | INT         | Volume identifier                                                   |
| Magic_symbol               | VARCHAR(32) | Magic value for log file                                            |
| Magic_symbol_location      | INT         | Magic symbol location from log page                                 |
| Creation_time              | DATETIME    | Volume creation time                                                |
| Release                    | VARCHAR(32) | CUBRID Release version                                              |
| Compatibility_disk_version | VARCHAR(32) | Compatibility of the database against the current release of CUBRID |
| Db_page_size               | INT         | Size of pages in the database                                       |

| Column name             | Type        | Description                                               |
|-------------------------|-------------|-----------------------------------------------------------|
| Log_page_size           | INT         | Size of log pages in the database                         |
| Shutdown                | INT         | Was the log shutdown                                      |
| Next_trans_id           | INT         | Next transaction identifier                               |
| Num_avg_trans           | INT         | Number of average transactions                            |
| Num_avg_locks           | INT         | Average number of object locks                            |
| Num_active_log_pages    | INT         | Number of pages in the active log portion                 |
| Db_charset              | INT         | Charset number of database                                |
| First_active_log_page   | BIGINT      | Logical pageid at physical location 1 in active log       |
| Current_append          | VARCHAR(64) | Current append location                                   |
| Checkpoint              | VARCHAR(64) | Lowest log sequence address to start the recovery process |
| Next_archive_page_id    | BIGINT      | Next logical page to archive                              |
| Active_physical_page_id | INT         | Physical location of logical page to archive              |

| Column name                     | Type         | Description                                                                    |
|---------------------------------|--------------|--------------------------------------------------------------------------------|
| Next_archive_num                | INT          | Next log archive number                                                        |
| Last_archive_num_for_syscrashes | INT          | Last log archive needed for system crashes                                     |
| Last_deleted_archive_num        | INT          | Last deleted archive number                                                    |
| Backup_lsa_level0               | VARCHAR(64)  | LSA of backup level 0                                                          |
| Backup_lsa_level1               | VARCHAR(64)  | LSA of backup level 1                                                          |
| Backup_lsa_level2               | VARCHAR(64)  | LSA of backup level 2                                                          |
| Log_prefix                      | VARCHAR(256) | Log prefix name                                                                |
| Has_logging_been_skipped        | INT          | Whether or not logging skipped                                                 |
| Perm_status                     | VARCHAR(64)  | Reserved for future expansion                                                  |
| Backup_info_level0              | VARCHAR(128) | detail information of backup level 0. currently only backup start-time is used |
| Backup_info_level1              | VARCHAR(128) | detail information of backup level 1. currently only backup start-time is used |
| Backup_info_level2              | VARCHAR(128) |                                                                                |

| Column name                     | Type        | Description                                                                                                       |
|---------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------|
|                                 |             | detail information of backup level 2. currently only backup start-time is used                                    |
| Ha_server_state                 | VARCHAR(32) | current ha state, one of flowing value: na, idle, active, to-be-active, standby, to-be-standby, maintenance, dead |
| Ha_file                         | VARCHAR(32) | ha replication status, one of following value: clear, archived, sync                                              |
| Eof_lsa                         | VARCHAR(64) | EOF LSA                                                                                                           |
| Smallest_lsa_at_last_checkpoint | VARCHAR(64) | The smallest LSA of the last checkpoint, can be NULL LSA                                                          |
| Next_mvcc_id                    | BIGINT      | The next MVCCID will be used for the next transaction                                                             |
| Mvcc_op_log_lsa                 | VARCHAR(32) | The LSA used to link log entries for MVCC operation                                                               |
| Last_block_oldest_mvcc_id       | BIGINT      | Used to find the oldest MVCCID in a block of log data, can be NULL                                                |
| Last_block_newest_mvcc_id       | BIGINT      | Used to find the newest MVCCID in a block of log data, can be NULL                                                |

The following shows the examples of this syntax.

```
-- csql> ;line on
SHOW LOG HEADER;
```

```
<00001> Volume_id           : -2
        Magic_symbol        : 'CUBRID/LogActive'

      Last_block_newest_mvcc_id : NULL

```

## SHOW ARCHIVE LOG HEADER

It shows the header information of an archive log file.

```
SHOW ARCHIVE LOG HEADER OF file_name;
```

In file\_path, you can input either the relative path or the absolute path of the archive log file. When entering a relative path, the base path is the directory where the archive log file is located.

This query has the following columns:

| Column name           | Type        | Description                                           |
|-----------------------|-------------|-------------------------------------------------------|
| Volume_id             | INT         | Identifier of log volume                              |
| Magic_symbol          | VARCHAR(32) | Magic value for file/magic Unix utility               |
| Magic_symbol_location | INT         | Magic symbol location from log page                   |
| Creation_time         | DATETIME    | Volume creation time                                  |
| Next_trans_id         | BIGINT      | Next transaction identifier                           |
| Num_pages             | INT         | Number of pages in the archive log                    |
| First_page_id         | BIGINT      | Logical page id at physical location 1 in archive log |
| Archive_num           | INT         | The archive log number                                |

The following shows the examples of this syntax.

```
-- csql> ;line on
SHOW ARCHIVE LOG HEADER OF 'demodb_lgar001';
```

```
<00001> Volume_id           : -20
        Magic_symbol        : 'CUBRID/LogArchive'
        Magic_symbol_location: 16
        Creation_time        : 04:42:28.000 PM 12/11/2013
        Next_trans_id        : 22695
        Num_pages            : 1278
```

```
First_page_id      : 1278
Archive_num        : 1
```

## SHOW HEAP HEADER

It shows shows the header page of the table.

```
SHOW [ALL] HEAP HEADER OF [schema_name.]table_name;
```

- ALL: If “ALL” is given in syntax in the partition table, the basic table and its partitioned tables are shown.

This query has the following columns:

| Column name    | Type         | Description                                 |
|----------------|--------------|---------------------------------------------|
| Class_name     | VARCHAR(256) | Table name                                  |
| Class_oid      | VARCHAR(64)  | Format: (volid pageid slotid)               |
| Volume_id      | INT          | Volume identifier where the file reside     |
| File_id        | INT          | File identifier                             |
| Header_page_id | INT          | First page identifier (the header page)     |
| Overflow_vfid  | VARCHAR(64)  | Overflow file identifier (if any)           |
| Next_vpid      | VARCHAR(64)  | Next page (i.e., the 2nd page of heap file) |
| Unfill_space   | INT          |                                             |

| Column name                    | Type         | Description                                                                                                                                                                                            |
|--------------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |              | Stop inserting when page has run below this. leave it for updates                                                                                                                                      |
| Estimates_num_pages            | BIGINT       | Estimation of number of heap pages.                                                                                                                                                                    |
| Estimates_num_recs             | BIGINT       | Estimation of number of objects in heap                                                                                                                                                                |
| Estimates_avg_rec_len          | INT          | Estimation total length of records                                                                                                                                                                     |
| Estimates_num_high_best        | INT          | Number of pages in the best array that we believe have at least HEAP_DROP_FREE_SPACE. When this number goes to zero and there are at least other HEAP_NUM_BEST_SPACESTATS best pages, we look for them |
| Estimates_num_others_high_best | INT          | Total of other believed known best pages, which are not included in the best array and we believe they have at least HEAP_DROP_FREE_SPACE                                                              |
| Estimates_head                 | INT          | Head of best circular array                                                                                                                                                                            |
| Estimates_best_list            | VARCHAR(512) | Format: '((best[0].vpid.volid best[0].vpid.pageid), best[0].freespace), ... ,                                                                                                                          |

| Column name                 | Type         | Description                                                                                                                                   |
|-----------------------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
|                             |              | ((best[9].vpid.volid <br>best[9].vpid.pageid),<br>best[9].freespace)'                                                                         |
| Estimates_num_second_best   | INT          | Number of second best hints. The hints are in "second_best" array. They are used when finding new best pages.                                 |
| Estimates_head_second_best  | INT          | Index of head of second best hints. A new second best hint will be stored on this index.                                                      |
| Estimates_num_substitutions | INT          | Number of page substitutions. This will be used to insert a new second best page into second best hints.                                      |

## SHOW HEAP CAPACITY

It shows the capacity of the table.

```
SHOW [ALL] HEAP CAPACITY OF [schema_name.]table_name;
```

- ALL: If “all” is given in syntax, the basic table and its partition table(s) is shown.

This query has the following columns:

| Column name         | Type         | Description                             |
|---------------------|--------------|-----------------------------------------|
| Table_name          | VARCHAR(256) | Table name                              |
| Class_oid           | VARCHAR(64)  | Heap file descriptor                    |
| Volume_id           | INT          | Volume identifier where the file reside |
| File_id             | INT          | File identifier                         |
| Header_page_id      | INT          | First page identifier (the header page) |
| Num_recs            | BIGINT       | Total Number of objects                 |
| Num_relocated_recs  | BIGINT       | Number of relocated records             |
| Num_overflowed_recs | BIGINT       | Number of big records                   |
| Num_pages           | BIGINT       | Total number of heap pages              |

| Column name                               | Type | Description                                                           |
|-------------------------------------------|------|-----------------------------------------------------------------------|
| Avg_rec_len                               | INT  | Average object length                                                 |
| Avg_free_space_per_page                   | INT  | Average free space per page                                           |
| Avg_free_space_per_page_without_last_page | INT  | Average free space per page without taking in consideration last page |
| Avg_overhead_per_page                     | INT  | Average overhead per page                                             |
| Repr_id                                   | INT  | Currently cached catalog column info                                  |
| Num_total_attrs                           | INT  | total number of columns                                               |
| Num_fixed_width_attrs                     | INT  | Number of the fixed width columns                                     |
| Num_variable_width_attrs                  | INT  | Number of variable width columns                                      |
| Num_shared_attrs                          | INT  | Number of shared columns                                              |
| Num_class_attrs                           | INT  | Number of table columns                                               |
| Total_size_fixed_width_attrs              | INT  | Total size of the fixed width columns                                 |

```

## SHOW SLOTTED PAGE SLOTS

It shows the information of all slots in the specified slotted page.

```
SHOW SLOTTED PAGE SLOTS (WHERE | OF) VOLUME = volume_num AND PAGE =
page_num;
```

This query has the following columns:

| Column name | Type | Description           |
|-------------|------|-----------------------|
| Volume_id   | INT  | Volume id of the page |

| Column name | Type        | Description                                                                                                                                                                   |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Page_id     | INT         | Page id of the page                                                                                                                                                           |
| Slot_id     | INT         | The slot id                                                                                                                                                                   |
| Offset      | INT         | Byte offset from the beginning of the page to the beginning of the record                                                                                                     |
| Type        | VARCHAR(32) | Record type, one of flowing:<br>REC_UNKNOWN,<br>REC_ASSIGN_ADDRESS,<br>REC_HOME, REC_NEWHOME,<br>REC_RELOCATION,<br>REC_BIGONE,<br>REC_MARKDELETED,<br>REC_DELETED_WILL_REUSE |
| Length      | INT         | Length of record                                                                                                                                                              |
| Waste       | INT         | Whether or not wasted                                                                                                                                                         |

The following shows the examples of this syntax.

```
-- csql> ;line on
SHOW SLOTTED PAGE HEADER OF VOLUME=0 AND PAGE=140;
```

```
<00001> Volume_id: 0
        Page_id  : 140
        Slot_id  : 0
        Offset   : 40
        Type     : 'HOME'
        Length   : 292
        Waste    : 0
<00002> Volume_id: 0
        Page_id  : 140
        Slot_id  : 1
```

```

      Offset      : 332
      Type        : 'HOME'
      Length      : 64
      Waste       : 0
<00003> Volume_id: 0
      Page_id     : 140
      Slot_id     : 2
      Offset      : 396
      Type        : 'HOME'
      Length      : 64
      Waste       : 0

```

## SHOW INDEX HEADER

It shows the index header page of the index of the table.

```
SHOW INDEX HEADER OF [schema_name.]table_name.index_name;
```

If ALL keyword is used and an index name is omitted, it shows the entire headers of the indexes of the table.

```
SHOW ALL INDEXES HEADER OF [schema_name.]table_name;
```

This query has the following columns:

| Column name | Type         | Description                                     |
|-------------|--------------|-------------------------------------------------|
| Table_name  | VARCHAR(256) | Table name                                      |
| Index_name  | VARCHAR(256) | Index name                                      |
| Btid        | VARCHAR(64)  | BTID (valid fileid root_pageid)                 |
| Node_level  | INT          | Node level (1 for LEAF, 2 or more for NON_LEAF) |

| Column name   | Type         | Description                                                      |
|---------------|--------------|------------------------------------------------------------------|
| Max_key_len   | INT          | Maximum key length for the subtree                               |
| Num_oids      | INT          | Number of OIDs stored in the Btree                               |
| Num_nulls     | INT          | Number of NULLs (they aren't stored)                             |
| Num_keys      | INT          | Number of unique keys in the Btree                               |
| Topclass_oid  | VARCHAR(64)  | Topclass oid or NULL OID (non unique index)(volid pageid slotid) |
| Unique        | INT          | Unique or non-unique                                             |
| Overflow_vfid | VARCHAR(32)  | VFID (volid fileid)                                              |
| Key_type      | VARCHAR(256) | Type name                                                        |
| Columns       | VARCHAR(256) | the list of columns which consists of the index                  |

The following shows the examples of this syntax.

```
-- Prepare test environment
CREATE TABLE tbl1(a INT, b VARCHAR(5));
CREATE INDEX index_ab ON tbl1(a ASC, b DESC);
```

```
-- csql> ;line on
SHOW INDEX HEADER OF tbl1.index_ab;
```

```
<00001> Table_name      : 'tbl1'
        Index_name     : 'index_ab'
        Btid           : '(0|378|950)'
        Node_level     : 'LEAF'
        Max_key_len    : 0
        Num_oids        : -1
        Num_nulls      : -1
        Num_keys        : -1
        Topclass_oid    : '(0|469|4)'
        Unique          : 0
        Overflow_vfid   : '(-1|-1)'
        Key_type        : 'midxkey(integer,character varying(5))'
        Columns         : 'a,b DESC'
```

## SHOW INDEX CAPACITY

It shows the index capacity of the index of the table.

```
SHOW INDEX CAPACITY OF [schema_name.]table_name.index_name;
```

If ALL keyword is used and an index name is omitted, it shows the entire capacity of the indexes of the table.

```
SHOW ALL INDEXES CAPACITY OF [schema_name.]table_name;
```

This query has the following columns:

| Column name | Type         | Description                     |
|-------------|--------------|---------------------------------|
| Table_name  | VARCHAR(256) | Table name                      |
| Index_name  | VARCHAR(256) | Index name                      |
| Btid        | VARCHAR(64)  | BTID (valid fileid root_pageid) |

| Column name                       | Type | Description                                          |
|-----------------------------------|------|------------------------------------------------------|
| Num_distinct_key                  | INT  | Distinct key count (in leaf pages)                   |
| Total_value                       | INT  | Total number of values stored in tree                |
| Deduplicate_distinct_key          | INT  | Deduplicated distinct key count (in leaf pages)      |
| Num_fence_key                     | INT  | Number of fence keys                                 |
| Avg_num_value_per_key             | INT  | Average number of values (OIDs) per key              |
| Avg_num_value_per_deduplicate_key | INT  | Average number of values (OIDs) per deduplicated key |
| Num_leaf_page                     | INT  | Leaf page count                                      |
| Num_non_leaf_page                 | INT  | NonLeaf page count                                   |
| Num_ovf_page                      | INT  | Leaf's overflow page count                           |
| Num_total_page                    | INT  | Total page count                                     |
| Height                            | INT  | Height of the tree                                   |
| Avg_key_len                       | INT  | Average key length                                   |
| Avg_rec_len                       | INT  | Average page record length                           |

| Column name                     | Type        | Description                                                            |
|---------------------------------|-------------|------------------------------------------------------------------------|
| Total_space                     | VARCHAR(64) | Total space occupied by index                                          |
| Total_used_space_non_ovf        | VARCHAR(64) | Total space used in allocated pages (excluded leaf's overflow pages)   |
| Total_free_space_non_ovf        | VARCHAR(64) | Total space unused in allocated pages (excluded leaf's overflow pages) |
| Total_used_space_ovf            | VARCHAR(64) | Total space used in pages allocated to leaf's overflow                 |
| Total_free_space_ovf            | VARCHAR(64) | Total space unused in pages allocated to leaf's overflow               |
| Avg_num_key_per_page_non_ovf    | INT         | Average page key count in leaf pages                                   |
| Avg_free_space_per_page_non_ovf | VARCHAR(64) | Average page free space                                                |
| Avg_num_ovf_page_per_key        | INT         | Average page key count in leaf pages                                   |
| Avg_free_space_per_page_ovf     | VARCHAR(64) | Average page free space in leaf's overflow pages                       |
| Max_num_ovf_page_a_key          | INT         | Maximum number of leaf's overflow pages for one key                    |

**Note**

Fence key is a virtual key added to a leaf node to help operate the B-tree index.

The following shows the examples of this syntax.

```
-- Prepare test environment
CREATE TABLE tbl1(a INT, b VARCHAR(5));
CREATE INDEX index_a ON tbl1(a ASC);
CREATE INDEX index_b ON tbl1(b ASC);
```

```
-- csql> ;line on
SHOW INDEX CAPACITY OF tbl1.index_a;
```

```
<00001> Table_name           : 'dba.tbl1'
        Index_name          : 'index_a'
        Btid                 : '(0|4160|4161)'

## SHOW CRITICAL SECTIONS

Total critical section (hereafter CS) information of a database is shown.

```
SHOW CRITICAL SECTIONS;
```

This query has the following columns:

| Column name         | Type        | Description                                                                                |
|---------------------|-------------|--------------------------------------------------------------------------------------------|
| Index               | INT         | The index of CS                                                                            |
| Name                | VARCHAR(32) | The name of CS                                                                             |
| Num_holders         | VARCHAR(16) | The number of CS holders.<br>This has one of these values: 'N readers', '1 writer', 'none' |
| Num_waiting_readers | INT         | The number of waiting readers                                                              |
| Num_waiting_writers | INT         | The number of waiting writers                                                              |
| Owner_thread_index  | INT         | The thread index of CS owner writer, NULL if no owner                                      |
| Owner_tran_index    | INT         | Transaction index of CS owner writer, NULL if no owner                                     |

| Column name                   | Type          | Description                                                       |
|-------------------------------|---------------|-------------------------------------------------------------------|
| Total_enter_count             | BIGINT        | Total count of enterers                                           |
| Total_waiter_count            | BIGINT        | Total count of waiters                                            |
| Waiting_promoter_thread_index | INT           | The thread index of waiting promoter, NULL if no waiting promoter |
| Max_waiting_msecs             | NUMERIC(10,3) | Maximum waiting time (millisecond)                                |
| Total_waiting_msecs           | NUMERIC(10,3) | Total waiting time (millisecond)                                  |

The following shows the examples of this syntax.

```
SHOW CRITICAL SECTIONS;

```

## SHOW TRANSACTION TABLES

It shows internal information of transaction descriptors which is internal data structure to manage each transaction. It only shows valid transactions and the result may not be a consistent snapshot of a transaction descriptor.

```
SHOW { TRAN | TRANSACTION } TABLES [ WHERE expr ];
```

This query has the following columns:

| Column name | Type | Description                                |
|-------------|------|--------------------------------------------|
| Tran_index  | INT  | Index on the transaction table or NULL for |

| Column name  | Type        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |             | unassigned transaction descriptor slot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Tail_top_result_lsa | VARCHAR(64) | Address of last partial abort/<br>commit.                                                                 |
| Client_id           | INT         | Unique identifier of client<br>application bind to<br>transaction.                                        |

| Column name       | Type         | Description                                                                                                                                                                                                                                                                                                                        |
|-------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client_type       | VARCHAR(40)  | Type of the client. Either one of the followings: 'SYSTEM_INTERNAL', 'DEFAULT', 'CSQL', 'READ_ONLY_CSQL', 'BROKER', 'READ_ONLY_BROKER', 'SLAVE_ONLY_BROKER', 'ADMIN_UTILITY', 'ADMIN_CSQL', 'LOG_COPIER', 'LOG_APPLIER', 'RW_BROKER_REPLICA_ONLY', 'RO_BROKER_REPLICA_ONLY', 'SO_BROKER_REPLICA_ONLY', 'ADMIN_CSQL_WOS', 'UNKNOWN' |
| Client_info       | VARCHAR(256) | General information of client application.                                                                                                                                                                                                                                                                                         |
| Client_db_user    | VARCHAR(40)  | Current login database account from client application.                                                                                                                                                                                                                                                                            |
| Client_program    | VARCHAR(256) | Program name of client application.                                                                                                                                                                                                                                                                                                |
| Client_login_user | VARCHAR(16)  | Current login user of OS which running the client application.                                                                                                                                                                                                                                                                     |
| Client_host       | VARCHAR(64)  | Host name of client application.                                                                                                                                                                                                                                                                                                   |
| Client_pid        | INT          | Process id of client application.                                                                                                                                                                                                                                                                                                  |

| Column name              | Type        | Description                                                                                    |
|--------------------------|-------------|------------------------------------------------------------------------------------------------|
| Topop_depth              | INT         | Depth of nested top operation.                                                                 |
| Num_unique_btrees        | INT         | Number of unique btrees contained in unique_stat_info array.                                   |
| Max_unique_btrees        | INT         | Size of unique_stat_info_array.                                                                |
| Interrupt                | INT         | The flag of whether or not interrupt current transaction. 0 for No, 1 for Yes.                 |
| Num_transient_classnames | INT         | Number of transient classnames by this transaction.                                            |
| Repl_max_records         | INT         | Capacity of replication record array.                                                          |
| Repl_records             | VARCHAR(20) | Replication record buffer array, display address pointer as 0x12345678 or NULL for 0x00000000. |
| Repl_current_index       | INT         | Current position of replication record in the array.                                           |

| Column name             | Type        | Description                                                                                            |
|-------------------------|-------------|--------------------------------------------------------------------------------------------------------|
| Repl_append_index       | INT         | Current position of appended record in the array.                                                      |
| Repl_flush_marked_index | INT         | Index of flush marked replication record at first.                                                     |
| Repl_insert_lsa         | VARCHAR(64) | Insert Replication target LSA.                                                                         |
| Repl_update_lsa         | VARCHAR(64) | Update Replication target LSA.                                                                         |
| First_save_entry        | VARCHAR(20) | First save entry for the transaction, display address pointer as 0x12345678 or NULL for 0x00000000.    |
| Tran_unique_stats       | VARCHAR(20) | Local statistical info for multiple row. display address pointer as 0x12345678 or NULL for 0x00000000. |
| Modified_class_list     | VARCHAR(20) | List of dirty classes, display address pointer as 0x12345678 or NULL for 0x00000000.                   |
| Num_temp_files          | INT         | Number of temporary files.                                                                             |

| Column name           | Type        | Description                                                                                    |
|-----------------------|-------------|------------------------------------------------------------------------------------------------|
| Waiting_for_res       | VARCHAR(20) | Waiting resource. Just display address pointer as 0x12345678 or NULL for 0x00000000.           |
| Has_deadlock_priority | INT         | Whether or not have deadlock priority. 0 for No, 1 for Yes.                                    |
| Suppress_replication  | INT         | Suppress writing replication logs when flag is set.                                            |
| Query_timeout         | DATETIME    | A query should be executed before query_timeout time or NULL for waiting until query complete. |
| Query_start_time      | DATETIME    | Current query start time or NULL for query completed.                                          |
| Tran_start_time       | DATETIME    | Current transaction start time or NULL for transaction completed.                              |
| Xasl_id               | VARCHAR(64) | vpid:(valid pageid),vfid:(valid pageid) or NULL for query completed.                           |
| Disable_modifications | INT         | Disable modification if greater than zero.                                                     |
| Abort_reason          | VARCHAR(40) | Reason of transaction aborted. Either one of the followings: 'NORMAL',                         |

| Column name | Type | Description                                                        |
|-------------|------|--------------------------------------------------------------------|
|             |      | 'ABORT_DUE_TO_DEADLOCK',<br>'ABORT_DUE_ROLLBACK_ON_<br>ESCALATION' |

The following shows the examples of the statement.

```
SHOW TRAN TABLES WHERE CLIENT_TYPE = 'CSQL';
```

```
=== <Result of SELECT Command in Line 1> ===
```

```
<00001> Tran_index           : 1

```

## SHOW THREADS

It shows internal information of each thread. The results are sorted by “Index” column with ascending order and may not be a consistent snapshot of thread entries. The statement under SA MODE shows an empty result.

```
SHOW THREADS [ WHERE EXPR ];
```

This query has the following columns:

| Column name | Type       | Description                                                                     |
|-------------|------------|---------------------------------------------------------------------------------|
| Index       | INT        | Thread entry index.                                                             |
| Jobq_index  | INT        | Job queue index only for worker threads. NULL for non-worker threads.           |
| Thread_id   | BIGINT     | Thread id.                                                                      |
| Tran_index  | INT        | Transaction index to which this thread belongs. If no related tran index, NULL. |
| Type        | VARCHAR(8) | Thread type. Either one of the followings: ‘MASTER’,                            |

| Column name   | Type        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Status        | VARCHAR(8)  | Thread status. Either one of the followings: 'FREE', 'RUN', 'WAIT', 'CHECK'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Resume_status | VARCHAR(32) | Resume status. Either one of the followings:<br>'RESUME_NONE',<br>'RESUME_DUE_TO_INTERRUPT',<br>'RESUME_DUE_TO_SHUTDOWN', 'PGBUF_SUSPENDED',<br>'PGBUF_RESUMED',<br>'JOB_QUEUE_SUSPENDED',<br>'JOB_QUEUE_RESUMED',<br>'CSECT_READER_SUSPENDED',<br>'CSECT_READER_RESUMED',<br>'CSECT_WRITER_SUSPENDED',<br>'CSECT_WRITER_RESUMED',<br>'CSECT_PROMOTER_SUSPENDED',<br>'CSECT_PROMOTER_RESUMED',<br>'CSS_QUEUE_SUSPENDED',<br>'CSS_QUEUE_RESUMED',<br>'QMGR_ACTIVE_QRY_SUSPENDED',<br>'QMGR_ACTIVE_QRY_RESUMED',<br>'QMGR_MEMBUF_PAGE_SUSPENDED',<br>'QMGR_MEMBUF_PAGE_RESUMED',<br>'HEAP_CLSREPR_SUSPENDED', |

| Column name     | Type         | Description                                                                                                   |
|-----------------|--------------|---------------------------------------------------------------------------------------------------------------|
|                 |              | 'HEAP_CLSREPR_RESUMED',<br>'LOCK_SUSPENDED',<br>'LOCK_RESUMED',<br>'LOGWR_SUSPENDED',<br>'LOGWR_RESUMED'      |
| Net_request     | VARCHAR(64)  | The net request name in net_requests array, such as: 'LC_ASSIGN_OID'. If not request name, shows NULL         |
| Conn_client_id  | INT          | Client id whom this thread is responding, if no client id, shows NULL                                         |
| Conn_request_id | INT          | Request id which this thread is processing, if no request id, shows NULL                                      |
| Conn_index      | INT          | Connection index, if not connection index, shows NULL                                                         |
| Last_error_code | INT          | Last error code                                                                                               |
| Last_error_msg  | VARCHAR(256) | Last error message, if message length is more than 256, it will be truncated, If no error message, shows NULL |

| Column name            | Type        | Description                                                                                                                                                |
|------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Private_heap_id        | VARCHAR(20) | The address of id of thread private memory allocator, such as: 0x12345678. If no related heap id, shows NULL.                                              |
| Query_entry            | VARCHAR(20) | The address of the QMGR_QUERY_ENTRY*, such as: 0x12345678, if no related QMGR_QUERY_ENTRY, shows NULL.                                                     |
| Interrupted            | INT         | 0 or 1, is this request/transaction interrupted                                                                                                            |
| Shutdown               | INT         | 0 or 1, is server going down?                                                                                                                              |
| Check_interrupt        | INT         | 0 or 1                                                                                                                                                     |
| Wait_for_latch_promote | INT         | 0 or 1, whether this thread is waiting for latch promotion.                                                                                                |
| Lockwait_blocked_mode  | VARCHAR(24) | Lockwait blocked mode. Either one of the followings: 'NULL_LOCK', 'IS_LOCK', 'S_LOCK', 'IS_LOCK', 'IX_LOCK', 'SIX_LOCK', 'X_LOCK', 'SCH_M_LOCK', 'UNKNOWN' |
| Lockwait_start_time    | DATETIME    | Start blocked time, if not in blocked state, shows NULL                                                                                                    |
| Lockwait_msecs         | INT         |                                                                                                                                                            |

| Column name                 | Type        | Description                                                                                                                                                                                                    |
|-----------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |             | Time in milliseconds, if not in blocked state, shows NULL                                                                                                                                                      |
| Lockwait_state              | VARCHAR(24) | The lock wait state such as: 'SUSPENDED', 'RESUMED', 'RESUMED_ABORTED_FIRST', 'RESUMED_ABORTED_OTHER', 'RESUMED_DEADLOCK_TIMEOUT', 'RESUMED_TIMEOUT', 'RESUMED_INTERRUPT'. If not in blocked state, shows NULL |
| Next_wait_thread_index      | INT         | The next wait thread index, if not exist, shows NULL                                                                                                                                                           |
| Next_tran_wait_thread_index | INT         | The next wait thread index in lock manager, if not exist, shows NULL                                                                                                                                           |
| Next_worker_thread_index    | INT         | The next worker thread index in css_job_queue.worker_thrd_list, if not exist, shows NULL                                                                                                                       |

The following shows the examples of the statement.

```
SHOW THREADS WHERE RESUME_STATUS != 'RESUME_NONE' AND STATUS != 'FREE';
```

```
=== <Result of SELECT Command in Line 1> ===

## SHOW JOB QUEUES

It shows the status of job queue. The statement under SA MODE shows an empty result.

```
SHOW JOB QUEUES;
```

This query has the following columns:

| Column name            | Type | Description                                          |
|------------------------|------|------------------------------------------------------|
| Jobq_index             | INT  | The index of job queue                               |
| Num_total_workers      | INT  | Total number of work threads of the queue            |
| Num_busy_workers       | INT  | The number of busy worker threads of the queue       |
| Num_connection_workers | INT  | The number of connection worker threads of the queue |

## SHOW PAGE BUFFER STATUS

It shows the status of the data page buffer pool.

```
SHOW PAGE BUFFER STATUS;
```

This query has the following columns:

| Column name | Type           | Description                                         |
|-------------|----------------|-----------------------------------------------------|
| Hit_rate    | NUMERIC(13,10) | The buffer pool hit rate (deprecated, always NULL)  |
| Num_hit     | BIGINT         | The number of buffer hits (deprecated, always NULL) |

| Column name            | Type   | Description                                               |
|------------------------|--------|-----------------------------------------------------------|
| Num_page_request       | BIGINT | The number of page requests (deprecated, always NULL)     |
| Pool_size              | INT    | Buffer pool size in pages                                 |
| Page_size              | INT    | Data page size                                            |
| Free_pages             | INT    | The number of free pages in the buffer pool               |
| Victim_candidate_pages | INT    | The number of victim candidate pages in the cold LRU area |
| Clean_pages            | INT    | The number of clean pages in the buffer pool              |
| Dirty_pages            | INT    | The number of dirty pages in the buffer pool              |
| Num_index_pages        | INT    | The number of index pages in the buffer pool              |
| Num_data_pages         | INT    | The number of data pages in the buffer pool               |
| Num_system_pages       | INT    | The number of system pages in the buffer pool             |
| Num_temp_pages         | INT    | The number of temp pages in the buffer pool               |

| Column name                 | Type           | Description                                                                      |
|-----------------------------|----------------|----------------------------------------------------------------------------------|
