| default_value  | VARCHAR(255)           | Default value. Stores as a character string regardless of data types. If there is no default value, NULL. If the default value is <b>NULL, NULL</b> is used.<br><br>If the data type is an object, ‘volume id   page id   slot id’ is used. If the data type is a collection, ‘{element 1, element 2, ... is used. |
| domains        | SEQUENCE OF _db_domain | Domain information of the data type                                                                                                                                                                                                                                                                                |
| is_nullable    | INTEGER                | 0 if a not null constraint is configured, and 1 otherwise.                                                                                                                                                                                                                                                         |
| comment        | VARCHAR(2048)          | Comment to describe the attribute.                                                                                                                                                                                                                                                                                 |

### Data Types Supported by CUBRID

| Value | Meaning   | Value | Meaning       |
|-------|-----------|-------|---------------|
| 1     | INTEGER   | 23    | BIT           |
| 2     | FLOAT     | 24    | VARBIT        |
| 3     | DOUBLE    | 25    | CHAR          |
| 4     | STRING    | 27    | VARCHAR       |
| 5     | OBJECT    | 31    | BIGINT        |
| 6     | SET       | 32    | DATETIME      |
| 7     | MULTISET  | 33    | BLOB          |
| 8     | SEQUENCE  | 34    | CLOB          |
| 9     | ELO       | 35    | ENUM          |
| 10    | TIME      | 36    | TIMESTAMP TZ  |
| 11    | TIMESTAMP | 37    | TIMESTAMP LTZ |
| 12    | DATE      | 38    | DATETIME TZ   |
| 18    | SHORT     | 39    | DATETIME LTZ  |
| 22    | NUMERIC   | 40    | JSON          |

### Character Sets Supported by CUBRID

| Value | Meaning                      |
|-------|------------------------------|
| 0     | US English - ASCII encoding  |
| 2     | Binary                       |
| 3     | Latin 1 - ISO 8859 encoding  |
| 4     | KSC 5601 1990 - EUC encoding |
| 5     | UTF8 - UTF8 encoding         |

The following example shows how to retrieve user classes (from\_class\_of.is\_system\_class = 0) among the ones owned by user **'PUBLIC'** (for the *female\_event* class in the result, see the example in [ADD SUPERCLASS Clause](#)).

```
SELECT class_of.class_name, attr_name
FROM _db_attribute
WHERE class_of.owner.name = 'PUBLIC' AND
from_class_of.is_system_class = 0
ORDER BY 1, def_order;
```

```
class_of.class_name  attr_name
=====
'female_event'      'code'
'female_event'      'sports'
'female_event'      'name'
'female_event'      'gender'
'female_event'      'players'
```

## \_db\_domain

Represents domain information. Indexes for object\_of and data\_type are created.

| Attribute Name | Data Type                                 | Description                                                                                                                                      |
|----------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| object_of      | object                                    | Attribute that refers to the domain, which can be a method parameter or domain                                                                   |
| data_type      | INTEGER                                   | Data type of the domain (a value in the “Value” column of the “Data Types Supported by CUBRID” table in <a href="#">_db_attribute</a> )          |
| prec           | INTEGER                                   | Precision of the data type. 0 is used if the precision is not specified.                                                                         |
| scale          | INTEGER                                   | Scale of the data type. 0 is used if the scale is not specified.                                                                                 |
| class_of       | <a href="#">_db_class</a>                 | Domain class if the data type is an object, <b>NULL</b> otherwise.                                                                               |
| code_set       | INTEGER                                   | Character set (value of table “character sets supported by CUBRID” in <a href="#">_db_attribute</a> ) if it is character data type. 0 otherwise. |
| collation_id   | INTEGER                                   | Collation id                                                                                                                                     |
| enumeration    | SEQUENCE OF CHARACTER VARYING(1073741823) | String printed enumeration type definition                                                                                                       |

| Attribute Name | Data Type                     | Description                                                                                                        |
|----------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------|
| set_domains    | SEQUENCE OF _db_domain        | Domain information about the data type of collection element if it is collection data type. <b>NULL</b> otherwise. |
| json_schema    | CHARACTER VARYING(1073741823) | Schema information defining the JSON data structure if it is a JSON data type. <b>NULL</b> otherwise.              |

\_db\_charset

Represents charset information.

| Attribute Name    | Data type             | Description               |
|-------------------|-----------------------|---------------------------|
| charset_id        | INTEGER               | Charset ID                |
| charset_name      | CHARACTER VARYING(32) | Charset name              |
| default_collation | INTEGER               | Default collation ID      |
| char_size         | INTEGER               | One character's byte size |

\_db\_collation

The information on collation.

| Attribute Name | Data Type   | Description                                                                 |
|----------------|-------------|-----------------------------------------------------------------------------|
| coll_id        | INTEGER     | Collation ID                                                                |
| coll_name      | VARCHAR(32) | Collation name                                                              |
| charset_id     | INTEGER     | Charset ID                                                                  |
| built_in       | INTEGER     | Built-in or not while installing the product (0: Not built-in, 1: Built-in) |
| expansions     | INTEGER     | Expansion support (0: Not supported, 1: Supported)                          |
| contractions   | INTEGER     | Contraction support (0: Not supported, 1: Supported)                        |
| uca_strength   | INTEGER     | Weight strength                                                             |
| checksum       | VARCHAR(32) | Checksum of a collation file                                                |

### \_db\_method

Represents method information. An index for class\_of and meth\_name is created.

| Attribute Name | Data Type    | Description                       |
|----------------|--------------|-----------------------------------|
| class_of       | _db_class    | Class to which the method belongs |
| meth_name      | VARCHAR(255) | Method name                       |

| Attribute Name | Data Type                | Description                                                                                                                                               |
|----------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| meth_type      | INTEGER                  | Type of the method defined in the class. 0 for an instance method, and 1 for a class method.                                                              |
| from_class_of  | _db_class                | If the method is inherited, the super class in which it is defined is used otherwise <b>NULL</b>                                                          |
| from_meth_name | VARCHAR(255)             | If the method is inherited and its name is changed to resolve a name conflict, the original name defined in the super class is used otherwise <b>NULL</b> |
| signatures     | SEQUENCE OF _db_meth_sig | C function executed when the method is called                                                                                                             |

The following example shows how to retrieve class methods of the class with a class method (c.class\_meth\_count > 0), among classes owned by user 'DBA'.

```
SELECT class_name, SEQUENCE(SELECT meth_name
                             FROM _db_method m
                             WHERE m in c.class_meths)
FROM _db_class c
WHERE c.owner.name = 'DBA' AND c.class_meth_count > 0
ORDER BY 1;
```

```
class_name      sequence((select meth_name from _db_method m
where m in c.class_meths))
=====
'_db_serial'    {'change_serial_owner'}
'_db_user'      {'set_password', 'set_password_encoded',
'set_password_encoded_sha1', 'add_member',
                  'drop_member', 'print_authorizations',
'add_user', 'drop_user', 'find_user', 'login'}
```

```
'db_root'          {'add_user', 'drop_user', 'find_user',
'print_authorizations', 'info', 'change_owner',
                    'change_trigger_owner', 'get_owner',
'change_sp_owner'}
'db_user'          {'find_user', 'login'}
```

### \_db\_meth\_sig

Represents configuration information of C functions on the method. An index for meth\_of is created.

| Attribute Name | Data Type                | Description                                   |
|----------------|--------------------------|-----------------------------------------------|
| meth_of        | _db_method               | Method for the function information           |
| func_name      | VARCHAR(255)             | Function name                                 |
| arg_count      | INTEGER                  | The number of input arguments of the function |
| return_value   | SEQUENCE OF _db_meth_arg | Return value of the function                  |
| arguments      | SEQUENCE OF _db_meth_arg | Input arguments of the function               |

### \_db\_meth\_arg

Represents method argument information. An index for meth\_sig\_of is created.

| Attribute Name | Data Type    | Description                                               |
|----------------|--------------|-----------------------------------------------------------|
| meth_sig_of    | _db_meth_sig | Information of the function to which the argument belongs |

| Attribute Name | Data Type              | Description                                                                                                                         |
|----------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| data_type      | INTEGER                | Data type of the argument (a value in the “Value” column of the “Data Types Supported by CUBRID” in <a href="#">_db_attribute</a> ) |
| index_of       | INTEGER                | Order of the argument listed in the function definition. Begins with 0 if it is a return value, and 1 if it is an input argument.   |
| domains        | SEQUENCE OF _db_domain | Domain of the argument                                                                                                              |

#### \_db\_meth\_file

Represents information of a file in which a function is defined. An index for class\_of is created.

| Attribute Name | Data Type    | Description                                                                                                 |
|----------------|--------------|-------------------------------------------------------------------------------------------------------------|
| class_of       | _db_class    | Class to which the method file information belongs                                                          |
| from_class_of  | _db_class    | If the file information is inherited, the super class in which it is defined is used otherwise, <b>NULL</b> |
| path_name      | VARCHAR(255) | File path in which the method is located                                                                    |

## \_db\_query\_spec

Represents the SQL statement of a virtual class. An index for class\_of is created.

The data type of attribute 'spec' is VARCHAR (4096) for prior versions including 10.1 Patch 3.

| Attribute Name   | Data Type           | Description                                   | Classification (10.1 Only) |
|------------------|---------------------|-----------------------------------------------|----------------------------|
| class_of         | _db_class           | Class information of the virtual class        |                            |
| spec             | VARCHAR(1073741823) | SQL definition statement of the virtual class | 10.1 Patch 4 or later      |
|                  | VARCHAR(4096)       |                                               | 10.1 Patch 3 or earlier    |
| invalidated_time | DATETIME            | Time when the view query was invalidated      |                            |

## \_db\_index

Represents index information. An index for class\_of is created.

| Attribute Name | Data Type    | Description                                |
|----------------|--------------|--------------------------------------------|
| class_of       | _db_class    | Class to which the index belongs           |
| index_name     | VARCHAR(255) | Index name                                 |
| is_unique      | INTEGER      | 1 if the index is unique, and 0 otherwise. |

| Attribute Name    | Data Type                 | Description                                                                                       |
|-------------------|---------------------------|---------------------------------------------------------------------------------------------------|
| key_count         | INTEGER                   | The number of attributes that comprise the key                                                    |
| key_attrs         | SEQUENCE<br>_db_index_key | OF Attributes that comprise the key                                                               |
| is_reverse        | INTEGER                   | 1 for a reverse index, and 0 otherwise.                                                           |
| is_primary_key    | INTEGER                   | 1 for a primary key, and 0 otherwise.                                                             |
| is_foreign_key    | INTEGER                   | 1 for a foreign key, and 0 otherwise.                                                             |
| filter_expression | VARCHAR(1073741823)       | The conditions of filtered indexes                                                                |
| have_function     | INTEGER                   | 1 for a function index, and 0 otherwise.                                                          |
| status            | INTEGER                   | Index status                                                                                      |
| referential_index | _db_index                 | The index referenced by a foreign key (NULL if not a foreign key)                                 |
| delete_rule       | INTEGER                   | The delete rule for a foreign key constraint (0: CASCADE, 1: RESTRICT, 2: NO ACTION, 3: SET NULL) |

| Attribute Name           | Data Type      | Description                                                                                                                                                                                                                                           |
|--------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| update_rule              | INTEGER        | The update rule for a foreign key constraint (1: RESTRICT, 2: NO ACTION, 3: SET NULL)                                                                                                                                                                 |
| referential_match_option | INTEGER        | <p>The match option for a foreign key constraint (0: NONE)</p> <ul style="list-style-type: none"> <li>• NONE: Does not check if any NULL exists</li> </ul>                                                                                            |
| index_type               | INTEGER        | Index type (0: BTREE)                                                                                                                                                                                                                                 |
| options                  | INTEGER        | <p>Index options</p> <ul style="list-style-type: none"> <li>• <b>Bit 0 ~ Bit 3:</b> Represents the <b>deduplicate level</b> of the index. For more details, refer to <b>DEDUPLICATE</b>.</li> <li>• The other bits are not currently used.</li> </ul> |
| comment                  | VARCHAR (1024) | Comment to describe the index                                                                                                                                                                                                                         |
| created_time             | DATETIME       | Index creation time                                                                                                                                                                                                                                   |
| updated_time             | DATETIME       | Index modification time                                                                                                                                                                                                                               |

The following example shows how to retrieve names of indexes that belong to the class.

```

SELECT class_of.class_name, index_name
FROM _db_index
ORDER BY 1;

```

```

class_of.class_name    index_name

## \_db\_index\_key

Represents key information on an index. An index for index\_of is created.

| Attribute Name    | Data Type     | Description                                                        |
|-------------------|---------------|--------------------------------------------------------------------|
| index_of          | _db_index     | Index to which the key attribute belongs                           |
| key_attr_name     | VARCHAR(255)  | Name of the attribute that comprises the key                       |
| key_order         | INTEGER       | Order of the attribute in the key. Begins with 0.                  |
| asc_desc          | INTEGER       | 1 if the order of attribute values is descending, and 0 otherwise. |
| key_prefix_length | INTEGER       | Length of prefix to be used as a key                               |
| func              | VARCHAR(1023) | Functional expression of function based index                      |

The following example shows how to retrieve the names of index that belongs to the class.

```
SELECT class_of.class_name, SEQUENCE(SELECT key_attr_name
                                     FROM _db_index_key k
                                     WHERE k in i.key_attrs)
FROM _db_index i
WHERE key_count >= 2;
```

```

class_of.class_name  sequence((select key_attr_name from
_db_index_key k where k in
i.key_attrs))
=====
'_db_server'         {'link_name', 'owner'}
'_db_synonym'        {'name', 'owner', 'is_public'}
'_db_ha_apply_info'  {'db_name', 'copied_log_path'}
'_db_serial'         {'name', 'owner'}
'_db_data_type'      {'type_id', 'type_name'}
'_db_partition'      {'class_of', 'pname'}
'_db_method'         {'class_of', 'meth_name'}
'_db_attribute'      {'class_of', 'attr_name', 'attr_type'}
'_db_class'          {'class_name', 'owner'}
'participant'        {'host_year', 'nation_code'}
'game'               {'host_year', 'event_code', 'athlete_code'}
'record'             {'host_year', 'event_code', 'athlete_code',
'medal'}
'history'            {'event_code', 'athlete'}

```

## \_db\_auth

Represents user authorization information for objects. An index for grantee and an index for object\_of are created.

| Attribute Name | Data Type  | Description                                                                           |
|----------------|------------|---------------------------------------------------------------------------------------|
| grantor        | _db_user   | Authorization grantor                                                                 |
| grantee        | _db_user   | Authorization grantee                                                                 |
| object_type    | INTEGER    | Type of the object for which authorization is granted (0: class, 5: stored procedure) |
| object_of      | object     | Object for which authorization is granted                                             |
| auth_type      | VARCHAR(7) | Type name of the authorization granted                                                |

| Attribute Name | Data Type | Description                                                                       |
|----------------|-----------|-----------------------------------------------------------------------------------|
| is_grantable   | INTEGER   | 1 if authorization for the object can be granted to other users, and 0 otherwise. |
| created_time   | DATETIME  | Time when authorization was granted                                               |
| updated_time   | DATETIME  | Time when authorization was updated                                               |

Authorization types supported by CUBRID are as follows:

- **SELECT**
- **INSERT**
- **UPDATE**
- **DELETE**
- **ALTER**
- **INDEX**
- **EXECUTE**

The following example shows how to retrieve authorization information defined in the view *db\_trigger*.

```
SELECT a.grantor.name, a.grantee.name, a.auth_type
FROM _db_auth a JOIN _db_class c ON a.object_of = c.class_of
WHERE c.class_name = 'db_trigger';
```

```
grantor.name      grantee.name      auth_type
=====
'DBA'             'PUBLIC'          'SELECT'
```

## `_db_data_type`

Represents the data type supported by CUBRID (see the “Data Types Supported by CUBRID” table in `_db_attribute`).

| Attribute Name         | Data Type   | Description                                                                                            |
|------------------------|-------------|--------------------------------------------------------------------------------------------------------|
| <code>type_id</code>   | INTEGER     | Data type identifier. Corresponds to the “Value” column in the “Data Types Supported by CUBRID” table. |
| <code>type_name</code> | VARCHAR(16) | Data type name. Corresponds to the “Meaning” column in the “Data Types Supported by CUBRID” table.     |

The following example shows how to retrieve attributes and type names of the *event* class.

```
SELECT a.attr_name, t.type_name
FROM _db_attribute a JOIN _db_data_type t ON a.data_type = t.type_id
WHERE class_of.class_name = 'event'
ORDER BY a.def_order;
```

```
attr_name      type_name
=====
'code'         'INTEGER'
'sports'       'STRING'
'name'         'STRING'
'gender'       'CHAR'
'players'     'INTEGER'
```

## `_db_partition`

Represents partition information. An index for `class_of` and `pname` is created.

| Attribute Name       | Data Type     | Description                                                                                                                                                                                                                                                  |
|----------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| class_of             | _db_class     | OID of the parent class                                                                                                                                                                                                                                      |
| pname                | VARCHAR(255)  | Parent - <b>NULL</b>                                                                                                                                                                                                                                         |
| ptype                | INTEGER       | <ul style="list-style-type: none"> <li>• 0 - HASH</li> <li>• 1 - RANGE</li> <li>• 2 - LIST</li> </ul>                                                                                                                                                        |
| pexpr                | VARCHAR(2048) | Parent only                                                                                                                                                                                                                                                  |
| pvalues              | SEQUENCE OF   | <ul style="list-style-type: none"> <li>• HASH - Column name, Hash size</li> <li>• RANGE - MIN/MAX value : Infinite MIN/MAX is stored as <b>NULL</b></li> <li>• LIST - value list</li> </ul>                                                                  |
| class_partition_type | INTEGER       | Partition type of partition class (1: PARTITIONED CLASS, 2: PARTITION CLASS) <ul style="list-style-type: none"> <li>• PARTITIONED CLASS: Parent table that has partitions</li> <li>• PARTITION CLASS: Individual partition table that stores data</li> </ul> |
| comment              | VARCHAR(1024) | Comment to describe the partition                                                                                                                                                                                                                            |

## \_db\_stored\_procedure

Represents Stored procedure information. An index for unique\_name is created.

| Attribute Name      | Data Type                                | Description                                                |
|---------------------|------------------------------------------|------------------------------------------------------------|
| unique_name         | VARCHAR(255)                             | Stored procedure name prefixed with the schema name        |
| sp_name             | VARCHAR(255)                             | Stored procedure name                                      |
| sp_type             | INTEGER                                  | Stored procedure type (function or procedure)              |
| return_type         | INTEGER                                  | Return value type                                          |
| arg_count           | INTEGER                                  | The number of arguments                                    |
| args                | SEQUENCE OF<br>_db_stored_procedure_args | Argument list                                              |
| lang                | INTEGER                                  | Implementation language                                    |
| pkg_name            | VARCHAR(255)                             | Package name containing the stored procedure               |
| is_system_generated | INTEGER                                  | Indicates whether the stored procedure is system-generated |
| directive           | INTEGER                                  | Execution behavior attributes of the stored procedure      |
| sql_data_access     | INTEGER                                  |                                                            |

| Attribute Name | Data Type     | Description                                                                                     |
|----------------|---------------|-------------------------------------------------------------------------------------------------|
|                |               | SQL data access attribute (0: NO SQL, 1: CONTAINS SQL, 2: READS SQL DATA, 3: MODIFIES SQL DATA) |
| target_class   | VARCHAR(1024) | Class name of the stored procedure to execute                                                   |
| target_method  | VARCHAR(4096) | Method name of the stored procedure to execute                                                  |
| owner          | _db_user      | Owner                                                                                           |
| comment        | VARCHAR(1024) | Comment to describe the stored procedure                                                        |
| created_time   | DATETIME      | Stored procedure creation time                                                                  |
| updated_time   | DATETIME      | Stored procedure modification time                                                              |

#### Note

- **sp\_type**: A value of **1** indicates a stored procedure, and **2** indicates a stored function.
- **return\_type**: The return type is one of the following values:

```
NULL = 0, INTEGER = 1, FLOAT = 2, DOUBLE = 3,
STRING = 4,
SET = 6, MULTiset = 7, SEQUENCE = 8, TIME = 10,
TIMESTAMP = 11, DATE = 12, SHORT = 18, NUMERIC
```

```
= 22, CHAR = 25,
CURSOR = 28, BIGINT = 31, DATETIME = 32
```

- Java stored procedures support all the data types listed above.
- PL/CSQL supports the data types listed above except for SET, MULTISSET, SEQUENCE, and CURSOR.
- Data types not listed above are not supported.
- **lang**: A value of **0** indicates PL/CSQL, and **1** indicates Java.
- **pkg\_name**: Package name. Currently, the package name is only used in the **DBMS\_OUTPUT** system package.
- **is\_system\_generated**: A value of **1** indicates a system-generated stored procedure, while **0** indicates a user-created stored procedure.
- **directive**: The value uses bits from **Bit 0** to **Bit 31**, starting from the rightmost bit.
  - **Bit 0: Represents the execution rights (AUTHID) of the stored procedure.**
    - A value of **0** indicates owner's rights (also referred to as definer's rights), and **1** indicates caller's rights (also referred to as invoker's rights).
  - **Bit 1: Represents the deterministic property of the stored procedure.**
    - A value of **1** indicates deterministic, and **0** indicates non-deterministic.
  - The other bits (**Bit 2 ~ Bit 31**) are not currently used.

## \_db\_stored\_procedure\_args

Represents Stored procedure argument information. An index for sp\_of is created.

| Attribute Name      | Data Type               | Description                                                |
|---------------------|-------------------------|------------------------------------------------------------|
| sp_of               | _db_stored_procedure    | Stored procedure object                                    |
| index_of            | INTEGER                 | Order of the arguments                                     |
| is_system_generated | INTEGER                 | Indicates whether the stored procedure is system-generated |
| arg_name            | CHARACTER VARYING(255)  | Argument name                                              |
| data_type           | INTEGER                 | Argument data type                                         |
| mode                | INTEGER                 | Argument mode (IN, OUT, INOUT)                             |
| default_value       | CHARACTER VARYING(255)  | Default value of the argument                              |
| is_optional         | INTEGER                 | Whether the parameter is optional                          |
| comment             | CHARACTER VARYING(1024) | Comment to describe the argument                           |

#### Note

- **index\_of**: The order of the arguments starts from 0.
- **is\_system\_generated**: A value of **1** indicates a system-generated stored procedure argument, while **0** indicates a user-created stored procedure argument.
- **data\_type**: The data type of the argument is one of the following values

```
NULL = 0, INTEGER = 1, FLOAT = 2, DOUBLE = 3,
STRING = 4,
SET = 6, MULTiset = 7, SEQUENCE = 8, TIME = 10,
TIMESTAMP = 11, DATE = 12, SHORT = 18, NUMERIC
= 22, CHAR = 25,
CURSOR = 28, BIGINT = 31, DATETIME = 32
```

- Java stored procedures support all the data types listed above.
- PL/CSQL supports the data types listed above except for SET, MULTiset, SEQUENCE, and CURSOR.
- Data types not listed above are not supported.

- **mode:** The argument mode is one of the following values

```
IN = 0, OUT = 1, INOUT = 2
```

- **default\_value:** The default value of the argument. For more details, refer to [Using Default Arguments](#).
- **is\_optional:** A value of **1** indicates the argument is optional, while **0** indicates it is required.

## \_db\_stored\_procedure\_code

Represents Stored procedure code information. An index for name is created.

| Attribute Name | Data Type               | Description                       |
|----------------|-------------------------|-----------------------------------|
| name           | CHARACTER VARYING(1024) | Name of the stored procedure code |
| created_time   | CHARACTER VARYING(16)   | Creation time                     |
| owner          | _db_user                | Owner                             |

| Attribute Name      | Data Type                        | Description                                                      |
|---------------------|----------------------------------|------------------------------------------------------------------|
| is_static           | INTEGER                          | Indicates whether the stored procedure code is loaded statically |
| is_system_generated | INTEGER                          | Indicates whether the stored procedure code is system-generated  |
| stype               | INTEGER                          | Type of the source code                                          |
| scode               | CHARACTER<br>VARYING(1073741823) | Source code                                                      |
| otype               | INTEGER                          | Type of the object code                                          |
| ocode               | CHARACTER<br>VARYING(1073741823) | Object code                                                      |

#### Note

##### • **is\_static**

- A value of **1** indicates that the stored procedure code is loaded only once and changes to the procedure code are not applied until the server restarts.
- A value of **0** indicates that the stored procedure code is loaded every time, and changes are applied immediately using DDL or procedure load utilities.
- Used in [Java Native Interface \(JNI\) Support](#).

- **is\_system\_generated:** A value of **1** indicates that the code is system-generated, while **0** indicates it is user-written code.

- **stype**: Represents the type of the source code. Currently, only PL/CSQL code is supported, and the value is **0**.
- **score**: Stores the source code of the stored procedure entered by the user.
- **otype**: Represents the type of the object code compiled from the source code of the stored procedure.
  - A value of **0** indicates a Java class file.
  - A value of **1** indicates a Java archive file (Jar).
  - Other values are not currently supported.
- **ocode**: Stores the object code compiled from the source code of the stored procedure, which can be executed on the PL execution server.

#### \_db\_server

| Attribute Name | Data Type           | Description                        |
|----------------|---------------------|------------------------------------|
| link_name      | VARCHAR(255)        | Connection name                    |
| host           | VARCHAR(255)        | Hostname of a server               |
| port           | INTEGER             | Connection port of a server        |
| db_name        | VARCHAR(255)        | Database name of a server          |
| user_name      | VARCHAR(255)        | Database user name of a server     |
| password       | VARCHAR(1073741823) | Database user password of a server |
| properties     | VARCHAR(2048)       |                                    |

| Attribute Name   | Data Type     | Description                                              |
|------------------|---------------|----------------------------------------------------------|
|                  |               | Property information used for connection                 |
| owner            | _db_user      | The owner of this connection information                 |
| comment          | VARCHAR(1024) | Comment to describe the server                           |
| created_time     | DATETIME      | Server creation time                                     |
| updated_time     | DATETIME      | Server modification time                                 |
| invalidated_time | DATETIME      | Time when the external server connection was invalidated |

### \_db\_synonym

Represents target object information of synonyms. An index for unique\_name and an index for name owner, and is\_public are created.

| Attribute Name | Data Type    | Description                                       |
|----------------|--------------|---------------------------------------------------|
| unique_name    | VARCHAR(255) | Name prefixed with the schema name of the synonym |
| name           | VARCHAR(255) | The name of the synonym                           |
| owner          | _db_user     | The owner of the synonym                          |

| Attribute Name     | Data Type     | Description                                             |
|--------------------|---------------|---------------------------------------------------------|
| is_public          | INTEGER       | 1 for a public synonym, and 0 for a private synonym.    |
| target_unique_name | VARCHAR(255)  | Name prefixed with the schema name of the target object |
| target_name        | VARCHAR(255)  | The name of the target object                           |
| target_owner       | _db_user      | The owner name of the target object                     |
| comment            | VARCHAR(2048) | Comment to describe the synonym                         |
| created_time       | DATETIME      | Synonym creation time                                   |
| updated_time       | DATETIME      | Synonym modification time                               |

**⚠ Warning**

It does not support public synonym yet.

\_db\_user

Represents user information. An index for name is created.

| Attribute Name    | Data Type          | Description                                                                                      |
|-------------------|--------------------|--------------------------------------------------------------------------------------------------|
| name              | VARCHAR(32)        | User name                                                                                        |
| id                | INTEGER            | User identifier                                                                                  |
| password          | _db_password       | User password. Not displayed to the user.                                                        |
| direct_groups     | SET OF _db_user    | Groups to which the user belongs directly                                                        |
| groups            | SET OF _db_user    | Groups to which the user belongs directly or indirectly                                          |
| authorization     | _db_authorization  | Information of the authorization owned by the user                                               |
| triggers          | SEQUENCE OF object | Triggers that occur due to user actions                                                          |
| is_loginable      | INTEGER            | 1 if the user is allowed to log in, 0 otherwise                                                  |
| is_system_created | INTEGER            | 1 if the user is created by the system (for example, <b>DBA</b> and <b>PUBLIC</b> ), 0 otherwise |
| comment           | VARCHAR(1024)      | Comment to describe the user                                                                     |
| created_time      | DATETIME           | User creation time                                                                               |

| Attribute Name | Data Type | Description            |
|----------------|-----------|------------------------|
| updated_time   | DATETIME  | User modification time |

### Function Names

- **set\_password** ()
- **set\_password\_encoded** ()
- **set\_password\_encoded\_sha1** ()
- **add\_member** ()
- **drop\_member** ()
- **print\_authorizations** ()
- **add\_user** ()
- **drop\_user** ()
- **find\_user** ()
- **login** ()

### \_db\_authorization

Represents authorization summary per user.

| Attribute Name | Data Type | Description                                                                                                                       |
|----------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| owner          | _db_user  | Owner of this authorization object                                                                                                |
| grants         | SEQUENCE  | Sequence of {object for which the user has authorization, authorization grantor of the object, authorization type} for each grant |

## \_db\_serial

Represents serial information. An index for unique\_name and an index for name and owner are created.

[illegible]

| Attribute Name | Data Type           | Description                                                                               |
|----------------|---------------------|-------------------------------------------------------------------------------------------|
|                |                     | minimum value of the serial; 0 (NOCYCLE) if not.                                          |
| started        | INTEGER             | 1 if the value has been created at least once after creation, otherwise 0.                |
| class_name     | VARCHAR(1073741823) | AUTO_INCREMENT In case of serial, the table name is stored. or <b>NULL</b> .              |
| attr_name      | VARCHAR(1073741823) | AUTO_INCREMENT In case of serial, the column name is stored. or <b>NULL</b> .             |
| cached_num     | INTEGER             | The number of serial values to pre-create in memory to improve performance. Default is 0. |
| comment        | VARCHAR (1024)      | Comment to describe the serial.                                                           |
| created_time   | DATETIME            | Serial creation time.                                                                     |
| updated_time   | DATETIME            | Serial modification time.                                                                 |

### Method Name

· **change\_serial\_owner ()**

\_db\_trigger

Represents trigger information.

| Attribute Name         | Data Type           | Description                                                                                                                                                |
|------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unique_name            | VARCHAR(1073741823) | Trigger name prefixed with schema name                                                                                                                     |
| owner                  | _db_user            | Trigger owner                                                                                                                                              |
| name                   | VARCHAR(1073741823) | Trigger name                                                                                                                                               |
| status                 | INTEGER             | 1 for INACTIVE, and 2 for ACTIVE. The default value is 2.                                                                                                  |
| priority               | DOUBLE              | Execution priority between triggers. The default value is 0.                                                                                               |
| event                  | INTEGER             | 0 is set for UPDATE, 1 for UPDATE STATEMENT, 2 for DELETE, 3 for DELETE STATEMENT, 4 for INSERT, 5 for INSERT STATEMENT, 8 for COMMIT, and 9 for ROLLBACK. |
| target_class           | object              | Class object for the trigger target class                                                                                                                  |
| target_attribute       | VARCHAR(1073741823) | Trigger target attribute name. If the target attribute is not specified, <i>NULL*</i> is used.                                                             |
| target_class_attribute | INTEGER             | If the target attribute is an instance attribute, 0 is used.                                                                                               |

| Attribute Name    | Data Type           | Description                                                                                                 |
|-------------------|---------------------|-------------------------------------------------------------------------------------------------------------|
|                   |                     | If it is a class attribute, 1 is used. The default value is 0.                                              |
| condition_type    | INTEGER             | If a condition exist, 1; otherwise <b>NULL</b> .                                                            |
| condition         | VARCHAR(1073741823) | Action condition specified in the IF statement                                                              |
| condition_time    | INTEGER             | 1 for BEFORE, 2 for AFTER, and 3 for DEFERRED if a condition exists; <b>NULL</b> , otherwise.               |
| action_type       | INTEGER             | 1 for one of INSERT, UPDATE, DELETE, and CALL, 2 for REJECT, 3 for INVALIDATE_TRANSACTION, and 4 for PRINT. |
| action_definition | VARCHAR(1073741823) | Execution statement to be triggered                                                                         |
| action_time       | INTEGER             | 1 for BEFORE, 2 for AFTER, and 3 for DEFERRED.                                                              |
| comment           | VARCHAR (1024)      | Comment to describe the trigger                                                                             |
| created_time      | DATETIME            | Trigger creation time                                                                                       |
| updated_time      | DATETIME            | Trigger modification time                                                                                   |

## \_db\_ha\_apply\_info

A table that stores the progress status every time the **applylogdb** utility applies replication logs. This table is updated at every point the **applylogdb** utility commits, and the accumulative count of operations are stored in the \*\_counter column. The meaning of each column is as follows:

| Column Name          | Column Type   | Description                                                                                                                                 |
|----------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| db_name              | VARCHAR(255)  | Name of the database stored in the log                                                                                                      |
| db_creation_time     | DATETIME      | Creation time of the source database for the log to be applied                                                                              |
| copied_log_path      | VARCHAR(4096) | Path to the log file to be applied                                                                                                          |
| committed_lsa_pageid | BIGINT        | The page id of commit log lsa reflected last. Although applylogdb is restarted, the logs before last_committed_lsa are not reflected again. |
| committed_lsa_offset | INTEGER       | The offset of commit log lsa reflected last. Although applylogdb is restarted, the logs before last_committed_lsa are not reflected again.  |
| committed_rep_pageid | BIGINT        | The page id of the replication log lsa reflected last. Check whether the reflection of replication has been delayed or not.                 |

| Column Name          | Column Type | Description                                                                                                                                                                                                                                                                                                             |
|----------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| committed_rep_offset | INTEGER     | The offset of the replication log lsa reflected last. Check whether the reflection of replication has been delayed or not.                                                                                                                                                                                              |
| append_lsa_page_id   | BIGINT      | The page id of the last replication log lsa at the last reflection. Saves append_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log. |
| append_lsa_offset    | INTEGER     | The offset of the last replication log lsa at the last reflection. Saves append_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log.  |
| eof_lsa_page_id      | BIGINT      | The page id of the replication log EOF lsa at the last reflection. Saves eof_lsa of the replication                                                                                                                                                                                                                     |

| Column Name      | Column Type | Description                                                                                                                                                                                                                                                                                                        |
|------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |             | log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log.                                                                                                    |
| eof_lsa_offset   | INTEGER     | The offset of the replication log EOF lsa at the last reflection. Saves eof_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log. |
| final_lsa_pageid | BIGINT      | The pageid of replication log lsa processed last by applylogdb. Checks whether the reflection of replication has been delayed or not.                                                                                                                                                                              |
| final_lsa_offset | INTEGER     | The offset of replication log lsa processed last by applylogdb. Checks whether the reflection of replication has been delayed or not.                                                                                                                                                                              |
| required_page_id | BIGINT      | The smallest page which should not be deleted by the log_max_archives parameter. The log page                                                                                                                                                                                                                      |

| Column Name          | Column Type | Description                                                                                              |
|----------------------|-------------|----------------------------------------------------------------------------------------------------------|
|                      |             | number from which the replication will be reflected.                                                     |
| required_page_offset | INTEGER     | The offset of the log page from which the replication will be reflected.                                 |
| log_record_time      | DATETIME    | Timestamp included in replication log committed in the slave database, i.e. the creation time of the log |
| log_commit_time      | DATETIME    | The time of reflecting the last commit log                                                               |
| last_access_time     | DATETIME    | The final update time of the _db_ha_apply_info catalog                                                   |
| status               | INTEGER     | Progress status (0: IDLE, 1: BUSY)                                                                       |
| insert_counter       | BIGINT      | Number of times that applylogdb was inserted                                                             |
| update_counter       | BIGINT      | Number of times that applylogdb was updated                                                              |
| delete_counter       | BIGINT      | Number of times that applylogdb was deleted                                                              |
| schema_counter       | BIGINT      | Number of times that applylogdb changed the schema                                                       |

| Column Name    | Column Type | Description                                                                                              |
|----------------|-------------|----------------------------------------------------------------------------------------------------------|
| commit_counter | BIGINT      | Number of times that applylogdb was committed                                                            |
| fail_counter   | BIGINT      | Number of times that applylogdb failed to be inserted/updated/deleted/committed and to change the schema |
| start_time     | DATETIME    | Time when the applylogdb process accessed the slave database                                             |

## dual

The dual class is a one-row, one-column table that is used as a dummy table. It is used to select a constant, expression, or pseudo column such as SYS\_DATE or USER. Pseudo columns can be provided as functions in CUBRID. More details and examples are in [Operators and Functions](#). However, it is not mandatory to have FROM clause when selecting a constant, expression, or pseudo column because dual class will be referenced automatically. Like other system catalog classes, dual class is created to be owned by dba but dba can only execute SELECT operation. Unlike other system catalog classes, however, any user can execute SELECT operation on dual class.

| Attribute Name | Data Type  | Description                       |
|----------------|------------|-----------------------------------|
| dummy          | VARCHAR(1) | Value used for dummy purpose only |

The following example shows the result which ran the query that select pseudo column after inputting “;plan detail” or “SET OPTIMIZATION LEVEL 513;” in CSQL ([Viewing Query Plan](#)). This shows the dual class is referenced automatically even if there is no FROM clause.

```
SET OPTIMIZATION LEVEL 513;
SELECT SYS_DATE;
```

Join graph segments (f indicates final):

```
seg[0]: [0]
```

Join graph nodes:

```
node[0]: dual dual(1/1) (loc -1)
```

Query plan:

```
sscan
  class: dual node[0]
  cost:  1 card 1
```

Query stmt:

```
select  SYS_DATE  from dual dual
```

```
=== <Result of SELECT Command in Line 1> ===
```

```
      SYS_DATE
=====
      11/26/2020
```

## System Catalog Virtual Class

General users can only see information of classes for which they have authorization through system catalog virtual classes. This section explains which information each system catalog virtual class represents, and virtual class definition statements.

| Virtual Class Name    | Description                          |
|-----------------------|--------------------------------------|
| DB_CLASS              | Class information                    |
| DB_DIRECT_SUPER_CLASS | Super class information              |
| DB_VCLASS             | The SQL statement of a virtual class |
| DB_ATTRIBUTE          | Attribute information                |

| Virtual Class Name        | Description                                                                     |
|---------------------------|---------------------------------------------------------------------------------|
| DB_ATTR_SETDOMAIN_ELM     | Data type for elements of collection type (SET, MULTISSET, SEQUENCE) attributes |
| DB_CHARSET                | Charset information                                                             |
| DB_COLLATION              | Collation information                                                           |
| DB_METHOD                 | Method information                                                              |
| DB_METH_ARG               | Method argument information                                                     |
| DB_METH_ARG_SETDOMAIN_ELM | Data type for elements of collection type (SET, MULTISSET, SEQUENCE) argument   |
| DB_METH_FILE              | File information in which the method is defined                                 |
| DB_INDEX                  | Index information                                                               |
| DB_INDEX_KEY              | Key information on an index                                                     |
| DB_AUTH                   | User authorization information of classes                                       |
| DB_SERIAL                 | Serial information                                                              |
| DB_TRIGGER                | Trigger information                                                             |
| DB_HA_APPLY_INFO          | The progress status the <b>applylogdb</b> utility applies replication logs      |

| Virtual Class Name       | Description                           |
|--------------------------|---------------------------------------|
| DB_PARTITION             | Partition information                 |
| DB_STORED_PROCEDURE      | Stored procedure information          |
| DB_STORED_PROCEDURE_ARGS | Stored procedure argument information |
| DB_SERVER                | Server information for DBLink         |
| DB_SYNONYM               | Target object information of synonyms |

## DB\_CLASS

Represents information of classes for which the current user has access authorization to a database.

| Attribute Name      | Data Type    | Description                                           |
|---------------------|--------------|-------------------------------------------------------|
| class_name          | VARCHAR(255) | Class name                                            |
| owner_name          | VARCHAR(32)  | Owner Name of class                                   |
| class_type          | VARCHAR(6)   | 'CLASS' for a class, and 'VCLASS' for a virtual class |
| is_system_class     | VARCHAR(3)   | 'YES' for a system class, and 'NO' otherwise.         |
| tde_algorithm       | VARCHAR(32)  | TDE encryption algorithm                              |
| statistics_strategy | VARCHAR(8)   |                                                       |

| Attribute Name     | Data Type     | Description                                              |
|--------------------|---------------|----------------------------------------------------------|
|                    |               | Statistics collection strategy ('SAMPLING', 'FULLSCAN')  |
| partitioned        | VARCHAR(3)    | 'YES' for a partitioned group class, and 'NO' otherwise. |
| is_reuse_oid_class | VARCHAR(3)    | 'YES' for a REUSE_OID class, and 'NO' otherwise.         |
| collation          | VARCHAR(32)   | Collation name                                           |
| comment            | VARCHAR(2048) | Comment to describe the class                            |
| created_time       | DATETIME      | Class creation time                                      |
| updated_time       | DATETIME      | Class modification time                                  |
| checked_time       | DATETIME      | Class statistics information update time                 |

The following example shows how to retrieve classes owned by the current user.

```
/* CURRENT_USER: PUBLIC */
SELECT class_name, owner_name
FROM db_class
WHERE owner_name = CURRENT_USER;
```

```
class_name      owner_name
=====
'stadium'      'PUBLIC'
'code'         'PUBLIC'
'nation'       'PUBLIC'
'event'        'PUBLIC'
'athlete'      'PUBLIC'
```

```
'participant'      'PUBLIC'
'olympic'          'PUBLIC'
'game'             'PUBLIC'
'record'           'PUBLIC'
'history'          'PUBLIC'
```

The following example shows how to retrieve virtual classes that can be accessed by the current user.

```
SELECT class_name
FROM db_class
WHERE class_type = 'VCLASS';
```

```
class_name
=====
'db_synonym'
'db_server'
'db_charset'
'db_collation'
'db_stored_procedure_args'
'db_stored_procedure'
'db_partition'
'db_trigger'
'db_auth'
'db_index_key'
'db_index'
'db_meth_file'
'db_meth_arg_setdomain_elm'
'db_meth_arg'
'db_method'
'db_attr_setdomain_elm'
'db_attribute'
'db_vclass'
'db_direct_super_class'
'db_class'
```

The following example shows how to retrieve system classes that can be accessed by the current user.

```
SELECT class_name
FROM db_class
WHERE is_system_class = 'YES' AND class_type = 'CLASS'
ORDER BY class_name;
```

```
class_name
=====
```

```
'db_root'
'dual'
```

## DB\_DIRECT\_SUPER\_CLASS

Represents the names of super classes (if any) of the class for which the current user has access authorization to a database.

| Attribute Name   | Data Type    | Description               |
|------------------|--------------|---------------------------|
| class_name       | VARCHAR(255) | Class name                |
| owner_name       | VARCHAR(32)  | Owner Name of class       |
| super_class_name | VARCHAR(255) | Super class name          |
| super_owner_name | VARCHAR(32)  | Owner Name of super class |

The following example shows how to retrieve super classes of the *female\_event* class. (see [ADD SUPERCLASS Clause](#))

```
SELECT super_class_name
FROM db_direct_super_class
WHERE class_name = 'female_event';
```

```
super_class_name
=====
'event'
```

The following example shows how to retrieve super classes of the class owned by the current user. (see [ADD SUPERCLASS Clause](#))

```
/* CURRENT_USER: PUBLIC */
SELECT class_name, super_class_name
FROM db_direct_super_class
WHERE owner_name = CURRENT_USER
ORDER BY class_name;
```

```

class_name      super_class_name
=====
'female_event'  'event'

```

## DB\_VCLASS

Represents SQL definition statements of virtual classes for which the current user has access authorization to a database.

The data type of attribute 'vclass\_def' is VARCHAR (4096) for prior versions including 10.1 Patch 3.

| Attribute Name   | Data Type           | Description                                   | Classification (10.1 Only) |
|------------------|---------------------|-----------------------------------------------|----------------------------|
| vclass_name      | VARCHAR(255)        | Virtual class name                            |                            |
| owner_name       | VARCHAR(32)         | Owner name of virtual class                   |                            |
| vclass_def       | VARCHAR(1073741823) | SQL definition statement of the virtual class | 10.1 Patch 4 or later      |
|                  | VARCHAR(4096)       |                                               | 10.1 Patch 3 or earlier    |
| comment          | VARCHAR(2048)       | Comment to describe the virtual class         |                            |
| created_time     | DATETIME            | Virtual class creation time                   |                            |
| updated_time     | DATETIME            | Virtual class modification time               |                            |
| invalidated_time | DATETIME            |                                               |                            |

| Attribute Name | Data Type | Description                              | Classification (10.1 Only) |
|----------------|-----------|------------------------------------------|----------------------------|
|                |           | Time when the view query was invalidated |                            |

The following example shows how to retrieve SQL definition statements of the *db\_class* virtual class.

```
SELECT vclass_def
FROM db_vclass
WHERE vclass_name = 'db_class';
```

```
vclass_def
=====
'SELECT [c].[class_name] AS [class_name], [c].[owner].[name] AS
[owner_name], CASE [c].[class_type] WHEN 0 THEN 'CLASS' WHEN 1 THEN
'VCLASS' ELSE 'UNKNOWN' END AS [class_type], CASE WHEN [c].

ELSE NVL ((SELECT 'YES' FROM [_db_partition] AS [p] WHERE [p].
[class_of] = [c] AND [p].[pname] IS NULL), 'NO') END AS
[partitioned], CASE WHEN ([c].[flags] & 8) <> 0 THEN 'YES' ELSE 'NO'
END AS [is_reuse_oid_class], [coll].[coll_name] AS [collation], [c].
[comment] AS [comment], [c].[created_time] AS [created_time], [c].
[updated_time] AS [updated_time], [c].[checked_time] AS
[checked_time] FROM [_db_class] AS [c], [_db_collation] AS [coll]
WHERE [c].[collation_id] = [coll].[coll_id] AND ({'DBA'} SUBSETEQ
(SELECT SET {CURRENT_USER} + COALESCE (SUM (SET {[t].[g].[name]}),
SET {})) FROM [_db_user] AS [u], TABLE ([u].[groups]) AS [t] ([g])
WHERE [u].[name] = CURRENT_USER) OR {[c].[owner].[name]} SUBSETEQ
(SELECT SET {CURRENT_USER} + COALESCE (SUM (SET {[t].[g].[name]}),
SET {})) FROM [_db_user] AS [u], TABLE ([u].[groups]) AS [t] ([g])
WHERE [u].[name] = CURRENT_USER) OR {[c].[class_of]} SUBSETEQ
(SELECT SUM (SET {[au].[object_of]}) FROM [_db_auth] AS [au] WHERE
{[au].[grantee].[name]} SUBSETEQ (SELECT SET {CURRENT_USER} +
COALESCE (SUM (SET {[t].[g].[name]}), SET {})) FROM [_db_user] AS
[u], TABLE ([u].[groups]) AS [t] ([g]) WHERE [u].[name] =
CURRENT_USER) AND [au].[auth_type] = 'SELECT'))'
```

## DB\_ATTRIBUTE

Represents the attribute information of a class for which the current user has access authorization in the database.

| Attribute Name  | Data Type    | Description                                                                                                                      |
|-----------------|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| attr_name       | VARCHAR(255) | Attribute name                                                                                                                   |
| class_name      | VARCHAR(255) | Name of the class to which the attribute belongs                                                                                 |
| owner_name      | VARCHAR(32)  | Owner name of the class to which the attribute belongs                                                                           |
| attr_type       | VARCHAR(8)   | 'INSTANCE' for an instance attribute, 'CLASS' for a class attribute, and 'SHARED' for a shared attribute.                        |
| def_order       | INTEGER      | Order of attributes in the class. Begins with 0. If the attribute is inherited, the order is the one defined in the super class. |
| from_class_name | VARCHAR(255) | If the attribute is inherited, the super class in which it is defined is used. Otherwise, <b>NULL</b> .                          |
| from_owner_name | VARCHAR(32)  | If the attribute is inherited, the owner name of the super class in which it is defined is used. Otherwise, <b>NULL</b> .        |
| from_attr_name  | VARCHAR(255) |                                                                                                                                  |

| Attribute Name    | Data Type    | Description                                                                                                                                                      |
|-------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |              | If the attribute is inherited and its name is changed to resolve a name conflict, the original name defined in the super class is used. Otherwise, <b>NULL</b> . |
| data_type         | VARCHAR(9)   | Data type of the attribute (one in the “Meaning” column of the “Data Types Supported by CUBRID” table in <a href="#">_db_attribute</a> )                         |
| prec              | INTEGER      | Precision of the data type. 0 is used if the precision is not specified.                                                                                         |
| scale             | INTEGER      | Scale of the data type. 0 is used if the scale is not specified.                                                                                                 |
| charset           | VARCHAR (32) | charset name                                                                                                                                                     |
| collation         | VARCHAR (32) | collation name                                                                                                                                                   |
| domain_class_name | VARCHAR(255) | Domain class name if the data type is an object. <b>NULL</b> otherwise.                                                                                          |
| domain_owner_name | VARCHAR(32)  | Owner name of the domain class if the data type is an object. <b>NULL</b> otherwise.                                                                             |
| default_value     | VARCHAR(255) | Saved as a character string by default, regardless of                                                                                                            |

| Attribute Name | Data Type     | Description                                                                                                                                                                                                                                                                       |
|----------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |               | data types. If no default value is specified, <b>NULL</b> is stored. If a default value is <b>NULL</b> , it is displayed as 'NULL'. An object data type is represented as 'volume id   page id   slot id' while a set data type is represented as '{element 1, element 2, ... }'. |
| is_nullable    | VARCHAR(3)    | 'NO' if a not null constraint is set, and 'YES' otherwise.                                                                                                                                                                                                                        |
| comment        | VARCHAR(1024) | Comment to describe the attribute.                                                                                                                                                                                                                                                |

The following example shows how to retrieve attributes and data types of the *event* class.

```
SELECT attr_name, data_type, domain_class_name
FROM db_attribute
WHERE class_name = 'event'
ORDER BY def_order;
```

| attr_name | data_type | domain_class_name |
|-----------|-----------|-------------------|
| 'code'    | 'INTEGER' | NULL              |
| 'sports'  | 'STRING'  | NULL              |
| 'name'    | 'STRING'  | NULL              |
| 'gender'  | 'CHAR'    | NULL              |
| 'players' | 'INTEGER' | NULL              |

The following example shows how to retrieve attributes of the *female\_event* class and its super class. (see [ADD SUPERCLASS Clause](#))

```
SELECT attr_name, from_class_name
FROM db_attribute
```

```
WHERE class_name = 'female_event'
ORDER BY def_order;
```

```
attr_name          from_class_name
=====
'code'             'event'
'sports'           'event'
'name'             'event'
'gender'           'event'
'players'          'event'
```

The following example shows how to retrieve classes whose attribute names are similar to *name*, among the ones owned by the current user. (The user is **PUBLIC**.)

```
/* CURRENT_USER: PUBLIC */
SELECT class_name, attr_name
FROM db_attribute
WHERE owner_name = CURRENT_USER AND attr_name like '%name%'
ORDER BY class_name;
```

```
class_name          attr_name
=====
'athlete'           'name'
'code'              'f_name'
'code'              's_name'
'event'             'name'
'nation'            'name'
'stadium'           'name'
```

## DB\_ATTR\_SETDOMAIN\_ELM

Among attributes of the class to which the current user has access authorization in the database, if an attribute's data type is a collection (SET, MULTISSET, SEQUENCE), this macro represents the data type of the element of the collection.

| Attribute Name | Data Type    | Description    |
|----------------|--------------|----------------|
| attr_name      | VARCHAR(255) | Attribute name |
| class_name     | VARCHAR(255) |                |

| Attribute Name    | Data Type    | Description                                                                                               |
|-------------------|--------------|-----------------------------------------------------------------------------------------------------------|
|                   |              | Name of the class to which the attribute belongs                                                          |
| owner_name        | VARCHAR(32)  | Owner name of the class to which the attribute belongs                                                    |
| attr_type         | VARCHAR(8)   | 'INSTANCE' for an instance attribute, 'CLASS' for a class attribute, and 'SHARED' for a shared attribute. |
| data_type         | VARCHAR(9)   | Data type of the element                                                                                  |
| prec              | INTEGER      | Precision of the data type of the element                                                                 |
| scale             | INTEGER      | Scale of the data type of the element                                                                     |
| code_set          | INTEGER      | Character set if the data type of the element is a character                                              |
| domain_class_name | VARCHAR(255) | Domain class name if the data type of the element is an object                                            |
| domain_owner_name | VARCHAR(32)  | Owner name of the domain class if the data type of the element is an object                               |

If the set\_attr attribute of class D is of a SET (A, B, C) type, the following three records exist.

| Attr_name  | Class_name | Attr_type  | Data_type | Prec | Scale | Code_set | Domain_class_name |
|------------|------------|------------|-----------|------|-------|----------|-------------------|
| 'set_attr' | 'D'        | 'INSTANCE' | 'SET'     | 0    | 0     | 0        | 'A'               |
| 'set_attr' | 'D'        | 'INSTANCE' | 'SET'     | 0    | 0     | 0        | 'B'               |
| 'set_attr' | 'D'        | 'INSTANCE' | 'SET'     | 0    | 0     | 0        | 'C'               |

The following example shows how to retrieve collection type attributes and data types of the *city* class (the *city* table defined in [Containment Operators](#) is created).

```
SELECT attr_name, attr_type, data_type, domain_class_name
FROM db_attr_setdomain_elm
WHERE class_name = 'city';
```

```
attr_name      attr_type      data_type
domain_class_name
=====
=====
'sports'      'INSTANCE'    'STRING'
NULL
```

## DB\_CHARSET

Represents charset information.

| Attribute name | Data type             | Description  |
|----------------|-----------------------|--------------|
| charset_id     | INTEGER               | Charset ID   |
| charset_name   | CHARACTER VARYING(32) | Charset name |

| Attribute name    | Data type             | Description               |
|-------------------|-----------------------|---------------------------|
| default_collation | CHARACTER VARYING(32) | Default collation name    |
| char_size         | INTEGER               | One character's byte size |

## DB\_COLLATION

The information on collation.

| Attribute Name | Data Type    | Description                                                                                   |
|----------------|--------------|-----------------------------------------------------------------------------------------------|
| coll_id        | INTEGER      | Collation ID                                                                                  |
| coll_name      | VARCHAR(32)  | Collation name                                                                                |
| charset_name   | VARCHAR(32)  | Charset name                                                                                  |
| is_builtin     | VARCHAR(3)   | Built-in or not while installing the product(Yes, No)                                         |
| has_expansions | VARCHAR(3)   | Having expansion or not(Yes, No)                                                              |
| contractions   | INTEGER      | Whether to include abbreviation                                                               |
| uca_strength   | VARCHAR(255) | Weight strength (Not applicable, Primary, Secondary, Tertiary, Quaternary, Identity, Unknown) |

## DB\_METHOD

Represents method information of a class for which the current user has access authorization to a database.

| Attribute Name  | Data Type    | Description                                                                                                                                               |
|-----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| meth_name       | VARCHAR(255) | Method name                                                                                                                                               |
| class_name      | VARCHAR(255) | Name of the class to which the method belongs                                                                                                             |
| owner_name      | VARCHAR(32)  | Owner name of the class to which the method belongs                                                                                                       |
| meth_type       | VARCHAR(8)   | 'INSTANCE' for an instance method, and 'CLASS' for a class method.                                                                                        |
| from_class_name | VARCHAR(255) | If the method is inherited, the super class in which it is defined is used otherwise <b>NULL</b>                                                          |
| from_owner_name | VARCHAR(32)  | If the method is inherited, the owner name of the superclass in which the method is defined is used otherwise <b>NULL</b>                                 |
| from_meth_name  | VARCHAR(255) | If the method is inherited and its name is changed to resolve a name conflict, the original name defined in the super class is used otherwise <b>NULL</b> |

| Attribute Name | Data Type    | Description                           |
|----------------|--------------|---------------------------------------|
| func_name      | VARCHAR(255) | Name of the C function for the method |

The following example shows how to retrieve methods of the `_db_user` class.

```
SELECT meth_name, meth_type, func_name
FROM db_method
WHERE class_name = '_db_user'
ORDER BY meth_type, meth_name;
```

```
meth_name          meth_type  func_name
=====
'add_user'         'CLASS'    'au_add_user_method'
'drop_user'        'CLASS'    'au_drop_user_method'
'find_user'        'CLASS'    'au_find_user_method'
'login'            'CLASS'    'au_login_method'
'add_member'       'INSTANCE' 'au_add_member_method'
'drop_member'      'INSTANCE' 'au_drop_member_method'
'print_authorizations' 'INSTANCE' 'au_describe_user_method'
'set_password'     'INSTANCE' 'au_set_password_method'
'set_password_encoded' 'INSTANCE'
'au_set_password_encoded_method'
'set_password_encoded_sha1' 'INSTANCE'
'au_set_password_encoded_sha1_method'
```

## DB\_METH\_ARG

Represents the input/output argument information of the method of the class for which the current user has access authorization to a database.

| Attribute Name | Data Type    | Description                                   |
|----------------|--------------|-----------------------------------------------|
| meth_name      | VARCHAR(255) | Method name                                   |
| class_name     | VARCHAR(255) | Name of the class to which the method belongs |

| Attribute Name    | Data Type    | Description                                                                                                                              |
|-------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| owner_name        | VARCHAR(32)  | Owner name of the class to which the method belongs                                                                                      |
| meth_type         | VARCHAR(8)   | 'INSTANCE' for an instance method, and 'CLASS' for a class method.                                                                       |
| index_of          | INTEGER      | Order in which arguments are listed in the function definition. Begins with 0 if it is a return value, and 1 if it is an input argument. |
| data_type         | VARCHAR(9)   | Data type of the argument                                                                                                                |
| prec              | INTEGER      | Precision of the argument                                                                                                                |
| scale             | INTEGER      | Scale of the argument                                                                                                                    |
| code_set          | INTEGER      | Character set if the data type of the argument is a character.                                                                           |
| domain_class_name | VARCHAR(255) | Domain class name if the data type of the argument is an object.                                                                         |
| domain_owner_name | VARCHAR(32)  | Owner name of the domain class if the data type of the argument is an object.                                                            |

The following example shows how to retrieve input arguments of the method of the `_db_user` class.

```
SELECT meth_name, data_type, prec
FROM db_meth_arg
WHERE class_name = '_db_user';
```

```
meth_name      data_type      prec
=====
'append_data'  'STRING'      1073741823
```

### DB\_METH\_ARG\_SETDOMAIN\_ELM

If the data type of the input/output argument of the method of the class is a set, for which the current user has access authorization in the database, this macro represents the data type of the element of the set.

| Attribute Name | Data Type    | Description                                                                                                                    |
|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| meth_name      | VARCHAR(255) | Method name                                                                                                                    |
| class_name     | VARCHAR(255) | Name of the class to which the method belongs                                                                                  |
| owner_name     | VARCHAR(32)  | Owner name of the class to which the method belongs                                                                            |
| meth_type      | VARCHAR(8)   | 'INSTANCE' for an instance method, and 'CLASS' for a class method.                                                             |
| index_of       | INTEGER      | Order of arguments listed in the function definition. Begins with 0 if it is a return value, and 1 if it is an input argument. |
| data_type      | VARCHAR(9)   | Data type of the element                                                                                                       |

| Attribute Name    | Data Type    | Description                                                                 |
|-------------------|--------------|-----------------------------------------------------------------------------|
| prec              | INTEGER      | Precision of the element                                                    |
| scale             | INTEGER      | Scale of the element                                                        |
| code_set          | INTEGER      | Character set if the data type of the element is a character                |
| domain_class_name | VARCHAR(255) | Domain class name if the data type of the element is an object              |
| domain_owner_name | VARCHAR(32)  | Owner name of the domain class if the data type of the element is an object |

## DB\_METH\_FILE

Represents information of a file in which the method of the class for which the current user has access authorization in the database is defined.

| Attribute Name | Data Type    | Description                                              |
|----------------|--------------|----------------------------------------------------------|
| class_name     | VARCHAR(255) | Name of the class to which the method file belongs       |
| owner_name     | VARCHAR(32)  | Owner name of the class to which the method file belongs |
| path_name      | VARCHAR(255) | File path in which the C function is defined             |

| Attribute Name  | Data Type    | Description                                                                                                             |
|-----------------|--------------|-------------------------------------------------------------------------------------------------------------------------|
| from_class_name | VARCHAR(255) | Name of the super class in which the method file is defined if the method is inherited, and otherwise <b>NULL</b>       |
| from_owner_name | VARCHAR(32)  | Owner Name of the super class in which the method file is defined if the method is inherited, and otherwise <b>NULL</b> |

## DB\_INDEX

Represents information of indexes created for the class for which the current user has access authorization to a database.

| Attribute Name | Data Type    | Description                                        |
|----------------|--------------|----------------------------------------------------|
| index_name     | VARCHAR(255) | Index name                                         |
| is_unique      | VARCHAR(3)   | 'YES' for a unique index, and 'NO' otherwise.      |
| is_reverse     | VARCHAR(3)   | 'YES' for a reversed index, and 'NO' otherwise.    |
| class_name     | VARCHAR(255) | Name of the class to which the index belongs       |
| owner_name     | VARCHAR(32)  | Owner name of the class to which the index belongs |

| Attribute Name                     | Data Type           | Description                                                                     |
|------------------------------------|---------------------|---------------------------------------------------------------------------------|
| key_count                          | INTEGER             | The number of attributes that comprise the key                                  |
| is_primary_key                     | VARCHAR(3)          | 'YES' for a primary key, and 'NO' otherwise.                                    |
| is_foreign_key                     | VARCHAR(3)          | 'YES' for a foreign key, and 'NO' otherwise.                                    |
| filter_expression                  | VARCHAR(1073741823) | Conditions of filtered indexes                                                  |
| have_function                      | VARCHAR(3)          | 'YES' for function based and 'NO' otherwise.                                    |
| status                             | VARCHAR(255)        | Index status                                                                    |
| referential_index_class_owner_name | VARCHAR(32)         | Owner name of the class referenced by foreign key                               |
| referential_index_class_name       | VARCHAR(255)        | Class name of the index referenced by foreign key                               |
| referential_index_name             | VARCHAR(255)        | Index name referenced by foreign key                                            |
| delete_rule                        | VARCHAR(32)         | Delete rule for foreign key constraint (CASCADE, RESTRICT, NO ACTION, SET NULL) |
| update_rule                        | VARCHAR(32)         |                                                                                 |

| Attribute Name           | Data Type     | Description                                                                                                                                |
|--------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|
|                          |               | Update rule for foreign key constraint (RESTRICT, NO ACTION, SET NULL)                                                                     |
| referential_match_option | VARCHAR(7)    | Match option for foreign key constraint (NONE) <ul style="list-style-type: none"> <li>• NONE: Does not check if any NULL exists</li> </ul> |
| index_type               | VARCHAR(32)   | Index type (BTREE)                                                                                                                         |
| deduplicate_key_level    | INTEGER       | Deduplication level of the index                                                                                                           |
| comment                  | VARCHAR(1024) | Comment to describe the index                                                                                                              |
| created_time             | DATETIME      | Index creation time                                                                                                                        |
| updated_time             | DATETIME      | Index modification time                                                                                                                    |

The following example shows how to retrieve index information of the class.

```
SELECT class_name, index_name, is_unique
FROM db_index
ORDER BY owner_name, class_name;
```

```
class_name
index_name                                     is_unique
=====

```

## DB\_INDEX\_KEY

Represents the key information of indexes created for the class for which the current user has access authorization to a database.

| Attribute Name | Data Type    | Description                                        |
|----------------|--------------|----------------------------------------------------|
| index_name     | VARCHAR(255) | Index name                                         |
| class_name     | VARCHAR(255) | Name of the class to which the index belongs       |
| owner_name     | VARCHAR(32)  | Owner name of the class to which the index belongs |
| key_attr_name  | VARCHAR(255) | Name of attributes that comprise the key           |

| Attribute Name    | Data Type     | Description                                                                 |
|-------------------|---------------|-----------------------------------------------------------------------------|
| key_order         | INTEGER       | Order of attributes in the key. Begins with 0.                              |
| asc_desc          | VARCHAR(4)    | 'DESC' if the order of attribute values is descending, and 'ASC' otherwise. |
| key_prefix_length | INTEGER       | The length of prefix to be used as a key                                    |
| func              | VARCHAR(1023) | Functional expression of function based index                               |

The following example shows how to retrieve index key information of the class.

```
SELECT class_name, key_attr_name, index_name
FROM db_index_key
ORDER BY owner_name, class_name, key_order
LIMIT 20;
```

```
class_name      key_attr_name      index_name
=====
'_db_user'      'name'             'u__db_user_name'
'athlete'       'code'             'pk_athlete_code'
'code'          's_name'           'pk_code'
'event'         'code'             'pk_event_code'
'game'          'athlete_code'     'fk_game_athlete_code'
'game'          'host_year'
'pk_game_host_year_event_code_athlete_code'
'game'          'event_code'       'fk_game_event_code'
'game'          'event_code'
'pk_game_host_year_event_code_athlete_code'
'game'          'athlete_code'
'pk_game_host_year_event_code_athlete_code'
'histor'        'event_code'
'pk_history_event_code_athlete'
'histor'        'athlete'
'pk_history_event_code_athlete'
```

```

'nation'          'code'          'pk_nation_code'
'olympic'         'host_year'        'pk_olympic_host_year'
'participant'     'host_year'
'pk_participant_host_year_nation_code'
'participant'     'nation_code'
'fk_participant_nation_code'
'participant'     'host_year'
'fk_participant_host_year'
'participant'     'nation_code'
'pk_participant_host_year_nation_code'
'record'          'host_year'
'pk_record_host_year_event_code_athlete_code_medal'
'record'          'event_code'
'pk_record_host_year_event_code_athlete_code_medal'

```

## DB\_AUTH

Represents authorization information for objects the current user is authorized to access.

| Attribute Name | Data Type    | Description                                                                                |
|----------------|--------------|--------------------------------------------------------------------------------------------|
| grantor_name   | VARCHAR(32)  | Name of the user who grants authorization                                                  |
| grantee_name   | VARCHAR(32)  | Name of the user who is granted authorization                                              |
| object_type    | VARCHAR(16)  | Type of the object for which authorization is granted (CLASS, VCLASS, PROCEDURE, FUNCTION) |
| object_name    | VARCHAR(255) | Name of the object for which authorization is granted                                      |
| owner_name     | VARCHAR(32)  | Owner name of the object for which authorization is granted                                |

| Attribute Name | Data Type  | Description                                                                              |
|----------------|------------|------------------------------------------------------------------------------------------|
| auth_type      | VARCHAR(7) | Name of the authorization type granted                                                   |
| is_grantable   | VARCHAR(3) | 'YES' if authorization for the object can be granted to other users, and 'NO' otherwise. |
| created_time   | DATETIME   | Time when authorization was granted                                                      |
| updated_time   | DATETIME   | Time when authorization was updated                                                      |

The following example show how to retrieve authorization information for objects whose names begin with *db\_a*.

```
SELECT object_name, auth_type, grantor_name
FROM db_auth
WHERE object_name like 'db_a%'
ORDER BY 1;
```

```
object_name      auth_type      grantor_name
=====
'db_attr_setdomain_elm' 'SELECT'      'DBA'
'db_attribute'    'SELECT'      'DBA'
'db_auth'         'SELECT'      'DBA'
'db_authorization' 'SELECT'      'DBA'
```

## DB\_USER

Represents information of users for which the current user has access authorization to a database.

| Attribute Name    | Data Type          | Description                                                                                                |
|-------------------|--------------------|------------------------------------------------------------------------------------------------------------|
| name              | VARCHAR(32)        | User name                                                                                                  |
| id                | INTEGER            | User identifier                                                                                            |
| password          | _db_password       | Always <b>NULL</b> (kept for backward compatibility)                                                       |
| direct_groups     | SET OF VARCHAR(32) | Names of groups to which the user belongs directly                                                         |
| groups            | SET OF VARCHAR(32) | Names of groups to which the user belongs directly or indirectly                                           |
| authorization     | _db_authorization  | Always <b>NULL</b> (kept for backward compatibility)                                                       |
| triggers          | SEQUENCE OF object | Triggers that occur due to user actions                                                                    |
| is_loginable      | VARCHAR(3)         | 'YES' if the user is allowed to log in, 'NO' otherwise                                                     |
| is_system_created | VARCHAR(3)         | 'YES' if the user is a system-created account (for example, <b>DBA</b> and <b>PUBLIC</b> ), 'NO' otherwise |
| comment           | VARCHAR(1024)      | Comment to describe the user                                                                               |
| created_time      | DATETIME           | User creation time                                                                                         |

| Attribute Name | Data Type | Description            |
|----------------|-----------|------------------------|
| updated_time   | DATETIME  | User modification time |

#### Function Names

- **find\_user** ()
- **login** ()

### DB\_AUTHORIZATION

Represents user authorization information of classes for which the current user has access authorization to a database.

| Attribute Name | Data Type   | Description                                                                                                                       |
|----------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| owner          | VARCHAR(32) | Owner of this authorization object                                                                                                |
| grants         | SEQUENCE    | Sequence of {object for which the user has authorization, authorization grantor of the object, authorization type} for each grant |

### DB\_SERIAL

Represents information of serials for which the current user has access authorization to a database.

| Attribute Name | Data Type     | Description                                                                                                                     |
|----------------|---------------|---------------------------------------------------------------------------------------------------------------------------------|
| unique_name    | VARCHAR(255)  | Serial name prefixed with schema name.                                                                                          |
| name           | VARCHAR(255)  | Serial name.                                                                                                                    |
| owner          | VARCHAR(32)   | Serial owner.                                                                                                                   |
| current_val    | NUMERIC(38,0) | Current serial value.                                                                                                           |
| increment_val  | NUMERIC(38,0) | Interval of serial values.                                                                                                      |
| max_val        | NUMERIC(38,0) | The maximum value of the serial.                                                                                                |
| min_val        | NUMERIC(38,0) | The minimum value of the serial.                                                                                                |
| start_val      | NUMERIC(38,0) | The starting value of the serial.                                                                                               |
| cyclic         | INTEGER       | 1 (CYCLE) if a value can be generated by cycling after reaching the maximum or minimum value of the serial; 0 (NOCYCLE) if not. |
| started        | INTEGER       | 1 if the value has been created at least once after creation, otherwise 0.                                                      |
| class_name     | VARCHAR(255)  |                                                                                                                                 |

| Attribute Name | Data Type      | Description                                                                               |
|----------------|----------------|-------------------------------------------------------------------------------------------|
|                |                | AUTO_INCREMENT In case of serial, the table name is stored. or <b>NULL</b> .              |
| attr_name      | VARCHAR(255)   | AUTO_INCREMENT In case of serial, the column name is stored. or <b>NULL</b> .             |
| cached_num     | INTEGER        | The number of serial values to pre-create in memory to improve performance. Default is 0. |
| comment        | VARCHAR (1024) | Comment to describe the serial.                                                           |
| created_time   | DATETIME       | Serial creation time                                                                      |
| updated_time   | DATETIME       | Serial modification time                                                                  |

## DB\_TRIGGER

Represents information of a trigger that has the class for which the current user has access authorization to a database, or its attribute as the target.

| Attribute Name    | Data Type    | Description           |
|-------------------|--------------|-----------------------|
| trigger_name      | VARCHAR(255) | Trigger name          |
| owner_name        | VARCHAR(32)  | Owner name of trigger |
| target_class_name | VARCHAR(255) | Target class name     |

| Attribute Name    | Data Type     | Description                                                                                                                   |
|-------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| target_owner_name | VARCHAR(32)   | Target class owner name                                                                                                       |
| target_attr_name  | VARCHAR(255)  | Target attribute. If not specified in the trigger, <b>NULL</b>                                                                |
| target_attr_type  | VARCHAR(8)    | Target attribute type. If specified, 'INSTANCE' is used for an instance attribute, and 'CLASS' is used for a class attribute. |
| action_type       | INTEGER       | 1 for one of INSERT, UPDATE, DELETE, and CALL, 2 for REJECT, 3 for INVALIDATE_TRANSACTION, and 4 for PRINT.                   |
| action_time       | INTEGER       | 1 for BEFORE, 2 for AFTER, and 3 for DEFERRED.                                                                                |
| comment           | VARCHAR(1024) | Comment to describe the trigger.                                                                                              |
| created_time      | DATETIME      | Trigger creation time                                                                                                         |
| updated_time      | DATETIME      | Trigger modification time                                                                                                     |

## DB\_HA\_APPLY\_INFO

Represents information indicating the replication log application process and its progress status in the database.

| Column Name          | Column Type   | Description                                                                                                                                 |
|----------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| db_name              | VARCHAR(255)  | Name of the database stored in the log                                                                                                      |
| db_creation_time     | DATETIME      | Creation time of the source database for the log to be applied                                                                              |
| copied_log_path      | VARCHAR(4096) | Path to the log file to be applied                                                                                                          |
| committed_lsa_pageid | BIGINT        | The page id of commit log lsa reflected last. Although applylogdb is restarted, the logs before last_committed_lsa are not reflected again. |
| committed_lsa_offset | INTEGER       | The offset of commit log lsa reflected last. Although applylogdb is restarted, the logs before last_committed_lsa are not reflected again.  |
| committed_rep_pageid | BIGINT        | The page id of the replication log lsa reflected last. Check whether the reflection of replication has been delayed or not.                 |
| committed_rep_offset | INTEGER       | The offset of the replication log lsa reflected last. Check whether the reflection of replication has been delayed or not.                  |

| Column Name        | Column Type | Description                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| append_lsa_page_id | BIGINT      | The page id of the last replication log lsa at the last reflection. Saves append_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log. |
| append_lsa_offset  | INTEGER     | The offset of the last replication log lsa at the last reflection. Saves append_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log.  |
| eof_lsa_page_id    | BIGINT      | The page id of the replication log EOF lsa at the last reflection. Saves eof_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at                                                 |

| Column Name          | Column Type | Description                                                                                                                                                                                                                                                                                                        |
|----------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      |             | the time of reflecting the replication log.                                                                                                                                                                                                                                                                        |
| eof_lsa_offset       | INTEGER     | The offset of the replication log EOF lsa at the last reflection. Saves eof_lsa of the replication log header that is being processed by applylogdb at the time of reflecting the replication. Checks whether the reflection of replication has been delayed or not at the time of reflecting the replication log. |
| final_lsa_pageid     | BIGINT      | The pageid of replication log lsa processed last by applylogdb. Checks whether the reflection of replication has been delayed or not.                                                                                                                                                                              |
| final_lsa_offset     | INTEGER     | The offset of replication log lsa processed last by applylogdb. Checks whether the reflection of replication has been delayed or not.                                                                                                                                                                              |
| required_page_id     | BIGINT      | The smallest page which should not be deleted by the log_max_archives parameter. The log page number from which the replication will be reflected.                                                                                                                                                                 |
| required_page_offset | INTEGER     |                                                                                                                                                                                                                                                                                                                    |

| Column Name      | Column Type | Description                                                                                              |
|------------------|-------------|----------------------------------------------------------------------------------------------------------|
|                  |             | The offset of the log page from which the replication will be reflected.                                 |
| log_record_time  | DATETIME    | Timestamp included in replication log committed in the slave database, i.e. the creation time of the log |
| log_commit_time  | DATETIME    | The time of reflecting the last commit log                                                               |
| last_access_time | DATETIME    | The final update time of the _db_ha_apply_info catalog                                                   |
| status           | INTEGER     | Progress status (0: IDLE, 1: BUSY)                                                                       |
| insert_counter   | BIGINT      | Number of times that applylogdb was inserted                                                             |
| update_counter   | BIGINT      | Number of times that applylogdb was updated                                                              |
| delete_counter   | BIGINT      | Number of times that applylogdb was deleted                                                              |
| schema_counter   | BIGINT      | Number of times that applylogdb changed the schema                                                       |
| commit_counter   | BIGINT      | Number of times that applylogdb was committed                                                            |

| Column Name  | Column Type | Description                                                                                              |
|--------------|-------------|----------------------------------------------------------------------------------------------------------|
| fail_counter | BIGINT      | Number of times that applylogdb failed to be inserted/updated/deleted/committed and to change the schema |
| start_time   | DATETIME    | Time when the applylogdb process accessed the slave database                                             |

## DB\_PARTITION

Represents information of partitioned classes for which the current user has access authorization to a database.

| Attribute Name       | Data Type     | Description                                        |
|----------------------|---------------|----------------------------------------------------|
| class_name           | VARCHAR(255)  | Class name                                         |
| owner_name           | VARCHAR(32)   | Owner name                                         |
| partition_name       | VARCHAR(255)  | Partition name                                     |
| partition_class_name | VARCHAR(255)  | Partitioned class name                             |
| partition_type       | VARCHAR(32)   | Partition type (HASH, RANGE, LIST)                 |
| partition_expr       | VARCHAR(2048) | Partition expression                               |
| partition_values     | SEQUENCE OF   | MIN and MAX values if the partition type is RANGE, |

| Attribute Name       | Data Type     | Description                                                                                                                                                          |
|----------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      |               | <b>NULL</b> if MIN and MAX are infinite If the partition type is LIST, List of values                                                                                |
| class_partition_type | VARCHAR(32)   | Partition type of partition class (PARTITION CLASS) <ul style="list-style-type: none"> <li>• PARTITION CLASS: Individual partition table that stores data</li> </ul> |
| comment              | VARCHAR(1024) | Comment to describe the partition                                                                                                                                    |
| created_time         | DATETIME      | Class creation time (from parent class)                                                                                                                              |
| updated_time         | DATETIME      | Class modification time (from parent class)                                                                                                                          |

The following example shows how to retrieve the partition information currently configured for the `participant2` class.

```
SELECT *
FROM db_partition
WHERE class_name = 'participant2';
```

```
class_name      owner_name  partition_name
partition_class_name  partition_type  partition_expr
partition_values  comment
=====
=====
'participant2'  'PUBLIC'    'before_2000'
'participant2__p__before_2000'  'RANGE'        '[host_year]'
{NULL, 2000}    NULL
'participant2'  'PUBLIC'    'before_2008'
```

```
'participant2__p__before_2008'  'RANGE'  '[host_year]'
{2000, 2008}  NULL
```

## DB\_STORED\_PROCEDURE

Represents information of Stored procedure for which the current user has access authorization to a database.

| Attribute Name   | Data Type     | Description                                         |
|------------------|---------------|-----------------------------------------------------|
| sp_name          | VARCHAR(255)  | Stored procedure name                               |
| pkg_name         | VARCHAR(255)  | Package name containing the stored procedure        |
| sp_type          | VARCHAR(16)   | Stored procedure type (function or procedure)       |
| return_type      | VARCHAR(16)   | Return value type name                              |
| arg_count        | INTEGER       | The number of arguments                             |
| lang             | VARCHAR(16)   | Implementation language name                        |
| authid           | VARCHAR(16)   | Execution privileges of the stored procedure        |
| is_deterministic | VARCHAR(3)    | Indicates whether the function is deterministic     |
| target           | VARCHAR(4096) | Name of the target stored procedure code to execute |

| Attribute Name  | Data Type           | Description                                                                    |
|-----------------|---------------------|--------------------------------------------------------------------------------|
| owner           | VARCHAR(32)         | Owner                                                                          |
| code            | VARCHAR(1073741823) | Source code of the stored procedure                                            |
| sql_data_access | VARCHAR(17)         | SQL data-access mode (NO SQL, CONTAINS SQL, READS SQL DATA, MODIFIES SQL DATA) |
| comment         | VARCHAR(1024)       | Comment to describe the stored procedure                                       |
| created_time    | DATETIME            | Stored procedure creation time                                                 |
| updated_time    | DATETIME            | Stored procedure modification time                                             |

#### Note

- **sp\_type**
  - **PROCEDURE** or **FUNCTION**.
- **pkg\_name**: Package name. Currently, the package name is only used in the **DBMS\_OUTPUT** system package.
  - **dbms\_output** or **NULL**.
- **return\_type**: The return type can be one of the following values:

NULL, INTEGER, FLOAT, DOUBLE, STRING,  
SET, MULTISET, SEQUENCE, TIME,

TIMESTAMP, DATE, SHORT, NUMERIC, CHAR,  
CURSOR, BIGINT, DATETIME

- Other values are not currently supported.
- **lang:** The implementation language of the stored procedure, which can be one of the following values:
  - **PLCSQL:** PL/CSQL
  - **JAVA:** Java stored procedure
- **authid:** Indicates the execution rights (AUTHID) of the stored procedure.
  - **DEFINER:** Owner rights (or definer rights)
  - **CURRENT\_USER:** Invoker rights
- **is\_deterministic:** Indicates whether the function is deterministic.
  - **YES:** Deterministic function
  - **NO:** Non-deterministic function

The following example shows how to retrieve Java stored procedures owned by the current user.

```
CREATE OR REPLACE FUNCTION hello RETURN VARCHAR AS BEGIN RETURN
'Hello'; END;

CREATE OR REPLACE FUNCTION sp_int(p_int INTEGER) RETURN INTEGER AS
BEGIN RETURN p_int; END;

-- csql
;line on

/* CURRENT_USER: PUBLIC */
SELECT * from db_stored_procedure
WHERE sp_type = 'FUNCTION' AND owner = CURRENT_USER;

::

<00001> sp_name          : 'hello'
        pkg_name        : NULL
        sp_type         : 'FUNCTION'
        return_type     : 'STRING'
        arg_count       : 0
        lang            : 'PLCSQL'
        authid          : 'DEFINER'
        is_deterministic: 'NO'
```

```

target          : 'Func_HELLO_9.HELLO() return
java.lang.String'
owner           : 'DBA'
code            : 'CREATE OR REPLACE FUNCTION
hello RETURN VARCHAR AS BEGIN RETURN 'Hello'; END'
comment        : NULL
<00002> sp_name  : 'sp_int'
pkg_name       : NULL
sp_type        : 'FUNCTION'
return_type    : 'INTEGER'
arg_count      : 1
lang           : 'PLCSQL'
authid         : 'DEFINER'
is_deterministic : 'NO'
target         :
'Func_SP_INT_10.SP_INT(java.lang.Integer) return java.lang.Integer'
owner          : 'DBA'
code           : 'CREATE OR REPLACE FUNCTION
sp_int(p_int INTEGER) RETURN INTEGER AS BEGIN RETURN p_int; END'
comment        : NULL

```

## DB\_STORED\_PROCEDURE\_ARGS

Represents argument information of Stored procedure for which the current user has access authorization to a database.

| Attribute Name | Data Type    | Description                                  |
|----------------|--------------|----------------------------------------------|
| sp_name        | VARCHAR(255) | Stored procedure name                        |
| owner_name     | VARCHAR(32)  | Owner                                        |
| pkg_name       | VARCHAR(255) | Package name containing the stored procedure |
| index_of       | INTEGER      | Order of the arguments                       |
| arg_name       | VARCHAR(255) | Argument name                                |
| data_type      | VARCHAR(16)  | Data type of the argument                    |

| Attribute Name | Data Type     | Description                       |
|----------------|---------------|-----------------------------------|
| mode           | VARCHAR(6)    | Mode (IN, OUT, INOUT)             |
| is_optional    | VARCHAR(3)    | Whether the parameter is optional |
| default_value  | VARCHAR(255)  | Default value of the argument     |
| comment        | VARCHAR(1024) | Comment to describe the argument  |

**Note**

- **index\_of**: The order of the arguments starts from 0.
- **data\_type**: The data type of the argument is one of the following values

```
NULL, INTEGER, FLOAT, DOUBLE, STRING,  
SET, MULTISSET, SEQUENCE, TIME,  
TIMESTAMP, DATE, SHORT, NUMERIC, CHAR,  
CURSOR, BIGINT, DATETIME
```

- Other values are not currently supported.

- **mode**: The argument mode is one of the following values

```
IN, OUT, INOUT
```

- **is\_optional**: A value of **YES** indicates the argument is optional, while **NO** indicates it is required.
- **default\_value**: The default value of the argument. For more details, refer to [Using Default Arguments](#).

The following example shows how to retrieve arguments the 'process\_order' Stored procedure in the order of the arguments.

```
CREATE OR REPLACE PROCEDURE process_order(
  p_order_id IN NUMBER,
  p_status IN VARCHAR2 DEFAULT 'NEW'
)
AS
BEGIN
  DBMS_OUTPUT.PUT_LINE('Processing Order ID: ' || p_order_id);
  DBMS_OUTPUT.PUT_LINE('Order Status: ' || p_status);
END;

SELECT index_of, arg_name, data_type, mode, is_optional,
       default_value
FROM db_stored_procedure_args
WHERE sp_name = 'process_order'
ORDER BY index_of;
```

```
::

mode          index_of  arg_name          data_type
is_optional  default_value

=====
=====
'IN'          'NO'        0  'p_order_id'      'NUMBER'
              NULL
'IN'          'YES'       1  'p_status'        'VARCHAR2'
```

## DB\_SERVER

| Attribute Name | Data Type    | Description                 |
|----------------|--------------|-----------------------------|
| link_name      | VARCHAR(255) | Connection name             |
| host           | VARCHAR(255) | Hostname of a server        |
| port           | INTEGER      | Connection port of a server |

| Attribute Name   | Data Type     | Description                                              |
|------------------|---------------|----------------------------------------------------------|
| db_name          | VARCHAR(255)  | Database name of a server                                |
| user_name        | VARCHAR(255)  | Database user name of a server                           |
| properties       | VARCHAR(2048) | Property information used for connection                 |
| owner            | VARCHAR(32)   | The name of the owner of this connection information     |
| comment          | VARCHAR(1024) | Comment to describe the server                           |
| created_time     | DATETIME      | Server creation time                                     |
| updated_time     | DATETIME      | Server modification time                                 |
| invalidated_time | DATETIME      | Time when the external server connection was invalidated |

## DB\_SYNONYM

Represents target object information for the synonym to which the current user has access authorization in the database.

| Attribute Name | Data Type    | Description             |
|----------------|--------------|-------------------------|
| synonym_name   | VARCHAR(255) | The name of the synonym |

| Attribute Name     | Data Type     | Description                                                |
|--------------------|---------------|------------------------------------------------------------|
| synonym_owner_name | VARCHAR(32)   | The owner of the synonym                                   |
| is_public_synonym  | VARCHAR(3)    | “YES” for a public synonym, and “NO” for a private synonym |
| target_name        | VARCHAR(255)  | The name of the target object                              |
| target_owner_name  | VARCHAR(32)   | The owner name of the target object                        |
| comment            | VARCHAR(2048) | Comment to describe the synonym                            |
| created_time       | DATETIME      | Synonym creation time                                      |
| updated_time       | DATETIME      | Synonym modification time                                  |

### Warning

It does not support public synonym yet.

## Catalog Class/Virtual Class Authorization

Catalog classes are created to be owned by **dba**. However, **dba** can only execute **SELECT** operations. If **dba** executes operations such as **UPDATE** / **DELETE**, an authorization failure error occurs. General users cannot execute queries on system catalog classes.

Although catalog virtual classes are created to be owned by **dba**, all users can perform the **SELECT** statement on catalog virtual classes. Of course, **UPDATE** / **DELETE** operations on catalog virtual classes are not allowed.

Updating catalog classes/virtual classes is automatically performed by the system when users execute a DDL statement that creates/modifies/deletes a class/attribute/index/user/authorization.

## Querying on Catalog

To query on catalog classes, you must convert identifiers such as class, virtual class, attribute, trigger, method and index names to lowercases, and create them. Therefore, you must use lowercases when querying on catalog classes. But, DB user name is changed as uppercases and stored into `_db_user` system catalog table.

```
CREATE TABLE Foo(name varchar(255));
SELECT class_name, partitioned FROM db_class WHERE class_name =
'Foo';
```

There are no results.

```
SELECT class_name, partitioned FROM db_class WHERE class_name =
'foo';
```

```
class_name  partitioned
=====
'foo'      'NO'
```

```
CREATE USER tester PASSWORD 'testpwd';
SELECT name, password FROM _db_user;
```

```
name          password
=====
'DBA'         NULL
'PUBLIC'      NULL
'TESTER'      _db_password
```

## CUBRID Procedural Language

This chapter introduces the procedural language extension features provided by CUBRID to develop stored procedures and functions.

CUBRID supports stored procedures and stored functions as procedural language extension features. Stored procedures and functions help handle complex business logic that is difficult to implement with SQL alone and simplify data manipulation tasks.

They offer the following major advantages:

- **Productivity and Usability:** Once created, stored procedures and stored functions can be reused repeatedly. Users can call them from SQL and also invoke them easily from applications using JDBC.
- **Performance:** Since stored procedures and functions run on the database server, they reduce network traffic and enhance the performance of the database server.
- **Security:** Stored procedures can be granted execution privileges to specific users, enabling fine-grained control over data access and modification.
- **Interoperability and Portability:** Stored procedures and functions are designed to work across various languages and execution environments, maximizing the usability of the database.

CUBRID supports the following two procedural languages for stored procedures/functions:

- PL/CSQL
- Java

The main contents described in this chapter are as follows:

- **Create a Stored Procedure:** Describes the creation of stored procedures and stored functions.
- **Call a Stored Procedure:** Describes how to call stored procedures and stored functions.
- **Stored Procedure Authorization:** Describes how to grant call permissions to other users and the difference between Owner's Rights and Caller's Rights.
- **Transaction Commit and Rollback Support:** Describes the use of transaction commit and rollback within stored procedures.
- **Performance Tuning:** Describes methods to achieve optimized performance when using stored procedures.
- **System Package:** Describes the system packages supported by CUBRID.
- **PL/CSQL:** Describes the overview and syntax of PL/CSQL, an extension of CUBRID's SQL procedural language.
- **Java Stored Procedure:** Describes how to develop stored procedures using the Java language.
- **Method:** Describes the methods, which are built-in functions of CUBRID.

## Create a Stored Procedure

Stored procedures and stored functions can be created using `CREATE PROCEDURE` and `CREATE FUNCTION` respectively. In CUBRID, there is no significant functional difference between stored procedures and stored functions. The only difference is that stored functions define a return type, whereas stored procedures have a return type of void and always return NULL.

This chapter provides a detailed explanation of the considerations when creating stored procedures and stored functions.

### Schema and Procedure Naming

```
CREATE [OR REPLACE] [PROCEDURE] [schema_name.]procedure_name  
CREATE [OR REPLACE] [FUNCTION] [schema_name.]function_name
```

The names of stored procedures and stored functions are identifiers and must be created according to the principles outlined in `Identifier`. The name is limited to a maximum length of 222 bytes, and exceeding this length will result in an error.

When specifying the name of a stored procedure or stored function, the schema name (**schema\_name**) does not need to be specified; it will be created and stored in the schema of the currently logged-in `user`. Users with DBA privileges can create stored procedures and stored functions in other users' schemas, but regular users can only create them in their own schemas.

If a regular user attempts to create stored procedures and stored functions in another user's schema, an error will occur.

```
-- Login as DBA  
CREATE USER U1;  
CREATE USER U2;  
CALL login ('U1', '') ON CLASS db_user;  
CREATE PROCEDURE u2.test_proc (arg1 INT, arg2 INT)  
AS BEGIN  
    DBMS_OUTPUT.put_line (arg1 + arg2);  
END;
```

```
ERROR: before ' ; '  
Only DBA, members of the DBA group, and the owner can perform CREATE  
PROCEDURE/FUNCTION.
```

## Specifying Parameters for Stored Procedures

Specifying parameters for stored procedures and stored functions allows for passing arguments when the procedure or function is called. When specifying parameters, you must specify the name and data type of the parameter, and you can specify up to **64** parameters.

Stored functions receive input parameters and return a result value, so you must specify a result data type. Stored procedures, on the other hand, are of the void type and always return NULL. The result data type for stored procedures and stored functions is a subset of the data types supported by CUBRID SQL ([Data Types](#)). For more information, refer to [Supported Data Types of Arguments and Return](#).

```
CREATE PROCEDURE test_proc (arg1 INT, arg2 INT)
AS BEGIN
    DBMS_OUTPUT.put_line (arg1 + arg2);
END;

CREATE FUNCTION test_func (arg1 INT, arg2 INT) RETURN INT
AS BEGIN
    RETURN arg1 + arg2;
END;

SELECT test_proc(1, 2);
SELECT test_func(1, 2);
```

```
test_proc(1, 2)
=====
NULL

<DBMS_OUTPUT>
====
3

test_func(1, 2)
=====
3
```

### Note

Only the names of the data types of the parameters or return values of stored procedures and stored functions can be specified. That is, precision and scale are not specified for types such as VARCHAR or NUMERIC. Precision and scale are determined variably according to the actual data passed at runtime.

```

create or replace function t (i_min VARCHAR, i_max VARCHAR) RETURN
VARCHAR as
    var_min VARCHAR(5) := i_min;
    var_max VARCHAR(5) := i_max;
begin
    return var_min || ',' || var_max;
end;

```

## Supported Data Types of Arguments and Return

Only a subset of the data types supported by CUBRID SQL can be specified for stored procedure/function arguments and return values. The following table shows the data types supported by language extensions:

| Type      | Data Type                       | Support Status (O, X) |         |
|-----------|---------------------------------|-----------------------|---------|
|           |                                 | PL/CSQL               | Java SP |
| Numeric   | SHORT, SMALLINT                 | O                     | O       |
|           | INTEGER, INT                    | O                     | O       |
|           | BIGINT                          | O                     | O       |
|           | NUMERIC, DECIMAL                | O                     | O       |
|           | FLOAT, REAL                     | O                     | O       |
|           | DOUBLE, DOUBLE PRECISION        | O                     | O       |
| Date/Time | DATE, TIME, TIMESTAMP, DATETIME | O                     | O       |

| Type       | Data Type                                                  | Support Status (O, X) |         |
|------------|------------------------------------------------------------|-----------------------|---------|
|            |                                                            | PL/CSQL               | Java SP |
|            | TIMESTAMPLTZ,<br>TIMESTAMPTZ<br>DATETIMELTZ,<br>DATETIMETZ | X                     | X       |
| String     | CHAR, VARCHAR,<br>STRING, CHAR<br>VARYING                  | O                     | O       |
| Collection | SET, MULTISSET, LIST,<br>SEQUENCE                          | X                     | O       |
| Other      | BIT, BIT VARYING                                           | X                     | X       |
|            | ENUM                                                       | X                     | X       |
|            | BLOB/CLOB                                                  | X                     | X       |
|            | JSON                                                       | X                     | X       |
|            | CURSOR                                                     | X                     | O*      |

\* In Java SP, only return types are supported for CURSOR, not argument types.

If an unsupported data type is used when creating a stored procedure, the following errors occur:

```
CREATE FUNCTION unsupported_json() RETURN JSON
AS BEGIN RETURN NULL; END;
```

```
CREATE PROCEDURE unsupported_args (arg TIMESTAMPLTZ)
AS BEGIN NULL; END;
```

```

ERROR: Unsupported return type 'json' of the stored procedure

ERROR: before ' )
AS BEGIN NULL; END; '
Unsupported argument type 'timestamp_tz' of the stored procedure

```

## Specifying the Mode of Arguments

The modes of arguments are IN, OUT, and IN OUT. If no mode is specified when specifying arguments, they are assumed to be IN mode by default.

Stored procedures and stored functions can use the **CALL** statement and OUT or IN OUT arguments to return the values of arguments that have been changed in the stored procedure or stored function.

```

CREATE OR REPLACE PROCEDURE test_proc (arg1 OUT INT)
AS BEGIN
    arg1 := 5;
END;

CREATE OR REPLACE FUNCTION test_func (arg1 IN OUT INT) RETURN INT
AS BEGIN
    arg1 := arg1 + 1;
    RETURN arg1 + 5;
END;

```

```

SELECT 1 into :a;
select :a;
CALL test_proc(:a);
select :a;

```

```

-- select :a;

      :a
=====
      1

-- select :a;

      :a
=====
      5

```

If you specify the OUT or IN OUT mode for any argument in a stored procedure or stored function, it can not be called within a query statement (**SELECT**, **UPDATE**, **DELETE**, etc.); it will return an error.

```
SELECT test_func(1);
```

```
In the command from line 1,  
ERROR: Semantic: Stored procedure/function 'u1.test_func' has OUT or  
IN OUT arguments
```

## Using Default Arguments

You can specify default values for the arguments of stored procedures and stored functions.

- You can specify default values using the **:=** or **DEFAULT** keywords.
- When a default value is specified, you can omit the argument when calling the stored procedure or function. The omitted argument will be replaced with the default value.
- Default values can be specified as literal values and are stored as string values up to 255 bytes. An error will occur if this size is exceeded.
- The following functions are allowed as default values in addition to literal values:

| Default Value     | Data Type |
|-------------------|-----------|
| SYS_TIMESTAMP     | TIMESTAMP |
| UNIX_TIMESTAMP()  | INTEGER   |
| CURRENT_TIMESTAMP | TIMESTAMP |
| SYS_DATETIME      | DATETIME  |
| CURRENT_DATETIME  | DATETIME  |
| SYS_DATE          | DATE      |

| Default Value                | Data Type |
|------------------------------|-----------|
| CURRENT_DATE                 | DATE      |
| SYS_TIME                     | TIME      |
| CURRENT_TIME                 | TIME      |
| USER, USER()                 | STRING    |
| TO_CHAR(date_time[, format]) | STRING    |
| TO_CHAR(number[, format])    | STRING    |

### Note

If a function that is not listed in the table above is used as a **DEFAULT** value, the result evaluated at the time of procedure creation is stored as a **DEFAULT** value. Therefore, the default value of the column will be the result value of the function at the time of **INSERT** execution, not the result value of the function at the time of procedure creation. Stored functions cannot be used as **DEFAULT** values, so an error will be returned.

```
CREATE FUNCTION fn_int (a int) return int as begin return a; end;

-- error
CREATE FUNCTION default_val_func_test (id INT DEFAULT fn_int (1))
return int as begin return id; end;
```

```
ERROR: before ' ); '
'fn_int(1)' function can not be used in DEFAULT clause.
```

Here is a simple example of specifying a literal value as a default:

```
CREATE FUNCTION default_args (
    a INT := 1,
```

```

        b INT DEFAULT 2
    ) RETURN INT
AS BEGIN RETURN a + b; END;

SELECT default_args();
SELECT default_args(3);
SELECT default_args(3, 4);

```

```

default_args()
=====
                3

default_args(3)
=====
                5

default_args(3, 4)
=====
                7

```

Here is an example of specifying a function as a default value:

```

CREATE FUNCTION get_age (
    birth DATE DEFAULT DATE '2000-01-01',
    today DATE DEFAULT SYS_DATE
) RETURN INT
AS
BEGIN
    RETURN YEAR(today) - YEAR(birth)
        - CASE WHEN TO_CHAR(today, 'MMDD') < TO_CHAR(birth, 'MMDD')
THEN 1 ELSE 0 END;
END;

SELECT get_age();
SELECT get_age(DATE '2000-05-10');
SELECT get_age(DATE '2000-05-10', DATE '2025-03-24');

```

```

get_age()
=====
                25

get_age(date '2000-05-10')
=====
                24

get_age(date '2000-05-10', date '2025-03-24')

```

## Function Overloading Not Supported

Function overloading is the process of defining multiple functions with the same name but different argument types or numbers. **CUBRID does not support function overloading.** This means that you cannot create multiple stored procedures or stored functions with the same name if they have different argument types or numbers. Therefore, when using the **CREATE OR REPLACE** statement, the new procedure will overwrite the existing procedure rather than create a new one; use it with caution to avoid accidental replacement.

```
CREATE FUNCTION test_func (arg1 INT) RETURN INT AS
BEGIN
    RETURN arg1;
END;

SELECT test_func (1);

CREATE OR REPLACE FUNCTION test_func (arg1 INT, arg2 INT) RETURN INT
AS
BEGIN
    RETURN arg1 + arg2;
END;

SELECT test_func (1); -- error
SELECT test_func (1, 2); -- 3
```

```
ERROR: Parameter count is invalid. expected: 2, actual: 1
```

```
test_func(1, 2)
=====
3
```

## Object Dependencies

The dependencies of stored procedures and stored functions on the database objects they internally reference are only checked when registering in PL/CSQL. Therefore, if the table, view, sequence, or index objects referenced in the PL/CSQL procedure do not exist, an error will occur when registering the procedure.

```
DROP TABLE IF EXISTS test_tbl;
```

```
CREATE OR REPLACE FUNCTION test_func () RETURN INT
    k INT;
AS
BEGIN
    SELECT id INTO k FROM test_tbl LIMIT 1;
    RETURN k;
END;
```

```
ERROR: Stored procedure compile error: Syntax: before '  LIMIT 1'
Unknown class "dba.test_tbl". select id from [dba.test_tbl] limit 1
```

The following example will create the test\_tbl table correctly.

```
DROP TABLE IF EXISTS test_tbl;
CREATE TABLE test_tbl (id INT);
INSERT INTO test_tbl VALUES (1);

CREATE OR REPLACE FUNCTION test_func () RETURN INT
AS
    k INT;
BEGIN
    SELECT id INTO k FROM test_tbl LIMIT 1;
    RETURN k;
END;

SELECT test_func();
```

```
test_func()
=====
          1
```

In the case of PL/CSQL Dynamic SQL or Java SP, the stored string is executed at runtime, so it is not examined when registering the procedure, and is instead validated when the procedure is called.

```
DROP TABLE IF EXISTS test_tbl;

CREATE OR REPLACE FUNCTION test_func () RETURN INT
AS
    k INT;
BEGIN
    execute immediate 'SELECT id FROM test_tbl LIMIT 1' INTO k;
    RETURN k;
END;
```

```
SELECT test_func();
```

```
ERROR: Stored procedure execute error:
(line 5, column 9) Syntax: before ' LIMIT 1'
Unknown class "dba.test_tbl". select id from [dba.test_tbl] limit 1
```

If an object referenced internally by a stored procedure or stored function is deleted, the system does not perform dependency checks, so even if the routine is registered correctly, an error may occur when the procedure is called. Therefore, you should be careful so that the object referenced by the stored procedure or stored function is not deleted.

```
DROP TABLE IF EXISTS test_tbl;
CREATE TABLE test_tbl (id INT);
INSERT INTO test_tbl VALUES (1);

CREATE OR REPLACE FUNCTION test_func () RETURN INT
AS
    k INT;
BEGIN
    SELECT id INTO k FROM test_tbl LIMIT 1;
    RETURN k;
END;

DROP TABLE IF EXISTS test_tbl;
SELECT test_func();
```

```
ERROR: Stored procedure execute error:
(line 5, column 9) Syntax: Unknown class "dba.test_tbl". select
[dba.test_tbl].id from [dba.test_tbl] [dba.test_tbl] ...
```

## Considerations for String Charset Encoding

All string data in CUBRID has a charset. In the CUBRID PL engine, string data within stored procedures and stored functions is handled using a single charset. No charset conversion occurs when string data is input or output. String data is processed according to the following rules:

- The charset of **string type argument values** is assumed to be the same as the database's charset.
- The charset of **string type result values** is assumed to be the same as the database's charset.
- The charset of **string literal values** is assumed to be the same as the database's charset.

- If the **result of an SQL query** is of string type, the value is internally converted from the column's charset to the database's charset.

#### **Note**

- The database's charset is specified using the **charset** option in the **cubrid createdb** utility and cannot be changed after creation.
- All operations that input or output strings in stored procedures/functions must use a charset that matches the database's charset to obtain correct results.

### **Example 1**

The following example demonstrates a case where a string type argument is combined with the literal value '한글' to return a result. It is assumed that the charset of the string type argument, result, and literal value is the same as the database's charset. Therefore, to execute the following SQL statement correctly, it must be stored and executed with UTF-8 encoding.

```
CREATE OR REPLACE FUNCTION test_func (arg VARCHAR) RETURN VARCHAR
AS
BEGIN
    RETURN arg || ',' || '한글';
END;

SELECT test_func('큐브리드');
```

```
test_func('큐브리드')
=====
큐브리드,한글
```

### **Example 2**

The charset used for the result of an SQL query generally follows the database's charset, but as explained in **Charset and Collation of Column**, each column in a table can have its own specified charset. In such cases, the following scenarios may occur:

- If the column charset and the database charset are the same: No conversion is needed.
- If the column charset and the database charset differ: CUBRID internally converts the charset to the database's charset. Be cautious as incorrect character conversion or data loss may occur during this process.

The following example demonstrates a case where a database set to UTF-8 has a table column specified with the EUC-KR charset. The string returned as a result of the query is internally converted from EUC-KR to UTF-8 before being combined with a string literal and returned.

```
-- This file should be saved in euc-kr, and '큐브리드' should be
written with euc-kr encoding.
CREATE TABLE tblcharcol (col STRING CHARSET euckr) COLLATE euckr_bin;
INSERT INTO tblcharcol VALUES ('큐브리드');
```

```
-- This file should be saved in utf-8, and '한글' should be written
with utf-8 encoding.
CREATE OR REPLACE FUNCTION test_func () RETURN VARCHAR
AS
    v VARCHAR;
BEGIN
    SELECT col INTO v FROM tblcharcol LIMIT 1;
    RETURN v || '한글';
END;

SELECT test_func();
```

```
test_func()
=====
큐브리드한글
```

## Call a Stored Procedure

Registered stored procedures and stored functions can be called using the **CALL** statement or in SQL statements. In general, stored procedures are called using the **CALL** statement, and stored functions are used in SQL statements where a return value is needed.

This chapter provides a detailed explanation of the considerations when calling stored procedures and stored functions.

## CALL Statement

You can call a stored procedure using the **CALL** statement as follows in the CSQL interpreter.

```
-- Execute in csql
CREATE PROCEDURE hello ()
AS
```

```

BEGIN
    DBMS_OUTPUT.put_line('Hello, CUBRID!');
END;

;server-output on

-- Call
CALL hello();

```

```

Result
=====
NULL

<DBMS_OUTPUT>
====
Hello, CUBRID!

```

## Calling in SQL Statements

In the case of calling in SQL statements, stored functions are typically used to return values. The following example shows how to calculate the number of medals for a specific country using a stored function.

```

CREATE FUNCTION count_medals(nation STRING) RETURN INT
AS
cnt INT;
BEGIN
    SELECT COUNT(*) INTO cnt
    FROM game
    WHERE nation_code = nation;
    RETURN cnt;
END;

SELECT count_medals('USA');
SELECT count_medals('KOR');

```

```

count_medals('USA')
=====
1118

count_medals('KOR')
=====
316

```

## Limitations on Nested Procedure Calls

The maximum allowed nested procedure call limit is **16**. Nested procedure call refers to calling another procedure from within a procedure. In the case of recursive calls, the limit is not applied.

The following is an example of the limitations on nested procedure calls.

```
CREATE OR REPLACE FUNCTION test_factorial_query(n BIGINT) RETURN
BIGINT
AS
k BIGINT;
BEGIN
    IF n = 0 THEN
        RETURN 1;
    ELSE
        SELECT test_factorial_query(n - 1) INTO k;
        RETURN n * k;
    END IF;
END;

SELECT test_factorial_query(15);
SELECT test_factorial_query(16);
```

```
test_factorial_query(15)
=====
1307674368000

-- SELECT test_factorial_query(16);
ERROR: Stored procedure execute error:
...
(line 8, column 13) Stored procedure execute error:
(line 8, column 13) Stored procedure execute error: Too many
nested stored procedure call.
```

The following is an example of a recursive call that does not go through a query. In this case, the nested call limit is not applied. Recursively calling the following example may result in an overflow of the BIGINT value or excessive use of system resources, so be careful.

```
CREATE OR REPLACE FUNCTION test_factorial_constant(n BIGINT) RETURN
BIGINT
AS
k BIGINT;
BEGIN
    IF n = 0 THEN
        RETURN 1;
    ELSE
        RETURN n * test_factorial_constant(n - 1);
    END IF;
END;
```

```

    END IF;
END;

SELECT test_factorial_constant(16);
SELECT test_factorial_constant(25);

```

```

test_factorial_constant(16)
=====
                20922789888000

-- SELECT test_factorial_constant(25);
ERROR: Stored procedure execute error:
      (line 8, column 20) data overflow in multiplication of BIGINT
values

```

## Stored Procedure Authorization

This chapter explains the permissions required to call a stored procedure and how to grant call permissions to other users. It also details the difference between Owner's Rights and Caller's Rights, specifying under which user's permissions the call is made.

### Granting Procedure Call Permission

When a stored procedure is created, it belongs to the schema of the user who created it, and only users with **owner** and **DBA** permissions can call it. If the owner of the stored procedure grants call permission to another user, the user granted permission can call the stored procedure of the other user.

The important thing to note is that if a routine that is not authorized is referenced in the implementation, it may result in a compilation or execution error. Therefore, it is necessary to check whether the stored procedure references authorized objects.

CUBRID allows you to grant call permission to a stored procedure using the **GRANT** statement.

```

GRANT EXECUTE ON PROCEDURE procedure_name TO user_name;

```

Conversely, you can revoke the execution privilege on a procedure by using the **REVOKE** statement.

```

REVOKE EXECUTE ON PROCEDURE procedure_name FROM user_name;

```

**Note**

Stored procedures and stored functions do not support the **EXECUTE ON PROCEDURE** permission with the **WITH GRANT OPTION** option. Therefore, the owner of the stored procedure cannot grant the permission to another user.

## The Difference Between Owner's Rights and Caller's Rights

When a stored procedure or function has call permission, it can specify which user's rights to execute it. Stored procedures and functions can be executed with either **Owner's Rights** or **Caller's Rights**. The execution rights can be chosen during the creation of the stored procedure or function, and it will be executed with the specified rights.

The following explains each type of rights and their differences:

### • Owner's Rights (also known as Definer's Rights)

- Executed with the rights of the user who created the stored procedure.
- If the creator grants rights to another user, the granted user can also execute the stored procedure.
- All rights of the owner of the stored procedure take effect, allowing it to access database objects that the owner has permission to access without requiring additional grants. If a stored procedure is created with the **DBA's** owner's rights, it can access all database objects, so special attention should be paid to security issues such as SQL Injection when using dynamic SQL.
- Suitable for common tasks or data access needs.

In contrast, Caller's Rights are as follows:

### • Caller's Rights (also known as Invoker's Rights)

- Executed with the rights of the caller, not the creator of the stored procedure.
- If a stored procedure is created with Caller's Rights and rights are granted to another user, it will be executed with the rights of the user calling the stored procedure.
- When a stored procedure is created with Caller's Rights, it is executed at the caller's rights level, not the creator's, allowing access to database objects at the caller's rights level. Therefore, when creating a stored procedure with Caller's Rights, the caller's rights level should be considered.
- Suitable when different rights need to be applied per caller.

Understanding the difference between Owner's Rights and Caller's Rights when creating stored procedures and utilizing them can lead to more efficient database management.

When creating a stored procedure or function, the **AUTHID** attribute can be specified to determine whether it operates with **Owner's Rights** or **Caller's Rights**. For detailed definitions, refer to [STORED FUNCTION/PROCEDURE DEFINITION STATEMENTS](#).

The **AUTHID** attribute can be specified as follows, with **DEFINER** and **OWNER** being synonyms, as well as **CURRENT\_USER** and **CALLER**.

- **Owner's Rights:** AUTHID DEFINER or AUTHID OWNER
- **Caller's Rights:** AUTHID CURRENT\_USER or AUTHID CALLER

If the attribute is not specified, it defaults to **Owner's Rights**.

The following is an example of logging in as a DBA user, creating a stored function with DBA Owner's Rights that returns **CURRENT\_USER**, **USER**, and calling it from user U1.

```
-- Login as DBA
CREATE USER U1;

CREATE OR REPLACE FUNCTION fn_current_user() RETURN STRING AUTHID
DEFINER AS
BEGIN
    RETURN CURRENT_USER;
END;

GRANT EXECUTE ON PROCEDURE fn_current_user TO U1;

CALL login ('U1', '') ON CLASS db_user;

SELECT dba.fn_current_user();
```

```
-- As shown, even when called by user U1, the result shows 'DBA@'
because the function executes with Owner's Rights

dba.fn_current_user()
=====
'DBA@<host>'
```

#### Warning

- Currently, CUBRID's PL/CSQL only supports **Owner's Rights**, and does not support **Caller's Rights**.

- To use **Caller's Rights**, stored procedures must be written using Java SP.

#### **Note**

- **Owner's Rights** are supported from CUBRID version 11.4.

## Transaction Commit and Rollback Support

In stored procedures and stored functions, transactions can be completed or aborted by **COMMIT** or **ROLLBACK**. This is an important feature that maintains data integrity and provides flexibility in transaction processing. The logic within stored procedures and functions can control transactions based on conditions or exception handling, which greatly aids in managing complex data logic safely and efficiently.

### Advantages of Condition and Exception Handling with Transaction Control

1. **Condition-Based Transaction Processing** Within stored procedures and functions, transactions can be committed or rolled back based on conditions. For example, if certain conditions are not met, a rollback can ensure data integrity.
2. **Safe Rollback on Exception Occurrence** If an error (exception) occurs within a stored procedure, the transaction can be rolled back, returning the operation to a safe state. This is useful for preventing data corruption in unexpected situations.
3. **Stability in Handling Complex Logic** Even while processing complex logic involving multiple operations, the success of a transaction can be clearly controlled based on the situation. This enhances the reliability of data processing.

### Example: Condition and Exception Handling with Transaction Control

The following is an example of controlling transactions using conditions and exception handling in a stored procedure.

```
;server-output on
```

```
CREATE TABLE orders (  
  id INT NOT NULL PRIMARY KEY,
```

```

    product VARCHAR(100) NOT NULL,
    quantity INT NOT NULL
);

CREATE TABLE inventory (
    product VARCHAR(100) NOT NULL PRIMARY KEY,
    stock INT NOT NULL
);

CREATE OR REPLACE PROCEDURE process_transaction()
AS
current_stock INT;
BEGIN
    INSERT INTO orders (id, product, quantity) VALUES (1,
'Laptop', 5);

    UPDATE inventory SET stock = stock - 5 WHERE product =
'Laptop';

    SELECT stock INTO current_stock FROM inventory WHERE product
= 'Laptop';

    IF current_stock < 0 THEN
        ROLLBACK;
        DBMS_OUTPUT.PUT_LINE('Transaction failed: Insufficient
stock.');
```

```

    ELSE
        COMMIT;
        DBMS_OUTPUT.PUT_LINE('Transaction successful.');
```

```

    END IF;
EXCEPTION
    WHEN OTHERS THEN
        ROLLBACK;
        DBMS_OUTPUT.PUT_LINE('Transaction failed: An error
occurred.');
```

```

END;
```

```

process_transaction ();

=== <Result of CALL Command in Line 2> ===

Result
=====
NULL

<DBMS_OUTPUT>
====
Transaction successful.
```

This example covers the following scenarios:

- Rollback the transaction to maintain data integrity if there is insufficient stock.
- Safely rollback the transaction if an exception occurs during the operation.
- Commit the transaction to complete the operation if conditions are met.

## Cautions

- In PL/CSQL, **COMMIT** and **ROLLBACK** statements are supported by default, allowing explicit control of transaction processing within stored procedures.
- However, in case of Java Stored Procedures, the **pl\_transaction\_control** setting is used to maintain backward compatibility, and COMMIT and ROLLBACK statements can only be used when the parameter is set to **yes**.
- The default value of **pl\_transaction\_control** is **no**, and COMMIT and ROLLBACK are ignored.

## Performance Tuning

Since stored procedures and stored functions are written by users, performance tuning may be necessary. This chapter provides various guides to optimize the performance of stored procedures and stored functions.

Contents

|                                                    |             |
|----------------------------------------------------|-------------|

| ● Use Deterministic Functions                      | 1422        |

## SQL Query Optimization

The most common performance overhead in stored procedures and stored functions can occur from inefficient SQL statement execution. You should sufficiently tune the SQL statements used in internal routines to prevent the following inefficiencies:

- **Table Full Scan:** Performance can degrade if the entire table is scanned without using an index.
- **Communication Overhead:** To reduce communication overhead between the CUBRID database server and the CUBRID PL server, you should write queries to return the minimum number of records.
- **Inefficient Query Calls within Loops:** When using loops within stored procedures and stored functions, it is recommended to fetch data with a single query instead of calling multiple queries within the loop.

To tune inefficient queries used in stored procedures and stored functions, refer to the [Join Methods](#) document for query optimization.

## Optimization of Stored Function Calls in Queries

Unnecessary repeated calls to stored functions executed in queries can degrade performance. Therefore, consider the following methods to optimize stored function calls:

- **Minimize Unnecessary Repeated Calls: Reducing the number of calls to stored functions is the best way to improve performance.**
  - Use indexes to reduce the number of records for which the stored function is called.
  - Group duplicate data to handle it with a single call for avoiding repeated calls for the same arguments.
  - If the function logic is deterministic, use [Use Deterministic Functions](#) to improve performance by caching the results of correlated subqueries.
- **Minimize the Size of Function Arguments and Return Values:** Design the function to return only the necessary values, avoiding the return of unnecessarily large data.

## Use Built-in Functions

Built-in functions provided by CUBRID ([Operators and Functions](#)) are optimized to work efficiently with CUBRID's query execution behavior. On the other hand, user-written stored functions are **black boxes** whose internal routines are unknown, and thus may perform worse than built-in functions. Therefore, it is recommended to use built-in functions rather than implementing stored functions that can be achieved with simple combinations of built-in functions.

Below is an example of a stored function that performs the same function as the built-in CONCAT function. Using the built-in function `concat()` has performance advantages over the user-defined stored function `my_concat()`.

```
CREATE OR REPLACE FUNCTION my_concat (a STRING, b STRING) RETURN
STRING AS
BEGIN
    RETURN a || b;
END;

SELECT COUNT(*) FROM (SELECT /*+ NO_MERGE */ concat (name, event)
FROM athlete);

SELECT COUNT(*) FROM (SELECT /*+ NO_MERGE */ my_concat (name, event)
FROM athlete);
```

```
-- Using concat function
              count(*)
=====
              6677

1 row selected. (0.019853 sec) Committed. (0.000000 sec)

-- Using my_concat function
              count(*)
=====
              6677

1 row selected. (0.302333 sec) Committed. (0.000000 sec)
```

## Use Deterministic Functions

A deterministic function is a function that always returns the same result for the same arguments during a transaction. If a stored function is deterministic, its results can be reused to improve performance.

- To make a stored function deterministic, you can specify the **DETERMINISTIC** option in the **CREATE FUNCTION** statement. For more details, refer to [CREATE FUNCTION](#).
- When the **DETERMINISTIC** attribute is specified, the stored function can be used for correlated subquery result caching optimization and will always return the same result for the same arguments. For more details on correlated subquery cache behavior, refer to [SUBQUERY CACHE \(correlated\)](#).

Below is an example of a stored function created as a deterministic function with **DETERMINISTIC**. This example shows the process of optimizing performance by caching results when using correlated subqueries.

```
CREATE TABLE dummy_tbl (col1 INTEGER);
INSERT INTO dummy_tbl VALUES (1), (2), (1), (2);

CREATE OR REPLACE FUNCTION pl_csql_not_deterministic (n INTEGER)
RETURN INTEGER AS
BEGIN
    return n + 1;
END;

CREATE OR REPLACE FUNCTION pl_csql_deterministic (n INTEGER) RETURN
INTEGER DETERMINISTIC AS
BEGIN
    return n + 1;
END;

SELECT sp_name, owner, sp_type, is_deterministic from
db_stored_procedure;
```

```
      sp_name                owner
sp_type                is_deterministic
=====
=====
      'pl_csql_not_deterministic'  'DBA'
'FUNCTION'                'NO'
      'pl_csql_deterministic'     'DBA'
'FUNCTION'                'YES'
```

In the above example, the `pl_csql_not_deterministic` function does not use query caching in correlated subqueries because it is **NOT DETERMINISTIC**. On the other hand, the `pl_csql_deterministic` function uses query caching in correlated subqueries because it is specified with the **DETERMINISTIC** keyword, optimizing performance.

```
;trace on
SELECT (SELECT pl_csql_not_deterministic (t1.col1) FROM dual) AS
results FROM dummy_tbl t1;
```

```
      results
=====
          2
          3
          2
          3
```

```

=== Auto Trace ===
...
Trace Statistics:
  SELECT (time: 4, fetch: 11, fetch_time: 0, ioread: 0)
    FUNC (time: 4, fetch: 2, ioread: 0, calls: 4)
      SCAN (table: dba.dummy_tbl), (heap time: 0, fetch: 5, ioread:
0, readrows: 4, rows: 4)
        SUBQUERY (correlated)
          SELECT (time: 4, fetch: 6, fetch_time: 0, ioread: 0)
            FUNC (time: 4, fetch: 2, ioread: 0, calls: 4)
              SCAN (table: dual), (heap time: 0, fetch: 4, ioread: 0,
readrows: 4, rows: 4)

```

The `pl_csql_not_deterministic` function does not cache the results of correlated subqueries because it is **NOT DETERMINISTIC**.

```

;trace on
SELECT (SELECT pl_csql_deterministic (t1.col1) FROM dual) AS results
FROM dummy_tbl t1;

```

```

      results
=====
          2
          3
          2
          3

=== Auto Trace ===
...
Trace Statistics:
  SELECT (time: 2, fetch: 9, fetch_time: 0, ioread: 0)
    FUNC (time: 2, fetch: 2, ioread: 0, calls: 2)
      SCAN (table: dba.dummy_tbl), (heap time: 0, fetch: 5, ioread:
0, readrows: 4, rows: 4)
        SUBQUERY (correlated)
          SELECT (time: 2, fetch: 4, fetch_time: 0, ioread: 0)
            FUNC (time: 2, fetch: 2, ioread: 0, calls: 2)
              SCAN (table: dual), (heap time: 0, fetch: 2, ioread: 0,
readrows: 2, rows: 2)
                SUBQUERY_CACHE (hit: 2, miss: 2, size: 150808, status:
enabled)

```

In the trace results of the `pl_csql_deterministic` function, the **SUBQUERY\_CACHE** item is displayed (hit: 2, miss: 2, size: 150808, status: enabled), and the number of records read (**readrows**) in the **SCAN (table: dual)** at the top is reduced compared to the **NOT DETERMINISTIC** example.

**Warning**

- The **DETERMINISTIC** attribute is not supported in stored procedures.
- If a function that returns non-deterministic results is used the **DETERMINISTIC** option, it may not return the expected results.

```
CREATE TABLE test_table (
  id INT AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(100)
);

INSERT INTO test_table (name) VALUES
('Alice'),
('Bob'),
('Charlie'),
('Alice'),
('Bob');

CREATE SERIAL my_serial;
CREATE OR REPLACE FUNCTION cnt_name (name VARCHAR) RETURN VARCHAR
DETERMINISTIC AS BEGIN RETURN name || my_serial.NEXT_VALUE; END;

SELECT
id,
name,
(SELECT cnt_name(name) FROM DUAL) AS result
FROM test_table;
```

| id | name      | result     |
|----|-----------|------------|
| 1  | 'Alice'   | 'Alice1'   |
| 2  | 'Bob'     | 'Bob2'     |
| 3  | 'Charlie' | 'Charlie3' |
| 4  | 'Alice'   | 'Alice1'   |
| 5  | 'Bob'     | 'Bob2'     |

In the above example, the `my_serial.NEXT_VALUE` inside the `cnt_name` function returns non-deterministic results, so it returns unexpected results due to the correlated subquery cache. It is recommended to specify the **DETERMINISTIC** option considering the implementation of the stored function.

## System Package

CUBRID provides system packages for user convenience. More packages will be added in future versions to expand CUBRID's functionality, but currently, only the DBMS\_OUTPUT package is available.

### DBMS\_OUTPUT

The DBMS\_OUTPUT package provides functionality to store and read string messages in the DBMS\_OUTPUT buffer. Developers of stored procedures/functions can use the PUT\_LINE or PUT functions of this package to accumulate relevant messages in the DBMS\_OUTPUT buffer. Client tools like CSQL or DBeaver use the ENABLE, DISABLE, GET\_LINE, and GET\_LINES functions of this package to activate/deactivate the message storage feature and retrieve messages accumulated in the buffer. Developers can effectively use these messages for monitoring program progress or debugging.

This section explains the usage and examples of the DBMS\_OUTPUT package. The functions of the DBMS\_OUTPUT package are as follows:

- DBMS\_OUTPUT.ENABLE
- DBMS\_OUTPUT.DISABLE
- DBMS\_OUTPUT.PUT
- DBMS\_OUTPUT.PUT\_LINE
- DBMS\_OUTPUT.NEW\_LINE
- DBMS\_OUTPUT.GET\_LINE
- DBMS\_OUTPUT.GET\_LINES

#### DBMS\_OUTPUT.ENABLE

##### DBMS\_OUTPUT.ENABLE(*size*)

Enable the DBMS\_OUTPUT message buffer and sets the size of the buffer to store messages.

**Parameters:**

**size** – Specifies the size of the buffer in bytes. The maximum size is 32767 bytes, and exceeding this value will result in an error.

#### Note

Calling **server-output on** in the CSQL interpreter is internally equivalent to calling the default DBMS\_OUTPUT.ENABLE(20000). For more details, refer to [CSQL session command server-output](#).

## DBMS\_OUTPUT.DISABLE

### DBMS\_OUTPUT.DISABLE()

Clears the messages stored in the current buffer and deactivates it. Consequently, no output will appear even if other procedures in the DBMS\_OUTPUT package are called.

#### Note

Calling **server-output off** in the CSQL interpreter is internally equivalent to calling DBMS\_OUTPUT.DISABLE(). For more details, refer to [CSQL session command server-output](#).

## DBMS\_OUTPUT.PUT

### DBMS\_OUTPUT.PUT(*str* VARCHAR)

Stores the specified string in the buffer without a newline.

#### Parameters:

**str** – Specifies the string to store. If the string to store is NULL, no action is taken.

## DBMS\_OUTPUT.PUT\_LINE

### DBMS\_OUTPUT.PUT\_LINE(*line* VARCHAR)

Stores the specified string in the buffer and adds a newline.

**Parameters:**

**line** – Specifies the string to store. If the string to store is NULL, no action is taken.

## DBMS\_OUTPUT.NEW\_LINE

### DBMS\_OUTPUT.NEW\_LINE()

Adds a newline character to the buffer. After adding a string with the PUT function, call the NEW\_LINE function to read it line by line with GET\_LINE.

## DBMS\_OUTPUT.GET\_LINE

### DBMS\_OUTPUT.GET\_LINE(*line OUT VARCHAR, status OUT INTEGER*)

Reads the first line of the string message stored in the buffer. The read line is then deleted from the buffer.

**Parameters:**

- **line** – Stores the string read from the buffer.
- **status** – Stores 0 if the string is successfully read, otherwise stores 1.

## DBMS\_OUTPUT.GET\_LINES

### DBMS\_OUTPUT.GET\_LINES(*lines OUT VARCHAR, num\_lines IN OUT INTEGER*)

Reads the specified number of lines of string messages stored in the buffer. The read lines are deleted from the buffer.

**Parameters:**

- **lines** – Stores the string read from the buffer.
- **numlines** – Specifies the number of lines to read.

## Usage Example

The following is a simple example of using the DBMS\_OUTPUT package with the CSQL interpreter. The PUT\_LINE function is used by the stored function developer, and the ENABLE, DISABLE, GET\_LINE functions are used internally by the CSQL interpreter for functionality implementation.

```
;server-output on  -- CSQL internally calls DBMS_OUTPUT.ENABLE

CREATE OR REPLACE FUNCTION test() RETURN VARCHAR
AS
BEGIN
    DBMS_OUTPUT.PUT_LINE('Hello, World!');
    DBMS_OUTPUT.PUT_LINE('Hello, CUBRID!');
    DBMS_OUTPUT.PUT_LINE('Hello, DBMS_OUTPUT!');
    RETURN 'Success';
END;

SELECT test();

;server-output off  -- CSQL internally calls DBMS_OUTPUT.DISABLE
```

```
test ()
=====
'Success'

<DBMS_OUTPUT>      <-- CSQL internally calls DBMS_OUTPUT.GET_LINE
multiple times to retrieve messages for output
===
Hello, World!
Hello, CUBRID!
Hello, DBMS_OUTPUT!
```

## PL/CSQL

CUBRID supports the development of stored functions and procedures using PL/CSQL (Procedural Language extension of CUBRID SQL). PL/CSQL is an extension of CUBRID SQL to a procedural language, supporting procedural language features such as conditional statements, loops, variables, error handling, and modularization through internal procedures/functions, which are difficult to implement with declarative SQL alone. Of course, SQL statements can be included and used together within a PL/CSQL program.

## Overview

## Creating Stored Procedures/Functions

PL/CSQL is used to create stored procedures and stored functions. The behavior of the stored procedure or function to be created is described by writing PL/CSQL code after the AS (or IS) keyword in the CREATE PROCEDURE or CREATE FUNCTION statement.

```
<create_procedure> ::=
    CREATE [ OR REPLACE ] PROCEDURE [schema_name.]<identifier> [ (
<seq_of_parameters> ) ]
    [ <procedure_properties> ] { IS | AS } [ LANGUAGE PLCSQL ] [
<seq_of_declare_specs> ] <body> ;
<create_function> ::=
    CREATE [ OR REPLACE ] FUNCTION [schema_name.]<identifier> [ (
<seq_of_parameters> ) ] RETURN <type_spec>
    [ <function_properties> ] { IS | AS } [ LANGUAGE PLCSQL ] [
<seq_of_declare_specs> ] <body> ;
```

In the above syntax, the *body* of a stored procedure/function contains PL/CSQL statements. The declaration section, *seq\_of\_declare\_specs*, declares variables, constants, exceptions, etc., that will be used within the execution statements. For more details on these syntax elements, refer to [CREATE PROCEDURE](#), [CREATE FUNCTION](#), [Declarations](#) and [Statements](#).

Stored procedures/functions are always executed with auto-commit disabled. This applies even if the auto-commit feature is enabled in the calling session.

Stored procedures/functions cannot have the same name as any [CUBRID built-in functions](#). Declaring a procedure or function with the same name as a built-in function will result in a compilation error during the execution of the **CREATE** statement.

The following are examples of stored procedures/functions written using PL/CSQL.

```
CREATE OR REPLACE PROCEDURE insert_athlete(
    p_name VARCHAR,
    p_gender VARCHAR,
    p_nation_code VARCHAR,
    p_event VARCHAR)
AS
BEGIN
    INSERT INTO athlete (name, gender, nation_code, event)
    VALUES (p_name, p_gender, p_nation_code, p_event);

    COMMIT;
EXCEPTION
    WHEN OTHERS THEN
        ROLLBACK;
END;
```

```

CREATE OR REPLACE PROCEDURE delete_athlete(c INTEGER)
AS
    n_deleted INTEGER;
BEGIN
    DELETE FROM athlete
    WHERE code = c;

    n_deleted := SQL%ROWCOUNT;  -- number of deleted rows
    DBMS_OUTPUT.put_line(n_deleted || ' rows deleted');
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.put_line('exception occurred');
END;

```

```

CREATE OR REPLACE FUNCTION fibonacci(n INTEGER) RETURN INTEGER
IS
    invalid_input EXCEPTION;
BEGIN
    IF n <= 0 THEN
        RAISE invalid_input;
    END IF;

    IF n = 1 OR n = 2 THEN
        RETURN 1;
    ELSE
        RETURN fibonacci(n-1) + fibonacci(n-2);
    END IF;
EXCEPTION
    WHEN invalid_input THEN
        DBMS_OUTPUT.put_line('invalid input: ' || n);
        RETURN -1;
    WHEN OTHERS THEN
        DBMS_OUTPUT.put_line('unknown exception');
        RETURN -1;
END;

```

In the above examples, the `DBMS_OUTPUT.put_line()` statement stores the given string argument in the server's `DBMS_OUTPUT` buffer. If the argument is not of a string type, it is converted to a string before being stored. The string messages stored in the `DBMS_OUTPUT` buffer can be viewed in `CSQL` by executing the session command `;server-output on`. For more details, refer to [CSQL session command server-output](#).

When executing a `CREATE PROCEDURE/FUNCTION` statement, various rules related to the syntax and execution semantics of the stored procedure/function are checked. If any errors are found during this process, an error message is displayed indicating the location and cause of the error. The following is an example of a stored procedure containing errors and compiling it emits an error message.

```
CREATE OR REPLACE PROCEDURE athlete_code(p_name VARCHAR) AS
BEGIN
    -- Error: Static SQL SELECT statement must have an INTO clause
    SELECT code
    FROM athlete a
    WHERE a.name = p_name;
END;

ERROR: In line 4, column 5
Stored procedure compile error: SELECT statement must have an INTO
clause

0 command(s) successfully processed.
```

## Static SQL

Static SQL refers to SQL statements that are written directly within the code rather than being written in a string. It is a type of SQL where the access method is predefined, allowing syntax and semantics checks to be performed at compile time.

Although it has the drawback of being inflexible, it has the advantage of being optimized at compile time, making it faster and more efficient than Dynamic SQL, where the access method is determined at runtime.

The following SQL statements can be used directly as PL/CSQL statements:

- SELECT (including CTE, UNION, INTERSECT, MINUS)
- INSERT, UPDATE, DELETE, MERGE, REPLACE
- COMMIT, ROLLBACK
- TRUNCATE

For detailed syntax and meanings, refer to [CUBRID SQL](#). SQL statements not included in the above list cannot be used directly, but they can be executed using the Dynamic SQL statements described below.

The SELECT statement can be used not only as an execution statement but also when [declaring a cursor](#) or in the [OPEN-FOR](#) statement. The INTO clause of a SELECT statement can be used to store query results in program variables or OUT parameters. In this case, the number of retrieved values must match the number of variables or OUT parameters in the INTO clause, and the values must have types that can be assigned to the corresponding variables or OUT parameters.

When using a SELECT statement as an execution statement, the INTO clause must be included. However, when using a SELECT statement in a **cursor declaration** or an **OPEN-FOR** statement, the INTO clause may not be included.

```
CREATE OR REPLACE PROCEDURE test_into_clause_1
AS
    h int;
    s varchar(10);
    CURSOR c IS SELECT host_year, score INTO h, s FROM history;
-- Error: INTO clause
BEGIN
    ...
END;

CREATE OR REPLACE PROCEDURE test_into_clause_2
AS
    h int;
    s varchar(10);
    r SYS_REFCURSOR;
BEGIN
    OPEN r FOR SELECT host_year, score INTO h, s FROM history;
-- Error: INTO clause
    ...
END;

CREATE OR REPLACE PROCEDURE test_into_clause_3
AS
BEGIN
    SELECT host_year, score FROM history WHERE event_code = 20023;
-- Error: no INTO clause
    ...
END;
```

The query result of a SELECT statement without an INTO clause must be a single record. If more than one record is returned, a *TOO\_MANY\_ROWS* exception occurs. If no records are found, a *NO\_DATA\_FOUND* exception occurs.

In places where values are required, such as in the WHERE clause or VALUES clause of a Static SQL statement, variables, constants, and procedure/function parameters declared in PL/CSQL can be used. However, these must not have the *BOOLEAN* or *SYS\_REFCURSOR* type, as they are not included in **SQL Data Types**.

For Static SQL, the **DBLink** feature is supported for SELECT statements, but it is not supported for DML statements (INSERT, UPDATE, DELETE, MERGE, REPLACE). To use the DBLink feature inside DML statements, you have to use Dynamic SQL described below.

```
CREATE OR REPLACE PROCEDURE test_dblink_in_dml
AS
```

```
BEGIN
  INSERT INTO athlete@remote_svr(name, gender, nation_code, event)
  VALUES ('Park Taehwan', 'M', 'KOR', 'Swimming');
END;
```

In line 4, column 8,

```
ERROR: Stored procedure compile error: Semantic: before '
VALUES ('Park Taehwan', 'M', 'KOR', 'Swimming')'
DBLink DML is not yet supported for PL/CSQL Static SQL.
```

The following is an example of using Static SQL.

```
CREATE OR REPLACE FUNCTION get_medal_count(p_name VARCHAR, p_medal
CHAR) RETURN INTEGER
AS
  n INTEGER;
BEGIN
  -- SELECT statement as a regular execution statement
  SELECT COUNT(medal)
  INTO n
  FROM athlete a, record r
  WHERE a.code = r.athlete_code /* Join condition */
  AND a.name = p_name AND r.medal = p_medal; /* Filter
condition */

  RETURN n;
END;
```

```
CREATE OR REPLACE PROCEDURE athlete_history(p_name VARCHAR)
AS
BEGIN
  -- SELECT statement inside a FOR loop
  FOR r IN (SELECT host_year, score FROM history WHERE athlete =
p_name) LOOP
    DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);
  END LOOP;
END;
```

```
CREATE OR REPLACE PROCEDURE athlete_history(p_name VARCHAR)
AS
  -- SELECT statement in cursor definition
  CURSOR my_cursor IS
  SELECT host_year, score
  FROM history
  WHERE athlete = p_name;
BEGIN
```

```
FOR r IN my_cursor LOOP
    DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);
END LOOP;
END;
```

If an error occurs during the execution of Static SQL, an `SQL_ERROR` exception is raised.

## Dynamic SQL

Dynamic SQL refers to SQL statements that are stored in strings and executed by constructing the corresponding SQL string at runtime and executing it using the `EXECUTE IMMEDIATE` statement.

Dynamic SQL is mainly required in the following two cases:

- When it is difficult or impossible to determine the SQL statement at the time of program development
- When executing statements that are not supported by Static SQL, such as DDL statements

In the example below, the new table name includes a procedure parameter, which means it cannot be determined at the time of program development and is only decided at runtime. Additionally, the `DROP TABLE` and `CREATE TABLE` statements are DDL statements, which are not supported by Static SQL.

```
CREATE OR REPLACE PROCEDURE collect_athlete_history(p_name VARCHAR)
AS
    new_table VARCHAR := p_name || '_history';
BEGIN
    EXECUTE IMMEDIATE 'drop table if exists ' || new_table;
    EXECUTE IMMEDIATE 'create table ' || new_table || ' like
history';
    EXECUTE IMMEDIATE 'insert into ' || new_table || ' select * from
history where athlete = ?'
    USING p_name;
END;
```

## Writing Rules

When writing identifiers, reserved words, comments, and literals, follow the rules of [SQL writing rules](#) within [Static/Dynamic SQL](#).

The rules for writing Non-static/dynamic SQL statements in PL/SQL mostly follow the same rules, but there are some exceptions:

- Unlike SQL, the # symbol cannot be used in identifiers. That is, identifiers must consist only of English letters (uppercase and lowercase), Korean letters, digits, and the underscore (\_).
- Even if enclosed in double quotes, square brackets, or backticks, special characters cannot be used in identifiers. Only English letters (uppercase and lowercase), Korean letters, digits, and underscores (\_) are allowed.
- Bit string literals cannot be used.

#### Examples of Allowed Identifiers

```
a
a_b
athleteName2
"select"      -- Reserved word enclosed in double quotes
```

#### Examples of Disallowed Identifiers

```
1a      -- Starts with a digit
a@b     -- Contains special character
athlete-name-2 -- Contains special character
[a@b]   -- Special characters not allowed even within [ ]
select  -- Reserved word
```

PL/CSQL reserved words are listed in the table below. In Non-static/dynamic SQL statements, the words in the table below cannot be used as identifiers representing variables, constants, exceptions, internal procedures/functions, etc. However, as in SQL statements, they can be used as identifiers if enclosed in double quotes (" "), square brackets ([ ]), or backticks (` `). Inside Static/Dynamic SQL, the list below does not apply; instead, the **CUBRID reserved word list** applies, which is used for general SQL statements.

|                        |         |        |         |
|------------------------|---------|--------|---------|
| ADDDATE                | AND     | AS     | AUTHID  |
| AUTONOMOUS_TRANSACTION |         |        |         |
| BEGIN                  | BETWEEN | BIGINT | BOOLEAN |
| BOTH                   | BY      |        |         |

|                 |                  |               |             |
|-----------------|------------------|---------------|-------------|
| CALLER          | CASE             | CAST          | CHAR        |
| CHARACTER       | CHR              | CLOSE         | COMMENT     |
| COMMIT          | CONSTANT         | CONTINUE      | CREATE      |
| CURRENT_USER    | CURSOR           |               |             |
| DATE            | DATETIME         | DATETIMELTZ   | DATETIME TZ |
| DATE_ADD        | DATE_SUB         | DAY           | DAY_HOUR    |
| DAY_MILLISECOND | DAY_MINUTE       | DAY_SECOND    | DBMS_OUTPUT |
| DEC             | DECIMAL          | DECLARE       | DEFAULT     |
| DEFINER         | DELETE           | DETERMINISTIC | DIV         |
| DOUBLE          |                  |               |             |
| ELSE            | ELSIF            | END           | ESCAPE      |
| EXCEPTION       | EXECUTE          | EXIT          | EXTRACT     |
| FALSE           | FETCH            | FLOAT         | FOR         |
| FROM            | FUNCTION         |               |             |
| HOUR            | HOUR_MILLISECOND | HOUR_MINUTE   | HOUR_SECOND |
| IF              | IMMEDIATE        | IN            | INOUT       |

|                    |                        |                         |                        |
|--------------------|------------------------|-------------------------|------------------------|
| INSERT             | INT                    | INTEGER                 | INTERNAL               |
| INTO               | IS                     | ISO88591                | LANGUAGE               |
| LEADING            | LIKE                   | LIST                    | LOOP                   |
| MERGE              | MILLISECOND            | MINUTE                  | MINUTE_MILLISECON<br>D |
| MINUTE_SECOND      | MOD                    | MONTH                   | MULTISET               |
| NOT                | NULL                   | NUMERIC                 |                        |
| OF                 | OPEN                   | OR                      | OUT                    |
| OWNER              |                        |                         |                        |
| PLCSQL             | POSITION               | PRAGMA                  | PRECISION              |
| PROCEDURE          |                        |                         |                        |
| QUARTER            |                        |                         |                        |
| RAISE              | REAL                   | REPLACE                 | RETURN                 |
| REVERSE            | ROLLBACK               | RAISE_APPLICATION_ERROR |                        |
| SECOND             | SECOND_MILLISECON<br>D | SEQUENCE                | SELECT                 |
| SECOND_MILLISECOND | SEQUENCE               | SELECT                  | SET                    |

|              |               |           |               |
|--------------|---------------|-----------|---------------|
| SETEQ        | SETNEQ        | SHORT     | SMALLINT      |
| SQL          | SQLCODE       | SQLERRM   | STRING        |
| SUBDATE      | SUBSET        | SUBSETEQ  | SUPERSET      |
| SUPERSETEQ   | SYS_REFCURSOR |           |               |
| THEN         | TIME          | TIMESTAMP | TIMESTAMPPLTZ |
| TIMESTAMPPTZ | TRAILING      | TRIM      | TRUE          |
| TRUNCATE     |               |           |               |
| UPDATE       | USING         | UTF8      |               |

The CREATE PROCEDURE/FUNCTION statement for creating PL/CSQL stored procedures/functions goes through a separate PL/CSQL syntax check, not the general SQL syntax check, and a different set of reserved words is applied. However, up to the AS/IS keywords, the general SQL syntax check also applies, so the **CUBRID reserved word list** is also in effect there.

In the following example, the parameter name *add* is not a PL/CSQL reserved word, but since it is a CUBRID reserved word, it causes a syntax error.

```
CREATE OR REPLACE PROCEDURE test_cubrid_reserved_word(add INT) AS
BEGIN
    NULL;
END;

ERROR: invalid create procedure
... ..
```

Among the list above, *AUTONOMOUS\_TRANSACTION* is a reserved word that is pre-included for functionality to be added in the future.

## Data Types

In Static/Dynamic SQL, all **data types** provided by SQL can be used.

On the other hand, in Non-static/dynamic SQL, only *BOOLEAN*, *SYS\_REFCURSOR*, and a subset of SQL-provided data types can be used.

- *BOOLEAN*: Can have values TRUE, FALSE, or NULL. Since the *BOOLEAN* type is not supported in SQL, it cannot be used as a parameter or return type in the *CREATE PROCEDURE/FUNCTION* statement. However, it *can* be used as a parameter or return type when declaring **local procedures/functions**.
- *SYS\_REFCURSOR*: Used when declaring cursor variables. For usage of cursor variables, see the **OPEN-FOR** statement. Similar to *BOOLEAN*, *SYS\_REFCURSOR* cannot be used as a parameter or return type in the *CREATE PROCEDURE/FUNCTION* statement, but it *can* be used in **local procedures/functions**.

Among the data types provided by SQL, some are supported and others are not in PL/CSQL. (As noted above, all SQL-provided data types *can* be used in Static/Dynamic SQL.)

| Category  | Supported Types                                                                                                | Unsupported Types                                      |
|-----------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Numeric   | SHORT, SMALLINT,<br>INTEGER, INT,<br>BIGINT,<br>NUMERIC, DECIMAL,<br>FLOAT, REAL,<br>DOUBLE, DOUBLE PRECISION, |                                                        |
| Date/Time | DATE, TIME, TIMESTAMP,<br>DATETIME,                                                                            | TIMESTAMPTZ,<br>TIMESTAMPTZ,<br>DATETIMETZ, DATETIMETZ |

| Category   | Supported Types                        | Unsupported Types                                            |
|------------|----------------------------------------|--------------------------------------------------------------|
| String     | CHAR, VARCHAR, STRING,<br>CHAR VARYING |                                                              |
| Collection |                                        | SET, MULTISET, LIST,<br>SEQUENCE                             |
| Others     |                                        | BIT, BIT VARYING,<br><br>ENUM,<br><br>BLOB/CLOB,<br><br>JSON |

## %TYPE

Appending `%TYPE` after a table column name allows you to reference the data type of that column. Below is an example using `%TYPE`.

```
CREATE OR REPLACE FUNCTION get_athlete_name(p_code
athlete.code%TYPE) RETURN athlete.name%TYPE
AS
    name athlete.name%TYPE;
BEGIN
    SELECT a.name
    INTO name
    FROM athlete a
    WHERE a.code = p_code;

    RETURN name;
END;
```

`<table>.<column>%TYPE` represents the data type of the specified table column at the time the `CREATE PROCEDURE/FUNCTION` statement is executed. However, if the column's data type is later changed, it will *not* be automatically reflected in the behavior of stored procedures/functions that use `<table>.<column>%TYPE`. Therefore, when the data type of a column using `%TYPE` is

changed, you must recompile all stored procedures/functions that use that *%TYPE* by executing *ALTER PROCEDURE/FUNCTION <name> COMPILE*.

In addition to table columns, *%TYPE* can also be appended to procedure/function parameter or variable names to represent their data types.

```
...  
a VARCHAR(10);  
a_like a%TYPE;    -- Declares variable a_like with the same type as  
variable a  
...
```

### *%ROWTYPE*

Appending *%ROWTYPE* after a table name represents a record type composed of fields that have the same names and types as the columns of that table. For example, for a table *tbl* declared as follows:

```
CREATE TABLE tbl(a INT, b CHAR, c VARCHAR);
```

Declaring a variable *r* with the type *tbl%ROWTYPE*:

```
r tbl%ROWTYPE;
```

The value of *r* becomes a record with fields *a*, *b*, and *c*, and *r.a*, *r.b*, and *r.c* will be of types *INT*, *CHAR*, and *VARCHAR*, respectively.

You can also append *%ROWTYPE* to a cursor name. In this case, it represents a record type corresponding to the result of the *SELECT* statement defined in the cursor.

```
CURSOR c IS SELECT a, b FROM tbl;  
p c%ROWTYPE;    -- p.a and p.b are of types INT and CHAR,  
respectively
```

If no initial value is provided in the declaration of a record variable, it is initialized as an “empty record” in which all fields are *NULL*.

```
r tbl%ROWTYPE;    -- r.a, r.b, r.c are all NULL, but r itself is not  
NULL
```

Assigning *NULL* to a record variable initializes each field to *NULL*, but the record variable itself does not become *NULL*. In other words, a record variable never holds a *NULL* value after being declared.

Records of the same type can be compared using *=* and *!=* operators. Here, “same type” means not only records derived from the same table, but also records from different tables whose corresponding field names and types match exactly. The result of a *=* operation between two records is *TRUE* only if the *<=>* operation between all corresponding fields returns *TRUE*; otherwise, it returns *FALSE*. The result of the *!=* operation is the logical opposite of the *=* operation. Using *=* or *!=* between records of different types will result in a compile-time error.

```
create table tblA(a INT, b CHAR, c VARCHAR);
create table tblB(a INT, b CHAR, c VARCHAR);      -- tblA%ROWTYPE
and tblB%ROWTYPE are of the same type
create table tblC(aa INT, bb CHAR, cc VARCHAR);   -- tblA%ROWTYPE
and tblC%ROWTYPE are not of the same type

CREATE OR REPLACE PROCEDURE test_record_equality AS
  r1 tblA%ROWTYPE;
  r2 tblB%ROWTYPE;
  r3 tblC%ROWTYPE;
BEGIN
  ...
  if (r1 = r2) then      -- OK
  ...
  if (r1 = r3) then      -- Error
  ...
END;
```

Comparison operators other than *=* and *!=*, such as *<=>*, *<*, *>*, *<=*, and *>=*, cannot be used for record comparisons.

Assignment from one record variable *s* to another record variable *t* is allowed when the following conditions are met:

- The number of fields in *s* and *t* are the same.
- For each field position *i*, let the types of the *i*-th fields in *s* and *t* be  $S_i$  and  $T_i$ , respectively. It must be possible to assign a value from  $S_i$  to  $T_i$ .

The names of corresponding fields do *not* need to match in order for assignment between record variables to be valid.

```
CREATE TABLE tblAA(a NUMERIC, b DATETIME);
CREATE TABLE tblBB(m INT, n VARCHAR);
CREATE TABLE tblCC(x INT, y TIME);
```

```

CREATE OR REPLACE PROCEDURE test_record_assign AS
    r1 tblAA%ROWTYPE;
    r2 tblBB%ROWTYPE;
    r3 tblCC%ROWTYPE;
BEGIN
    ...
    r1 := r2;    -- OK
    r1 := r3;    -- Error: Cannot assign TIME to DATETIME
                  (incompatible types)
END;

```

%ROWTYPE can be used as parameter types and return types for local procedures/functions. However, since record types are not supported in SQL statements, %ROWTYPE cannot be used as parameter or return type in stored procedures/functions.

```

CREATE OR REPLACE PROCEDURE sp(a tbl%ROWTYPE) AS    -- Error

    PROCEDURE inner(b tbl%ROWTYPE) AS                -- OK
    BEGIN
        ...
    END;
BEGIN
    ...
END;

```

Record variables can be used in the *INTO* clause of Static/Dynamic SQL *SELECT* statements and *FETCH* statements. When using a record variable in an *INTO* clause, other variables cannot be used together. Also, the column names of the query result do not need to match the field names of the record variable, but the number of columns retrieved and the number of fields in the record variable must be the same. Additionally, the column types and record field types must be compatible.

```

CURSOR c IS SELECT a, b FROM tbl;
whole tbl%ROWTYPE;
part c%ROWTYPE;

-- Static SQL
SELECT * INTO whole FROM tbl;

-- Dynamic SQL
EXECUTE IMMEDIATE 'SELECT * FROM tbl' INTO whole;
EXECUTE IMMEDIATE 'SELECT a, b FROM tbl' INTO part;

-- Fetch
FETCH c INTO part;

```

In the *VALUES* clause of a Static SQL *INSERT/REPLACE* statement, a record variable can be used. When a record variable is used, it cannot be combined with other variables in the same *VALUES* clause. Also, the names of the target columns and the record fields do not need to match, but the number of columns and fields must be the same, and the column types must be compatible with the record field types.

```
INSERT INTO tbl VALUES whole;
INSERT INTO tbl(a, b) VALUES part;
```

The following forms are also allowed:

```
INSERT INTO tbl SET ROW = whole;
INSERT INTO tbl(a, b) SET ROW = part;
```

In a Static SQL *UPDATE* statement, a record variable can also be used with the *SET ROW = <record>* syntax as shown below. This is allowed only for single-table updates, and the field types of the record must be compatible with the corresponding column types in the same order.

```
UPDATE tbl SET ROW = whole WHERE a % 2 = 0;
```

## Precision and Scale Specification Exceptions

Among the **data types supported in PL/CSQL**, *NUMERIC* allows specification of precision and scale, while *CHAR* and *VARCHAR* allow specification of length. However, specifying precision and scale is *not allowed* for parameter types and return types of stored procedures/functions. This restriction also applies to local procedures/functions.

```
CREATE OR REPLACE FUNCTION sf(a NUMERIC(5, 3)) RETURN VARCHAR(10)
AS ...      -- Error
CREATE OR REPLACE FUNCTION sf(a NUMERIC) RETURN VARCHAR
AS ...      -- OK
```

Generally, *NUMERIC* without precision and scale amounts to *NUMERIC(15, 0)*. However, in the *parameter type* position, it exceptionally means that any precision and scale are allowed with precision from 1 to 38 and scale from 0 to the precision, while in the *return type* position, it is treated as *NUMERIC(p, s)*, where *p* and *s* are determined by the system configuration parameter **STORED\_PROCEDURE\_RETURN\_NUMERIC\_SIZE**. The default values for *p* and *s* are 38 and 15, respectively.

```
CREATE OR REPLACE FUNCTION test_any_precision_scale(a NUMERIC)
RETURN NUMERIC
AS
```

```

BEGIN
    RETURN a;
END;

SELECT test_any_precision_scale(1.23);      -- Result:
1.2300000000000000
SELECT test_any_precision_scale(1.234);    -- Result:
1.2340000000000000
SELECT test_any_precision_scale(1.2345);   -- Result:
1.2345000000000000

```

In addition, when *CHAR* and *VARCHAR* are used as parameter or return types, they do not behave as *CHAR*(1) or *VARCHAR*(1073741823) as in other contexts. Instead, they indicate that any string length is allowed with length  $\leq 2048$  for *CHAR* and length  $\leq 1073741823$  for *VARCHAR*.

```

CREATE OR REPLACE FUNCTION test_any_length(a CHAR) RETURN CHAR
AS
BEGIN
    RETURN a;
END;

SELECT test_any_length('ab');      -- Result: 'ab'
SELECT test_any_length('abc');    -- Result: 'abc'
SELECT test_any_length('abcd');   -- Result: 'abcd'

```

Even when parameter and return types are declared using *%TYPE*, the precision, scale, and length of the referenced original types are ignored, and the behavior follows the rules described above.

```

CREATE TABLE tbl(p NUMERIC(3,2), q CHAR(3));

CREATE OR REPLACE FUNCTION test_ptype_precision_scale(a tbl.p%TYPE)
RETURN tbl.p%TYPE
AS
BEGIN
    RETURN a;
END;

SELECT test_ptype_precision_scale(1.23);      -- Result:
1.2300000000000000
SELECT test_ptype_precision_scale(1.234);    -- Result:
1.2340000000000000
SELECT test_ptype_precision_scale(1.2345);   -- Result:
1.2345000000000000

CREATE OR REPLACE FUNCTION test_ptype_length(a tbl.q%TYPE) RETURN
tbl.q%TYPE
AS
BEGIN

```

```

RETURN a;
END;

SELECT test_ptype_length('ab');           -- Result: 'ab'
SELECT test_ptype_length('abc');          -- Result: 'abc'
SELECT test_ptype_length('abcd');         -- Result: 'abcd'

```

## Operators and Functions

In Static/Dynamic SQL, all operators and functions provided by SQL can be used. On the other hand, in Non-static/dynamic SQL statements, most SQL-provided operators and functions can also be used in the same way, but there are a few exceptions:

- Operators and functions that take or return unsupported types (*BIT*, *ENUM*, *BLOB/CLOB*, *JSON*, etc.) cannot be used.
- The modulo operator `%` is not allowed. However, the *MOD* function with the same meaning can be used instead.
- Logical operators `&&`, `//`, and `!` are not allowed. Instead, use their equivalents: *AND*, *OR*, and *NOT*, respectively.

The following example shows that string functions *locate* and *substr*, as well as the string concatenation operator `||`, can be used in Non-static/dynamic SQL statements.

```

CREATE OR REPLACE PROCEDURE family_name_to_last
AS
    delim INTEGER;
    family_name VARCHAR;
    given_name VARCHAR;
BEGIN
    FOR r IN (SELECT a.name FROM athlete a LIMIT 5,5) LOOP
        delim := locate(' ', r.name);           -- locate
function
        family_name := substr(r.name, 1, delim - 1);    -- substr
function
        given_name := substr(r.name, delim + 1);        -- substr
function
        DBMS_OUTPUT.put_line(given_name || ' ' || family_name);
-- string concatenation operator ||
    END LOOP;
END;

```

## Exception

PL/CSQL, like many other programming languages, supports error handling through exception handlers (see: [Block Statements](#)). Users can define their own exceptions in the declarative section and use them in the execution section (see: [Exception Declarations](#)). Additionally, for major error situations, the following system-defined exceptions are available:

| Name                | SQLCODE | Description                                                      |
|---------------------|---------|------------------------------------------------------------------|
| CASE_NOT_FOUND      | 0       | No matching WHEN clause and no ELSE clause in a CASE statement   |
| CURSOR_ALREADY_OPEN | 1       | Attempt to open a cursor that is already open                    |
| INVALID_CURSOR      | 2       | Invalid cursor operation (e.g., trying to close an unopened one) |
| NO_DATA_FOUND       | 3       | <i>SELECT INTO</i> returned zero rows                            |
| PROGRAM_ERROR       | 4       | Internal system error                                            |
| STORAGE_ERROR       | 5       | Memory allocation failed due to insufficient memory              |
| SQL_ERROR           | 6       | Static/Dynamic SQL execution failed                              |
| TOO_MANY_ROWS       | 7       | <i>SELECT INTO</i> returned more than one row                    |
| VALUE_ERROR         | 8       | Error caused by an invalid value                                 |

| Name        | SQLCODE | Description                |
|-------------|---------|----------------------------|
| ZERO_DIVIDE | 9       | Attempted division by zero |

The *SQLCODE* of each exception above can be used inside an **OTHERS** exception handler block to identify the type of exception.

- *SQLCODE* values up to 999 are reserved for system exceptions.
- **User-declared exceptions** have a *SQLCODE* of 1000.
- The first argument to **RAISE\_APPLICATION\_ERROR** must be greater than 1000.

The following is a simple example that handles the system exceptions *NO\_DATA\_FOUND* and *TOO\_MANY\_ROWS* that can occur when executing a Static SQL *SELECT* statement.

```
CREATE OR REPLACE FUNCTION athlete_code(p_name VARCHAR) RETURN
integer
AS
    c INTEGER;
BEGIN
    -- The SELECT INTO statement must return exactly one row
    SELECT code
    INTO c
    FROM athlete a
    WHERE a.name = p_name;

    RETURN c;
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        DBMS_OUTPUT.put_line('error: no rows found for athlete name
' || p_name);
        RETURN -1;
    WHEN TOO_MANY_ROWS THEN
        DBMS_OUTPUT.put_line('error: more than one rows found for
athlete name ' || p_name);
        RETURN -1;
END;
```

If an exception is not explicitly handled using a *WHEN ... THEN ...* clause, the location in the code where the exception occurred and the corresponding error message will be displayed.

For example, if the exception handler clauses are removed from the above *athlete\_code()* function:

```
CREATE OR REPLACE FUNCTION athlete_code(p_name VARCHAR) RETURN
integer
AS
    c INTEGER;
BEGIN
    -- The SELECT INTO statement must return exactly one row
    SELECT code
    INTO c
    FROM athlete a
    WHERE a.name = p_name;

    RETURN c;
END;
```

Then, if a name that does not exist in the *athlete* table is passed as an argument in CSQL, a *NO\_DATA\_FOUND* exception will be raised as the result.

```
select athlete_code('x');
```

In line 1, column 22,

ERROR: Stored **procedure execute** error:  
(line 6, column 5) **no data found**

0 command(s) successfully processed.

In the example above, position (1, 22) indicates the location within the *SELECT* statement, and (6, 5) indicates the location within the *CREATE* statement that declares *athlete\_code()*.

## System Configuration Parameters Application

The behavior of Static/Dynamic SQL statements is uniformly affected by all **system configuration parameters**.

In contrast, in Non-static/dynamic SQL statements, only the following four system configuration parameters are effective:

- *compat\_numeric\_division\_scale*
- *oracle\_compat\_number\_behavior*
- *oracle\_style\_empty\_string*
- *timezone*

```
CREATE OR REPLACE PROCEDURE test_system_config
AS
BEGIN
    -- When compat_numeric_division_scale is 'no': 0.125000000, when
    'yes': 0.1
    dbms_output.put_line(1.0 / 8.0);

    -- When oracle_compat_number_behavior is 'no': 1, when 'yes': 2
    dbms_output.put_line(3 / 2);

    -- When oracle_style_empty_string is 'no': 'false', when 'yes':
    'true'
    IF '' IS NULL THEN
        dbms_output.put_line('true');
    ELSE
        dbms_output.put_line('false');
    END IF;
END;
```

For details about these parameters, see [system configuration parameters](#).

Other than the four listed above, system settings do not apply to Non-static/dynamic SQL statements. In particular:

- Regardless of the *no\_backslash\_escapes* setting, the backslash character is *not* treated as an escape character.
- Regardless of the *pipes\_as\_concat* setting, *||* is *not* used as a logical OR operator.
- Regardless of the *plus\_as\_concat* setting, *+* is treated as a string concatenation operator when applied to strings.

```
CREATE OR REPLACE PROCEDURE test_system_config_2
AS
BEGIN
    -- Regardless of no_backslash_escapes, prints: 'Hello\nworld'
    dbms_output.put_line('Hello\\nworld');

    -- Regardless of pipes_as_concat, prints: 'ab'
    dbms_output.put_line('a' || 'b');

    -- Regardless of plus_as_concat, prints: '12'
    dbms_output.put_line('1' + '2');
END;
```

## Declarations

Stored procedure/function declarations and block statements contain a declaration section called *seq\_of\_declare\_specs*. Within this section, you can declare variables, constants, exceptions, cursors, and local procedures/functions as defined by the grammar below. Each declared item can be referenced within the *body* that follows the declaration section.

```
<seq_of_declare_specs> ::= <declare_spec> [ <declare_spec> ... ]
<declare_spec> ::=
    <variable_decl>
  | <constant_decl>
  | <exception_decl>
  | <cursor_decl>
  | <inner_procedure_decl>
  | <inner_function_decl>
```

See the sections below for descriptions of each declaration type.

**Local procedure/function declarations** and **Block statements** have their own declaration and execution blocks, forming nested scopes. When an inner scope declares a new item with the same name as one declared in an outer scope, the name in the inner scope refers to the newly defined item, hiding the outer declaration. However, outside the inner scope, the name still refers to the outer item.

```
CREATE OR REPLACE PROCEDURE hidden_variable
AS
    a INT := 3;
    b VARCHAR(10);

    -- Inner procedure
    PROCEDURE inner_proc
    AS
        a INT := 5;
        b FLOAT;
    BEGIN
        -- Here, a = 5, b is of type FLOAT
        ...
    END;

BEGIN
    -- Here, a = 3, b is of type VARCHAR(10)
    ...

    -- Block statement
    DECLARE
        a INT := 7;
        b DATETIME;
    BEGIN
```

```

        -- Here, a = 7, b is of type DATETIME
        ...
    END;

    -- Back to a = 3, b is VARCHAR(10)
    ...
END;

```

This kind of “name hiding” also applies to other types of declarations, such as constants, procedure/function parameters, exceptions, cursors, and local procedures/functions.

However, if the hidden name is referenced earlier in the same declaration block, such as in an initializer expression, a compile-time error will occur. Here’s a simple example: in procedure *poo*, the parameter *a* is referenced in the initializer of variable *i* inside the inner procedure. Then, a new variable with the same name *a* is declared below. This results in a compile error message stating that the name has already been used in the same declaration block.

```

CREATE OR REPLACE PROCEDURE poo(a INT) AS

    PROCEDURE inner AS
        i INT := a;
        a NUMERIC;
    BEGIN
        ...
    END;

BEGIN
    ...
END;

ERROR: In line 5, column 9
Stored procedure compile error: name A has already been used at line
4 and column 18 in the same declaration block

```

## Variable Declarations

```

<variable_decl> ::=
    <identifier> <type_spec> [ [ NOT NULL ] <initial_value_part> ] ;

<type_spec> ::=
    <builtin_type>
    | <table>.<column>%TYPE
    | <variable>%TYPE
    | <table>%ROWTYPE

```

```
| <cursor>%ROWTYPE
<initial_value_part> ::= { := | DEFAULT } <expression>
```

- *builtin\_type*: system-defined types as described in [Data Types](#)

When declaring variables, you may optionally specify a *NOT NULL* constraint and an initial value. If *NOT NULL* is specified, a non-null initial value must also be provided. If no initializer is provided, the variable will implicitly be assigned *NULL*.

```
CREATE OR REPLACE PROCEDURE test_variable
AS
  a INT NOT NULL := 3;
  b VARCHAR(1) := 's';
  c FLOAT;      -- c = NULL
BEGIN
  ...
END;
```

## Constant Declarations

```
<constant_decl> ::=
  <identifier> CONSTANT <type_spec> [ NOT_NULL ] <value_part> ;

<type_spec> ::=
  <builtin_type>
  | <table>.<column>%TYPE
  | <variable>%TYPE
  | <table>%ROWTYPE
  | <cursor>%ROWTYPE
<value_part> ::= { := | DEFAULT } <expression>
```

- *builtin\_type*: system-defined types as described in [Data Types](#)

Constant declarations must always include a value. If *NOT NULL* is specified, the value must not be *NULL*.

```
CREATE OR REPLACE PROCEDURE test_constant
AS
  a CONSTANT INT NOT NULL := 3;
  b CONSTANT VARCHAR := 's';
  --c CONSTANT FLOAT;      -- Error
BEGIN
  ...
END;
```

## Exception Declarations

```
<exception_decl> ::=
    <identifier> EXCEPTION ;
```

You can declare exceptions with any identifier name you choose. The declared exceptions can be used in the **RAISE** statement and in the **WHEN** clause of exception handling.

```
CREATE OR REPLACE FUNCTION text_exception(n INT) RETURN INT
AS
    negative_argument EXCEPTION;
    too_big_argument EXCEPTION;
BEGIN
    IF n < 0 THEN
        RAISE negative_argument;
    ELSIF n > 100 THEN
        RAISE too_big_argument;
    ELSIF n = 0 THEN
        RETURN 0;
    END IF;
    ...
EXCEPTION
    WHEN negative_argument THEN
        DBMS_OUTPUT.put_line('error: negative argument ' || n);
        RETURN -1;
    WHEN too_big_argument THEN
        DBMS_OUTPUT.put_line('error: too big argument ' || n);
        RETURN -2;
END;
```

## Cursor Declarations

```
<cursor_decl> ::=
    CURSOR <identifier> [ ( <seq_of_cursor_parameters> ) ] IS
    <select_statement> ;

<seq_of_cursor_parameters> ::= <cursor_parameter> [,
    <cursor_parameter>, ...]
<cursor_parameter> ::= <identifier> [ IN ] <type_spec>
<type_spec> ::=
    <builtin_type>
    | <table>.<column>%TYPE
    | <variable>%TYPE
```

```
| <table>%ROWTYPE
| <cursor>%ROWTYPE
```

- *builtin\_type*: system-defined types described in [Data Types](#)

Cursors can have parameters just like procedures/functions, but only *IN* parameters are allowed. These parameters can be referenced within the *select\_statement*. When calling **OPEN**, the provided arguments must match the declared number and types of the cursor parameters, and the *SELECT* statement will execute accordingly.

```
CREATE OR REPLACE PROCEDURE test_cursor(p_name VARCHAR, p_year
INTEGER)
AS
    CURSOR my_cursor(a VARCHAR, y INTEGER) IS
    SELECT host_year, score
    FROM history
    WHERE athlete = a AND host_year >= y;

    target_year INT;
    target_score VARCHAR(10);
BEGIN
    OPEN my_cursor(p_name, p_year);
    LOOP
        FETCH my_cursor INTO target_year, target_score;
        EXIT WHEN my_cursor%NOTFOUND;
        DBMS_OUTPUT.put_line('host_year: ' || target_year || '
score: ' || target_score);
    END LOOP;
    CLOSE my_cursor;
END;
```

Cursors can be used explicitly as shown above via *OPEN*, *FETCH*, and *CLOSE* statements. Alternatively, they can be used with a *FOR-LOOP*, in which the *OPEN*, *FETCH*, and *CLOSE* steps are performed implicitly:

```
CREATE OR REPLACE PROCEDURE test_cursor_loop(p_name VARCHAR, p_year
INTEGER)
AS
    CURSOR my_cursor(a VARCHAR, y INTEGER) IS
    SELECT host_year, score
    FROM history
    WHERE athlete = a AND host_year >= y;
BEGIN
    FOR r IN my_cursor(p_name, p_year) LOOP
        DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);
    END LOOP;
```

```
END LOOP;
END;
```

Note that *SELECT* statements used in cursor declarations must not include an *INTO* clause.

## Local Procedure/Function Declarations

You can define local procedures/functions that are only used inside the currently defined stored procedure/function, following the syntax below. If a task is somewhat large or repeated, modularizing it as a local procedure/function improves code readability and reusability.

```
<inner_procedure_decl> ::=
    PROCEDURE <identifier> [ ( <seq_of_parameters> ) ] { IS | AS } [
<seq_of_declare_specs> ] <body> ;
<inner_function_decl> ::=
    FUNCTION <identifier> [ ( <seq_of_parameters> ) ] RETURN
<type_spec> { IS | AS } [ <seq_of_declare_specs> ] <body> ;

<seq_of_parameters> ::= [ <parameter> [, <parameter> ...] ]
<parameter> ::= <identifier> [ { IN | IN OUT | INOUT | OUT } ]
<type_spec> [ COMMENT 'param_comment_string' ]
<type_spec> ::=
    <builtin_type>
    | <table>.<column>%TYPE
    | <variable>%TYPE
    | <table>%ROWTYPE
    | <cursor>%ROWTYPE
<body> ::= BEGIN <seq_of_statements> [ EXCEPTION <seq_of_handlers> ]
END [ <label_name> ]
<seq_of_declare_specs> ::= <declare_spec> [ <declare_spec> ... ]
<seq_of_statements> ::= <statement> ; [ <statement> ; ... ]
<seq_of_handlers> ::= <handler> [ <handler> ... ]
<handler> ::= WHEN <exception_name> [ OR <exception_name> OR ... ]
THEN <seq_of_statements>
<exception_name> ::= identifier | OTHERS
```

- *parameter*: parameters can be declared as IN, IN OUT, INOUT, or OUT. IN OUT and INOUT are equivalent.
- *param\_comment\_string*: a comment string for the parameter.
- *builtin\_type*: system-defined types described in [Data Types](#)
- *body*: consists of at least one statement and optionally one or more exception handlers.
- *label\_name*: must match the name of the procedure/function.

- *declare\_spec*: one of variable, constant, exception, cursor, or local procedure/function declarations.
- *statement*: see the [Statements](#) section.
- *handler*: specifies the statements to execute when the designated exception is raised.
- *exception\_name*: the exception *identifier* must be a [System Exception](#) or a user-declared one via [Exception Declaration](#). *OTHERS* matches any unhandled exceptions, and cannot be combined with other exception names using *OR*.

Unlike [stored procedures/functions](#), a local procedure/function may have the same name as a [CUBRID built-in function](#). In this case, the built-in function will be hidden within the scope of the local declaration.

In the case of a function, the *body* must return a value of the declared return type using a *RETURN* statement. If a control path reaches the end of the function body without a *RETURN*, a compile-time error will occur. For procedures, *RETURN* statements must not specify a return value.

Procedures/functions can reference themselves, enabling recursive calls.

```
CREATE OR REPLACE FUNCTION choose(m INT, n INT) RETURN INT
AS
    invalid_argument EXCEPTION;

    -- Local function declaration
    FUNCTION factorial(n INT) RETURN INT
    AS
    BEGIN
        IF n < 0 THEN
            RAISE invalid_argument;
        ELSIF n <= 1 THEN
            RETURN 1;
        ELSE
            RETURN n * factorial(n - 1);    -- Recursive call
        END IF;
    END;
BEGIN
    IF n > m OR n < 0 THEN
        RAISE invalid_argument;
    ELSE
        RETURN factorial(m) / factorial(n) / factorial(m - n);
    END IF;
END;
```

Mutual recursive calls are also possible between inner procedures/functions declared in the same declaration block.

```

CREATE OR REPLACE PROCEDURE ping_pong(cnt INT)
AS
  PROCEDURE ping(n INT)
  AS
  BEGIN
    IF n <= 0 THEN
      DBMS_OUTPUT.put_line('-- end --');
    ELSE
      DBMS_OUTPUT.put_line('ping ->');
      pong(n - 1);      -- mutual recursive call
    END IF;
  END;

  PROCEDURE pong(n INT)
  AS
  BEGIN
    IF n <= 0 THEN
      DBMS_OUTPUT.put_line('-- end --');
    ELSE
      DBMS_OUTPUT.put_line('      <- pong');
      ping(n - 1);      -- mutual recursive call
    END IF;
  END;
BEGIN
  ping(cnt);
END;

```

When using recursion, be sure to include an appropriate termination condition to avoid infinite loops.

## Statements

Currently, PL/CSQL provides the following 15 types of statements:

```

<statement> ::=
  <block>
  | <sql_statement>
  | <cursor_manipulation>
  | <raise_application_error>
  | <execute_immediate>
  | <assignment_statement>
  | <continue_statement>
  | <exit_statement>
  | <null_statement>
  | <raise_statement>
  | <return_statement>
  | <procedure_call>
  | <if_statement>

```

```
| <loop_statement>
| <case_statement>
```

## BLOCK

The BLOCK statement creates a nested scope within the list of executable statements, allowing new variables, constants, etc. to be declared and used inside it. Like procedures/functions, a BLOCK can have an exception handling structure.

```
<block> ::=
    [ DECLARE <seq_of_declare_specs> ] <body>

<body> ::= BEGIN <seq_of_statements> [ EXCEPTION <seq_of_handlers> ]
END [ <label_name> ]
<seq_of_declare_specs> ::= <declare_spec> [ <declare_spec> ... ]
<seq_of_statements> ::= <statement> ; [ <statement> ; ... ]
<seq_of_handlers> ::= <handler> [ <handler> ... ]
<handler> ::= WHEN <exception_name> [ OR <exception_name> OR ... ]
THEN <seq_of_statements>
<exception_name> ::= identifier | OTHERS
```

- *body*: must consist of one or more statements, optionally followed by exception handlers.
- *declare\_spec*: variable, constant, exception, cursor, or inner procedure/function declarations (see: [Declarations](#))
- *handler*: statements to be executed when the specified exception occurs.
- *exception\_name*: the *identifier* must be either a [system exception](#) or a [user-declared exception](#). *OTHERS* matches all exceptions not otherwise matched, and cannot be combined with other exception names using *OR*.

Items declared inside a BLOCK cannot be accessed from outside the BLOCK. If an item declared in a BLOCK has the same name as one in an outer scope, the outer item is hidden within that BLOCK.

```
CREATE OR REPLACE PROCEDURE test_block
IS
    a INT := 3;
    b INT := 3;
    c INT := 3;
BEGIN
    DECLARE
        a INT := 5;
        b INT := 5;
    BEGIN
        DECLARE
```

```

        a INT := 7;
    BEGIN
        DBMS_OUTPUT.put_line(a || b || c); -- '753'
    END;

    DBMS_OUTPUT.put_line(a || b || c);      -- '553'
END;

    DBMS_OUTPUT.put_line(a || b || c);      -- '333'
END;

```

If any statements inside the body are unreachable during execution, a compile-time error will occur. The following is a simple example containing an unreachable statement:

```

CREATE OR REPLACE PROCEDURE test_unreachable_statement
AS
BEGIN
    RETURN;
    DBMS_OUTPUT.put_line('Hello world');
END;

ERROR: In line 5, column 5
Stored procedure compile error: unreachable statement

```

## Static SQL

As explained in the [Static SQL](#) section, the following SQL statements (SELECT, INSERT, UPDATE, DELETE, MERGE, REPLACE, COMMIT, ROLLBACK, and TRUNCATE) can be used directly as executable statements within a program.

## Cursor Manipulation

Cursor manipulation statements come in the following four forms:

```

<cursor_manipulation> ::=
    <open_statement>
  | <fetch_statement>
  | <close_statement>
  | <open_for_statement>

<open_statement> ::= OPEN <cursor> [ <function_argument> ]
<fetch_statement> ::= FETCH <cursor_expression> INTO <identifier>
[ , <identifier> , ... ]
<close_statement> ::= CLOSE <cursor_expression>

```

```
<open_for_statement> ::= OPEN <identifier> FOR <select_statement>
```

- *cursor\_expression*: an expression that evaluates to a cursor or SYS\_REFCURSOR variable
- *open\_statement*: opens a cursor. Note that this can only be used with explicitly declared cursors, not SYS\_REFCURSOR variables. For cursors declared with parameters, the actual values provided must match the number and types of parameters. If you attempt to open an already open cursor, a *CURSOR\_ALREADY\_OPEN* exception will be raised.
- *fetch\_statement*: fetches one row from the cursor into the specified variables or OUT parameters. The number of columns in the fetched row must match the number of target variables, and their types must be compatible. Attempting to fetch from a cursor that is not open will raise an *INVALID\_CURSOR* exception.
- *close\_statement*: closes a cursor. Attempting to close a cursor that is not open will raise an *INVALID\_CURSOR* exception.
- *open\_for\_statement*: the *identifier* must be a variable declared with type SYS\_REFCURSOR. Internally, this statement opens a cursor for the given *select\_statement* and assigns it to the variable. If the *select\_statement* includes an INTO clause, a compile-time error will occur.

The following example shows how to use the OPEN, FETCH, and CLOSE statements:

```
CREATE OR REPLACE PROCEDURE test_cursor(p_name VARCHAR, p_year
INTEGER)
AS
    CURSOR my_cursor(a VARCHAR, y INTEGER) IS
    SELECT host_year, score
    FROM history
    WHERE athlete = a AND host_year >= y;

    target_year INT;
    target_score VARCHAR(10);
BEGIN

    OPEN my_cursor(p_name, p_year);
    LOOP
        FETCH my_cursor INTO target_year, target_score;
        EXIT WHEN my_cursor%NOTFOUND;
        DBMS_OUTPUT.put_line('host_year: ' || target_year || '
score: ' || target_score);
    END LOOP;
    CLOSE my_cursor;
END;
```

The following example demonstrates how to use a local procedure with a SYS\_REFCURSOR OUT parameter along with the OPEN-FOR statement to bind a specific SELECT statement to a SYS\_REFCURSOR variable and fetch its result:

```
CREATE OR REPLACE PROCEDURE test_ref_cursor(p_name VARCHAR)
AS
    my_refcursor SYS_REFCURSOR;

    target_year INT;
    target_score VARCHAR(10);

    PROCEDURE open_refcursor(athlete_name VARCHAR, rc OUT
SYS_REFCURSOR)
    AS
        refcursor SYS_REFCURSOR;
    BEGIN
        OPEN refcursor FOR SELECT host_year, score FROM history
WHERE athlete = athlete_name;
        rc := refcursor;
    END;
BEGIN
    open_refcursor(p_name, my_refcursor);
    LOOP
        FETCH my_refcursor INTO target_year, target_score;
        EXIT WHEN my_refcursor%NOTFOUND;
        DBMS_OUTPUT.put_line('host_year: ' || target_year || '
score: ' || target_score);
    END LOOP;
    CLOSE my_refcursor;
END;
```

## RAISE\_APPLICATION\_ERROR

*RAISE\_APPLICATION\_ERROR* is used to raise an **Exception** with a user-defined **code and error message**. Although it appears to be a built-in procedure call, it is internally handled as a PL/CSQL executable statement. The first argument must be an *INTEGER* value greater than 1000, as values ≤1000 are reserved for the system. The second argument can be any string message.

```
CREATE OR REPLACE PROCEDURE test_raise_app_err(i INT)
AS
BEGIN
    CASE i
    WHEN 1 THEN
        RAISE_APPLICATION_ERROR(1001, 'my error 1');
    WHEN 2 THEN
        RAISE_APPLICATION_ERROR(1002, 'my error 2');
    WHEN 3 THEN
```

```

        RAISE_APPLICATION_ERROR(1003, 'my error 3');
    END CASE;
EXCEPTION
    WHEN OTHERS THEN
        dbms_output.put_line('code=' || SQLCODE || ', message=' ||
SQLERRM || ' ');
END;

CALL test_raise_app_err(1);      -- DBMS_OUTPUT output: code=1001,
message='my error 1'
CALL test_raise_app_err(2);      -- DBMS_OUTPUT output: code=1002,
message='my error 2'
CALL test_raise_app_err(3);      -- DBMS_OUTPUT output: code=1003,
message='my error 3'

```

## EXECUTE IMMEDIATE

As described in the [Dynamic SQL](#) section, you can dynamically build SQL statements at runtime and execute them using the *EXECUTE IMMEDIATE* statement. The *USING* clause allows you to bind values from the program to host variables in the SQL. The *INTO* clause allows the program to retrieve result values from a *SELECT* query into variables or OUT parameters. The number of result columns must match the number of variables or OUT parameters, and the types must be compatible.

If an error occurs while executing the SQL, a *SQL\_ERROR* exception will be raised. When using the *INTO* clause, the *SELECT* must return exactly one row. If there are no results, *NO\_DATA\_FOUND* is raised; if more than one row is returned, *TOO\_MANY\_ROWS* is raised.

```

<execute_immediate> ::=
    EXECUTE IMMEDIATE <dynamic_sql> { [ <into_clause> ] [
<using_clause> ] | <using_clause> <into_clause> }
    <using_clause> ::= USING <using_element> [ ,
<using_element>, ... ]
    <using_element> ::= [ IN ] <expression>
    <into_clause> ::= INTO <identifier> [ , <identifier>, ... ]

```

- *dynamic\_sql*: an expression of string type. It must evaluate to a syntactically valid SQL string. You may use ? placeholders for values. The number of ? placeholders must match the number of expressions in the *using\_clause*.
- *using\_clause*: specifies the values to replace ? placeholders in the SQL string. Expressions of type *BOOLEAN* or *SYS\_REFCURSOR* are not allowed. Record-type values declared with *%ROWTYPE* or cursors are also not allowed.

- *into\_clause*: specifies the variables or OUT parameters to receive result values from a *SELECT* statement. If *dynamic\_sql* is a *SELECT* but no *INTO* clause is present, or vice versa, then a *SQL\_ERROR* exception is raised.

Here is an example usage of *EXECUTE IMMEDIATE*:

```
CREATE OR REPLACE PROCEDURE collect_athlete_history(p_name VARCHAR)
AS
    new_table VARCHAR := p_name || '_history';
BEGIN
    EXECUTE IMMEDIATE 'drop table if exists ' || new_table;
    EXECUTE IMMEDIATE 'create table ' || new_table || ' like
history';
    EXECUTE IMMEDIATE 'insert into ' || new_table || ' select * from
history where athlete = ?'
    USING p_name;
END;
```

## Assignment

```
<assignment_statement> ::=
    <identifier> := <expression>
```

- *identifier*: must be a variable or OUT parameter
- *expression*: an expression that evaluates to the value to be assigned (see the expressions section)

The type of *expression* must be the same as or implicitly convertible to the type of *identifier*. Otherwise, a compile-time error occurs.

## CONTINUE, EXIT

```
<continue_statement> ::=
    CONTINUE [ <label_name> ] [ WHEN <expression> ]
```

```
<exit_statement> ::=
    EXIT [ <label_name> ] [ WHEN <expression> ]
```

The *CONTINUE* and *EXIT* statements can only be used within loop statements. The *CONTINUE* statement stops the current execution flow and jumps to the beginning of the loop to start the next iteration. The *EXIT* statement terminates the current loop and jumps to the statement

immediately following the loop. If *label\_name* is omitted, the statement applies to the innermost enclosing loop. If *label\_name* is specified, it must reference a label declared in one of the enclosing loops; otherwise, a compile-time error occurs. When multiple loops are nested, *label\_name* can be used to specify the target loop. The *WHEN* clause allows the branch to occur only when the *BOOLEAN expression* evaluates to TRUE.

```
CREATE OR REPLACE PROCEDURE test_continue_exit
AS
    i INT := 0;
BEGIN
    LOOP
        DBMS_OUTPUT.put_line(i);           -- 0, 1, 2, 3, 4, 5
        i := i + 1;
        CONTINUE WHEN i < 3;
        DBMS_OUTPUT.put_line(i);           -- 3, 4, 5
        EXIT WHEN i = 5;
    END LOOP;

    DBMS_OUTPUT.put_line(i);               -- 5
END;
```

## NULL

```
<null_statement> ::=
    NULL
```

*NULL* can be used to explicitly indicate a no-operation statement, or as a placeholder for a statement to be implemented later. It is syntactically treated as a valid placeholder where a statement is required.

```
CREATE OR REPLACE PROCEDURE test_null(medal CHAR)
AS
BEGIN
    CASE medal
        WHEN 'G' THEN
            DBMS_OUTPUT.put_line('Gold');
        WHEN 'S' THEN
            DBMS_OUTPUT.put_line('Silver');
        WHEN 'B' THEN
            DBMS_OUTPUT.put_line('Bronze');
        ELSE
            NULL;
    END CASE;
END;
```

## RAISE

```
<raise_statement> ::=  
    RAISE [ <identifier> ]
```

Raises an exception. The exception name *identifier* must be a **system exception** or a **user-declared exception**. Within an exception handler's *THEN* clause, the exception name may be omitted, in which case the currently handled exception is raised again.

```
CREATE OR REPLACE FUNCTION fibonacci(n INTEGER) RETURN INTEGER  
IS  
    invalid_input EXCEPTION;  
BEGIN  
    IF n <= 0 THEN  
        RAISE invalid_input;  
    END IF;  
  
    IF n = 1 OR n = 2 THEN  
        RETURN 1;  
    ELSE  
        RETURN fibonacci(n-1) + fibonacci(n-2);  
    END IF;  
EXCEPTION  
    WHEN invalid_input THEN  
        DBMS_OUTPUT.put_line('invalid input: ' || n);  
        RAISE; -- Re-raises the currently handled  
`invalid_input` exception  
    WHEN OTHERS THEN  
        DBMS_OUTPUT.put_line('unknown exception');  
        RAISE; -- Re-raises the currently handled exception  
END;
```

## RETURN

```
<return_statement> ::=  
    RETURN [ <expression> ]
```

Branches execution to the point following the call to the current routine. If the current routine is a function, a return value *expression* must be provided that is convertible to the function's declared return type. If the current routine is a procedure, specifying a return value causes an error.

## Procedure Call

```
<procedure_call> ::=
    <identifier> [ <function_argument> ]
<function_argument> ::= ( [ <expression> [ , <expression>, ... ] ] )
```

Calls the procedure identified by *identifier*, optionally passing *function\_argument* values. The number and types of arguments must match those declared in the procedure. Arguments passed to OUT parameters must be variables or other OUT parameters, as their values will be modified by the called procedure.

```
CREATE OR REPLACE PROCEDURE callee(o OUT INT)
AS
BEGIN
    ...
END;

CREATE OR REPLACE PROCEDURE proc(i INT, o OUT INT)
AS
    v INT;
    c CONSTANT INT := 0;
BEGIN
    callee(i);    -- Error: IN parameter
    callee(o);    -- OK: OUT parameter
    callee(v);    -- OK: variable
    callee(c);    -- Error: constant
END;
```

The called procedure may be a stored procedure or a local procedure. If an error occurs during the execution of a stored procedure call, a *SQL\_ERROR* exception is raised.

## IF

```
<if_statement> ::=
    IF <expression> THEN <seq_of_statements>
    [ <elsif_part> [ <elsif_part> ... ] ]
    [ <else_part> ]
    END IF
<elsif_part> ::= ELSIF <expression> THEN <seq_of_statements>
<else_part> ::= ELSE <seq_of_statements>
```

Provides an If-Then-Else construct similar to those in general-purpose programming languages. The *expression* following *IF* and *ELSIF* must be of type *BOOLEAN*.

## LOOP

PL/CSQL provides five forms of loop statements as shown below. The first three are similar to loops found in general-purpose programming languages. The last two are used for iterating over the results of a SELECT statement.

```

<loop_statement> ::=
    <label_declaration>? LOOP <seq_of_statements> END
LOOP                                     # basic-loop
    | <label_declaration>? WHILE <expression> LOOP
<seq_of_statements> END LOOP           # while-loop
    | <label_declaration>? FOR <iterator> LOOP <seq_of_statements>
END LOOP                               # for-iter-loop
    | <label_declaration>? FOR <for_cursor> LOOP <seq_of_statements>
END LOOP                               # for-cursor-loop
    | <label_declaration>? FOR <for_static_sql> LOOP
<seq_of_statements> END LOOP          # for-static-sql-loop

<label_declaration> ::= '<<' <identifier> '>>'

<iterator> ::= <identifier> IN [ REVERSE ] <lower_bound> ..
<upper_bound> [ BY <step> ]

<for_cursor>      ::= <record> IN <cursor> [ <function_argument> ]
<for_static_sql>  ::= <record> IN ( <select_statement> )

```

- *label\_declaration*: a label can only be declared at the beginning of a loop statement. It is used by CONTINUE or EXIT statements in the loop body to indicate which loop to branch to.
- In the *while-loop*, the condition *expression* must be of type BOOLEAN.
- In the *for-iter-loop*, *lower\_bound*, *upper\_bound*, and *step* must all be of types convertible to INTEGER. At runtime, if *step* is less than or equal to 0, a VALUE\_ERROR exception is raised. If REVERSE is not specified, the *identifier* is initialized with *lower\_bound* and the loop body is executed if the value is less than or equal to *upper\_bound*. After each iteration, it increases by *step* and continues while still satisfying the condition. If REVERSE is specified, *identifier* is initialized with *upper\_bound* and the loop body is executed if the value is greater than or equal to *lower\_bound*. After each iteration, it decreases by *step* and continues while the condition holds. The loop variable *identifier* is treated as an INTEGER-type variable within the loop body.
- *for-cursor-loop* and *for-static-sql-loop* forms are used to iterate over the result set of a cursor or SELECT statement. The SELECT statement must not contain an INTO clause or a compile-time error occurs. For each iteration, a row from the result set is assigned to *record*, and the loop body executes. Each column of the row can be referenced as *record.column* within the body.

A basic form of LOOP typically includes an internal condition to exit the loop, as shown below:

```
CREATE OR REPLACE PROCEDURE print_nation_athletes(nation CHAR)
AS
    code INT;
    name VARCHAR(40);
    CURSOR c IS SELECT code, name FROM athlete WHERE nation_code =
nation;
BEGIN
    OPEN c;
    LOOP
        FETCH c INTO code, name;
        EXIT WHEN c%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE('code: ' || code || ' name: ' || name);
    END LOOP;
    CLOSE c;
END;
```

The following is a simple example of using a WHILE loop:

```
CREATE OR REPLACE FUNCTION sum_upto(n INT) RETURN INT
AS
    sum INT := 0;
    i INT := 1;
BEGIN
    WHILE i <= n LOOP
        sum := sum + i;
        i := i + 1;
    END LOOP;

    RETURN sum;
END;
```

The example below demonstrates the usage of a FOR iterator loop:

```
CREATE OR REPLACE PROCEDURE mult_tables
AS
BEGIN
    FOR i IN 2 .. 9 LOOP
        DBMS_OUTPUT.put_line('table ' || i);

        FOR j IN 1 .. 9 LOOP
            DBMS_OUTPUT.put_line(i || ' x ' || j || ' = ' || i*j);
        END LOOP;

        DBMS_OUTPUT.put_line('');
    END LOOP;
END;
```

The following shows an example of querying the same SELECT statement using two different forms of FOR loop.

```
CREATE OR REPLACE PROCEDURE athlete_history(p_name VARCHAR)
AS
    CURSOR my_cursor IS
        SELECT host_year, score
        FROM history
        WHERE athlete = p_name;
BEGIN
    -- For-Cursor Loop
    FOR r IN my_cursor LOOP
        DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);
    END LOOP;

    -- For-Select Loop
    FOR r IN (SELECT host_year, score FROM history WHERE athlete =
p_name) LOOP
        DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);
    END LOOP;
END;
```

## CASE Statement

The CASE statement sequentially evaluates multiple conditions and executes the statements associated with the first condition that evaluates to true.

```
<case_statement> ::=
    CASE <expression> { WHEN <expression> THEN
<seq_of_statements> }... [ ELSE <seq_of_statements> ] END CASE
| CASE { WHEN <expression> THEN <seq_of_statements> }... [ ELSE
<seq_of_statements> ] END CASE
```

There are two forms of CASE statements:

- The first form includes an expression immediately after the CASE keyword. It first evaluates this expression once, then compares it sequentially with the expressions in the WHEN clauses to find a match. If a match is found, the corresponding THEN clause statements are executed.
- The second form does not include an expression after the CASE keyword. Each WHEN clause expression must be of BOOLEAN type and is evaluated one by one until the first TRUE expression is found. The associated THEN clause statements are then executed.

Both forms may optionally include an ELSE clause, which specifies statements to execute if no WHEN clause matches. If no WHEN clause matches and there is no ELSE clause, the system exception CASE\_NOT\_FOUND is raised.

The following is an example of the first form of the CASE statement:

```
CREATE OR REPLACE PROCEDURE print_even_odd(i INTEGER)
AS
BEGIN
    CASE i MOD 2
        WHEN 0 THEN
            DBMS_OUTPUT.put_line('Even');
        WHEN 1 THEN
            DBMS_OUTPUT.put_line('Odd');
        ELSE
            DBMS_OUTPUT.put_line('Null');
    END CASE;
END;
```

The following is an example of the second form of the CASE statement with similar behavior:

```
CREATE OR REPLACE PROCEDURE print_even_odd(i INTEGER)
AS
BEGIN
    CASE
        WHEN i MOD 2 = 0 THEN
            DBMS_OUTPUT.put_line('Even');
        WHEN i MOD 2 = 1 THEN
            DBMS_OUTPUT.put_line('Odd');
        ELSE
            DBMS_OUTPUT.put_line('Null');
    END CASE;
END;
```

## Expressions

The types of expressions in PL/CSQL are summarized by the following syntax:

```
<expression> ::=
    <literal>                                # literal
    | <identifier>                            # identifier
    | SQL%ROWCOUNT                          # result size of
Static SQL
    | <cursor_expression> <cursor_attribute> # cursor attribute
    | <expression> <binary_op> <expression>  # binary operation
    | <unary_op> <expression>                # unary operation
```

```

| ( <expression> ) # parentheses
| <identifier>.<identifier> # record field
reference
| <identifier> <function_argument> # function call
| <case_expression> # CASE expression
| SQLCODE # exception code
| SQLERRM # exception message
| <expression> IS [ NOT ] NULL # IS NULL expression
| <expression> [ NOT ] BETWEEN <expression> AND
<expression> # BETWEEN expression
| <expression> [ NOT ] IN ( <expression> [ ,
<expression>, ... ] ) # IN expression
| <expression> [ NOT ] LIKE <expression> [ ESCAPE
<expression> ] # LIKE expression

<literal> ::=
    DATE <quoted_string>
    | TIME <quoted_string>
    | DATETIME <quoted_string>
    | TIMESTAMP <quoted_string>
    | <numeric>
    | <quoted_string>
    | NULL
    | TRUE
    | FALSE

<numeric> ::= UNSIGNED_INTEGER | FLOATING_POINT_NUM

<case_expression_when_part> ::= WHEN <expression> THEN <expression>

```

## Literals

Literals include date/time, numeric, string, NULL, TRUE, and FALSE values. Except that bit strings and collections are not supported, literal-related rules are the same as described in [SQL Literals](#).

## Identifiers

In PL/CSQL statements other than Static/Dynamic SQL, the following kinds of identifiers can be used:

- Variables, constants, cursors, exceptions, and local procedures/functions declared in the declaration section
- Parameters of procedures/functions
- Implicitly declared iterators of **FOR loops** of type integer or record

Using an identifier without explicit or implicit declaration results in a compile-time error.

## Result Count for Static SQL

`SQL%ROWCOUNT` is an expression that represents the result count immediately after executing a Static SQL statement.

- For SELECT statements not associated with cursors, the INTO clause must be used, and the result must contain exactly one row. Therefore, when the SELECT executes successfully, `SQL%ROWCOUNT` will be 1. If the result has 0 or more than 1 row and causes a runtime error, the value of `SQL%ROWCOUNT` is undefined.
- For INSERT, UPDATE, DELETE, MERGE, REPLACE, and TRUNCATE statements, it returns the number of affected rows.
- For COMMIT and ROLLBACK, it returns 0.

## Cursor Attributes

By appending `%ISOPEN`, `%FOUND`, `%NOTFOUND`, or `%ROWCOUNT` to a *cursor\_expression* that evaluates to a cursor or `SYS_REFCURSOR` variable, you can check one of four cursor attributes.

- `%ISOPEN`: Whether the cursor is open (BOOLEAN)
- `%FOUND`: NULL before the first FETCH. Otherwise, whether the last FETCH returned 1 row (BOOLEAN). Raises `INVALID_CURSOR` Exception if the cursor is not open.
- `%NOTFOUND`: NULL before the first FETCH. Otherwise, whether the last FETCH returned 0 rows (BOOLEAN). Raises `INVALID_CURSOR` Exception if the cursor is not open.
- `%ROWCOUNT`: 0 before the first FETCH. Otherwise, the number of rows fetched so far (BIGINT). Raises `INVALID_CURSOR` Exception if the cursor is not open.

In the example below, the internal function `iterate_cursor()` iterates over records using cursor attributes and returns the total row count. If the passed cursor is not open (`%ISOPEN` is False), the function returns -1. Whether there are more records is determined using the `%NOTFOUND`

attribute after FETCH. The `%ROWCOUNT` attribute increments with each FETCH and reflects the total number of rows fetched after the loop ends.

```
CREATE OR REPLACE PROCEDURE cursor_attributes AS
...

FUNCTION iterate_cursor(rc SYS_REFCURSOR) RETURN INT
AS
    v VARCHAR;
BEGIN
    IF rc%ISOPEN THEN
        LOOP
            FETCH rc INTO v;
            EXIT WHEN rc%NOTFOUND;

            -- do something with v
            ...

        END LOOP;

        RETURN rc%ROWCOUNT;    -- number of records
    ELSE
        RETURN -1;              -- error
    END IF;
END;
begin
...

end;
```

If the *cursor\_expression* evaluates to NULL, an `INVALID_CURSOR` Exception is raised.

## Binary Ops, Unary Ops, Parentheses

PL/CSQL uses the following precedence for operators:

| Operator                    | Description                                         |
|-----------------------------|-----------------------------------------------------|
| <code>+, -, ~</code>        | Unary sign, bitwise NOT                             |
| <code>*, /, DIV, MOD</code> | Multiplication, division, integer division, modulus |

| Operator                     | Description           |
|------------------------------|-----------------------|
| +, -                         | Addition, subtraction |
|                              | String concatenation  |
| <<, >>                       | Bitwise shift         |
| &                            | Bitwise AND           |
| ^                            | Bitwise XOR           |
|                              | Bitwise OR            |
| IS NULL                      | NULL test             |
| LIKE                         | String pattern test   |
| BETWEEN                      | Range test            |
| IN                           | Inclusion test        |
| =, <=>, <, >, <=, >=, <>, != | Comparison            |
| NOT                          | Logical NOT           |
| AND                          | Logical AND           |
| XOR                          | Logical XOR           |

| Operator | Description |
|----------|-------------|
|----------|-------------|

OR

Logical OR

- In Non-static/dynamic SQL statements, the % operator cannot be used for modulo, so use MOD instead.
- In Non-static/dynamic SQL statements, logical operators &&, ||, and ! cannot be used, so use AND, OR, and NOT instead.
- In Non-static/dynamic SQL statements, string comparisons follow UTF8 encoding regardless of DB settings, using lexicographical order of Unicode values. In Static/Dynamic SQL statements, encoding and comparison rules follow the database and table settings.

Parentheses can be used to explicitly specify evaluation precedence.

## Record Field Reference

PL/CSQL supports record variables in the following two cases:

- Implicitly declared record variables used for iterating over SELECT results in a FOR loop
- Record variables declared using %ROWTYPE

To reference a field in a record variable, append a dot and the field name to the record variable.

```
CREATE PROCEDURE athlete_history(p_name VARCHAR)
AS
  CURSOR my_cursor IS
    SELECT host_year, score
    FROM history
    WHERE athlete = p_name;
BEGIN
  FOR r IN my_cursor LOOP      -- r: implicitly declared
    DBMS_OUTPUT.put_line('host_year: ' || r.host_year || '
score: ' || r.score);        -- r.<column-name>
  END LOOP;
END;
```

## Function Call

In a function call expression, the number and types of arguments must match the function's declaration. Arguments passed to OUT parameters of the function must be assignable variables or other OUT parameters, as their values will be changed by the function call.

```

CREATE OR REPLACE FUNCTION callee(o OUT INT) RETURN INT
AS
BEGIN
    ...
END;

CREATE OR REPLACE PROCEDURE proc(i INT, o OUT INT)
AS
    v INT;
    c CONSTANT INT := 0;
BEGIN
    ... callee(i) ...    -- Error: IN argument
    ... callee(o) ...    -- OK: OUT argument
    ... callee(v) ...    -- OK: variable
    ... callee(c) ...    -- Error: constant
END;

```

Callable functions may be stored functions, local functions, or built-in functions. Among these, built-in functions refer to the CUBRID built-in functions listed in [Operators and Functions](#). However, the built-in function **IF** cannot be used because it conflicts with PL/CSQL syntax.

If an error occurs while calling another stored function or built-in function, an SQL\_ERROR Exception is raised.

## CASE Expression

A CASE expression sequentially evaluates conditions and returns the value associated with the first condition that is satisfied.

Like the [CASE statement](#), CASE expressions come in two forms:

- The first form includes an expression immediately after the CASE keyword. That expression is evaluated once, then compared against each WHEN clause's expression. When a match is found, the corresponding THEN expression is evaluated and becomes the result of the CASE expression.
- The second form does not have an expression after the CASE keyword. In this case, each WHEN clause must be a BOOLEAN expression. The first one that evaluates to TRUE determines which THEN expression is returned as the CASE result.

Both forms may include an optional ELSE clause, whose expression becomes the CASE value if no conditions match. If no conditions match and no ELSE is present, the CASE expression evaluates to NULL.

The following is an example of the first form:

```
CREATE OR REPLACE PROCEDURE print_even_odd(i INTEGER)
AS
    s VARCHAR(5);
BEGIN
    s := CASE i MOD 2
        WHEN 0 THEN 'Even'
        WHEN 1 THEN 'Odd'
        ELSE 'NULL'
    END;

    DBMS_OUTPUT.put_line(s);
END;
```

The following shows the second form with equivalent behavior:

```
CREATE OR REPLACE PROCEDURE print_even_odd(i INTEGER)
AS
    s VARCHAR(5);
BEGIN
    s := CASE
        WHEN i MOD 2 = 0 THEN 'Even'
        WHEN i MOD 2 = 1 THEN 'Odd'
        ELSE 'NULL'
    END;

    DBMS_OUTPUT.put_line(s);
END;
```

## SQLCODE, SQLERRM

Inside an exception handling block, SQLCODE and SQLERRM represent the error code (INTEGER) and error message (STRING) of the current Exception. Outside an exception block, SQLCODE is 0 and SQLERRM is 'no error'.

```
CREATE OR REPLACE PROCEDURE test_sql_code_errm
AS
BEGIN
    ...
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.put_line('code=' || SQLCODE);
        DBMS_OUTPUT.put_line('error message' || SQLERRM);
END;
```

## Java Stored Procedure

CUBRID supports the development of stored functions and procedures using Java. Java stored functions and procedures are executed on a Java Virtual Machine (JVM) hosted by CUBRID. Since Java stored functions and procedures use the JVM, they offer excellent interoperability and portability.

### Introduction to Java Stored Procedure

CUBRID supports the development of stored functions and procedures in Java. Java stored functions/procedures are executed on the JVM (Java Virtual Machine) hosted by CUBRID.

You can call Java stored functions/procedures from SQL statements or from Java applications using JDBC.

The advantages of using Java stored functions/procedures are as follows:

- **Productivity and usability:** Java stored functions/procedures, once created, can be reused anytime. They can be called from SQL statements or from Java applications using JDBC.
- **Excellent interoperability and portability:** Java stored functions/procedures use the Java Virtual Machine. Therefore, they can be used on any system where the Java Virtual Machine is available.

#### Note

- The other languages except Java do not support stored function/procedure. In CUBRID, only Java can implement stored function/procedure.

### Prerequisites for Writing and Using Java Stored Functions/Procedures

To use Java stored functions/procedures, the procedure language server must be ready. The procedure language server starts automatically when the database server is started. For more details, refer to [CUBRID Procedural Language Server](#) and [Procedural Language Server Configuration](#).

### How to Write and Load Java Stored Function/Procedure

To use a Java stored function/procedure, you can write and publish Java stored function/procedure as follows.

- **Step 1: Write the Java source code**

- **Step 2: Compile the Java source code**
- **Step 3: Load Java Class**
- **Step 4: Publish Stored function/procedure**

Write the Java source code

The following example shows how to write Java stored function/procedure. Here, the Java class method must be **public static**.

```
public class SpCubrid{
    public static String HelloCubrid() {
        return "Hello, Cubrid !!";
    }

    public static int SpInt(int i) {
        return i + 1;
    }

    public static void outTest(String[] o) {
        o[0] = "Hello, CUBRID";
    }
}
```

To access the database from a Java stored function/procedure, you must create a Connection object. See details on how to use the server-side JDBC driver, refer to the [Using Server-side Internal JDBC Driver](#).

Compile the Java source code

Compile the SpCubrid.java file as follows:

```
javac SpCubrid.java
```

When using the server-side JDBC driver, you must compile as follows by specifying the path of JDBC using the **classpath(cp)** option. Note that you must use the latest JDBC driver of the database server to be loaded.

```
javac SpCubrid.java -cp $CUBRID/jdbc/cubrid_jdbc.jar
```

Load the compiled Java class into CUBRID

Load the compiled Java class into CUBRID. You can refer to the [loadjava Utility](#).

```
% loadjava demodb SpCubrid.class
```

## Registering Stored Functions/Procedures

CUBRID requires a process to register (publish) Java classes so that Java methods can be called from SQL statements or applications. Create a CUBRID stored function as follows to register the Java class.

```
...  
AS LANGUAGE JAVA NAME '<java_call_specification>';
```

In the string following JAVA NAME, specify the class and method names to call the method of the Java class. This is called a **Java Call Specification**.

```
CREATE FUNCTION hello() RETURN STRING  
AS LANGUAGE JAVA  
NAME 'SpCubrid.HelloCubrid() return java.lang.String';
```

## Java Call Specification

You must publish Java classes by using call specifications because it is not known how a function in a class will be called by SQL statements or applications when Java classes are loaded.

With call specifications, Java function names, parameter types, return values and their types can be accessed by SQL statements or applications. To write call specifications, use **CREATE FUNCTION** or **CREATE PROCEDURE** statement.

- Java stored function/procedure names are not case sensitive.
- The maximum number of characters a Java stored function/procedure can have is 254 bytes.
- The maximum number of parameters a Java stored function/procedure can have is 64.
- If the parameter of a Java stored function/procedure is set to **OUT**, it will be passed as a one-dimensional array whose length is 1. Therefore, a Java method must store its value to pass in the first space of the array.

```
CREATE PROCEDURE test_out(x OUT STRING)
AS LANGUAGE JAVA
NAME 'SpCubrid.outTest(java.lang.String[] o)';
```

## Java Stored Function/Procedure Call

Java stored functions/procedures, once registered, can be called in the same way as PL/CSQL. For more details, refer to [Call a Stored Procedure](#).

If an exception occurs during the execution of a Java stored function/procedure, the exception is logged and stored in the `dbname_pl.log` file. To display the exception on the screen, change a handler value of the `$CUBRID/java/logging.properties` file to "java.lang.logging.ConsoleHandler". Then, the exception details are displayed on the screen.

## Java Stored Procedure Examples

To call a Java stored function/procedure from a Java application, use a **CallableStatement** object.

Create a phone class in the CUBRID database.

```
CREATE TABLE phone(
    name VARCHAR(20),
    phoneno VARCHAR(20)
);
```

Compile the following **PhoneNumber.java** file, load the Java class file into CUBRID, and publish it.

```
import java.sql.*;
import java.io.*;

public class PhoneNumber{
    public static void Phone(String name, String phoneno) throws
Exception{
    String sql="INSERT INTO PHONE(NAME, PHONENO)+" + "VALUES
(?, ?)";
    try{
        Connection conn =
DriverManager.getConnection("jdbc:default:connection:");
        PreparedStatement pstmt = conn.prepareStatement(sql);

        pstmt.setString(1, name);
        pstmt.setString(2, phoneno);
        pstmt.executeUpdate();

        pstmt.close();
        conn.commit();
    }
}
```

```

        conn.close();
    } catch (SQLException e) {
        System.err.println(e.getMessage());
    }
}
}

```

```

create PROCEDURE phone_info(name varchar, phoneno varchar) as
language java
name 'PhoneNumber.Phone(java.lang.String, java.lang.String)';

```

Create and run the following Java application.

```

import java.sql.*;

public class StoredJDBC{
    public static void main(){
        Connection conn = null;
        Statement stmt= null;
        int result;
        int i;

        try{
            conn =
DriverManager.getConnection("jdbc:CUBRID:localhost:
33000:demodb::", "", "");

            CallableStatement cs;
            cs = conn.prepareCall("CALL PHONE_INFO(?, ?)");

            cs.setString(1, "Jane");
            cs.setString(2, "010-1111-1111");
            cs.executeUpdate();

            conn.commit();
            cs.close();
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

```

Retrieve the phone class after executing the program above; the following result would be displayed.

```

SELECT * FROM phone;

```

```
name                phoneno
=====
' Jane '            '010-111-1111'
```

## Using Server-side Internal JDBC Driver

To access the database from a Java stored function/procedure, you must use the server-side JDBC driver. The following are possible with the server-side JDBC driver.

- **Executing SQL Statements**
- **Processing Query Result**

The following classes are supported by the server-side JDBC driver. For details on JDBC API support, refer to [Appendix](#).

- **java.sql.Connection**
- **java.sql.Statement**
- **java.sql.PreparedStatement**
- **java.sql.CallableStatement**
- **java.sql.ResultSet**
- **java.sql.ResultSetMetaData**

### Warning

**java.sql.DatabaseMetaData** is not supported yet.

Database operations using the server-side JDBC have the following characteristics.

- Database operations executed in the Java stored function/procedure belongs to the transaction that is called the Java stored function/procedure.
- Transaction-related APIs are ignored.
- There is no need to make the connection to the server-side JDBC driver again.

## Creating Connection

To access the database from a Java stored function/procedure, you must use the server-side JDBC driver. To acquire a connection to the database using the server-side JDBC driver, you can use **"jdbc:default:connection:"** as the URL for JDBC connection.

```
Connection conn =  
DriverManager.getConnection("jdbc:default:connection:");
```

### Note

From the CUBRID 11.2, Acquiring a connection in the following way is no longer supported:

```
Connection conn = cubrid.jdbc.driver.CUBRIDDriver.getDefaultConnection();
```

### Note

The server-side JDBC is already registered, and you do not need to call `"Class.forName("cubrid.jdbc.driver.CUBRIDDriver")"`

## Executing SQL Statements

When implementing Java stored functions/procedures, queries can be executed using the following JDBC interface in the same way as developing Java applications.

- **java.sql.Statement**
- **java.sql.PreparedStatement**
- **java.sql.CallableStatement**

The following are the queries that can be executed using the above class.

- **DML (Data Manipulation Language):** [Data Manipulation Statements](#)
- **DDL (Data Definition Language):** [Data Definition Statements](#)

### Note

The JDBC Statement objects must contain only one SQL statement. Therefore, an error occurs in the following cases:

```
stmt = new Statement ("select * from t1;select * from t2;");
```

The following statements are not supported.

- **TCL (Transaction Control Language):** Database Transaction

#### Note

- *commit()*, *rollback()* JDBC API methods corresponding to **COMMIT** and **ROLLBACK** statements respectively are ignored.
- JDBC API methods corresponding to **SAVEPOINT** statement are not supported.

The example of executing statements

#### **Execute a query that returns a result set and process the query result set**

The following example shows how to execute a **SELECT** statement that returns a result set. **SELECT** statement can be executed by creating a **java.sql.Statement** or **java.sql.PreparedStatement** object. The query result can be processed using the result set (**java.sql.ResultSet**).

#### Note

- **java.sql.ResultSet** is forward-only and read-only.
- In the case of the client-side JDBC driver, when a query result set is created, **cursor holdability** is performed by default. In the server-side JDBC driver, resources are managed by the server, so the query result set is internally closed at the end of the stored function/procedure without maintaining a cursor.

Also, result set metadata (**java.sql.ResultSetMetaData**) can be created from the query result set by using the **getMetaData()** function.

```
CREATE OR REPLACE FUNCTION sp_get_athlete_by_ncode (nc STRING)
RETURN STRING as language java name
'TestQuery.printAthelete(java.lang.String) return java.lang.String';
```

```
import java.sql.*;

public class TestQuery {
    public static String printAthelete(String nation_code_filter)
    throws SQLException {
        String sql = "SELECT * FROM public.athlete WHERE nation_code
= ?";

        StringBuilder builder = new StringBuilder();
        Connection conn = null;
        PreparedStatement pstmt = null;

        try {
            conn =
DriverManager.getConnection("jdbc:default:connection:");
            pstmt = conn.prepareStatement(sql);

            pstmt.setString(1, nation_code_filter);

            ResultSet rs = pstmt.executeQuery();
            ResultSetMetaData rsmd = rs.getMetaData();

            builder.append("<Column Details>:\n");
            int colCount = rsmd.getColumnCount();
            for (int i = 1; i <= colCount; i++) {
                String colName = rsmd.getColumnName(i);
                String colType = rsmd.getColumnTypeName(i);
                builder.append(colName + "," + colType);

                if (i != colCount) builder.append("|");
            }

            builder.append("\n<Rows>:\n");
            while (rs.next()) {
                for (int i = 1; i <= rsmd.getColumnCount(); i++) {
                    Object object = rs.getObject(i);
                    if (object != null) {
                        readColumn(i, rsmd, rs, builder);
                    }

                    if (i != rsmd.getColumnCount()) builder.append
("|");
                }
                builder.append("\n");
            }
        }
    }
}
```

```

        rs.close();
    } catch (Exception e) {
        builder.append(e.getMessage());
    } finally {
        if (pstmt != null) pstmt.close();
        if (conn != null) conn.close();
    }

    return builder.toString();
}

private static void readColumn(int idx, ResultSetMetaData rsmd,
ResultSet rs, StringBuilder stringBuilder) throws SQLException {
    switch (rsmd.getColumnType(idx)) {
        case java.sql.Types.DOUBLE:
            stringBuilder.append(rs.getDouble(idx));
            break;
        case java.sql.Types.FLOAT:
            stringBuilder.append(rs.getFloat(idx));
            break;
        case java.sql.Types.VARCHAR:
            stringBuilder.append("\"").append(rs.getString(idx)).append("\"");
            break;
        case java.sql.Types.INTEGER:
        case java.sql.Types.TINYINT:
        case java.sql.Types.SMALLINT:
        case java.sql.Types.BIGINT:
            stringBuilder.append(rs.getInt(idx));
            break;
        case java.sql.Types.DATE:
            stringBuilder.append("\"").append(rs.getDate(idx)).append("\"");
            break;
        case java.sql.Types.TIMESTAMP:
            stringBuilder.append("\"").append(rs.getTimestamp(idx)).append("\"");
            break;
        default:
            stringBuilder.append(rs.getObject(idx));
            break;
    }
}
}
}

```

```

SELECT sp_get_athlete_by_ncode ('ESP');

sp_get_athlete_by_ncode('ESP')
=====
'<Column Details>:

```

```
code,INTEGER|name,VARCHAR|gender,CHAR|nation_code,CHAR|event,VARCHAR
<Rows>:
10999|"Fernandez Jesus"|M|ESP|"Handball"
10997|"Fernandez Isabel"|W|ESP|"Judo"
10994|"Fernandez Abelardo"|M|ESP|"Football"
10948|"Etxaburu Aitor"|M|ESP|"Handball"
10941|"Estiarte Manuel"|M|ESP|"Water Polo"
...
```

## INSERT, UPDATE, DELETE

The following is an example of executing the **INSERT** statement. **INSERT**, **UPDATE**, **DELETE** statements can be executed through the **executeUpdate()** function.

```
import java.sql.*;

public class Athlete {
    public static void insertAthlete(String name, String gender,
String nation_code, String event) throws SQLException {
        String sql = "INSERT INTO ATHLETE(NAME, GENDER, NATION_CODE,
EVENT)" + "VALUES (?, ?, ?, ?)";

        Connection conn = null;
        PreparedStatement pstmt = null;

        try{
            conn =
DriverManager.getConnection("jdbc:default:connection:");
            pstmt = conn.prepareStatement(sql);

            pstmt.setString(1, name);
            pstmt.setString(2, gender);
            pstmt.setString(3, nation_code);
            pstmt.setString(4, event);
            pstmt.executeUpdate();

            pstmt.close();
            conn.commit();
            conn.close();
        } catch (Exception e) {
            System.err.println(e.getMessage());
        } finally {
            if (pstmt != null) pstmt.close();
            if (conn != null) conn.close();
        }
    }
}
```

**Note**

conn.commit() is ignored at the Athlete class example above.

## OUT Parameters of Primitive Types

When changing an argument value in Java in a Java stored function/procedure of CUBRID, the changed value must be passed when an argument is passed as an OUT argument as a one-dimensional array.

```
CREATE PROCEDURE sp_increment_me(x IN OUT INT) AS LANGUAGE JAVA NAME
'OutTest.incrementInt(int[])';
```

```
public class OutTest {
    public static void incrementInt(int[] arg) {
        arg[0] = arg[0] + 1;
    }
}
```

## OUT Parameters of Set Types

Parameters of Java methods corresponding to an OUT (or IN OUT) parameter of an SQL set type must be declared as an two-dimensional array of an appropriate type.

```
CREATE PROCEDURE setoid(x in out set, z object) AS LANGUAGE JAVA
NAME 'SetOIDTest.SetOID(cubrid.sql.CUBRIDOID[][],
cubrid.sql.CUBRIDOID)';
```

```
import cubrid.sql.CUBRIDOID;

public class SetOIDTest {
    public static void SetOID(CUBRIDOID[][] set, CUBRIDOID aoid) {
        String ret="";
        Vector v = new Vector();

        CUBRIDOID[] set1 = set[0];

        try {
            if(set1 != null) {
                int len = set1.length;
                int i = 0;
```

```

        for (i = 0; i < len; i++)
            v.add(set1[i]);
    }

    v.add(aoid);
    set[0] = (CUBRIDOID[]) v.toArray(new CUBRIDOID[]{});

} catch (Exception e) {
    e.printStackTrace();
    System.err.println("SQLException:" + e.getMessage());
}
}
}

```

### OUT Parameters of CUBRID OID type

In case of using an OUT (or IN OUT) parameter of CUBRID OID type, declare the corresponding parameter of the Java method as an array of CUBRIDOID class (cubrid.sql.CUBRIDOID).

```

CREATE PROCEDURE tOID(i inout object, q string) AS LANGUAGE JAVA
NAME 'OIDtest.tOID(cubrid.sql.CUBRIDOID[], java.lang.String)';

```

```

import java.sql.*;
import cubrid.sql.CUBRIDOID;

public class OIDtest {
    public static void tOID(CUBRIDOID[] oid, String query)
    {
        Connection conn = null;
        Statement stmt = null;
        String ret = "";

        try {
            conn =
DriverManager.getConnection("jdbc:default:connection:");

            conn.setAutoCommit(false);
            stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery(query);
            System.out.println("query:" + query);

            while(rs.next()) {
                oid[0] = (CUBRIDOID) rs.getObject(1);
                System.out.println("oid:" + oid[0].getTableName());
            }

            stmt.close();
            conn.close();

```

```

    } catch (SQLException e1) {
        e1.printStackTrace();
        System.err.println("SQLException:" + e1.getMessage());
    } catch (Exception e2) {
        e2.printStackTrace();
        system.err.println("Exception:" + e2.getMessage());
    }
}
}

```

## Returning java.sql.ResultSet in Java Stored Procedure

In CUBRID, a query result set (**java.sql.ResultSet**) can be returned, and **CURSOR** is used as the returned data type when declared.

### Note

- **java.sql.ResultSet** cannot be used as an input argument of a function, and an error occurs if it is passed as an IN argument.
- An error also occurs when calling a function that returns **ResultSet** in a non-Java environment.

```

CREATE FUNCTION rset() RETURN CURSOR AS LANGUAGE JAVA
NAME 'JavaSP2.TResultSet() return java.sql.ResultSet'

```

```

import java.sql.*;

public class JavaSP2 {
    public static ResultSet TResultSet(){
        try {
            Connection conn =
DriverManager.getConnection("jdbc:default:connection:");

            String sql = "select * from station";
            Statement stmt=conn.createStatement();
            ResultSet rs = stmt.executeQuery(sql);

            return rs;
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

```

```

        return null;
    }
}

```

In the calling block, you must set the OUT argument with **Types.JAVA\_OBJECT**, get the argument to the **getObject ()** function, and then cast it to the **java.sql.ResultSet** type before you use it. In addition, the **java.sql.ResultSet** is only available to use in **CallableStatement** of JDBC.

```

import java.sql.*;

public class TestResultSet{
    public static void main(String[] args) {
        Connection conn = null;

        try {
            conn =
DriverManager.getConnection("jdbc:default:connection:");

            CallableStatement cstmt = conn.prepareCall("=?=CALL
rset()");
            cstmt.registerOutParameter(1, Types.JAVA_OBJECT);
            cstmt.execute();
            ResultSet rs = (ResultSet) cstmt.getObject(1);

            while(rs.next()) {
                System.out.println(rs.getString(1));
            }

            rs.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

```

Getting information about connection client

```

CREATE OR REPLACE FUNCTION sp_client_info () RETURN STRING as
language java name 'SpTestClientInfo.getClientInfo() return
java.lang.String';

```

```

import java.util.Properties;
import java.sql.*;

public class SpTestClientInfo {

```

```

public static String getClientInfo() {
    Connection conn = null;
    String result = "";

    try {
        conn =
DriverManager.getConnection("jdbc:default:connection:");

        Properties props = conn.getClientInfo();

        // How to get from the Properties
        // String user = props.getProperty ("user");

        result = props.toString ();
    } catch (Exception e) {
        result = e.getMessage ();
    }
    return result;
}
}

```

```

SELECT sp_client_info ();

sp_client_info()
=====
'{pid=200270, user=DBA, login=cubrid, program=csql, type=2,
host=cubrid, ip=192.168.2.201}'

```

## Connecting to Other Databases

You can connect to another outside database instead of the currently connected one even when the server-side JDBC driver is being used. Acquiring a connection to an outside database is not different from a generic JDBC connection. For details, see JDBC API.

### Warning

If you connect to other databases, the connection to the CUBRID database does not terminate automatically even when the execution of the Java method ends. Therefore, the connection must be explicitly closed so that the result of transaction operations such as **COMMIT** or **ROLLBACK** will be reflected in the database. That is, a separate transaction will be performed because the database that called the Java stored function/procedure is different from the one where the actual connection is made.

```

import java.sql.*;

public class SelectData {
    public static void SearchSubway(String[] args) throws Exception {
        Connection conn = null;
        Statement stmt = null;
        ResultSet rs = null;

        try {
            conn =
DriverManager.getConnection("jdbc:CUBRID:localhost:
33000:demodb::", "", "");

            String sql = "select line_id, line from line";
            stmt = conn.createStatement();
            rs = stmt.executeQuery(sql);

            while(rs.next()) {
                int host_year = rs.getString("host_year");
                String host_nation = rs.getString("host_nation");

                System.out.println("Host Year ==> " + host_year);
                System.out.println(" Host Nation==> " + host_nation);
                System.out.println("\n=====\n");
            }

            rs.close();
        } catch (SQLException e1) {
            System.err.println(e1.getMessage());
        } catch (Exception e2) {
            System.err.println(e2.getMessage());
        } finally {
            if (stmt != null) stmt.close();
            if (conn != null) conn.close();
        }
    }
}

```

When Java stored functions/procedures are executed, they should run only on a JVM located in the database server. You can check where they are running by calling `System.getProperty("cubrid.server.version")` from the Java programs. The result is the database version if it is called from the database; otherwise, it is **NULL**.

## Java Native Interface (JNI) Support

Using the Java Native Interface (JNI), you can invoke functions in native languages like C/C++ from the Java Virtual Machine (JVM). Java Stored Procedures (SP) in CUBRID provide support for JNI functionality, but you should be cautious when using it because issues in native code can have

unexpected impacts on Procedural Language Server (cub\_pl) process and its operation. Java Classes used for loading native libraries should be registered using the **-j** option of **loadjava** to prevent them from being dynamically loaded. For more details, refer to :ref:jsp-load-java.

The following is an example of invoking a native function through JNI in a CUBRID Java stored function:

HelloJNI.h

```
#include <jni.h>

#ifndef _Included_HelloJNI
#define _Included_HelloJNI
#ifdef __cplusplus
extern "C" {
#endif

/*
 * Class:      HelloJNI
 * Method:     sayHello
 * Signature:  ()V
 */
JNIEXPORT jstring JNICALL Java_HelloJNI_sayHello(JNIEnv *,
jobject, jstring);

#ifdef __cplusplus
}
#endif
#endif
```

HelloJNI.c

```
#include <jni.h>
#include <stdio.h>
#include <string.h>
#include "HelloJNI.h"

// Implementation of native method sayHello() of HelloJNI class
JNIEXPORT jstring JNICALL Java_HelloJNI_sayHello(JNIEnv *env,
jobject thisObj, jstring javaString) {
    const char *nativeString = (*env)->GetStringUTFChars(env,
javaString, 0);
    // printf("Java_HelloJNI_sayHello : %sn", nativeString);
    const char *greeting = " Hello!";
    char cap[1024];
    strcpy(cap, nativeString);
    strcat(cap, greeting);
    (*env)->ReleaseStringUTFChars(env, javaString, nativeString);
```

```

    return (*env)->NewStringUTF(env, cap);
}

```

HelloJNI.java

```

import java.io.File;

public class HelloJNI {
    static {
        try {
            String cubridPath = System.getenv("CUBRID"); // get
$CUBRID
            System.load(
                cubridPath
                + File.separator
                + "jni"
                + File.separator
                + "libhello.so"); // $CUBRID/jni/libhello.so
        } catch (UnsatisfiedLinkError e) {
            e.printStackTrace();
        }
    }

    // Declare
    private native String sayHello(String string);

    // CUBRID
    public static String cubridSayHello(String string) {
        return new HelloJNI().sayHello(string); // invoke the
native method
    }
}

```

```

-- compile and copy HelloJNI.c
gcc -fPIC -I${JAVA_HOME}/include -I${JAVA_HOME}/include/linux -
shared -o libhello.so HelloJNI.c
mkdir -p $CUBRID/jni
cp libhello.so $CUBRID/jni

-- loadjava
javac HelloJNI.java
loadjava -j demodb HelloJNI.class

```

```

CREATE FUNCTION hello(str VARCHAR) RETURN VARCHAR AS LANGUAGE JAVA
NAME 'HelloJNI.cubridSayHello(java.lang.String) return
java.lang.String';

```

```
SELECT hello ('CUBRID');
```

```
hello('CUBRID')
=====
'CUBRID Hello!'
```

### Warning

When a java stored procedure/function included JNI code is loaded without **-j** or **-jni** option, the following error is returned during execution. 'Library load not allowed. Please load your class by using 'loadjava' with '-jni' option'

To address this issue, please consider the following:

- **If you are loading multiple Java class files that call `System.load()` for the same native library path:**
  - Modify the Java class files to load the native library from only one class file.
  - Register the class that loads the native library using the **-j** option of loadjava.
  - Restart the PL server. (see [CUBRID Procedural Language Server](#))
- **If you are overwriting a previously loaded Java class file using loadjava:**
  - Re-register the class using the **-j** option with loadjava.
  - Restart the pl utility. (see [CUBRID Procedural Language Server](#))

## loadjava Utility

You can load a Java \*.class or \*.jar file using **loadjava** utility. The file is moved to a database internal path.

```
loadjava [option] database-name java-class-file
```

- *database-name*: The name of the database where the Java file to be loaded.
- *java-class-file*: The name of the Java class or jar file to be loaded.

• *[option]*

- **-y** (or **-overwrite**): Automatically overwrites an existing file with the same name. By default, the tool prompts for confirmation if a file with the same name exists and this option is not provided.
- **-j** (or **-jni**): Specifies that the Java \*.class or \*.jar file includes JNI (native libraries). This prevents native library loading errors and moves the file to the static load path.
- **-p** (or **-package**): Specifies the package name when loading Java class files with a package declaration. If the class belongs to the default package, this option is not required.

```
* In the examples provided in the manual, the Java files do not
specify a package at the top of the code. In this case, the default
package is used, and there is no need to use the **-p** option.
* However, when loading a Java file that includes a package
declaration, you must use the **-p** option to specify the package
name.
```

Example: Loading a Java Class with a Java package name

If a Java class includes a package declaration, such as:

```
package org.cubrid;

public class NumberUtils {
    public static int addIntegers(int num1, int num2) {
        return num1 + num2;
    }
}
```

### 1. Compile the Java File

```
javac NumberUtils.java
```

### 2. Load the Compiled File into the Database

```
loadjava demodb -p org.cubrid NumberUtils.class
```

### 3. Create a Stored Function in SQL

```
CREATE OR REPLACE FUNCTION add_integer(a INT, b INT) RETURN INT
AS LANGUAGE JAVA
NAME 'org.cubrid.NumberUtils.addIntegers(int, int) return int';
```

#### 4. Use the Function

```
SELECT add_integer(1, 2);
```

Output:

```
add_integer(1, 2)
=====
3
```

## Caution

- java.sql.DatabaseMetaData is not supported.
- JDBC API related to BLOB/CLOB type is not supported.
- Functions not related to query execution and used only in client-side JDBC are not supported. For details, refer to [Appendix](#).
- Multiple SQL statements are not supported when executing a query with one JDBC object.
- ResultSet created by query execution is non-updatable, non-scrollable, and non-sensitive.
- Java ignores precision, scale, and length parts of SQL types of IN/OUT parameters, matches only the type name parts, and delivers values as they are.
- A stored procedure can call another stored procedure or call itself recursively. The maximum nesting depth is 16.

## Limitations on the precision of IN/OUT parameters and a return value

To limit the return value of Java stored function/procedure and precision type on IN/OUT, CUBRID processes as follows:

- Checks the SQL type of the Java stored function/procedure.
- Passes the value returned by Java to the database with only the type converted if necessary, ignoring the number of digits defined during creating the Java stored function/procedure.

- In principle, the user should directly manipulate the data which is passed to the database.

Take a look at the following **typestring** () Java stored function.

```
public class JavaSP1 {  
    public static String typestring() {  
        String temp = " ";  
        for(int i = 0; i < 1; i++) {  
            temp = temp + "1234567890";  
        }  
        return temp;  
    }  
}
```

```
CREATE FUNCTION typestring() RETURN CHAR(5) AS LANGUAGE JAVA  
NAME 'JavaSP1.typestring()' return java.lang.String;  
  
CALL typestring();
```

```
Result  
=====  
' 1234567890'
```

## Appendix

### Data Type Mapping

When a Java stored function/procedure is published, it is not checked whether the return definition of the Java stored function/procedure coincides with the one in the declaration of the Java method. Therefore, the Java stored function/procedure follows the return definition (SQL Type) provided at the time of registration. The return definition in the declaration is significant only as user-defined information.

In call specifications, the data types of SQL must correspond to the data types of Java parameter and return value. In addition, when implementing a Java stored function/procedure, the data types of Java must match the data types of query result (ResultSet). The following table shows SQL/Java data types allowed in CUBRID.

### Data Type Mapping

| Category        | SQL Type                      | Java Type                |
|-----------------|-------------------------------|--------------------------|
| Numeric Types   | SHORT, SMALLINT               | short, java.lang.Short   |
|                 | INT, INTEGER                  | int, java.lang.Integer   |
|                 | BIGINT                        | long, java.lang.Long     |
|                 | NUMERIC, DECIMAL              | java.math.BigDecimal     |
|                 | FLOAT, REAL                   | float, java.lang.Float   |
|                 | DOUBLE, PRECISION      DOUBLE | double, java.lang.Double |
| Date/Time Types | DATE                          | java.sql.Date            |
|                 | TIME                          | java.sql.Time            |
|                 | TIMESTAMP                     | java.sql.Timestamp       |
|                 | DATETIME                      | java.sql.Timestamp       |
|                 | TIMESTAMPPLTZ                 | X (not supported)        |
|                 | TIMESTAMPTZ                   | X (not supported)        |
|                 | DATETIMELTZ                   | X (not supported)        |
|                 | DATETIMEZ                     | X (not supported)        |

| Category               | SQL Type      | Java Type                                                                         |
|------------------------|---------------|-----------------------------------------------------------------------------------|
| Bit String Types       | BIT           | X (not supported)                                                                 |
|                        | VARBIT        | X (not supported)                                                                 |
| Character String Types | CHAR          | java.lang.String                                                                  |
|                        | VARCHAR       | java.lang.String                                                                  |
| Enum Type              | ENUM          | X (not supported)                                                                 |
| LOB Types              | CLOB, BLOB    | X (not supported)                                                                 |
| Collection Types       | SET, SEQUENCE | MULTISET, java.lang.Object[], java primitive type array, java wrapper class array |
| Special Types          | JSON          | X (not supported)                                                                 |
|                        | OBJECT, OID   | cubrid.sql.CUBRIDOID<br><interface>                                               |
|                        | CURSOR        | java.sql.ResultSet<br><interface>                                                 |

### Implicit Data Type Conversion

If the data type of SQL and the data type of Java do not correspond as shown in the table above, CUBRID implicitly attempts data type conversion according to the following table. Please note that implicit data conversion may result in data loss.

[illegible]

| Java Data Types |                      |                        |                        |                      |                        |                          |                      |                  |               |                    |
|-----------------|----------------------|------------------------|------------------------|----------------------|------------------------|--------------------------|----------------------|------------------|---------------|--------------------|
| SQL Data Types  | byte, java.lang.Byte | short, java.lang.Short | int, java.lang.Integer | long, java.lang.Long | float, java.lang.Float | double, java.lang.Double | java.math.BigDecimal | java.lang.String | java.sql.Time | java.sql.Timestamp |

## Table of Supproting JDBC API

| JDBC Interface             | Support/Unsupport                               |
|----------------------------|-------------------------------------------------|
| java.sql.CallableStatement | Support                                         |
| java.sql.Connection        | Support                                         |
| java.sql.Driver            | Support ( <a href="#">Creating Connection</a> ) |
| java.sql.PreparedStatement | Support                                         |
| java.sql.ResultSet         | Support                                         |
| java.sql.ResultSetMetaData | Support                                         |
| CUBRIDOID                  | Support                                         |
| java.sql.Statement         | Support                                         |
| java.sql.DriverManager     | Support                                         |
| Java.sql.SQLException      | Support                                         |
| java.sql.Array             | Unsupport                                       |
| java.sql.Blob              | Unsupport                                       |
| java.sql.Clob              | Unsupport                                       |

| JDBC Interface             | Support/Unsupport |
|----------------------------|-------------------|
| java.sql.DatabaseMetaData  | Unsupport         |
| java.sql.ParameterMetaData | Unsupport         |
| java.sql.Ref               | Unsupport         |
| java.sql.Savepoint         | Unsupport         |
| java.sql.SQLData           | Unsupport         |
| java.sql.SQLInput          | Unsupport         |
| java.sql.Struct            | Unsupport         |

#### Note

JDBC APIs not specified in the table below are not supported and return SQLException.

java.sql.Connection

| Method                      | Description                                 |
|-----------------------------|---------------------------------------------|
| Properties getClientInfo()  | Getting information about connection client |
| void rollback()             | do nothing                                  |
| Statement createStatement() | Executing SQL Statements                    |
|                             | Executing SQL Statements                    |

| Method                                                                                                           | Description              |
|------------------------------------------------------------------------------------------------------------------|--------------------------|
| Statement createStatement(int resultSetType, int resultSetConcurrency)                                           |                          |
| Statement createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)                 | Executing SQL Statements |
| CallableStatement prepareCall(String sql)                                                                        | Executing SQL Statements |

## Method

A method is a program written in C with built-in functions of the CUBRID database system, and is called by the **CALL** statement. When a method is called, the program is loaded and linked with the running application by a dynamic loader. The return value generated by the method execution is delivered to the caller.

### Limitations

- Currently, methods are only available in some systems of the CUBRID database, such as the [User Authorization Management METHOD](#).
- User-defined methods are not recommended due to many constraints and are only used in system-built methods.

## Method Type

The CSQL language supports the following two types of methods: class and instance methods.

- The **class method** is a method called by a class object. It is usually used to create a new class instance or to initialize it. It is also used to access or update class attributes.
- The **instance method** is a method called by a class instance. It is used more often than the class method because most operations are executed in the instance. For example, an instance method can be written to calculate or update the instance attribute. This method can be called from any instance of the class in which the method is defined or of the sub class that inherits the method.

The method inheritance rules are similar to those of the attribute inheritance. The sub class inherits classes and instance methods from the super class. The sub class can follow the class or instance method definition from the super class.

The rules for resolving method name conflicts are same as those for attribute name conflicts. For details about attribute/method inheritance conflicts, see [Class Conflict Resolution](#).

## CALL Statement

The **CALL** statement is used to call a method defined in the database. Both class and instance methods can be called by the **CALL** statement. If you want to see example of using the CALL statement, see [User Authorization Management METHOD](#).

```
CALL <method_call> ;

<method_call> ::=
    method_name ([<arg_value> [{, <arg_value> } ...]]) ON
<call_target> [<to_variable>] |
    method_name (<call_target> [, <arg_value> [{,
<arg_value>} ...]] ) [<to_variable>]

    <arg_value> ::=
        any CSQL expression

    <call_target> ::=
        an object-valued expression

    <to_variable> ::=
        INTO variable |
        TO variable
```

- The *method\_name* is either the method name defined in the table or the system-defined method name. A method requires one or more parameters. If there is no parameter for the method, a set of blank parentheses must be used.
- <call\_target> can use an object-valued expression that contains a class name, a variable, another method call (which returns an object). To call a class method for a class object, you must place the **CLASS** keyword before the <call\_target>. In this case, the table name must be the name of the class where the table method is defined. To call a record method, you must specify the expression representing the record object. You can optionally store the value returned by the table or record method in the <to\_variable>. This returned variable value can be used in the **CALL** statement just like the <call\_target> or <arg\_value> parameter.
- Calling nested methods is possible when other *method\_call* is the <call\_target> of the method or given as one of the <arg\_value> parameters.

# CUBRID Management

This chapter describes how the database administrators (**DBA**) operates the CUBRID system.

- It includes instructions on how to use the **cubrid** utility, which starts and stops various processes of the CUBRID server, the broker, procedure language server, and manager server. See [Controlling CUBRID Processes](#).
- It includes instructions on the following: database management tasks (creating and deleting databases, adding volume, etc.), migration tasks (moving database to a different location or making changes so that it fits the system's version), and making back-ups and rollbacks of the database in case of failures. See [cubrid Utilities](#).
- It includes instructions on the system configuration. See [System Parameters](#).
- It includes how to use SystemTap, which can monitors and traces the operating processes dynamically. See [SystemTap](#).
- It includes instructions on troubleshooting. See [Troubleshooting](#).

The **cubrid** utilities provide features that can be used to comprehensively manage the CUBRID service. The CUBRID utilities are divided into the service management utility, which is used to manage the CUBRID service process, and the database management utility, which is used to manage the database.

The service management utilities are as follows:

- Service utility : Operates and manages the master process.
  - [cubrid service](#)
- Server utility : Operates and manages the server process.
  - [cubrid server](#)
- Broker utility : Operates and manages the broker process and application server (CAS) process.
  - [cubrid broker](#)
- Gateway utility : Operates and manages the gateway process and application server (CAS) process. \* [cubrid gateway](#)
- Manager utility : Operates and manages the manager server process.
  - [cubrid manager](#)

- HA utility : Operates and manages the HA-related processes.
  - `cubrid heartbeat`
- PL utility : Operates and manages the procedure language (PL) server.
  - `cubrid pl`

See [Controlling CUBRID Processes](#) for details.

The database management utilities are as follows:

- Creating database, adding volume, and deleting database
  - `cubrid createdb`
  - `cubrid addvoldb`
  - `cubrid deletedb`
- Renaming database, altering host, copying/moving database, and registering database
  - `cubrid renamedb`
  - `cubrid alterdbhost`
  - `cubrid copydb`
  - `cubrid installdb`
- Backing up database
  - `cubrid backupdb`
- Restoring database
  - `cubrid restoredb`
- Unloading and Loading database
  - `cubrid unloaddb`
  - `cubrid loaddb`
- Checking and compacting database space

  - `cubrid dumplocale`

See [cubrid Utilities](#) for details.

#### Note

If you want to control the service by using **cubrid** utility on Windows Vista or later, it is recommended that you run the command prompt with an administrator account. If you use **cubrid** utility without an administrator account, the result message is not displayed even though you can run it through the User Account Control (UAC) dialog.

To run the command prompt on Windows Vista or later with an administrator account, right-click [Start] > [All Programs] > [Accessories] > [Command Prompt] and select [Run as

Administrator]. In the dialog verifying authorization, click [Yes], and then the command prompt is run as an administrator account.

## Controlling CUBRID Processes

CUBRID processes can be controlled by **cubrid** utility.

### Controlling CUBRID Service

The following **cubrid** utility syntax shows how to control services registered in the configuration file. One of the following can be specified in <command>.

```
cubrid service <command>  
<command>: {start|stop|restart|status}
```

- start: start services.
- stop: stop services.
- restart: restart services.
- status: check status.

No additional options or arguments are required.

### Controlling Database Server

The following **cubrid** utility syntax shows how to control database server process.

```
cubrid server <command> [database_name]  
<command>: {start|stop|restart|status}
```

One of the following can be specified in <command>:

- start: start a database server process.
- stop: stop a database server process.
- restart: restart a database server process.
- status: check status of a database server process.

Every command can specify a database name (**[database\_name]**) as an argument.

If the database name is not specified, the **status** command displays the currently running database servers' information, and the commands except **status** refer to the database names in the **server** property of the **[service]** section of **cubrid.conf**.

```
# cubrid.conf

[service]

...

server=demodb,testdb

...
```

```
% cubrid server start

@ cubrid server start: demodb

This may take a long time depending on the amount of recovery works
to do.

CUBRID 11.4

++ cubrid server start: success

@ cubrid server start: testdb

This may take a long time depending on the amount of recovery works
to do.

CUBRID 11.4

++ cubrid server start: success
```

## Controlling Broker

The following cubrid utility syntax shows how to control CUBRID broker process. One of the following can be specified in <command>: start is used to run services; stop is used to stop services; restart is used to restart services; status is used to check status; acl is used to limit broker access; on/off is used to enable/disable the specified broker; reset is used to reset the connection to broker; info is used to display the broker configuration information; getid is used to get the SHARD ID(SHARD database ID) with SHARD key.

And more, SHARD feature can be used only after the broker is started and "SHARD", the broker parameter, whose value in cubrid\_broker.conf is set to ON.

```
cubrid broker <command>
<command>: start
            |stop
            |restart
            |status [options] [broker_name_expr]
            |acl {status|reload} broker_name
            |on <broker_name> |off <broker_name>
            |reset broker_name
            |info
            |getid -b <broker_name> [-f] shard_key
```

## Controlling Gateway

The following **cubrid** utility syntax shows how to control CUBRID gateway process.

```
cubrid gateway <command>
<command>: start
            |stop
            |restart
            |status [options] [gateway_name_expr]
            |acl {status|reload} gateway_name
            |on <gateway_name> |off <gateway_name>
            |reset gateway_name
            |info
```

- start: start gateway processes.
- stop: stop gateway processes.
- restart: restart gateway processes.
- status: check status of gateway processes.
- acl: limit gateway access.
- on/off: enable/disable the specified gateway.
- reset: reset the connection to gateway.
- info: display the gateway configuration information.

## Controlling CUBRID Manager Server

To use the CUBRID Manager, the Manager server must be running where database server is running. The following **cubrid** utility syntax shows how to control the CUBRID Manager processes.

```
cubrid manager <command>  
<command>: {start|stop|status}
```

- start: start manager server processes.
- stop: stop manager server processes.
- status: check the status of manager processes.

## Controlling CUBRID HA

The following **cubrid heartbeat** utility syntax shows how to use CUBRID HA. One of the following can be specified in *command*.

```
cubrid heartbeat <command>  
<command>: {start|stop|copylogdb|applylogdb|reload|status}
```

- start: start HA-related processes.
- stop: stop HA-related processes.
- copylogdb: start or stop copylogdb process.
- applylogdb: start or stop applylogdb process.
- reload: reload information on HA configuration.
- status: check HA status.

For details, see [cubrid heartbeat Utility](#).

## Controlling CUBRID Procedural Language (PL) Server

The following **cubrid** utility syntax is used to control the CUBRID Procedural Language (PL) server process.

```
cubrid pl <command> [database_name]  
<command>: {restart|status}
```

- restart: restart the procedural language server process.
- status: check the status of the procedural language server process.

**Note**

- Every command can specify a database name (**[database\_name]**) as an argument.
- The **restart** command forcibly stops the procedural language server, and the database server detects this and automatically restarts the procedural language server.
- If the database name is not specified when executing the **status** command, it displays the status information of the procedural language server for all running databases.

```
% cubrid pl restart demodb

@ cubrid pl start: demodb
++ cubrid pl start: success

% cubrid pl status demodb

@ cubrid pl status
Procedural Language Server (demodb, pid 12345, UDS)
VM arguments:
-----
...
-----
```

**Note**

From CUBRID version 11.4, the CUBRID Procedural Language (PL) server has replaced the previously used CUBRID Java Stored Procedure (Java SP) server.

## CUBRID Services

### Registering Services

You can register database servers, CUBRID brokers, CUBRID gateways, CUBRID Manager(s) or CUBRID HA as CUBRID service in the configuration file ( **cubrid.conf** ). To register services, you can input for each **server**, **broker**, **gateway**, **manager** or **heartbeat** as a parameter value, and it is possible to input several values by concatenating them in comma(,).

If you do not register any service, only master process is registered by default. It is convenient for you to view status of all related processes at a glance or start and stop the processes at once with the **cubrid service** utility once it is registered as CUBRID service.

- For details on CUBRID HA configuration, see [Registering HA to cubrid service](#).

The following example shows how to register database server and broker, gateway as service in the **cubrid.conf** file and enable databases ( *demodb* and *testdb* ) to start automatically at once when CUBRID server starts running.

```
# cubrid.conf
...

[service]

# The list of processes to be started automatically by 'cubrid
service start' command
# Any combinations are available with server, broker, gateway,
manager and heartbeat.
service=server,broker,gateway

# The list of database servers in all by 'cubrid service start'
command.
# This property is effective only when the above 'service' property
contains 'server' keyword.
server=demodb,testdb
```

## Starting Services

In Linux environment, you can enter the code below to start CUBRID after installation. If no server is registered in the configuration file, only master process (cub\_master) runs by default.

In the Windows environment, the code below is normally executed only if a user with system permission has logged in. An administrator or general user can start or stop the CUBRID server by clicking its icon on the taskbar tray.

```
% cubrid service start

@ cubrid master start
++ cubrid master start: success
```

The following message is returned if master process is already running.

```
% cubrid service start
```

```
@ cubrid master start
++ cubrid master is running.
```

The following message is returned if master process fails to run. The example shows that service fails to start due to conflicts of the **cubrid\_port\_id** parameter value specified in the cubrid.conf file. In such a case, you can resolve the problem by changing the port. If it fails to start even though no port is occupied by process, delete /tmp/CUBRID1523 file and then restart the process.

```
% cubrid service start

@ cubrid master start
cub_master: '/tmp/CUBRID1523' file for UNIX domain socket exist....
Operation not permitted
++ cubrid master start: fail
```

After registering service as explained in [CUBRID Services](#), enter the code below to start the service. You can verify that database server process and broker, gateway as well as registered *demodb* and *testdb* are starting at once.

```
% cubrid service start

@ cubrid master start
++ cubrid master start: success
@ cubrid server start: demodb

This may take a long time depending on the amount of restore works
to do.
CUBRID 11.4

++ cubrid server start: success
@ cubrid server start: testdb

This may take a long time depending on the amount of recovery works
to do.
CUBRID 11.4

++ cubrid server start: success
@ cubrid broker start
++ cubrid broker start: success
@ cubrid gateway start
++ cubrid gateway start: success
```

## Stopping Services

Enter code below to stop CUBRID service. If no services are registered by a user, only master process stops and then restarts.

```
% cubrid service stop
@ cubrid master stop
++ cubrid master stop: success
```

Enter code below to stop registered CUBRID service. You can verify that server process, broker process, gateway process and master process as well as *demodb* and *testdb* stop at once.

```
% cubrid service stop
@ cubrid server stop: demodb

Server demodb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
@ cubrid server stop: testdb
Server testdb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
@ cubrid broker stop
++ cubrid broker stop: success
@ cubrid gateway stop
++ cubrid gateway stop: success
@ cubrid master stop
++ cubrid master stop: success
@ cubrid master stop
++ cubrid master stop: success
```

## Restarting Services

Enter code below to restart CUBRID service. If no services are registered by a user, only master process stops and then restarts.

```
% cubrid service restart

@ cubrid master stop
++ cubrid master stop: success
@ cubrid master start
++ cubrid master start: success
```

Enter code below to restart registered CUBRID service. You can verify that server process, broker process, gateway process and master process as well as *demodb* and *testdb* stop and then restart at once.

```
% cubrid service restart

@ cubrid server stop: demodb
```

```

Server demodb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
@ cubrid server stop: testdb
Server testdb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
@ cubrid broker stop
++ cubrid broker stop: success
@ cubrid gateway stop
++ cubrid gateway stop: success
@ cubrid master stop
++ cubrid master stop: success
@ cubrid master start
++ cubrid master start: success
@ cubrid server start: demodb

```

This may take a long time depending on the amount of recovery works to do.

CUBRID 11.4

```

++ cubrid server start: success
@ cubrid server start: testdb

```

This may take a long time depending on the amount of recovery works to do.

CUBRID 11.4

```

++ cubrid server start: success
@ cubrid broker start
++ cubrid broker start: success
@ cubrid gateway start
++ cubrid gateway start: success

```

## Managing Service Status

The following example shows how to check the status of master process and database server registered.

```

% cubrid service status

@ cubrid master status
++ cubrid master is running.
@ cubrid server status

Server testdb (rel 11.4, pid 31059)
Server demodb (rel 11.4, pid 30950)

```

```

@ cubrid broker status
NAME                PID  PORT    AS   JQ
TPS                 QPS  SELECT  INSERT  UPDATE  DELETE
OTHERS             LONG-T  LONG-Q    ERR-Q  UNIQUE-ERR-Q  #CONNECT
#REJECT
=====
=====
=====
* query_editor      10877 30000    5    0
0                  0      0      0      0      0
0      0/60.0      0/60.0    0      0
0                  0
* broker1          10889 33000    5    0
0                  0      0      0      0      0
0      0/60.0      0/60.0    0      0
0                  0
@ cubrid gateway status
NAME                PID  PORT    AS   JQ
TPS                 QPS  SELECT  INSERT  UPDATE  DELETE
OTHERS             LONG-T  LONG-Q    ERR-Q  UNIQUE-ERR-Q  #CONNECT
#REJECT
=====
=====
=====
* oracle_gateway   10903 53000    5    0
0                  0      0      0      0      0
0      0/60.0      0/60.0    0      0
0                  0
@ cubrid manager server status
++ cubrid manager server is not running.

```

The following message is returned if master process has stopped.

```

% cubrid service status
@ cubrid master status
++ cubrid master is not running.

```

## cubrid Utility Logging

CUBRID supports a logging feature about cubrid utility's running result.

### Logging contents

The following contents are written to the **\$CUBRID/log/cubrid\_utility.log** file.

- All commands through cubrid utilities: only usage, version and parsing errors are not logged.

- Execution results by cubrid utilities: success/failure.
- An error message when failure.

### Log file size

A size of **cubrid\_utility.log** file is expanded by the size specified by **error\_log\_size** parameter in **cubrid.conf**, if this size is enlarged as the specified size, it is backed up as the **cubrid\_utility.log.bak** file.

### Log format

```
<time> (cubrid PID) <contents>
```

The following is an example of printing the log file.

```
13-11-19 15:27:19.426 (17724) cubrid manager stop
13-11-19 15:27:19.430 (17724) FAILURE: ++ cubrid manager server is
not running.
13-11-19 15:27:19.434 (17726) cubrid service start
13-11-19 15:27:19.439 (17726) FAILURE: ++ cubrid master is running.
13-11-19 15:27:22.931 (17726) SUCCESS
13-11-19 15:27:22.936 (17756) cubrid service restart
13-11-19 15:27:31.667 (17756) SUCCESS
13-11-19 15:27:31.671 (17868) cubrid service stop
13-11-19 15:27:34.909 (17868) SUCCESS
```

However, in Windows, some **cubrid** commands are executed through a service process; therefore, a duplicated information can be displayed again.

```
13-11-13 17:17:47.638 ( 3820) cubrid service stop
13-11-13 17:17:47.704 ( 7848) d:\CUBRID\bin\cubrid.exe service stop
--for-windows-service
13-11-13 17:17:56.027 ( 7848) SUCCESS
13-11-13 17:17:57.136 ( 3820) SUCCESS
```

And, in Windows, a process run through the service process cannot print out an error message; therefore, for error messages related to the service start, you should definitely check them in the **cubrid\_utility.log** file.

## Database Server

### Starting Database Server

The following example shows how to run *demodb* server.

```
% cubrid server start demodb

@ cubrid server start: demodb

This may take a long time depending on the amount of recovery works
to do.

CUBRID 11.4

++ cubrid server start: success
```

If you start *demodb* server while master process has stopped, master process automatically runs at first and then a specified database server runs.

```
% cubrid server start demodb

@ cubrid master start
++ cubrid master start: success
@ cubrid server start: demodb

This may take a long time depending on the amount of recovery works
to do.

CUBRID 11.4

++ cubrid server start: success
```

The following message is returned while *demodb* server is running.

```
% cubrid server start demodb

@ cubrid server start: demodb
++ cubrid server 'demodb' is running.
```

**cubrid server start** runs `cub_server` process of a specific database regardless of HA mode configuration. To run database in HA environment, you should use **cubrid heartbeat start**.

## Stopping Database Server

The following example shows how to stop *demodb* server.

```
% cubrid server stop demodb

@ cubrid server stop: demodb
Server demodb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
```

The following message is returned while *demodb* server has stopped.

```
% cubrid server stop demodb

@ cubrid server stop: demodb
++ cubrid server 'demodb' is not running.
```

**cubrid server stop** stops `cub_server` process of a specific database regardless of HA mode configuration. Be careful not to restart the database server or occur failover. To stop database in HA environment, you should use **cubrid heartbeat stop**.

## Restarting Database Server

The following example shows how to restart *demodb* server. *demodb* server that has already run stops and the server restarts.

```
% cubrid server restart demodb

@ cubrid server stop: demodb
Server demodb notified of shutdown.
This may take several minutes. Please wait.
++ cubrid server stop: success
@ cubrid server start: demodb

This may take a long time depending on the amount of recovery works
to do.

CUBRID 11.4

++ cubrid server start: success
```

## Checking Database Server Status

The following example shows how to check the status of a database server. Names of currently running database servers are displayed.

```
% cubrid server status

@ cubrid server status
Server testdb (rel 11.4, pid 24465)
Server demodb (rel 11.4, pid 24342)
```

The following example shows the message when master process has stopped.

```
% cubrid server status

@ cubrid server status
++ cubrid master is not running.
```

## Limiting Database Server Access

To limit brokers and the CSQL Interpreter connecting to the database server, configure the parameter value of **access\_ip\_control** in the **cubrid.conf** file to yes and enter the path of a file in which the list of IP addresses allowed to access the **access\_ip\_control\_file** parameter value is written. You should enter the absolute file path. If you enter the relative path, the system will search the file under the **\$CUBRID/conf** directory on Linux and under the **%CUBRID%\conf** directory on Windows.

The following example shows how to configure the **cubrid.conf** file.

```
# cubrid.conf
access_ip_control=yes
access_ip_control_file="/home1/cubrid1/CUBRID/db.access"
```

The following example shows the format of the **access\_ip\_control\_file** file.

```
[@<db_name>]
<ip_addr>
...
```

- <db\_name>: The name of a database in which access is allowed

- `<ip_addr>`: The IP address allowed to access a database. Using an asterisk (\*) at the last digit means that all IP addresses are allowed. Several lines of `<ip_addr>` can be added in the next line of the name of a database.

To configure several databases, it is possible to specify additional `[@<db_name>]` and `<ip_addr>`.

Accessing any IP address except localhost is blocked by server if **access\_ip\_control** is set to yes but **ip\_control\_file** is not configured. A server will not run if analyzing **access\_ip\_control\_file** fails caused by incorrect format.

The following example shows **access\_ip\_control\_file**.

```
[@dbname1]
192.10.20.30
192.156.*

[@dbname2]
*

[@dbname3]
192.168.1.15
```

The example above shows the *dbname1* database allows the access connections from the IP address 192.10.20.30 or from any IP address that starts with 192.156. *dbname2* database allows the access of every IP address; *dbname3* database allows the access of an IP address, 192.168.1.15, only.

For the database which has already been running, you can modify a configuration file or you can check the currently applied status by using the following commands.

To change the contents of **access\_ip\_control\_file** and apply it to server, use the following command.

```
cubrid server acl reload <database_name>
```

To display the IP configuration of a server which is currently running, use the following command.

```
cubrid server acl status <database_name>
```

## Database Server Log

### Error Log

The following log is created in the file of a server error log if an IP address that is not allowed to access is used.

```
Time: 10/29/10 17:32:42.360 - ERROR *** ERROR CODE = -1022, Tran =
0, CLIENT = (unknown):(unknown)(-1), EID = 2
Address(10.24.18.66) is not authorized.
```

An error log of the database server is saved into **\$CUBRID/log/server** directory, and the format of the file name is `<db_name>_<yyyymmdd>_<hhmmi>.err`. The extension is “.err”.

```
demodb_20130618_1655.err
```

#### Note

For details on how to limit an access to the broker server, see [Limiting Broker Access](#).

### Event Log

If an event which affects on the query performance occurs, this is saved into the event log.

The events which are saved on the event log are *SLOW\_QUERY*, *MANY\_IOREADS*, *LOCK\_TIMEOUT*, *DEADLOCK* and *TEMP\_VOLUME\_EXPAND*.

This log file is saved into the **\$CUBRID/log/server** directory, and the format of the file name is `<db_name>_<yyyymmdd>_<hhmmi>.event`. The extension is “.event”.

```
demodb_20130618_1655.event
```

### SLOW\_QUERY

If a slow query occurs, this event is written. If **sql\_trace\_slow** parameter value of cubrid.conf is set, this event will arise. The output example is as follows.

```
06/12/13 16:41:05.558 - SLOW_QUERY
client: PUBLIC@testhost|csql(13173)
sql: update [y] [y] set [y].[a]=?:1 where [y].[a]=?:0 using
```

```
index [y].[pk_y_a](+)
  bind: 5
  bind: 200
  time: 1015
  buffer: fetch=48, ioread=2, iowrite=0
  wait: cs=1, lock=1010, latch=0
```

- client: <DB user>@<application client host name>|<program name>(<process ID>)
- sql: slow query
- bind: binding value. it is printed out as the number of <num> in the sql item, “?:<num>”. The value of “?:0” is 5, and the value of “?:1” is 200.
- time: execution time(ms)
- buffer: execution statistics in the buffer
  - fetch: fetching pages count
  - ioread: I/O read pages count
  - iowrite: I/O write pages count
- wait: waiting time
  - cs: waiting time on the critical section(ms)
  - lock: waiting time to acquire the lock(ms)
  - latch: waiting time to acquire the latch(ms)

On the above example, the query execution time was 1015ms, and lock waiting time was 1010ms, so we can indicate that almost all execution time was from lock waiting.

## MANY\_IOREADS

Queries which brought many I/O reads are written on the event log. If I/O reads occurs more than **sql\_trace\_ioread\_pages** parameter value of cubrid.conf, the event is written on the event log. The following is an output example.

```
06/12/13 17:07:29.457 - MANY_IOREADS
  client: PUBLIC@testhost|csql(12852)
  sql: update [x] [x] set [x].[a]=?:1 where ([x].[a]>?:0) using
index [x].[idx](+)
  bind: 8
  bind: 100
```

```
time: 528
ioreads: 15648
```

- client: <DB user>@<application client host name>|<process name>(<process ID>)
- sql: an SQL which brought many I/O reads
- bind: binding value. it is printed out as the number of <num> in the sql item, “?:<num>”. The value of “?:0” is 8, and the value of “?:1” is 100.
- time: execution time(ms)
- ioread: I/O read pages count

## LOCK\_TIMEOUT

When lock timeout occurs, queries of a waiter and a blocker are written on the event log. The following is an output example.

```
02/02/16 20:56:18.650 - LOCK_TIMEOUT
waiter:
  client: public@testhost|csql(21529)
  lock:   X_LOCK (oid=0|650|3, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 2
  bind: 1

blocker:
  client: public@testhost|csql(21541)
  lock:   X_LOCK (oid=0|650|3, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 3
  bind: 1
```

- waiter: a waiting client to acquire locks.
  - lock: lock type, table and index names
  - sql: a waiting SQL to acquire locks.
  - bind: binding value.
- blocker: a client to have locks.
  - lock: lock type, table and index names
  - sql: a SQL which is acquiring locks
  - bind: binding value

On the above, you can indicate the blocker which brought lock timeout and the waiter which is waiting locks.

## DEADLOCK

When a deadlock occurs, lock information of that transaction is written into the event log. The following is an output example.

```
02/02/16 20:56:17.638 - DEADLOCK
hold:
  client: public@testhost|csql(21541) (Deadlock Victim)
  lock: X_LOCK (oid=0|650|5, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 3
  bind: 1

wait:
  client: public@testhost|csql(21529)
  lock: X_LOCK (oid=0|650|5, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 4
  bind: 1

hold:
  client: public@testhost|csql(21529)
  lock: X_LOCK (oid=0|650|6, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 5
  bind: 2

wait:
  client: public@testhost|csql(21541) (Deadlock Victim)
  lock: X_LOCK (oid=0|650|6, table=t)
  sql: update [t] [t] set [t].[a]= ?:0 where [t].[a]= ?:1
  bind: 6
  bind: 2
```

- hold: an object which is acquiring a lock
  - client: <DB user>@<application client host name>|<process name>(<process ID>)
  - lock: lock type, table name
  - sql: SQL which is acquiring locks
  - bind: binding value
- wait: an object which is waiting a lock
  - client: <DB user>@<application client host name>|<process name>(<process ID>)

- lock: lock type, table name
- sql: SQL which is waiting a lock
- bind: binding value

On the above output, you can check the application clients and SQLs which brought the deadlock.

For more details on locks, see [lockdb](#) and [Lock Protocol](#).

## TEMP\_VOLUME\_EXPAND

When a temporary volumes are expanded, this time is written to the event log. By this log, you can check what transaction brought the expansion of a temporary volumes.

```
06/15/13 18:55:43.458 - TEMP_VOLUME_EXPAND
  client: public@testhost|csql(17540)
  sql: select [x].[a], [x].[b] from [x] [x] where (([x].[a]< ?:0 ))
group by [x].[b] order by 1
  bind: 1000
  time: 44
  pages: 24399
```

- client: <DB user>@<application client host name>|<process name>(<process ID>)
- sql: SQL which requires a more space for temporary data. All INSERT statement except for INSERT ... SELECT syntax, and DDL statement are not delivered to the DB server, so it is shown as EMPTY SELECT, UPDATE and DELETE statements are shown on this item
- bind: binding value
- time: the required time to create a temporary volume(ms)
- pages: the number of available pages within new temporary volume.

## Database Server Errors

Database server error processes use the server error code when an error has occurred. A server error can occur in any task that uses server processes. For example, server errors may occur while using the query handling program or the **cubrid** utility.

### Checking the Database Server Error Codes

- Every data definition statement starting with **#define ER\_** in the **\$CUBRID/include/error\_code.h** file indicate the server error codes.

- All message groups under “\$set 5 MSGCAT\_SET\_ERROR” in the **\$CUBRID/msg/en\_US (in Korean, ko\_KR.euckKR or ko\_KR.utf8)/cubrid.msg** \$ file indicates the server error messages.

When you write a C code with CCI driver, we recommend you to write a code with an error code name than with an error code number. For example, the error code number for violating the unique key is -670 or -886, but users can easily recognize the error when it is written as **ER\_BTREE\_UNIQUE\_FAILED** or **ER\_UNIQUE\_VIOLATION\_WITHKEY**.

However, when you write a JAVA code with JDBC driver, you have to use error code numbers because “dbi.h” file cannot be included into the JAVA code. For JDBC program, you can get an error number by using `getErrorCode()` method of `SQLException` class.

```
$ vi $CUBRID/include/error_code.h

#define NO_ERROR                                0
#define ER_FAILED                              -1
#define ER_GENERIC_ERROR                       -1
#define ER_OUT_OF_VIRTUAL_MEMORY              -2
#define ER_INVALID_ENV                         -3
#define ER_INTERRUPTED                        -4
...
#define ER_LK_OBJECT_TIMEOUT_SIMPLE_MSG       -73
#define ER_LK_OBJECT_TIMEOUT_CLASS_MSG        -74
#define ER_LK_OBJECT_TIMEOUT_CLASSOF_MSG      -75
#define ER_LK_PAGE_TIMEOUT                    -76
...
#define ER_PT_SYNTAX                          -493
...
#define ER_BTREE_UNIQUE_FAILED                 -670
...
#define ER_UNIQUE_VIOLATION_WITHKEY           -886
...
#define ER_LK_OBJECT_DL_TIMEOUT_SIMPLE_MSG     -966
#define ER_LK_OBJECT_DL_TIMEOUT_CLASS_MSG      -967
#define ER_LK_OBJECT_DL_TIMEOUT_CLASSOF_MSG    -968
...
```

The following are some of the server error code names, error code numbers, and error messages.

| Error Code Name                 | Error Code Number | Error Message                                                                   |
|---------------------------------|-------------------|---------------------------------------------------------------------------------|
| ER_LK_OBJECT_TIMEOUT_SIMPLE_MSG | -73               | Your transaction (index ?, ? @? ?) timed out waiting on ? lock on object ? ? ?. |

| Error Code Name                      | Error Code Number | Error Message                                                                                                                       |
|--------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
|                                      |                   | You are waiting for user(s) ? to finish.                                                                                            |
| ER_LK_OBJECT_TIMEOUT_CLAS<br>S_MSG   | -74               | Your transaction (index ?, ? @? ?) timed out waiting on ? lock on class ?. You are waiting for user(s) ? to finish.                 |
| ER_LK_OBJECT_TIMEOUT_CLAS<br>SOF_MSG | -75               | Your transaction (index ?, ? @? ?) timed out waiting on ? lock on instance ? ? of class ?. You are waiting for user(s) ? to finish. |
| ER_LK_PAGE_TIMEOUT                   | -76               | Your transaction (index ?, ? @? ?) timed out waiting on ? on page ? ?. You are waiting for user(s) ? to release the page lock.      |
| ER_PT_SYNTAX                         | -493              | Syntax: ?                                                                                                                           |
| ER_BTREE_UNIQUE_FAILED               | -670              | Operation would have caused one or more unique constraint violations.                                                               |
| ER_UNIQUE_VIOLATION_WITHK<br>EY      | -886              | "?" caused unique constraint violation.                                                                                             |

| Error Code Name                      | Error Code Number | Error Message                                                                                                                                     |
|--------------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ER_LK_OBJECT_DL_TIMEOUT_SIMPLE_MSG   | -966              | Your transaction (index ?, ? @? ?) timed out waiting on ? lock on object ? ? ? because of deadlock. You are waiting for user(s) ? to finish.      |
| ER_LK_OBJECT_DL_TIMEOUT_CLASS_MSG    | -967              | Your transaction (index ?, ? @? ?) timed out waiting on ? lock on class ? because of deadlock. You are waiting for user(s) ? to finish.           |

## Broker

### Starting Broker

Enter the command below to start the broker. The SHARD function is activated when SHARD, which is the broker parameter of cubrid\_broker.conf, is set to ON.

```
$ cubrid broker start
@ cubrid broker start
++ cubrid broker start: success
```

The following message is returned if the broker is already running.

```
$ cubrid broker start
@ cubrid broker start
++ cubrid broker is running.
```

### Warning

The number of required file descriptor(fd) when starting SHARD in Linux system will be a little bit more than SHARD\_MAX\_CLIENTS in cubrid\_broker.conf. Therefore, when you limit the number of fd by using “ulimit -n”, it should be a little bit greater than the value of SHARD\_MAX\_CLIENTS. When the limited number of fd in Linux system is smaller than the fd number which is required in SHARD, starting SHARD fails and the required fd number is displayed in the error message.

## Stopping Broker

Enter the command below to stop the broker. If SHARD, the broker parameter of the cubrid\_broker.conf, is set to ON, the SHARD function is stopped.

```
$ cubrid broker stop
@ cubrid broker stop
++ cubrid broker stop: success
```

The following message is returned if the broker has stopped.

```
$ cubrid broker stop
@ cubrid broker stop
++ cubrid broker is not running.
```

## Restarting Broker

Enter the command below to restart the whole brokers.

```
$ cubrid broker restart
```

## Checking Broker Status

The **cubrid broker status** utility allows you to check the broker status such as number of completed jobs and the number of standby jobs by providing various options. The status of

clients accessed SHARD or the status of SHARD can be displayed by using **-c** and **-m** options when the **SHARD** broker parameter in **cubrid\_broker.conf** is set to ON. Also, by using **-S** option or **-P** option, each shard DB or each proxy information can be displayed.

```
cubrid broker status [options] [expr]
```

• *expr*: A part of the broker name or "SERVICE=ON|OFF"

Specifying *expr* performs that the status of specific brokers which include *expr* in their names is monitored; specifying no argument means that status of all brokers which are registered in the broker environment configuration file ( **cubrid\_broker.conf** ) is monitored.

If "SERVICE=ON" is specified on *expr*, only the status of working brokers is displayed; if "SERVICE=OFF" is specified, only the status of stopped brokers is displayed.

The following [options] are available with the **cubrid broker status** utility. **-b**, **-q**, **-c**, **-m**, **-S**, **-P** and **-f** are options to define the information to print; **-s**, **-l** and **-t** are options to control printing; **-c**, **-m**, **-S** and **-P** are options applied when using SHARD feature. All of these are possible to use as combining each other.

#### **-b**

Displays the status information of a broker but does not display information on broker application server. In addition, QPS and TPS are displayed as cumulative values since the broker was started. When used with the **-s** option, QPS and TPS are displayed based on the time specified by the **-s** option.

#### **-q**

Displays standby jobs in the job queue.

#### **-c**

Displays the information of clients which access the proxy when **SHARD** in **cubrid\_broker.conf** is set to ON.

#### **-m**

Displays the SHARD status and the statistical information when **SHARD** in **cubrid\_broker.conf** is set to ON.

#### **-S**

For each shard DB, it displays **-b** option's items except NAME, PID, PORT and JQ and #CONNECT; in addition, it displays ID, SHARD-Q and #REQUEST.

#### **-P**

For each proxy, it displays **-b** option's items except NAME, PID, PORT and JQ; in addition, it displays ID, SHARD-Q and #RESTART.

#### **-f**

Displays information of DB and host accessed by broker.

If it is used with the **-b** option, additional information on CAS is displayed. But SELECT, INSERT, UPDATE, DELETE, OTHERS items which shown on **-b** option are excluded.

If it is used with the **-m** option, more detailed SHARD statistics are output.

If it is used with the **-c** option, each shard proxy additionally outputs CLIENT-ID, CLIENT-IP, CONN-TIME, LAST-REQ-TIME, LAST-RES-TIME, and LAST-REQ-CODE items.

If it is used with the **-P** option, STMT-POOL-RATIO is additionally printed. This item shows the ratio to use statements in the pool when you are using prepared statements.

### **-l SECOND**

The **-l** option is only used with **-f** option together. It specifies accumulation period (unit: sec.) when displaying the number of application servers whose client status is Waiting or Busy. If it is omitted, the default value (1 second) is specified.

### **-t**

Displays results in tty mode on the screen. The output can be redirected and used as a file.

### **-s SECOND**

Regularly displays the status of broker based on specified period. It returns to a command prompt if q is entered.

If you do not specify options or arguments, the status of all brokers is displayed.

```
$ cubrid broker status
@ cubrid broker status
% query_editor
-----
ID   PID   QPS   LQS  PSIZE STATUS
-----
1 28434    0     0 50144 IDLE
2 28435    0     0 50144 BUSY
3 28436    0     0 50144 CLIENT_WAIT
4 28437    0     0 50140 CLIENT_WAIT
5 28438    0     0 50144 CLOSE_WAIT

% broker1 OFF
```

- % query\_editor: The broker name
- ID: Serial number of CAS within the broker
- PID: CAS process ID within the broker
- QPS: The number of queries processed per second

- LQS: The number of long-duration queries processed per second
- PSIZE: Size of CAS
- STATUS: The current status of CAS (BUSY, IDLE, CLIENT\_WAIT, CLOSE\_WAIT)
  - IDLE: The state in which the database is not connected and no operations are being performed.
  - BUSY: The state in which an SQL statement is being executed or a task requested by the application is being processed.
  - CLIENT\_WAIT: The requested operation has been completed, but the transaction has not yet ended.
  - CLOSE\_WAIT: The transaction has been completed, but the connection remains open.
- % broker1 OFF: broker1's SERVICE parameter is set to OFF. So, broker1 is not started.

#### Note

ID column which is displayed when checking the SHARD status shows the composition of “ (serial number of proxy) - (serial number of shard DB) - (serial number of CAS accessing shard DB)”

```
$ cubrid broker status
@ cubrid broker status
% shard1
```

| ID    | PID  | QPS | LQS | PSIZE | STATUS |
|-------|------|-----|-----|-------|--------|
| 1-1-1 | 2580 | 100 | 3   | 55968 | IDLE   |
| 1-2-1 | 2581 | 200 | 4   | 55968 | IDLE   |

The following shows the detail status of broker for 5 seconds. The display will reset per 5 seconds as the new status information. To escape the display of the status, press <Q>.

```
$ cubrid broker status -b -s 5
@ cubrid broker status
```

| NAME   | PID          | PORT     | AS      | JQ     | TPS    | QPS    |

```

- NAME: The broker name
- PID: Process ID of the broker
- PORT: Port number of the broker
- AS: The number of CAS
- JQ: The number of standby jobs in the job queue
- TPS: The number of transactions processed per second (calculated only when the option is configured to “-b -s <sec>”)
- QPS: The number of queries processed per second (calculated only when the option is configured to “-b -s <sec>”)
- SELECT: The number of SELECT queries after starting of the broker. When there is an option of “-b -s <sec>”, it is updated every time with the number of SELECTs which have been executed during the seconds specified by this option.
- INSERT: The number of INSERT queries after starting of the broker. When there is an option of “-b -s <sec>”, it is updated every time with the number of INSERTs which have been executed during the seconds specified by this option.
- UPDATE: The number of UPDATE queries after starting of the broker. When there is an option of “-b -s <sec>”, it is updated every time with the number of UPDATES which have been executed during the seconds specified by this option.
- DELETE: The number of DELETE queries after starting of the broker. When there is an option of “-b -s <sec>”, it is updated every time with the number of DELETES which have been executed during the seconds specified by this option.
- OTHERS: The number of queries like CREATE and DROP except for SELECT, INSERT, UPDATE, DELETE. When there is an option of “-b -s <sec>”, it is updated every time with the number of queries which have been executed during the seconds specified by this option.
- LONG-T: The number of transactions which exceed LONG\_TRANSACTION\_TIME. / the value of the LONG\_TRANSACTION\_TIME parameter. When there is an option of “-b -s <sec>”, it is updated every time with the number of transactions which have been executed during the seconds specified by this option.

- **LONG-Q:** The number of queries which exceed `LONG_QUERY_TIME`. / the value of the `LONG_QUERY_TIME` parameter. When there is an option of “-b -s <sec>”, it is updated every time with the number of queries which have been executed during the seconds specified by this option.
- **ERR-Q:** The number of queries with errors found. When there is an option of “-b -s <sec>”, it is updated every time with the number of errors which have occurred during the seconds specified by this option.
- **UNIQUE-ERR-Q:** The number of queries with unique key errors found. When there is an option of “-b -s <sec>”, it is updated every time with the number of unique key errors which have occurred during the seconds specified by this option.
- **#CONNECT:** The number of connections that an application client accesses to CAS after starting the broker.
- **#REJECT:** The count that an application client excluded from ACL IP list is rejected to access a CAS. Regarding ACL setting, see [Limiting Broker Access](#).

The following checks the status of broker whose name includes broker1 and job status of a specific broker in the job queue with the **-q** option. If you do not specify broker1 as an argument, list of jobs in the job queue for all brokers is displayed.

```
% cubrid broker status -q broker1
@ cubrid broker status
% broker1
```

| ID | PID   | QPS | LQS | PSIZE | STATUS |
|----|-------|-----|-----|-------|--------|
| 1  | 28444 | 0   | 0   | 50144 | IDLE   |
| 2  | 28445 | 0   | 0   | 50140 | IDLE   |
| 3  | 28446 | 0   | 0   | 50144 | IDLE   |
| 4  | 28447 | 0   | 0   | 50144 | IDLE   |
| 5  | 28448 | 0   | 0   | 50144 | IDLE   |

The following monitors the status of a broker whose name includes broker1 with the **-s** option. If you do not specify broker1 as an argument, monitoring status for all brokers is performed regularly. It returns to a command prompt if q is not entered.

```
% cubrid broker status -s 5 broker1
% broker1
```

| ID | PID   | QPS | LQS | PSIZE | STATUS |
|----|-------|-----|-----|-------|--------|
| 1  | 28444 | 0   | 0   | 50144 | IDLE   |
| 2  | 28445 | 0   | 0   | 50140 | IDLE   |
| 3  | 28446 | 0   | 0   | 50144 | IDLE   |

```
4 28447      0      0 50144 IDLE
5 28448      0      0 50144 IDLE
```

With the **-t** option, it display information of TPS and QPS to a file. To cancel displaying, press <Ctrl+C> to stop program.

```
% cubrid broker status -b -t -s 1 > log_file
```

The following views information of server/database accessed by broker, the last access times of applications, the IP addresses accessed to CAS and the versions of drivers etc. with the **-f** option.

```
$ cubrid broker status -f broker1
@ cubrid broker status
% broker1
-----

```

Meaning of each column in code above is as follows:

- LAST ACCESS TIME: Time when CAS runs or the latest time when an application client accesses CAS

- DB: Name of a database which CAS accesses most recently
- HOST: Name of a which CAS accesses most recently
- LAST CONNECT TIME: Most recent time when CAS accesses a database
- CLIENT IP: IP of an application clients currently being connected to an application server(CAS). If no application client is connected, 0.0.0.0 is displayed.
- CLIENT VERSION: A driver's version of an application client currently being connected to a CAS
- SQL\_LOG\_MODE: SQL logging mode of CAS. If the mode is same as the mode configured in the broker, "-" is displayed. For details, see [SQL\\_LOG](#) .
- TRANSACTION STIME: Transaction start time
- #CONNECT: The number of connections that an application client accesses to CAS after starting the broker
- #RESTART: The number of connection that CAS is re-running after starting the broker

Enter the command below with the **-b** and **-f** options to display AS(T W B Ns-W Ns-B) and CANCELED additionally.

```
// The -f option is added upon execution of broker status
information. Configuring Ns-W and Ns-B are displayed as long as N
seconds by using the -l.
% cubrid broker status -b -f -l 2
@ cubrid broker status
NAME          PID    PSIZE PORT  AS(T W B 2s-W 2s-B) JQ TPS QPS LONG-
T LONG-Q  ERR-Q UNIQUE-ERR-Q CANCELED ACCESS_MODE SQL_LOG  #CONNECT
#REJECT

4      1
```

Meaning of added columns in code above is as follows:

- AS(T): Total number of CAS being executed
- AS(W): The number of CAS in the status of Waiting
- AS(B): The number of CAS in the status of Busy
- AS(Ns-W): The number of CAS that the client belongs to has been waited for N seconds.

- AS(Ns-B): The number of CAS that the client belongs to has been Busy for N seconds.
- CANCELED: The number of queries have cancelled by user interruption since the broker starts (if it is used with the **-l N** option, it specifies the number of accumulations for N seconds).
- ACCESS\_MODE: The mode in which the broker connects to the DB. Broker mode is classified into three types: Read Write, Read Only, and Standby Only. For details, see [Broker Mode](#).
- SQL\_LOG: SQL logging mode of CAS. SQL LOG is classified into five types: ALL, OFF, ERROR, NOTICE, and TIMEOUT. For details, see [SQL\\_LOG](#).

Use the **-m** option to display SHARD status and statistics information. For details on the parameter of **cubrid\_broker.conf**, see [Broker Configuration](#).

```
$ cubrid broker status -m
@ cubrid broker status
% shard1
MODULAR : 256, LIBRARY_NAME : NOT DEFINED, FUNCTION_NAME : NOT
DEFINED
ACTIVE-PROXY : 1, NUM-NO-HINT-ERR-Q : 0

SHARD STATISTICS
ID  NUM-KEY-Q  NUM-ID-Q  NUM-NO-HINT-Q  SUM
-----
  0      1281      0           0           1281
  1      1281      0           0           1281
  2      1281      0           0           1281
  3      1281      0           0           1281

NUM_SHARD_Q
PROXY_ID      1
SHARD_ID
-----
0              1
1              0
2              0
3              2
```

The description of each column is as follows.

- shard1: The broker name
- MODULAR: The **SHARD\_KEY\_MODULR** parameter value of **cubrid\_broker.conf**
- LIBRARY\_NAME: The **SHARD\_KEY\_LIBRARY\_NAME** parameter value of **cubrid\_broker.conf**
- FUNCTION\_NAME: The **SHARD\_KEY\_FUNCTION\_NAME** parameter value of **cubrid\_broker.conf**
- ACTIVE-PROXY: The number of proxy processes which are running

- NUM-NO-HINT-ERR-Q: The number of errored queries because of no shard hints
- SHARD STATISTICS: The shard ID query information
  - ID: The shard DB serial number (shard ID)
  - NUM-KEY-Q: The number of query requests which include the shard key
  - NUM-ID-Q: The number of query requests which include the shard ID
  - NUM-NO-HINT-Q: The number of requests handled by load balancing without hint when **SHARD\_IGNORE\_HINT** is configured
  - SUM: NUM-KEY-Q + NUM-ID-Q
- NUM\_SHARD\_Q: The number of requests to run queries waiting on SHARD-Q
  - PROXY\_ID: The proxy serial number
  - SHARD\_ID: The shard DB serial number

SHARD-Q is an abbreviation of “Shard Waiting Queue”. If proxy process requested to run the query but there was no CAS process to run this, then this request is waiting on SHARD-Q for a while. If the value of SHARD-Q is larger, it means that waiting cases are more. Therefore, you can consider to enlarge the value of MAX\_NUM\_APPL\_SERVER.

Use the **-m -f** option to display more detailed SHARD statistics information. For details on the parameter of **cuprid\_broker.conf**, see [Broker Configuration](#).

```
$ cuprid broker status -m -f

     224 ~   255 :          3      1152

DB Alias : shard1 [USER : shard, PASSWD : shard123]

```

A description of the added column is as follows.

- SHARD: About shard DB within proxy
  - 0: shard DB serial number (shard ID)
  - [HostA]: shard Connection Information
  - [shard1]: Physical DB Name
- RANGE STATISTICS: shard key query information
  - user\_no: The shard key name
  - MIN: The minimum range of a shard key
  - MAX: The maximum range of a shard key
  - SHARD: The shard DB serial number (shard ID)
  - NUM-Q: The number of query requests which include the shard key

The below displays the information of clients which access the proxy by using the **-c** option.

```

$ cubrid broker status -c
@ cubrid broker status
% shard1(0), MAX-CLIENT : 50, CUR-CLIENT : 0
% shard1(1), MAX-CLIENT : 50, CUR-CLIENT : 0

```

- MAX-CLIENT: Maximum number of application clients that can access that proxy

- CUR-CLIENT: Number of application clients connected to that proxy

Adding the **-f** option to the **-c** option will output more detailed client information.

```
$ cubrid broker status -c -f
@ cubrid broker status
% shardqa(0), MAX-CLIENT : 50, CUR-CLIENT : 0
-----
CLIENT-ID      CLIENT-IP      CONN-TIME      LAST-
REQ-TIME      LAST-RES-TIME  LAST-REQ-CODE

          2      127.0.0.1    2014/01/21 18:07:29    2014/01/21
18:07:56    2014/01/21 18:07:56          2
% shardqa(1), MAX-CLIENT : 50, CUR-CLIENT : 0
-----
CLIENT-ID      CLIENT-IP      CONN-TIME      LAST-
REQ-TIME      LAST-RES-TIME  LAST-REQ-CODE
-----
-----
```

A description of the added column is as follows.

- CLIENT-ID: Client serial numbers assigned sequentially within the proxy
- CLIENT-IP: Client IP address
- CONN-TIME: Time of access to proxy
- LAST-REQ-TIME: Last time a query was requested from proxy
- LAST-RES-TIME: Last time a response was received from proxy
- LAST-REQ-CODE: Code of the last function performed. The functions corresponding to the main code are as follows.
  - 0: end\_tran(Termination of transaction)
  - 1: prepare
  - 2: execute
  - 7: fetch

The following display the information for each shard DB with **-S** option.

```

$ cubrid broker status -S
@ cubrid broker status
% shard1
  SHARD_ID    AS SHARD-Q    TPS    QPS    SELECT    INSERT
UPDATE  DELETE  OTHERS    LONG-T    LONG-Q    ERR-Q    UNIQUE-ERR-
Q #REQUEST
=====
=====

0      6983

```

The following explains the additional columns.

- SHARD\_ID: The index of a shard(starting from 0).
- SHARD-Q: The number of queries waiting on SHARD-Q(see [SHARD-Q](#)) for each shard.
- #REQUEST: The total number of requests which a CAS belonging to the shard get from application clients(requests includes not only a query-execution request, but also a connection request and etc.)

If **-f** option is added to **-S** option, AS items are divided into (T W B 1s-W 1s-B) and displayed in detail. Regarding AS items, see [AS](#).

The below displays the information for each proxy with **-P** option.

```

$ cubrid broker status -P
% shard1
  PROXY_ID    AS SHARD-Q    TPS    QPS    SELECT    INSERT
UPDATE  DELETE  OTHERS    LONG-T    LONG-Q    ERR-Q    UNIQUE-ERR-
Q #CONNECT #REJECT #RESTART
=====
=====

      1      4      0    22174    26160    26160      0
0      0      0    0/60.0    0/60.0    5256
0      165      0      0
      2      4      0    35257    37903    23599    5152

```

```

4576      4576      0      0/60.0      0/60.0      4300
0         264       1         0

```

The additional displayed items with **-P** option compared to **-b** option are as below.

- PROXY\_ID: The index of a proxy(starting from 1)
- SHARD-Q: The number of queries waiting on SHARD-Q(see [SHARD-Q](#)) for each proxy.
- #CONNECT: The count that application clients tried accessing a proxy
- #REJECT: The count that an application client excluded from ACL IP list is rejected to access a proxy. Regarding ACL setting, see [Limiting Broker Access](#).
- #RESTART: The count that a proxy is restarted.

If **-f** option is added to **-S** option, AS items are divided into (T W B 1s-W 1s-B) and displayed in detail and STMT-POOL-RATIO item is added. Regarding AS items, see [AS](#).

```

$ cubrid broker status -P -f
% shard1
  PROXY_ID AS(T      W      B  1s-W  1s-B) SHARD-Q  TPS  QPS
LONG-T    LONG-Q  ERR-Q  UNIQUE-ERR-Q  #CONNECT  #REJECT  #RESTART
STMT-POOL-RATIO (%)
=====
=====
=====

0/60.0    0/60.0    0      0      0      165      0
0         -
      2      4      0      0      0      0      0      0      0
0/60.0    0/60.0    0      0      0      264      1
0         -

```

A description of the added column is as follows.

- STMT-POOL-RATIO: Percentage of use of statements in the pool when using prepare statements

When the **-b**, **-S** and **-P** options are used at the same time, the output is as follows.

```

$ cubrid broker status -b -S -P

@ cubrid broker status
  NAME      PID  PORT  AS  JQ      TPS      QPS  SELECT

## Limiting Broker Access

To limit the client applications accessing the broker, set to **ON** for the **ACCESS\_CONTROL** parameter in the **cubrid\_broker.conf** file, and enter a name of the file in which the users and the list of databases and IP addresses allowed to access the **ACCESS\_CONTROL\_FILE** parameter value are written. If a broker name is not listed in the **ACCESS\_CONTROL\_FILE**, access to that broker is determined by the **ACCESS\_CONTROL\_DEFAULT\_POLICY** parameter. If this parameter is set to **DENY**, access is restricted; if set to **ALLOW**, access is permitted. The default value of the **ACCESS\_CONTROL** broker parameter is **OFF**, and the default value of **ACCESS\_CONTROL\_DEFAULT\_POLICY** is **DENY**. The **ACCESS\_CONTROL**, **ACCESS\_CONTROL\_FILE**, and **ACCESS\_CONTROL\_DEFAULT\_POLICY** parameters must be specified under the [broker] section, where common parameters are defined.

The format of **ACCESS\_CONTROL\_FILE** is as follows:

```
[%<broker_name>]
<db_name>:<db_user>:<ip_list_file>
...
```

- <broker\_name>: A broker name. It is the one of broker names specified in **cubrid\_broker.conf**.
- <db\_name>: A database name. If it is specified as \*, all databases are allowed to access the broker server.
- <db\_user>: A database user ID. If it is specified as \*, all database user IDs are allowed to access the broker server.
- <ip\_list\_file>: Names of files in which the list of accessible IPs are stored. Several files such as ip\_list\_file1, ip\_list\_file2, ... can be specified by using a comma (,).

[%<broker\_name>] and <db\_name>:<db\_user>:<ip\_list\_file> can be specified separately for each broker. A separated line can be specified for the same <db\_name> and the same <db\_user>. List of IPs can be written up to the maximum of 256 lines per <db\_name>:<db\_user> in a broker.

#### Note

When using an absolute path name in Windows, the DRIVE name must be specified (for example, C:\CUBRID\CONF\CUBRID\_ACL.CONF).

The format of the ip\_list\_file is as follows:

```
<ip_addr>
...
```

- <ip\_addr>: An IP address that is allowed to access the server. If the last digit of the address is specified as \*, all IP addresses in that range are allowed to access the broker server.

Even if the **ACCESS\_CONTROL** value is set to ON, access from localhost is always allowed. (In other words, specifying the localhost IP (127.0.0.1) in the ip\_list\_file is ignored.)

Broker access restrictions not specified in **ACCESS\_CONTROL\_FILE**.

- Allow access only from localhost. (default)
- If **ACCESS\_CONTROL\_DEFAULT\_POLICY** is set to **ALLOW**, all access is allowed.

If the analysis of **ACCESS\_CONTROL\_FILE** and ip\_list\_file fails when starting a broker, the broker will not be run.

```
# cubrid_broker.conf
[broker]
MASTER_SHM_ID           =30001
ADMIN_LOG_FILE           =log/broker/cubrid_broker.log
ACCESS_CONTROL           =ON
ACCESS_CONTROL_FILE      =/home1/cubrid/access_file.txt
[%QUERY_EDITOR]
SERVICE                 =ON
BROKER_PORT              =30000
.....
```

The following example shows the content of **ACCESS\_CONTROL\_FILE**. The \* symbol represents everything, and you can use it when you want to specify database names, database user IDs and IPs in the IP list file which are allowed to access the broker server.

```
[%QUERY_EDITOR]
dbname1:dbuser1:READIP.txt
dbname1:dbuser2:WRITEIP1.txt,WRITEIP2.txt
*:dba:READIP.txt
*:dba:WRITEIP1.txt
*:dba:WRITEIP2.txt

[%BROKER2]
dbname:dbuser:iplist2.txt

[%BROKER3]
dbname:dbuser:iplist2.txt

[%BROKER4]
dbname:dbuser:iplist2.txt
```

The brokers specified above are QUERY\_EDITOR, BROKER2, BROKER3, and BROKER4.

The QUERY\_EDITOR broker only allows the following application access requests.

- When a user logging into *dbname1* with a *dbuser1* account connects from IPs registered in READIP.txt
- When a user logging into *dbname1* with a *dbuser2* account connects from IPs registered in WRITEIP1.txt and WRITEIP2.txt
- When a user logging into every database with a **DBA** account connects from IPs registered in READIP.txt, WRITEIP1.txt, and WRITEIP2.txt

The following example shows how to specify the IPs allowed in ip\_list\_file.

```
192.168.1.25
192.168.*
192.*
*
```

The descriptions for the IPs specified in the example above are as follows:

- The first line setting allows access from 192.168.1.25.
- The second line setting allows access from all IPs starting with 192.168.
- The third line setting allows access from all IPs starting with 192.
- The fourth line setting allows access from all IPs.

For the broker which has already been running, you can modify the configuration file or check the currently applied status of configuration by using the following commands.

To configure databases, database user IDs and IPs allowed to access the broker and then apply the modified configuration to the server, use the following command.

```
cubrid broker acl reload [<BR_NAME>]
```

- <BR\_NAME>: A broker name. If you specify this value, you can apply the changes only to specified brokers. If you omit it, you can apply the changes to all brokers.

#### Note

Existing connections are not affected by reconfiguration of the access control list using the `acl reload` command. It means, it is applied only to new connections. To take effect changes on the connected connections, the broker must be restarted.

To display the databases, database user IDs and IPs that are allowed to access the broker in running on the screen, use the following command.

```
cubrid broker acl status [<BR_NAME>]
```

- <BR\_NAME>: A broker name. If you specify the value, you can display the specified broker configuration. If you omit it, you can display all broker configurations.

The below is an example of displaying results.

```

$ cubrid broker acl status
ACCESS_CONTROL=ON
ACCESS_CONTROL_FILE=access_file.txt
ACCESS_CONTROL_DEFAULT_POLICY=ALLOW

[%broker1]
demodb:dba:iplist1.txt
      CLIENT IP LAST ACCESS TIME
=====
192.20.30.40
192.168.1.0 2023-11-07 15:19:14
192.168.2.0
192.168.3.0
192.169.* 2023-11-07 15:20:50

testdb:dba:iplist2.txt
      CLIENT IP LAST ACCESS TIME
=====
* 2013-11-08 10:10:12

[%broker2]

++ cubrid broker acl: success

```

## Broker Logs

If you try to access brokers through IP addresses that are not allowed, the following logs will be created.

- ACCESS\_LOG

```

1 192.10.10.10 - - 1288340944.198 1288340944.198 2010/10/29
17:29:04 ~ 2010/10/29 17:29:04 14942 - -1 db1 dba : rejected

```

- SQL LOG

```

10/29 10:28:57.591 (0) CLIENT IP 192.10.10.10 10/29 10:28:
57.592 (0) connect db db1 user dba url jdbc:cubrid:
192.10.10.10:30000:db1::: - rejected

```

### Note

For details on how to limit an access to the database server, see [Limiting Database Server Access](#).

## Packet Encryption

In an unencrypted communication environment, someone can monitor and interpret all the traffic between clients and a database server, and collected information could be used illegally. In order to access information in an unsafe communication environment while avoiding such an information leakage, data transmitted and received must be encrypted. CUBRID Broker can be configured in safe mode. In this case, all data transmitted and received between the database server and the client are encrypted.

CUBRID supports encrypted connections between clients and the server using TLS (Transport Layer Security) protocol. TLS provides data encryption mechanism as well as detecting data tampering, loss, hence ensures providing secure and trusted communication channel between clients and the server. CUBRID provides these TLS functions using [OpenSSL](#).

CUBRID Broker can be configured for encrypted mode (**SSL = ON**) or non-encrypted mode (**SSL = OFF**) using **SSL** parameter in **cubrid\_broker.conf**. A Broker must be restarted when the encryption parameter is changed. When a Broker is configured in encryption mode, clients such as **jdbc client** must connect in encryption mode, otherwise the connection to the broker will be rejected. The opposite is also true. That is, a connection request of clients using encryption mode to non-secure broker will be refused.

When SSL parameter is not specified in cubrid\_broker.conf, that broker will be started in non-encrypted mode (**'SSL = OFF'** is the default). The following is an example of setting the Broker **'query\_editor'** in **encrypted mode** (cubrid\_broker.conf).

```
# cubrid_broker.conf
[query_editor]
SERVICE                =ON
SSL                      =ON
BROKER_PORT              =30000
...
```

### Certificate and Private Key

In order to exchange an encrypted **symmetric session key** which will be used in a secure communication session, a public key and a private key are required in the server.

The public key used by the server is included in the certificate **'cas\_ssl\_cert.crt'**, and the private key is included in **'cas\_ssl\_cert.key'**. The certificate and private key are located in the **\$CUBRID/conf** directory.

This certificate, **'self-signed'** certificate, was created with the OpenSSL command tool utility, and can be replaced with another certificate issued by a public **CA** (Certificate Authorities, for example

**IdenTrust** or **DigiCert**) if desired. Or, existing certificate/private key can be replaced by generating new one using OpenSSL command utility as shown below.

```
$ openssl genrsa -out my_cert.key
2048                                     # create 2048 bit
size RSA private key
$ openssl req -new -key my_cert.key -out
my_cert.csr                             # create CSR
(Certificate Signing Request)
$ openssl x509 -req -days 365 -in my_cert.csr -signkey my_cert.key -
out my_cert.crt # create a certificate valid for 1 year.
```

And replace **my\_cert.key** and **my\_cert.crt** with `$CUBRID/conf/cas_ssl_cert.key` and `$CUBRID/conf/cas_ssl_cert.crt` respectively.

## Managing a Specific Broker

Enter the code below to run *broker1* only. Note that *broker1* should have already been configured in the shared memory.

```
% cubrid broker on broker1
```

The following message is returned if *broker1* has not been configured in the shared memory.

```
% cubrid broker on broker1
Cannot open shared memory
```

Enter the code below to stop *broker1* only. Note that service pool of *broker1* can also be removed.

```
% cubrid broker off broker1
```

The broker reset feature enables broker application servers (CAS) to disconnect the existing connection and reconnect when the servers are connected to unwanted databases due to failover, etc. in HA. For example, once Read Only broker is connected to active servers, it is not automatically connected to standby servers although standby servers are available. Connecting to standby servers is allowed only with the **cubrid broker reset** command.

Enter the code below to reset broker1.

```
% cubrid broker reset broker1
```

## Dynamically Changing Broker Parameters

You can configure the parameters related to running the broker in the configuration file ( **cubrid\_broker.conf** ). You can also modify some broker parameters temporarily while the broker is running by using the **broker\_changer** utility. For details, see [Broker Configuration](#).

The syntax for the **broker\_changer** utility, which is used to change broker parameters while the broker is running, is as follows. Enter the name of the currently running broker for the *broker\_name* . The *parameters* can be used only for dynamically modifiable parameters. The *value* must be specified based on the parameter to be modified. You can specify the broker CAS identifier ( *cas\_id* ) to apply the changes to the specific broker CAS.

### Note

When CUBRID SHARD feature is activated(SHARD=ON in cubrid\_broker.conf), you cannot apply the changes to the specific broker CAS by specifying the broker CAS identifier(cas\_id).

*cas\_id* is an ID to be output by **cubrid broker status** command.

```
broker_changer <broker_name> [<cas_id>] <conf-name> <conf-value>
```

Enter the following to configure the **SQL\_LOG** parameter to **ON** so that SQL logs can be written to the currently running broker. Such dynamic parameter change is effective only while the broker is running.

```
% broker_changer query_editor sql_log on
OK
```

Enter the following to change the **ACCESS\_MODE** to **Read Only** and automatically reset the broker in HA environment.

```
% broker_changer broker_m access_mode ro
OK
```

### Note

If you want to control the service using cubrid utilities on Windows Vista or the later versions of Window, you are recommended to open the command prompt window as an administrator. For details, see the notes of [CUBRID Utilities](#).

## Broker configuration information

**cubrid broker info** dumps the currently “working” broker parameters’ configuration information(cubrid\_broker.conf). broker parameters’ information can be dynamically changed by **broker\_changer** command; with **cubrid broker info** command, you can see the configuration information of the working broker.

```
% cubrid broker info
```

As a reference, to see the configuration information of the currently “working” system(cubrid.conf), use **cubrid paramdump database\_name** command. By **SET SYSTEM PARAMETERS** syntax, the configuration information of the system parameters can be changed dynamically; with **cubrid broker info** command, you can see the configuration information of the system parameters.

## Check CUBRID SHARD ID

**cubrid broker getid** prints out SHARD ID to know in what DB a specific key is included.

```
cubrid broker getid -b <broker-name> [-f] shard-key
```

- -b <broker-name>: broker name
- -f: print detail information
- *shard-key*: shard key

The following is an example of outputting the SHARD ID for key 1 from the shard1 broker.

```
$ cubrid broker getid -b shard1 1
@ cubrid broker getid
% shard1
  SHARD_ID : 0, SHARD_KEY: 1
```

The following is an example of outputting detailed information using the -f option.

```
$ cubrid broker getid -b shard1 -f 1
@ cubrid broker getid
% shard1
  SHARD_ID : 0, SHARD_KEY : 1, KEY_COLUMN : student_no
  MODULAR : 256, LIBRARY_NAME : NOT DEFINED, FUNCTION_NAME : NOT
  DEFINED
  RANGE STATISTICS : student_no
```

```

      MIN ~    MAX :      SHARD
      -----
      0 ~    31 :      0

SHARD CONNECTION :
SHARD_ID          DB NAME          CONNECTION_INFO
-----
      0            shard1          192.168.10.1

```

## Broker to DB Connection Test

**cubrid broker test** is a command to perform user-defined queries on a DB that connects to a specified broker. When the shard function is activated, query all SHARD DBs. After performing the query, the transaction is rolled back. This command allows you to check the success of the query for each SHARD DB by performing a query to all SHARD DBs accessing the specified broker, and if you set the SHARD HASH function, you can check on which SHARD DB the query you entered was performed.

```

cubrid broker test <broker_name> [-D <db_name>] [-u <db_user>] [-p
<db_password>] {-c <query> | -i <input_file>} [-o <output_file>] [-
s] [-v]

```

- db\_name: DB name
- db\_user: DB user account
- db\_password: DB user password
- query: query
- input\_file: File that stores the query you want to enter
- output\_file: File to save the results

The following options are available with the **cubrid broker test** utility.

### -D DB\_NAME

Specifies the DB name of the test target. When this option is omitted, the value of SHARD\_DB\_NAME parameter is used if the value of a SHARD parameter in cubrid\_broker.conf is ON. If the value of a SHARD parameter is OFF, an error occurs.

### -u DB\_USER

Specifies the DB account of the test target. When this option is omitted, the value of SHARD\_DB\_USER parameter is used if the value of a SHARD parameter in cubrid\_broker.conf is ON. If the value of a SHARD parameter is OFF, "public" is input in CUBRID.

**-p DB\_PASSWORD**

Specifies the DB password of the test target. When this option is omitted, the value of SHARD\_DB\_PASSWORD parameter is used if the value of a SHARD parameter in cubrid\_broker.conf is ON. If the value of a SHARD parameter is OFF, an empty string("") is input in CUBRID.

**-c QUERY**

Specifies the query string. **-c** or **-i** option can be used to specify a query. If they are omitted, only the connection information between a broker and a DB is printed.

**-i FILE\_NAME**

Specifies the file where you saved the queries to input. **-c** or **-i** option can be used to specify a query. If they are omitted, only the connection information between a broker and a DB is printed.

**-o FILE\_NAME**

Specifies the file name to save the execution result to be displayed to the console. If this is omitted, the execution result is output only to the console.

**-s**

A query which includes a SHARD hint is performed only in the SHARD DB. If this is omitted, a query is performed on all SHARD DBs.

If the value of a SHARD parameter is OFF, this option does not affect to the query execution.

**-v**

The error message and the result set of the SELECT are output together with the following information.

- RESULT: Error returned after performing query. output [OK | FAIL]
- SHARD\_ID: ID of the SHARD DB where the query was performed (if the SHARD parameter value is OFF, the item is not output)
- ROW COUNT: Number of rows affected by DML, or number of rows in case of SELECT query. Outputs -1 in case of query execution error
- EXECUTION TIME: Time the query was performed
- QUERY: Queries entered by the user

If this option is omitted, only "RESULT, SHARD\_ID, ROW COUNT, EXECUTION TIME, QUERY" will be output.

The following is an example of using the above options.

- Query to DB

### When the SHARD parameter value of the cubrid\_broker.conf is OFF

Check if the DB connection is good.

```
$ cubrid broker test shard1 -D shard -u shard -p shard123 -c
"select 1 from db_root where charset = 3"

@ cubrid broker test
@ [OK] CONNECT broker1 DB [demodb] USER [shard]

@ SHARD OFF

RESULT ROW COUNT EXECUTION TIME QUERY
=====
OK 1 0.011341 sec select 1,'a' from db_root where charset = 3
@ [OK] QUERY TEST
```

### When the SHARD parameter value of the cubrid\_broker.conf is ON

Check if all SHARD DBs are accessible.

```
$ cubrid broker test shard1 -D shard -u shard -p shard123 -c
"select 1 from db_root where charset = 3"

@ cubrid broker test
@ [OK] CONNECT shard1 DB [shard] USER [shard]

@ SHARD ON

RESULT SHARD_ID ROW COUNT EXECUTION TIME QUERY
=====
OK 0 1 0.003436 sec select 1 from db_root where charset = 3
OK 1 1 0.003010 sec select 1 from db_root where charset = 3
OK 2 1 0.003039 sec select 1 from db_root where charset = 3
OK 3 1 0.002916 sec select 1 from db_root where charset = 3
@ [OK] QUERY TEST
```

- Check User Permissions

### User do not have INSERT privileges on one of the SHARD DBs

If user you do not have INSERT privileges, RESULT is displayed as FAIL.

```
$ cubrid broker test shard1 -c "insert into foo values (1,"a") " -v

@ cubrid broker test
@ [OK] CONNECT shard1 DB [shard] USER [shard]
```

```
@ SHARD ON
```

```
RESULT SHARD_ID ROW COUNT EXECUTION TIME QUERY
=====

```

```
OK 0 0.001534 sec delete foo where b = 3
@ [FAIL] QUERY TEST
```

- Check SHARD HASH normal operation

Check if the hashing is good for a specific key.

```
$ vi test_query.txt
```

```
#query
select number from demo_db where key = /*+ shard_key */ 14
select number from demo_db where key = /*+ shard_key */ 50
select number from demo_db where key = /*+ shard_key */ 80
select number from demo_db where key = /*+ shard_key */ 120
..
```

```
$ cubrid broker test shard1 -D shard -u shard -p shard123 -i
shard_key.txt -v -s
```

```
@ cubrid broker test
@ [OK] CONNECT shard1 DB [shard] USER [shard]
```

```
@ SHARD ON
```

```
RESULT SHARD_ID ROW COUNT EXECUTION TIME QUERY
```

```
=====
```

```
OK 0 1 0.002225 sec select * from foo where a = /*+ shard_key */ 10
<Result of SELECT Command>
```

```
  a b
```

```
-----
```

```
  10 'aaaa'
```

```
OK 1 1 0.001870 sec select * from foo where a = /*+ shard_key */ 40
<Result of SELECT Command>
```

```
  a b
```

```
-----
```

```
  40 'bbb'
```

```
OK 2 1 0.002004 sec select * from foo where a = /*+ shard_key */ 70
<Result of SELECT Command>
```

```
  a b
```

```
-----
```

```
  70 'cccc'
```

```
OK 3 1 0.002025 sec select * from foo where a = /*+ shard_key */ 100
<Result of SELECT Command>
```

```
  a b
```

```
-----
100 'dddd'

@ [OK] QUERY TEST
```

- Whether to using the -v option

### When using -v option

When the SELECT query is successful, the result set is output, and when the SELECT query is unsuccessful, an error message is output.

```
$ cubrid broker test broker1 -D demodb -u shard -p shard123 -i
dml.txt -v
@ cubrid broker test
@ [OK] CONNECT broker1 DB [demodb] USER [shard]

@ SHARD OFF

RESULT ROW COUNT EXECUTION TIME QUERY
OK 1 0.001311 sec select a from foo
<Result of SELECT Command>
  a
-----
  1

OK 1 0.001083 sec insert into foo(b) values(3)
FAIL(-494) -1 0.001166 sec update foo set c = 2 where b = 3
<Error>
ERROR CODE : -494
Semantic: UPDATE is not authorized on foo. update foo foo set
foo.c=2 where foo.b=3[CAS INFO - 127.0.0.1:52001, 1, 18139].

OK 0 0.001399 sec delete foo where b = 3
@ [FAIL] QUERY TEST
```

### When not using the -v option

It only prints the success or failure of the query.

```
$ cubrid broker test broker1 -D demodb -u shard -p shard123 -i
dml.txt

@ cubrid broker test
@ [OK] CONNECT broker1 DB [demodb] USER [shard]

@ SHARD OFF

RESULT ROW COUNT EXECUTION TIME QUERY
```

```
OK 1 0.001485 sec select a from foo
OK 1 0.001123 sec insert into foo(b) values(3)
FAIL(-494) -1 0.001180 sec update foo set c = 2 where b = 3
OK 0 0.001393 sec delete foo where b = 3
@ [FAIL] QUERY TEST
```

- Check SHARD key value

When SHARD key hint is given with the -s option, query to its SHARD DB, and outputs the result. With SHARD\_ID, you can confirm that the query is executed from any SHARD DB.

```
$ cubrid broker test shard1 -i shard_key.txt -s -v

@ cubrid broker test
@ [OK] CONNECT shard1 DB [shard1] USER [shard]

@ SHARD ON

RESULT SHARD_ID ROW COUNT EXECUTION TIME QUERY
OK 0 1 0.144730 sec select * from foo where a = /** shard_key */ 10
<Result of SELECT Command>
  a b
-----
  10 'aaaa'

OK 1 1 0.001870 sec select * from foo where a = /** shard_key */ 40
<Result of SELECT Command>
  a b
-----
  40 'bbb'

OK 2 1 0.002004 sec select * from foo where a = /** shard_key */ 70
<Result of SELECT Command>

<Result of SELECT Command>
  a b
-----
  100 'dddd'

@ [OK] QUERY TEST
```

## Broker Logs

There are three types of logs that relate to starting the broker: access, error and SQL logs. Each log can be found in the log directory under the installation directory. You can change the directory where these logs are to be stored through **LOG\_DIR** and **ERROR\_LOG\_DIR** parameters of the broker configuration file (**cubrid\_broker.conf**).

When **SHARD** = ON, the log directory of CUBRID proxy can be configured by using the **SHARD\_PROXY\_LOG\_DIR** parameter.

### Checking the Access Log

The access log file records information on the application client and is stored to **\$CUBRID/log/broker/<broker\_name>.access** file. If the **ACCESS\_LOG** parameter is configured to **ON** in the broker configuration file, when the broker stops properly, the access log file is stored.

The maximum size of the ACCESS\_LOG file can be specified through the ACCESS\_LOG\_MAX\_SIZE parameter. When the ACCESS\_LOG file is larger than the specified size, it is backed up in the name of broker\_name.access.YYYYMMDDHHMISS, and the log is recorded in a new file (broker\_name.access).

The record of denied access is recorded in broker\_name.access.denied. It is backed up with the same rules as the ACCESS\_LOG file.

The following example and description show an access log file created in the log directory:

```
1 192.168.56.4 2020/11/10 14:41:55 testdb dba NEW 6
```

- 1: ID assigned to the application server of the broker
- 192.168.56.4: IP address of the application client
- 2020/11/10 14:41:55: Time when the client's request processing started
- testdb: The name of the database that the client requested to connect to
- dba: The user name of the database that the client requested to connect to
- NEW: Connection type
  - NEW: New connection
  - OLD: Change client or reconnection of existing connection due to CAS restart
  - REJ: Connction denied (Recorded only in access.denied file)
- 6: session-id (session-id assigned by server)

## Checking the Error Log

The error log file records information on errors that occurred during the client's request processing and is stored to **\$CUBRID/log/broker/error\_log<broker\_name>\_<app\_server\_num>.err** file. For error codes and error messages, see [CAS Error](#).

The following example and description show an error log:

```
Time: 02/04/09 13:45:17.687 - SYNTAX ERROR *** ERROR CODE = -493,
Tran = 1, EID = 38
Syntax: Unknown class "unknown_tbl". select * from unknown_tbl
```

- Time: 02/04/09 13:45:17.687: Time when the error occurred
- ◦ SYNTAX ERROR: Type of error (e.g. SYNTAX ERROR, ERROR, etc.)
- \*\*\* ERROR CODE = -493: Error code
- Tran = 1: Transaction ID. -1 indicates that no transaction ID is assigned.
- EID = 38: Error ID. This ID is used to find the SQL log related to the server or client logs when an error occurs during SQL statement processing.
- Syntax ...: Error message (An ellipsis ( ... ) indicates omission.)

## Managing the SQL Log

The SQL log file records SQL statements requested by the application client and is stored with the name of <broker\_name>\_<app\_server\_num>.sql.log. The SQL log is generated in the log/broker/sql\_log directory when the SQL\_LOG parameter is set to ON. Note that the size of the SQL log file to be generated cannot exceed the value set for the SQL\_LOG\_MAX\_SIZE parameter. CUBRID offers the **broker\_log\_top** and **cubrid\_replay** utilities to manage SQL logs. Each utility should be executed in a directory where the corresponding SQL log exists.

The following examples and descriptions show SQL log files:

```
13-06-11 15:07:39.282 (0) STATE idle

```

- 13-06-11 15:07:39.282: Time when the application sent the request
- (1): Sequence number of the SQL statement group. If prepared statement pooling is used, it is uniquely assigned to each SQL statement in the file.
- CLIENT IP: An IP of an application client
- CLIENT VERSION: A driver's version of an application client

- prepare 0: Whether or not it is a prepared statement
- prepare srv\_h\_id 1: Prepares the SQL statement as srv\_h\_id 1.
- (PC): It is displayed if the data in the plan cache is used.
- Execute 0 tuple 1 time 0.001: One row is executed. The time spent is 0.001 seconds.
- auto\_commit/auto\_rollback: Automatically committed or rolled back. The second auto\_commit/auto\_rollback is an error code. 0 indicates that the transaction has been completed without an error.

## broker\_log\_top

The **broker\_log\_top** utility analyzes the SQL logs which are generated for a specific period. As a result, the information of SQL statements and time execution are displayed in files by order of the longest execution time; the results of SQL statements are stored in **log.top.q** and those of execution time are stored in **log.top.res**, respectively.

The **broker\_log\_top** utility is useful to analyze a long running query. The syntax is as follows:

```
broker_log_top [options] sql_log_file_list
```

- *sql\_log\_file\_list*: names of log files to analyze.

The following is [options] used on **broker\_log\_top**.

### -t

The result is displayed in transaction unit.

### -F DATETIME

Specifies the execution start date and time of the SQL statements to be analyzed. The input format is YY-MM-DD[ hh[:mm[:ss[:msec]]]], and the part enclosed by [] can be omitted. If you omit the value, it is regarded as that 0 is input for hh, mm, ss and msec.

### -T DATETIME

Specifies the execution end date and time of the SQL statements to be analyzed. The input format is the same with the *DATE* in the **-F** options.

All logs are displayed by SQL statement if any option is not specified.

The following sets the search range to milliseconds

```
broker_log_top -F "13-01-19 15:00:25.000" -T "13-01-19 15:15:25.180"
log1.log
```

The part where the time format is omitted is set to 0 by default. This means that -F "13-01-19 00:00:00.000" -T "13-01-20 00:00:00.000" is input.

```
broker_log_top -F "13-01-19" -T "13-01-20" log1.log
```

The following logs are the results of executing the broker\_log\_top utility; logs are generated from Nov. 11th to Nov. 12th 2013, and it is displayed in the order of the longest execution of SQL statements. Each month and day are separated by a hyphen (-) when specifying period. Note that "\*.sql.log" is not recognized so the SQL logs should be separated by a white space on Windows.

```
--Execution broker_log_top on Linux
% broker_log_top -F "13-11-11" -T "13-11-12" -t *.sql.log

query_editor_1.sql.log
query_editor_2.sql.log
query_editor_3.sql.log
query_editor_4.sql.log
query_editor_5.sql.log

--Executing broker_log_top on Windows
% broker_log_top -F "13-11-11" -T "13-11-12" -t
query_editor_1.sql.log query_editor_2.sql.log query_editor_3.sql.log
query_editor_4.sql.log query_editor_5.sql.log
```

The **log.top.q** and **log.top.res** files are generated in the same directory where the analyzed logs are stored when executing the example above; In the **log.top.q** file, you can see each SQL statement, and its line number. In the **log.top.res** file, you can see the minimum execution time, the maximum execution time, the average execution time, and the number of execution queries for each SQL statement.

```
--log.top.q file
[Q1]-----
broker1_6.sql.log:137734
13-11-11 18:17:59.396 (27754) execute_all srv_h_id 34 select

## cubrid\_replay

**cubrid\_replay** utility replays the SQL log in the broker and outputs the results sorted in order from the large difference(from the slower query than the existing one) by comparing the difference in the execution time of playback and the existing execution time.

This utility plays back the queries that are logged in the SQL log, but does not execute the queries to change the data. If any options are not given, only SELECT queries are run; if **-r** option is given, it changes the UPDATE and DELETE queries into SELECT queries and runs them.

This utility can be used to compare the performance between two different hosts; for example, there can be a performance difference for a same query between master and slave even if their h/w specs are the same.

```
cubrid_replay -I <broker_host> -P <broker_port> -d <db_name>
[options] <sql_log_file> <output_file>
```

- *broker\_host*: IP address or host name of the CUBRID broker
- *broker\_port*: Port number of the CUBRID broker
- *db\_name*: The name of database to run the query
- *sql\_log\_file*: SQL log file of the CUBRID broker(\$CUBRID/log/broker/sql\_log/\*.log, \*.log.bak)
- *output\_file*: File name to save the execution result

The following is [options] used in **cubrid\_replay**.

### -u DB\_USER

Specifies the DB account(default: public).

### -p DB\_PASSWORD

Specifies database password

### -r

Changes UPDATE and DELETE queries into SELECT queries

**-h SECOND**

Specifies the term to wait between queries to run(default: 0.01 sec)

**-D SECOND**

The queries are output to *output\_file* only when the specified term is bigger than (replayed execution time - previous execution time)(default: 0.01 sec).

**-F DATETIME**

Specifies the execution start date and time of the SQL statements to be replayed. The input format is YY[-MM[-DD[ hh[:mm[:ss[:msec]]]]]], and the part enclosed by [] can be omitted. If you omit the value, it is regarded as that 01 is input for MM and DD, and 0 is input for hh, mm, ss and msec.

**-T DATETIME**

Specifies the execution end date and time of the SQL statements to be replayed. The input format is the same with the *DATE* in the **-F** options.

```
$ cubrid_replay -I testhost -P 33000 -d testdb -u dba -r
testdb_1_11_1.sql.log.bak output.txt
```

If you run the above command, the summary of execution result is displayed on the console.

```
----- Result Summary -----
* Total queries : 153103
* Skipped queries (see skip.sql) : 5127
* Error queries (see replay.err) : 30
* Slow queries (time diff > 0.000 secs) : 89987
* Max execution time diff : 0.016
* Avg execution time diff : -0.001

cubrid_replay run time : 245.308417 sec
```

- Total queries: Number of total queries within the specified date and time. They include DDL and DML
- Skipped queries: Number of queries which cannot be changed from UPDATE/DELETE into SELECT when **-r** option is specified. These queries are saved into skip.sql
- Slow queries: Number of queries of which execution time difference is bigger than the specified value by **-D** option(the replayed execution time is slower than the previous execution time plus the specified value). If you omit the **-D** option, this option value is specified as 0.01 second
- Max execution time diff: The biggest value among the differences of the execution time(unit: sec)
- Avg execution time diff: Average value of the differences of the execution time(unit: sec)

- cubrid\_replay run time: Execution time of this utility

“Skipped queries” are the cases which query-transform from UPDATE/DELETE to SELECT is impossible by the internal reason; the queries which are written to skip.sql are needed to check separately.

Also, you should consider that the execution time of the transformed queries does not include the data modification time.

In the *output.txt* file, SQLs that the replayed SQL execution time is slower than the SQL execution time in SQL log are written. That is, {(the replayed SQL execution time) - {(the execution time in SQL log) + (the specified time by **-D** option)}} is sorted in descending order. Because **-r** option is used, UPDATE/DELETE is rewritten into SELECT and run.

```
EXEC TIME (REPLAY / SQL_LOG / DIFF): 0.003 / 0.001 / 0.002
SQL: UPDATE NDV_QUOTA_INFO SET last_mod_date = now() , used_quota =
( SELECT IFNULL(sum(file_size),0) FROM NDV_RECYCLED_FILE_INFO WHERE
user_id= ? ) + ( SELECT IFNULL(sum(file_size),0) FROM NDV_FILE_INFO
WHERE user_id = ? ) WHERE user_id = ? /+shard_val(6900403)/ /* SQL :
NDVMUpdResetUsedQuota */
REWRITE SQL: select NDV_QUOTA_INFO, class NDV_QUOTA_INFO,
cast( SYS_DATETIME as datetime), cast((select
ifnull(sum(NDV_RECYCLED_FILE_INFO.file_size), 0) from
NDV_RECYCLED_FILE_INFO NDV_RECYCLED_FILE_INFO where
(NDV_RECYCLED_FILE_INFO.user_id= ?:0 ))+(select
ifnull(sum(NDV_FILE_INFO.file_size), 0) from NDV_FILE_INFO
NDV_FILE_INFO where (NDV_FILE_INFO.user_id= ?:1 )) as bigint) from
NDV_QUOTA_INFO NDV_QUOTA_INFO where (NDV_QUOTA_INFO.user_id= ?:2 )
BIND 1: 'babaemo'
BIND 2: 'babaemo'
BIND 3: 'babaemo'
```

- EXEC TIME: (replay time / execution time in the SQL log / difference between the two execution times)
- SQL: The original SQL which exists in the SQL log of the broker
- REWRITE SQL: Transformed SELECT queries from UPDATE/DELETE queries by **-r** option.

#### Note

broker\_log\_runner is deprecated from 9.3. Therefore, instead of broker\_log\_runner, use cubrid\_replay.

## CAS Error

CAS error is an error which occurs in broker application server(CAS), and it can happen on all applications which access to CAS with drivers.

Below shows the CAS error code table. CCI and JDBC's error messages can be different each other on the same CAS error code. If there is only one message, they are the same, but if there are two messages, then the first one is CCI error message and the second one is JDBC error message.

| Error Code                    | Name(Error Number) | Error Message (CCI / JDBC)                                         | Note                                                                                     |
|-------------------------------|--------------------|--------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| CAS_ER_INTERNAL(-10001)       |                    |                                                                    |                                                                                          |
| CAS_ER_NO_MORE_MEMORY(-10002) |                    | Memory allocation error                                            |                                                                                          |
| CAS_ER_COMMUNICATION(-10003)  |                    | Cannot receive data from client / Communication error              |                                                                                          |
| CAS_ER_ARGS(-10004)           |                    | Invalid argument                                                   |                                                                                          |

## Gateway

### Starting Gateway

Enter the command below to start the gateway.

```
$ cubrid gateway start
@ cubrid gateway start
++ cubrid gateway start: success
```

The following message is returned if the gateway is already running.

```
$ cubrid gateway start
@ cubrid gateway start
++ cubrid gateway is running.
```

## Stopping Gateway

Enter the command below to stop the gateway.

```
$ cubrid gateway stop
@ cubrid gateway stop
++ cubrid gateway stop: success
```

The following message is returned if the gateway has stopped.

```
$ cubrid gateway stop
@ cubrid gateway stop
++ cubrid gateway is not running.
```

## Restarting Gateway

Enter the command below to restart the whole gateways.

```
$ cubrid gateway restart
```

## Checking Gateway Status

The **cubrid gateway status** utility allows you to check the gateway status such as number of completed jobs and the number of standby jobs by providing various options.

```
cubrid gateway status [options] [expr]
```

- *expr*: A part of the gateway name or "SERVICE=ON|OFF"

Specifying *expr* performs that the status of specific gateways which include *expr* in their names is monitored; specifying no argument means that status of all gateways which are registered in the gateway environment configuration file ( **cubrid\_gateway.conf** ) is monitored.

If "SERVICE=ON" is specified on *expr*, only the status of working gateways is displayed; if "SERVICE=OFF" is specified, only the status of stopped gateways is displayed.

The following [options] are available with the **cubrid gateway status** utility. -b, -q, -c, -m, -S, -P and -f are options to define the information to print; -s, -l and -t are options to control printing. All of these are possible to use as combining each other.

**-b**

Displays the status information of a gateway but does not display information on gateway application server.

### **-q**

Displays standby jobs in the job queue.

### **-f**

Displays information of DB and host accessed by gateway.

If it is used with the **-b** option, additional information on CAS is displayed. But SELECT, INSERT, UPDATE, DELETE, OTHERS items which shown on **-b** option are excluded.

If it is used with the **-P** option, STMT-POOL-RATIO is additionally printed. This item shows the ratio to use statements in the pool when you are using prepared statements.

### **-l SECOND**

The **-l** option is only used with **-f** option together. It specifies accumulation period (unit: sec.) when displaying the number of application servers whose client status is Waiting or Busy. If it is omitted, the default value (1 second) is specified.

### **-t**

Displays results in tty mode on the screen. The output can be redirected and used as a file.

### **-s SECOND**

Regularly displays the status of gateway based on specified period. It returns to a command prompt if q is entered.

If you do not specify options or arguments, the status of all gateways is displayed.

```
$ cubrid gateway status
@ cubrid gateway status
% oracle_gateway
-----
ID   PID   QPS   LQS PSIZE STATUS
-----
1 28434    0    0 50144 IDLE
2 28435    0    0 50144 IDLE
3 28436    0    0 50144 IDLE
4 28437    0    0 50140 IDLE
5 28438    0    0 50144 IDLE
```

- % oracle\_gateway: The gateway name
- ID: Serial number of CAS within the gateway
- PID: CAS process ID within the gateway
- QPS: The number of queries processed per second

- LQS: The number of long-duration queries processed per second
- PSIZE: Size of CAS
- STATUS: The current status of CAS (BUSY, IDLE, CLIENT\_WAIT, CLOSE\_WAIT)

The following shows the detail status of gateway for 5 seconds. The display will reset per 5 seconds as the new status information. To escape the display of the status, press <Q>.

```
$ cubrid gateway status -b -s 5
@ cubrid gateway status
```

| NAME             | PID          | PORT     | AS      | JQ     | TPS    | QPS    |
|------------------|--------------|----------|---------|--------|--------|--------|
| SELECT           | INSERT       | UPDATE   | DELETE  | OTHERS | LONG-T | LONG-Q |
| ERR-Q            | UNIQUE-ERR-Q | #CONNECT | #REJECT |        |        |        |
| =====            |              |          |         |        |        |        |
| =====            |              |          |         |        |        |        |
| =====            |              |          |         |        |        |        |
| * oracle_gateway | 13200        | 30000    | 5       | 0      | 0      | 0      |
| 0                | 0            | 0        | 0       | 0      | 0/60.0 | 0/60.0 |
| 0                | 0            | 0        | 0       | 0      |        |        |

- NAME: The gateway name
- PID: Process ID of the gateway
- PORT: Port number of the gateway
- AS: The number of CAS
- JQ: The number of standby jobs in the job queue
- TPS: The number of transactions processed per second (calculated only when the option is configured to “-b -s <sec>”)
- QPS: The number of queries processed per second (calculated only when the option is configured to “-b -s <sec>”)
- SELECT: The number of SELECT queries after starting of the gateway. When there is an option of “-b -s <sec>”, it is updated every time with the number of SELECTs which have been executed during the seconds specified by this option.
- INSERT: The number of INSERT queries after starting of the gateway. When there is an option of “-b -s <sec>”, it is updated every time with the number of INSERTs which have been executed during the seconds specified by this option.

- **UPDATE:** The number of UPDATE queries after starting of the gateway. When there is an option of “-b -s <sec>”, it is updated every time with the number of UPDATES which have been executed during the seconds specified by this option.
- **DELETE:** The number of DELETE queries after starting of the gateway. When there is an option of “-b -s <sec>”, it is updated every time with the number of DELETES which have been executed during the seconds specified by this option.
- **OTHERS:** The number of queries like CREATE and DROP except for SELECT, INSERT, UPDATE, DELETE. When there is an option of “-b -s <sec>”, it is updated every time with the number of queries which have been executed during the seconds specified by this option.
- **LONG-T:** The number of transactions which exceed LONG\_TRANSACTION\_TIME. / the value of the LONG\_TRANSACTION\_TIME parameter. When there is an option of “-b -s <sec>”, it is updated every time with the number of transactions which have been executed during the seconds specified by this option.
- **LONG-Q:** The number of queries which exceed LONG\_QUERY\_TIME. / the value of the LONG\_QUERY\_TIME parameter. When there is an option of “-b -s <sec>”, it is updated every time with the number of queries which have been executed during the seconds specified by this option.
- **ERR-Q:** The number of queries with errors found. When there is an option of “-b -s <sec>”, it is updated every time with the number of errors which have occurred during the seconds specified by this option.
- **UNIQUE-ERR-Q:** The number of queries with unique key errors found. When there is an option of “-b -s <sec>”, it is updated every time with the number of unique key errors which have occurred during the seconds specified by this option.
- **#CONNECT:** The number of connections that an application client accesses to CAS after starting the gateway.
- **#REJECT:** The count that an application client excluded from ACL IP list is rejected to access a CAS. Regarding ACL setting, see [Limiting Broker Access](#).

The following checks the status of gateway whose name includes oracle\_gateway and job status of a specific gateway in the job queue with the **-q** option. If you do not specify oracle\_gateway as an argument, list of jobs in the job queue for all gateways is displayed.

```
% cubrid gateway status -q oracle_gateway
@ cubrid gateway status
% oracle_gateway
```

| ID | PID   | QPS | LQS | PSIZE | STATUS |
|----|-------|-----|-----|-------|--------|
| 1  | 28444 | 0   | 0   | 50144 | IDLE   |

```

2 28445      0      0 50140 IDLE
3 28446      0      0 50144 IDLE
4 28447      0      0 50144 IDLE
5 28448      0      0 50144 IDLE

```

The following monitors the status of a gateway whose name includes oracle\_gateway with the **-s** option. If you do not specify oracle\_gateway as an argument, monitoring status for all gateways is performed regularly. It returns to a command prompt if q is not entered.

```

% cubrid gateway status -s 5 oracle_gateway
% oracle_gateway
-----
ID   PID   QPS   LQS  PSIZE STATUS
-----
1 28444      0      0 50144 IDLE
2 28445      0      0 50140 IDLE
3 28446      0      0 50144 IDLE
4 28447      0      0 50144 IDLE
5 28448      0      0 50144 IDLE

```

With the **-t** option, it display information of TPS and QPS to a file. To cancel displaying, press <Ctrl+C> to stop program.

```

% cubrid gateway status -b -t -s 1 > log_file

```

The following views information of server/database accessed by gateway, the last access times of applications, the IP addresses accessed to CAS and the versions of drivers etc. with the **-f** option.

```

$ cubrid gateway status -f oracle_gateway
@ cubrid gateway status
% oracle_gateway
-----
-----
-----
ID   PID   QPS   LQS  PSIZE STATUS          LAST ACCESS TIME

0.0.0.0      -            -
0            0

```

Meaning of each column in code above is as follows:

- LAST ACCESS TIME: Time when CAS runs or the latest time when an application client accesses CAS
- DB: Name of a database which CAS accesses most recently
- HOST: Name of a which CAS accesses most recently
- LAST CONNECT TIME: Most recent time when CAS accesses a database
- CLIENT IP: IP of an application clients currently being connected to an application server(CAS). If no application client is connected, 0.0.0.0 is displayed.
- CLIENT VERSION: A driver's version of an application client currently being connected to a CAS
- SQL\_LOG\_MODE: SQL logging mode of CAS. If the mode is same as the mode configured in the gateway, "-" is displayed.
- TRANSACTION STIME: Transaction start time
- #CONNECT: The number of connections that an application client accesses to CAS after starting the gateway
- #RESTART: The number of connection that CAS is re-running after starting the gateway

Enter the command below with the **-b** and **-f** options to display AS(T W B Ns-W Ns-B) and CANCELED additionally.

```

// The -f option is added upon execution of gateway status
information. Configuring Ns-W and Ns-B are displayed as long as N
seconds by using the -l.
% cubrid gateway status -b -f -l 2
@ cubrid gateway status
NAME          PID    PSIZE PORT  AS(T W B 2s-W 2s-B) JQ TPS QPS LONG-
T LONG-Q  ERR-Q UNIQUE-ERR-Q CANCELED ACCESS_MODE SQL_LOG  #CONNECT

```

```
#REJECT
=====

oracle_gateway 16784 56700 30000      5 0 0      0 0 0 16 29 0/
60.0 0/60.0      1      1      0      RW      ALL
4      1
```

Meaning of added columns in code above is as follows:

- AS(T): Total number of CAS being executed
- AS(W): The number of CAS in the status of Waiting
- AS(B): The number of CAS in the status of Busy
- AS(Ns-W): The number of CAS that the client belongs to has been waited for N seconds.
- AS(Ns-B): The number of CAS that the client belongs to has been Busy for N seconds.
- CANCELED: The number of queries have cancelled by user interruption since the gateway starts (if it is used with the **-l N** option, it specifies the number of accumulations for N seconds).

#### **Note**

Gateway is almost similar to broker, see below for more information on gateway

## CUBRID Manager Server

### Starting the CUBRID Manager Server

The following example shows how to start the CUBRID Manager server.

```
% cubrid manager start
```

The following message is returned if the CUBRID Manager server is already running.

```
% cubrid manager start
@ cubrid manager server start
++ cubrid manager server is running.
```

## Stopping the CUBRID Manager Server

The following example shows how to stop the CUBRID Manager server.

```
% cubrid manager stop
@ cubrid manager server stop
++ cubrid manager server stop: success
```

## CUBRID Manager Server Log

The logs of CUBRID Manager server are stored in the log/manager directory under the installation directory. There are four types of log files depending on server process of CUBRID Manager.

- auto\_backupdb.log: Backup log about the backup-automated jobs which was reserved by the CUBRID Manager Client
- auto\_execquery.log: Execution log about the query-automated jobs which was reserved by the CUBRID Manager Client
- cub\_js.access.log: Access log regarding the successful logins and tasks in CUBRID Manager Server.
- cub\_js.error.log: Access log regarding the failed logins and tasks in CUBRID Manager Server.

## Configuring CUBRID Manager Server

The configuration file name for the CUBRID Manager server is **cm.conf** and located in the **\$CUBRID/conf** directory. In the CUBRID Manager server configuration file, where parameter names and values are stored, comments are prefaced by “#.” Parameter names and values are separated by spaces or an equal sign (=).

This page describes parameters that are specified in the **cm.conf** file.

### **cm\_port**

**cm\_port** is a parameter used to configure a communication port for the connection between the CUBRID Manager server and the client. The default value is **8001** .

#### **monitor\_interval**

**monitor\_interval** is a parameter used to configure the monitoring interval of **cub\_auto** in seconds. The default value is **5** .

#### **allow\_user\_multi\_connection**

**allow\_user\_multi\_connection** is a parameter used to have multiple client connections allowed to the CUBRID Manager server. The default value is **YES** . Therefore, more than one CUBRID Manager client can connect to the CUBRID Manager server, even with the same user name.

#### **server\_long\_query\_time**

**server\_long\_query\_time** is a parameter used to configure delay reference time in seconds when configuring **slow\_query** which is one of server diagnostics items. The default value is **10** . If the execution time of the query performed on the server exceeds this parameter value, the number of the **slow\_query** parameters will increase.

#### **auto\_job\_timeout**

**auto\_job\_timeout** is a parameter used to configure timeout of auto job for **cub\_auto**. The default value is 43200 (12 hour).

#### **mon\_cub\_auto**

**mon\_cub\_auto** is a parameter used to allow **cub\_js** to restart **cub\_auto** process when **cub\_auto** is not running or not. The default value is NO.

#### **token\_active\_time**

**token\_active\_time** is a parameter used to configure timeout of token. The default value is 7200 (2 hour).

#### **support\_mon\_statistic**

**support\_mon\_statistic** is a parameter used to configure monitoring statistic of system or not. The default value is NO.

#### **cm\_process\_monitor\_interval**

**cm\_process\_monitor\_interval** is an interval time for collecting statistics. The default and the minimum value is 5 (5 minutes).

## CUBRID Manager User Management Console

The account and password of CUBRID Manager user are used to access the CUBRID Manager server when starting the CUBRID Manager client, distinguishing this user from the database user. CUBRID Manager Administrator (cm\_admin) is a CLI tool that manages user information and it executes commands in the console window to manage users. This utility only supports Linux OS.

The following shows how to use the CUBRID Manager (hereafter, CM) Administrator utilities. The utilities can be used through GUI on the CUBRID Manager client.

```
cm_admin <utility_name>
<utility_name>:
  adduser [<option>] <cmuser-name> <cmuser-password>  --- Adds a
CM user
  deluser <cmuser-name>  --- Deletes a CM user
  viewuser [<cmuser-name>]  --- Displays CM user information
  changeuserauth [<option>] <cmuser-name>  --- Changes the CM user
authority
  changeuserpwd [<option>] <cmuser-name>  --- Changes the CM user
password
  adddbinfo [<option>] <cmuser-name> <database-name>  --- Adds
database information of the CM user

information of the CM user
  changedbinfo [<option>] <database-name> number-of-pages  ---
Changes database information of the CM user
```

### CM Users

Information about CM users consists of the following:

- CM user authority: Includes the following information.
  - The permission to configure broker
  - The permission to create a database. For now, this authority is only given to the **admin** user.
  - The permission to monitor status
- Database information: A database that a CM user can use
- CM user password

The default user authority of CUBRID Manager is **admin** and its password is admin. Users who has **admin** authority have full administrative controls.

### Adding CM Users

The **cm\_admin adduser** utility creates a CM user who has been granted a specific authority and has database information. The permissions to configure broker, create a database, and monitor status can be granted to the CM user.

```
cm_admin adduser [options] cmuser-name cmuser-password
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **adduser**: A command to create a new CM user
- *cmuser-name*: Specifies a unique name to a CM user. Usable characters are 0~9, A~Z, a~z and `_`. Minimum length is 4 and maximum length is 32. If the specified name in *cmuser-name* is identical to the existing one, **cm\_admin** will stop creating a new CM user.
- *cmuser-password*: A password of a CM user. Usable characters are 0~9, A~Z, a~z and `_`. Minimum length is 4 and maximum length is 32.

The following is [options] of **cm\_admin adduser**.

#### **-b, --broker AUTHORITY**

Specifies the broker authority which will be granted to a new CM user.

You can use **admin**, **none** (default), and **monitor** as *AUTHORITY*

The following example shows how to create a CM user whose name is *testcm* and password is *testcmpwd* and then configure broker authority to monitor.

```
cm_admin adduser -b monitor testcm testcmpwd
```

#### **-c, --dbcreate AUTHORITY**

Specifies the authority to create a database which will be granted to a new CM user.

You can use **none** (default) and **admin** as *AUTHORITY*.

The following example shows how to create a CM user whose name is *testcm* and password is *testcmpwd* and then configure database creation authority to admin.

```
cm_admin adduser -c admin testcm testcmpwd
```

#### **-m, --monitor AUTHORITY**

Specifies the authority to monitor status which will be granted to a new CM user. You can use **admin**, **none** (default), and **monitor** as *AUTHORITY*

The following example shows how to create a CM user whose name is *testcm* and password is *testcmpwd* and then configure monitoring authority to admin.

```
cm_admin adduser -m admin testcm testcmpwd
```

### **-d, --dbinfo INFO\_STRING**

Specifies database information of a new CM user. The format of *INFO\_STRING* must be "<dbname>;<uid>;<broker\_ip>;<broker\_port>". The following example shows how to add database information "testdb;dba;localhost,30000" to a CM user named *testcm*.

```
cm_admin adduser -d "testdb;dba;localhost,30000" testcm  
testcmpwd
```

## **Deleting CM Users**

The **cm\_admin deluser** utility deletes a CM user.

```
cm_admin deluser cmuser-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **deluser**: A command to delete an existing CM user
- *cmuser-name*: The name of a CM user to be deleted

The following example shows how to delete a CM user named *testcm*.

```
cm_admin deluser testcm
```

## **Displaying CM User information**

The **cm\_admin viewuser** utility displays information of a CM user.

```
cm_admin viewuser cmuser-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **viewuser**: A command to display the CM user information
- *cmuser-name*: A CM user name. If this value is entered, information only for the specified user is displayed; if it is omitted, information for all CM users is displayed.

The following example shows how to display information of a CM user named *testcm* .

```
cm_admin viewuser testcm
```

The information will be displayed as follows:

```
CM USER: testcm
Auth info:
  broker: none
  dbcreate: none
  statusmonitorauth: none
DB info:

=====
=====
      DBNAME
UID          BROKER INFO
=====
=====
      testdb
dba          localhost,30000
```

## Changing the Authority of CM Users

The **cm\_admin changeuserauth** utility changes the authority of a CM user.

```
cm_admin changeuserauth options cmuser-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **changeuserauth**: A command to change the authority of a CM user
- *cmuser-name*: The name of a CM user whose authority to be changed

The following is [options] of **cm\_admin changeuserauth**.

### **-b, --broker AUTHORITY**

Specifies the broker authority that will be granted to a CM user. You can use **admin**, **none**, and **monitor** as *AUTHORITY*.

The following example shows how to change the broker authority of a CM user named *testcm* to monitor.

```
cm_admin changeuserauth -b monitor testcm
```

**-c, --dbcreate**

Specifies the authority to create a database which will be granted to a CM user. You can use **admin** and **none** as *AUTHORITY*.

The following example shows how to change the database creation authority of a CM user named *testcm* to admin.

```
cm_admin changeuserauth -c admin testcm
```

**-m, --monitor**

Specifies the authority to monitor status which will be granted to a CM user. You can use **admin**, **none**, and **monitor** as *AUTHORITY*.

The following example shows how to change the monitoring authority of a CM user named *testcm* to admin.

```
cm_admin changeuserauth -m admin testcm
```

**Changing the CM User Password**

The **cm\_admin changeuserpwd** utility changes the password of a CM user.

```
cm_admin changeuserpwd [options] cmuser-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **changeuserpwd**: A command to change the password of a CM user
- *cmuser-name*: The name of a CM user whose password to be changed

The following is [options] of **cm\_admin changeuserpwd**.

**-o, --oldpass PASSWORD**

Specifies the existing password of a CM user.

The following example shows how to change a password of a CM user named *testcm*.

```
cm_admin changeuserpwd -o old_password -n new_password  
testcm
```

**--adminpass PASSWORD**

The password of an admin user can be specified instead of old CM user's password that you don't know.

The following example shows how to change a password of a CM user named *testcm* by using an admin password.

```
cm_admin changeuserauth --adminpass admin_password -n  
new_password testcm
```

**-n, --newpass PASSWORD**

Specifies a new password of a CM user.

## Adding Database Information to CM Users

The **cm\_admin adddbinfo** utility adds database information (database name, UID, broker IP, and broker port) to a CM user.

```
cm_admin adddbinfo options cmuser-name database-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **adddbinfo**: A command to add database information to a CM user
- *cmuser-name*: CM user name
- *database-name*: The name of a database to be added

The following example shows how to add a database without specifying any user-defined values to a CM user named *testcm*.

```
cm_admin adddbinfo testcm testdb
```

The following is [options] of **cm\_admin adddbinfo**.

**-u, --uid ID**

Specifies the ID of a database user to be added. The default value is **dba**.

The following example shows how to add a database whose name is *testdb* and user ID is *cubriduser* to a CM user named *testcm*.

```
cm_admin adddbinfo -u cubriduser testcm testdb
```

**-h, --host IP**

Specifies the host IP of a broker used when clients access a database. The default value is **localhost**.

The following example shows how to add a database whose name is *testdb* and the host IP of is *127.0.0.1* to a CM user named *testcm*.

```
cm_admin adddbinfo -h 127.0.0.1 testcm testdb
```

**-p, --port NUMBER**

Specifies the port number of a broker used when clients access a database.  
The default value: **30000**.

### Deleting database information from CM Users

The **cm\_admin deldbinfo** utility deletes database information of a specified CM user.

```
cm_admin deldbinfo cmuser-name database-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **deldbinfo**: A command to delete database information of a CM user
- *cmuser-name*: CM user name
- *database-name*: The name of a database to be deleted

The following example shows how to delete database information whose name is *testdb* from a CM user named *testcm*.

```
cm_admin deldbinfo testcm testdb
```

### Changing Database Information of a CM user

The **cm\_admin changedbinfo** utility changes database information of a specified CM user.

```
cm_admin changedbinfo [options] cmuser-name database-name
```

- **cm\_admin**: An integrated utility to manage CUBRID Manager
- **changedbinfo**: A command to change database information of a CM user
- *cmuser-name*: CM user name
- *database-name*: The name of a database to be changed

The following is [options] of **cm\_admin changedbinfo**.

**-u, --uid ID**

Specifies the ID of a database user.

The following example shows how to update user ID information to *uid* in the *testdb* database which belongs to a CM user named *testcm* .

```
cm_admin changedbinfo -u uid testcm testdb
```

**-h, --host IP**

Specifies the host of a broker used when clients access a database.

The following example shows how to update host IP information to *10.34.63.132* in the *testdb* database which belongs to a CM user named *testcm* .

```
cm_admin changedbinfo -h 10.34.63.132 testcm testdb
```

**-p, --port NUMBER**

Specifies the port number of a broker used when clients access a database.

The following example shows how to update broker port information to *33000* in the *testdb* database which belongs to a CM user named *testcm* .

```
cm_admin changedbinfo -p 33000 testcm testdb
```

## CUBRID Procedural Language Server

### Starting CUBRID Procedural Language Server

The CUBRID Procedural Language Server automatically starts when the database server starts and stops when the database server stops.

If you do not want to start the Procedural Language Server with the database server, set the **stored\_procedure** value to **no** for the corresponding database in the CUBRID configuration file (**cubrid.conf**).

```
% cubrid server start demodb  
  
@ cubrid pl status
```

For more details on other types of errors that may occur when starting the CUBRID Procedural Language Server, see [CUBRID Procedural Language Errors](#).

## Restarting CUBRID Procedural Language Server

The following is a method to restart the Procedural Language Server for *demodb*. When the restart command for the Procedural Language Server is issued, the Procedural Language Server stops and is restarted by the database server. If the database server is not running, the restart command does not work.

```
% cubrid pl restart demodb

@ cubrid pl restart: demodb
++ cubrid pl restart: success
```

..note:

Since the database server automatically starts the Procedural Language Server, the restart command **is not** frequently used. It can be used to stabilize the server when the GC of the Procedural Language Server's VM is slow after performing large I/O operations or analysis tasks using procedures.

### Warning

Restarting the Procedural Language Server will interrupt and roll back any currently running transactions.

## Checking the Status of CUBRID Procedural Language Server

The following is an example of checking the status of the CUBRID Procedural Language Server for *demodb*. The name of the target database, *demodb*, on which the Procedural Language Server is currently running, is displayed. Additionally, the server's PID, port number, and applied JVM options are displayed.

```
% cubrid pl status demodb

@ cubrid pl status: demodb
Procedural Language Server (demodb, pid 9220, UDS)
VM arguments :
-----
...
-----
```

## Procedural Language Server Configuration

### Procedural Language Environment: Using Bundled JDK

To use the procedural language feature in CUBRID, a JVM environment is used. The CUBRID server includes the Eclipse Temurin JDK 8 version in the \$CUBRID/vm directory during installation, so there is no need to configure a separate JDK environment in the user's environment. This bundled JDK has been verified for use with the procedural language feature in CUBRID and is generally recommended for good performance and stability. To use a JDK configured in the user's environment instead of the bundled JDK, set the **CUBRID\_JAVA\_HOME** environment variable.

#### **CUBRID\_JAVA\_HOME**

The **CUBRID\_JAVA\_HOME** environment variable specifies the JDK installation directory. If the user does not specify the **CUBRID\_JAVA\_HOME** environment variable, the bundled JDK included during CUBRID installation is used. If an incorrect **CUBRID\_JAVA\_HOME** is specified, the procedural language server may not start properly and may return an error. The path of **CUBRID\_JAVA\_HOME** must include the JDK environment along with the libjvm library.

The following is an example of setting the **CUBRID\_JAVA\_HOME** environment variable.

```
**Example of setting in Windows environment**

set CUBRID_JAVA_HOME=C:\Program Files\Java\jdk1.8.0_421

**Example of setting in Linux environment**

export CUBRID_JAVA_HOME=/usr/java/jdk1.8.0_421
```

### Procedural Language Server System Parameters

The following table lists the server parameters related to the Procedural Language Server that can be set in the configuration file (**cubrid.conf**).

| Parameter Name       | Type | Default Value | Min | Max |
|----------------------|------|---------------|-----|-----|
| stored_procedure     | bool | yes           |     |     |
| stored_procedure_uds | bool | yes           |     |     |

|                  |     |   |   |       |
|------------------|-----|---|---|-------|
| stored_procedure | int | 0 | 0 | 65535 |
| _port            |     |   |   |       |

|                  |        |
|------------------|--------|
| stored_procedure | string |
| _vm_options      |        |

For more details on these parameters, see [cubrid.conf Configuration File and Default Parameters](#).

## CUBRID Procedural Language Server Logs

The logs of the CUBRID Procedural Language Server are stored in the **log/** directory of the installation directory. The following log files are created for each database.

- Error log (\$CUBRID/log/[db\_name]\_pl.err)
- Java log (\$CUBRID/log/[db\_name]\_pl.log)

### Error Log

The error log of the Procedural Language Server for each database is stored in the **\$CUBRID/log** directory, and the file name is in the format **<db\_name>\_pl.err**. The extension is **.err**.

```
demodb_pl.err
```

If an error occurs while starting the Procedural Language Server, the error message is saved in the error log file.

```
Time: 11/11/20 18:17:15.438 - ERROR *** file ../../src/jsp/jsp_sr.c,
line 501 ERROR CODE = -900, Tran = -1, EID = 1
Cannot find Java Virtual Machine library:
  Failed to get 'JVM_PATH' environment variable.
  Failed to load libjvm from 'JAVA_HOME' environment variable:

file: No such file or directory
    /lib/server/libjvm.so: cannot open shared object file: No
such file or directory.
```

### Note

For more details on what errors can occur, see [CUBRID Procedural Language Errors](#).

## Exception Log

The JVM exception messages that occur during the execution of procedures are saved. The exception log of the Procedural Language Server for each database is stored in the **\$CUBRID/log** directory, and the file name is in the format **<db\_name>\_pl.log**. The extension is **.log**.

```
demodb_pl.log
```

If an exception occurs while executing stored procedures/functions in the VM, the exception string is saved in the exception log.

```

| -905       | Networking with PL server failed: %1\$d | CAS received an incorrect packet from the Procedure Language Server |                                                                                                                                                                                                                                                                                                                                                                              |

## Database Management

### Database Users

A CUBRID database user can have members with the same authorization. If authorization **A** is granted to a user, the same authorization is also granted to all members belonging to the user. A database user and its members are called a “group.”; a user who has no members is called a “user.”

CUBRID provides **DBA** and **PUBLIC** users by default.

- **DBA** can access every object in the database, that is, it has authorization at the highest level. Only **DBA** has sufficient authorization to add, alter and delete the database users.

- All users including **DBA** are members of **PUBLIC**. Therefore, all database users have the authorization granted to **PUBLIC**. For example, if authorization **B** is added to **PUBLIC** group, all database members will automatically have the **B** authorization.

## databases.txt File

CUBRID stores information on the locations of all existing databases in the **databases.txt** file. This file is called the “database location file”. A database location file is used when CUBRID executes utilities for creating, renaming, deleting or replicating databases; it is also used when CUBRID runs each database. By default, this file is located in the **databases** directory under the installation directory. The directory is located through the environment variable **CUBRID\_DATABASES**.

```
db_name db_directory server_host logfile_directory
```

The format of each line of a database location file is the same as defined by the above syntax; it contains information on the database name, database path, server host and the path to the log files. The following example shows how to check the contents of a database location file.

```
% more databases.txt

dist_testdb /home1/user/CUBRID/bin d85007 /home1/user/CUBRID/bin
dist_demodb /home1/user/CUBRID/bin d85007 /home1/user/CUBRID/bin
testdb /home1/user/CUBRID/databases/testdb d85007 /home1/user/CUBRID/
databases/testdb
demodb /home1/user/CUBRID/databases/demodb d85007 /home1/user/CUBRID/
databases/demodb
```

By default, the database location file is stored in the **databases** directory under the installation directory. You can change the default directory by modifying the value of the **CUBRID\_DATABASES** environment variable. The path to the database location file must be valid so that the **cubrid** utility for database management can access the file properly. You must enter the directory path correctly and check if you have write permission on the file. The following example shows how to check the value configured in the **CUBRID\_DATABASES** environment variable.

```
% set | grep CUBRID_DATABASES
CUBRID_DATABASES=/home1/user/CUBRID/databases
```

An error occurs if an invalid directory path is set in the **CUBRID\_DATABASES** environment variable. If the directory path is valid but the database location file does not exist, a new location information file is created. If the **CUBRID\_DATABASES** environment variable has not been configured at all, CUBRID retrieves the location information file in the current working directory.

## Database Volume

The volumes of CUBRID database are classified as permanent volume, temporary volume and backup volume.

- In the permanent volumes,
  - there are data volumes that usually store permanent data, but can also store temporary data.
  - there is the active log volume that includes late changes of database.
- In the temporary volumes,
  - there are temporary temp volumes that store temporary data.
  - there are archive log volumes that store exhausted logs from the active log.
  - there is one background archive log volume that stores archive log in the background.

For more details on volumes, see [Database Volume Structure](#).

The following is an example of files related to the database when *testdb* database operates.

| File name   | Size  | Purpose        | Classification  | Description                                                                                                                                                                                                                                                                                            |
|-------------|-------|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| testdb      | 512MB | permanent data | Database volume | <p>The firstly created volume when DB is created.</p> <p>This volume stores permanent data (system, heap and index files).</p> <p>This volume includes database meta information.</p> <p><b>cubrid createdb</b> uses by default the size specified by <b>db_volume_size</b> in <b>cubrid.conf</b>.</p> |
| testdb_perm | 512MB | permanent data |                 | <p>Manually added volume using <b>cubrid addvoldb</b> utility</p> <p>This volume stores permanent data (system, heap and index files).</p>                                                                                                                                                             |
| testdb_temp | 512MB | temporary data |                 | <p>Manually added volume using <b>cubrid addvoldb</b> utility</p> <p>This volume stores temporary data (query results,</p>                                                                                                                                                                             |

| File name   | Size  | Purpose        | Classification | Description                                                                                                                |
|-------------|-------|----------------|----------------|----------------------------------------------------------------------------------------------------------------------------|
|             |       |                |                | list files, sort files, join object hashes).                                                                               |
| testdb_x003 | 512MB | permanent data |                | Automatically created when database requires more space. This volume stores permanent data (system, heap and index files). |
| testdb_x004 | 512MB | permanent data |                | Automatically created when database requires more space. This volume stores permanent data (system, heap and index files). |
| testdb_x005 | 512MB | permanent data |                | Automatically created when database requires more space. This volume stores permanent data (system, heap and index files). |

| File name     | Size  | Purpose              | Classification   | Description                                                                                                                                                                                |
|---------------|-------|----------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| testdb_x006   | 64MB  | permanent data       |                  | <p>Automatically created when database requires more space.</p> <p>This volume stores permanent data (system, heap and index files).</p> <p>The size of volume is not maximized (yet).</p> |
| testdb_t32766 | 512MB | temporary data       | Temporary Volume | <p>Automatically created when database requires more space.</p> <p>This volume stores temporary data (query results, list files, sort files, join object hashes).</p>                      |
| testdb_lgar_t | 512MB | background archiving | Log volume       | <p>A log file which is related to the background archiving feature.</p> <p>This is used when storing the archiving log.</p>                                                                |
| archive       |       |                      |                  |                                                                                                                                                                                            |

| File name      | Size  | Purpose        | Classification      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|-------|----------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| testdb_lgar224 | 512MB |                |                     | <p>Archiving logs are continuously archived and the files ending with three digits are created.</p> <p>At this time, archiving logs from 001~223 seem to be removed normally by <b>cubrid backupdb -r</b> option or the setting of <b>log_max_archives</b> in <b>cubrid.conf</b>.</p> <p>When archiving logs are removed, you can see the removed archiving log numbers in the REMOVE section of lginf file.</p> <p>See <a href="#">Managing Archive Logs</a>.</p> |
| testdb_lgat    | 512MB | active         |                     | Active log file                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| testdb_dwb     | 1MB   | temporary data | Double write buffer | Double write buffer storage file, where                                                                                                                                                                                                                                                                                                                                                                                                                            |

| File name | Size | Purpose | Classification | Description                      |
|-----------|------|---------|----------------|----------------------------------|
|           |      |         |                | flushed pages are written first. |

- Database volume file

- In the table above, *testdb*, *testdb\_perm*, *testdb\_temp*, *testdb\_x003* ~ *testdb\_x006* are classified as the database volume files.
- File size is determined by **db\_volume\_size** in **cubrid.conf** or the **--db-volume-size** option of **cubrid createdb** and **cubrid addvoldb**.
- When database remains out of space, it automatically expands existing volumes and creates new volumes.

- Temporary volume

- Temporary volumes are usually used to store temporary data. They are automatically created and destroyed by database.
- File size is determined by **db\_volume\_size** in **cubrid.conf**.

- Log volume file

- In the above, *testdb\_lgar\_t*, *testdb\_lgar224* and *testdb\_lgat* are classified as the log volume files.
- File size is determined by **log\_volume\_size** in **cubrid.conf** or the **--log-volume-size** option of **cubrid createdb**.

- Double write buffer file \* Double write buffer file is a storage area used to protect against I/O errors (partial writes). \* Every data page write is first written into the buffer and then flushed to its location in the permanent data volumes. \* During database reboot, partially written page is detected and replaced with the counterpart page in double write buffer. \* The file size is determined by **double\_write\_buffer\_size** in **cubrid.conf**. If set to zero, no file is created and double write buffer is disabled.

#### Note

Any data that has to be persistent over database restart and crash is stored in the database volumes created for permanent data purpose. The volumes store table rows (heap files), indexes (b-tree files) and several system files.

Intermediate and final results of query processing and sorting need only temporary storage. Based on the size of required temporary data, it will be first stored in memory (the space size is determined by the system parameter **temp\_file\_memory\_size\_in\_pages** specified in **cubrid.conf**). Exceeding data has to be stored on disk.

Database will usually create and use temporary volumes to allocate disk space for temporary data. Administrator may however assign permanent database volumes with the purpose of storing temporary data using by running **cubrid addvoldb -p temp** command. If such volumes exist, they will have priority over temporary volumes when disk space is allocated for temporary data.

The examples of queries that can use temporary data are as follows:

- Queries creating the resultset like **SELECT**
- Queries including **GROUP BY** or **ORDER BY**
- Queries including a subquery
- Queries executing sort-merge join
- Queries including the **CREATE INDEX** statement

To have complete control on the disk space used for temporary data and to prevent it from consuming all system disk space, our recommendation is to:

- create permanent database volumes in advance to secure the required space for temporary data
- limit the size of the space used in the temporary volumes when a queries are executed by setting **temp\_file\_max\_size\_in\_pages** parameter in **cubrid.conf** (there is no limit by default).

## cubrid Utilities

The following shows how to use the cubrid management utilities.

```
cubrid utility_name
utility_name:
    createdb [option] <database_name> <locale_name> --- Creating a
    database
    deletedb [option] <database_name> --- Deleting a database
```

```

installdb [option] <database-name>    --- Installing a database
renamedb [option] <source-database-name> <target-database-name>
--- Renaming a database
copydb [option] <source-database-name> <target-database-name>
--- Copying a database
backupdb [option] <database-name>    --- Backing up a database
restoredb [option] <database-name>    --- Restoring a database
addvoldb [option] <database-name>    --- Adding a database volume
file
    spacedb [option] <database-name>    --- Displaying details of
database space
    lockdb [option] <database-name>    --- Displaying details of
database lock
    tranlist [option] <database-name>    --- Checking transactions
    killtran [option] <database-name>    --- Removing transactions
    optimizedb [option] <database-name>    --- Updating database
statistics
    statdump [option] <database-name>    --- Dumping statistic
information of database server execution
    compactdb [option] <database-name>    --- Optimizing space by
freeing unused space
    diagdb [option] <database-name>    --- Displaying internal
information
    checkdb [option] <database-name>    --- Checking database
consistency
    alterdbhost [option] <database-name>    --- Altering database host
    plandump [option] <database-name>    --- Displaying details of the
query plan
    loadadb [option] <database-name>    --- Loading data and schema
    unloadadb [option] <database-name>    --- Unloading data and schema
    paramdump [option] <database-name>    --- Checking out the
parameter values configured in a database
    changemode [option] <database-name>    --- Displaying or changing
the server HA mode
    applyinfo [option] <database-name>    --- Displaying the status
of being applied transaction log to the other node in HA replication
environment
    synccolladb [option] <database-name>    --- Synchronizing the DB
collation with the system collation
    genlocale [option] <database-name>    --- Compiling the locale
information to use
    dumplocale [option] <database-name>    --- Printing human
readable text for the compiled binary locale information
    gen_tz [option] [<database-name>]    --- Generates C source file
containing timezone data ready to be compiled into a shared library
    dump_tz [option]    --- Displaying timezone related information
    tde <operation> [option] <database-name>    --- Managing
Transparent Data Encryption (TDE)
    vacuumdb [option] <database-name>    --- Vacuuming deleted records
or unnecessary mvcc related information from records in the database
    flashback [option] <database-name> <owner_name.class_name>    ---
Provides statements to rewind a specific transaction.

```

```
memmon [option] <database-name> --- Provides information of
current heap memory usage on the server.
```

## cubrid Utility Logging

CUBRID supports logging feature for the execution result of **cubrid** utilities; for details, see [cubrid Utility Logging](#).

## createdb

The **cubrid createdb** utility creates databases and initializes them with the built-in CUBRID system tables. It can also define initial users to be authorized in the database and specify the locations of the logs and databases. In general, the **cubrid createdb** utility is used only by DBA.

### Warning

When you create database, a locale name and a charset name after a DB name must be specified(e.g. ko\_KR.utf8). It affects the length of string type, string comparison operation, etc. The specified charset when creating database cannot be changed later, so you should be careful when specifying it.

For charset, locale and collation setting, see [An Overview of Globalization](#).

```
cubrid createdb [options] database_name locale_name.charset
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **createdb**: A command used to create a new database.
- *database\_name*: Specifies a unique name for the database to be created, without including the path name to the directory where the database will be created. If the specified database name is the same as that of an existing database name, CUBRID halts creation of the database to protect existing files.
- *locale\_name*: A locale name to use in the database should be input. For a locale name which can be used in CUBRID, refer to [Step 1: Selecting a Locale](#).
- *charset*: A character set to use in the database should be input. A character set which can be used in CUBRID is iso88591, euckr or utf8.
  - If *locale\_name* is en\_US and *charset* is omitted, a character set will be iso88591.

- If *locale\_name* is ko\_KR and *charset* is omitted, a character set will be utf8.
- All locale names except en\_US and ko\_KR cannot omit *charset*, and a *charset* can be specified only with utf8.

The maximum length of database name is 17 in English.

The following shows [options] available with the **cubrid createdb** utility.

```

--db-volume-size=SIZE      size of first information volume
--db-page-size=SIZE        database page SIZE in bytes
--log-volume-size=SIZE     size of log archives
--log-page-size=SIZE       log page SIZE in bytes
--comment=COMMENT          COMMENT for a database
-F, --file-path=PATH       directory PATH for database
volumes
-L, --log-path=PATH        directory PATH for log volumes
-B, --lob-base-path=PATH   base directory PATH for external
LOB data
--server-name=HOST         server's HOST name
-r, --replace              replace an existing database
--more-volume-file=FILE    FILE contain specifications for
creation of additional volumes
--user-definition-file=FILE FILE contain user definitions
--csql-initialization-file=FILE FILE contain SQLs for an
initialization of the database
-o, --output-file=FILE     redirect output messages to FILE
-v, --verbose              enable verbose status messages

```

### --db-volume-size=SIZE

This option specifies the size of the database volume that will be created first. The default value is the value of the system parameter **db\_volume\_size**. You can set units as K, M, G and T, which stand for kilobytes (KB), megabytes (MB), gigabytes (GB), and terabytes (TB) respectively; if you omit the unit, bytes will be applied. The size of the database is always rounded up to 64 disk sectors, which depends on the size of a page and can be 16M, 32M or 64M for page size 4k, 8k and 16k respectively.

The following example shows how to create a database named *testdb* and assign 512 MB to its first volume.

```
cubrid createdb --db-volume-size=512M testdb en_US
```

### --db-page-size=SIZE

This option specifies the size of the database page; the minimum value is 4K and the maximum value is **16K** (default). K stands for kilobytes (KB). The value of page size is one of

the following: 4K, 8K, or 16K. If a value between 4K and 16K is specified, system rounds up the number. If a value greater than 16K or less than 4K, the specified number is used.

The following example shows how to create a database named *testdb* and configure its page size 16K.

```
cubrid createdb --db-page-size=16K testdb en_US
```

### **--log-volume-size=SIZE**

This option specifies the size of the database log volume. The default value is the same as database volume size, and the minimum value is 20M. You can set units as K, M, G and T, which stand for kilobytes (KB), megabytes (MB), gigabytes (GB), and terabytes (TB) respectively. If you omit the unit, bytes will be applied.

The following example shows how to create a database named *testdb* and assign 256 MB to its log volume.

```
cubrid createdb --log-volume-size=256M testdb en_US
```

### **--log-page-size=SIZE**

This option specifies the size of the log volume page. The default value is the same as data page size. The minimum value is 4K and the maximum value is 16K. K stands for kilobytes (KB). The value of page size is one of the following: 4K, 8K, or 16K. If a value between 4K and 16K is specified, system rounds up the number. If a value greater than 16K or less than 4K, the specified number is used.

The following example shows how to create a database named *testdb* and configure its log volume page size 8K.

```
cubrid createdb --log-page-size=8K testdb en_US
```

### **--comment=COMMENT**

This option specifies a comment to be included in the database volume header. If the character string contains spaces, the comment must be enclosed in double quotes.

The following example shows how to create a database named *testdb* and add a comment to the database volume.

```
cubrid createdb --comment "a new database for study" testdb en_US
```

### **-F, --file-path=PATH**

The **-F** option specifies an absolute path to a directory where the new database will be created. If the **-F** option is not specified, the new database is created in the current working directory.

The following example shows how to create a database named *testdb* in the directory */dbtemp/new\_db*.

```
cubrid createdb -F "/dbtemp/new_db/" testdb en_US
```

#### **-L, --log-path=PATH**

The **-L** option specifies an absolute path to the directory where database log files are created. If the **-L** option is not specified, log files are created in the directory specified by the **-F** option. If neither **-F** nor **-L** option is specified, database log files are created in the current working directory.

The following example shows how to create a database named *testdb* in the directory */dbtemp/newdb* and log files in the directory */dbtemp/db\_log*.

```
cubrid createdb -F "/dbtemp/new_db/" -L "/dbtemp/db_log/" testdb en_US
```

#### **-B, --lob-base-path=PATH**

This option specifies a directory where **LOB** data files are stored when **BLOB/CLOB** data is used. If the **--lob-base-path** option is not specified, LOB data files are store in *<location of database volumes created>/lob* directory.

The following example shows how to create a database named *testdb* in the working directory and specify */home/data1* of local file system as a location of LOB data files.

```
cubrid createdb --lob-base-path "file:/home/data1" testdb en_US
```

#### **--server-name=HOST**

This option enables the server of a specific database to run in the specified host when CUBRID client/server is used. The information of a host specified is stored in the **databases.txt** file. If this option is not specified, the current localhost is specified by default.

The following example shows how to create a database named *testdb* and register it on the host *aa\_host*.

```
cubrid createdb --server-name aa_host testdb en_US
```

#### **-r, --replace**

This option creates a new database and overwrites an existing database if one with the same name exists.

The following example shows how to create a new database named *testdb* and overwrite the existing database with the same name.

```
cubrid createdb -r testdb en_US
```

### **--more-volume-file=FILE**

This option creates an additional volume based on the specification contained in the file specified by the option. The volume is created in the same directory where the database is created. Instead of using this option, you can add a volume by using the **cubrid addvoldb** utility.

The following example shows how to create a database named *testdb* as well as an additional volume based on the specification stored in the **vol\_info.txt** file.

```
cubrid createdb --more-volume-file vol_info.txt testdb en_US
```

The following is a specification of the additional volume contained in the **vol\_info.txt** file. The specification of each volume must be written on a single line.

```
#xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
# NAME volname COMMENTS volcmnts PURPOSE volpurp NPAGES volnpgs
NAME data_v1 COMMENTS "data information volume" PURPOSE data
NPAGES 1000
NAME data_v2 COMMENTS "data information volume" NPAGES 1000
NAME temp_v1 COMMENTS "temporary information volume" PURPOSE
temp NPAGES 500
#xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxx
```

As shown in the example, the specification of each volume consists following.

```
[NAME volname] [COMMENTS volcmnts] [PURPOSE volpurp] NPAGES
volnpgs
```

- *volname*: The name of the volume to be created. It must follow the UNIX file name conventions and be a simple name not including the directory path. The specification of a volume name can be omitted. If it is, the “database name to be created by the system\_volume identifier” becomes the volume name.

- *volcmnts*: Comment to be written in the volume header. It contains information on the additional volume to be created. The specification of the comment on a volume can also be omitted.
- *volpurp*: The purpose for which the volume will be used. It can be either permanent data (default option) or temporary.

#### Note

For backward compatibility, all old keywords, **data**, **index**, **temp**, or **generic** are accepted. **temp** stands for temporary data purpose, while the rest stand for permanent data purpose.

- *volnpgs*: The number of pages of the additional volume to be created. The specification of the number of pages of the volume cannot be omitted; it must be specified. The actual volume size is rounded up to the next multiple of **64 sectors**.

### --user-definition-file=FILE

This option adds users who have access to the database to be created. It adds a user based on the specification contained in the user information file specified by the parameter. Instead of using the **--user-definition-file** option, you can add a user by using the **CREATE USER** statement (for details, see [CREATE USER](#)).

The following example shows how to create a database named *testdb* and add users to *testdb* based on the user information defined in the **user\_info.txt** file.

```
cubrid createdb --user-definition-file=user_info.txt testdb en_US
```

The syntax of a user information file is as follows:

```
USER user_name [ <groups_clause> | <members_clause> ]
<groups_clause>:
  [ GROUPS <group_name> [ { <group_name> }... ] ]
<members_clause>:
  [ MEMBERS <member_name> [ { <member_name> }... ] ]
```

- The *user\_name* is the name of the user who has access to the database. It must not include spaces.

- The **GROUPS** clause is optional. The *group\_name* is the upper level group that contains the *user\_name* . Here, the *group\_name* can be multiply specified and must be defined as **USER** in advance.
- The **MEMBERS** clause is optional. The *member\_name* is the name of the lower level member that belongs to the *user\_name* . Here, the *member\_name* can be multiply specified and must be defined as **USER** in advance.

Comments can be used in a user information file. A comment line must begin with a consecutive hyphen lines (--). Blank lines are ignored.

The following example shows a user information in which *grandeur* and *sonata* are included in *sedan* group, *tuscan* is included in *suv* group, and *i30* is included in *hatchback* group. The name of the user information file is **user\_info.txt**.

```
--  
-- Example 1 of a user information file  
--  
USER sedan  
USER suv  
USER hatchback  
USER grandeur GROUPS sedan  
USER sonata GROUPS sedan  
USER tuscan GROUPS suv  
USER i30 GROUPS hatchback
```

The following example shows a file that has the same user relationship information as the file above. The difference is that the **MEMBERS** statement is used in the file below.

```
--  
-- Example 2 of a user information file  
--  
USER grandeur  
USER sonata  
USER tuscan  
USER i30  
USER sedan MEMBERS sonata grandeur  
USER suv MEMBERS tuscan  
USER hatchback MEMBERS i30
```

### **--csql-initialization-file=FILE**

This option executes an SQL statement on the database to be created by using the CSQL Interpreter. A schema can be created based on the SQL statement contained in the file specified by the parameter.

The following example shows how to create a database named *testdb* and execute the SQL statement defined in *table\_schema.sql* through the CSQL Interpreter.

```
cubrid createdb --csql-initialization-file table_schema.sql
testdb en_US
```

#### **-o, --output-file=FILE**

This option stores messages related to the database creation to the file given as a parameter. The file is created in the same directory where the database was created. If the **-o** option is not specified, messages are displayed on the console screen. The **-o** option allows you to use information on the creation of a certain database by storing messages, generated during the database creation, to a specified file.

The following example shows how to create a database named *testdb* and store the output of the utility to the **db\_output** file instead of displaying it on the console screen.

```
cubrid createdb -o db_output testdb en_US
```

#### **-v, --verbose**

This option displays all information on the database creation operation onto the screen. Like the **-o** option, this option is useful in checking information related to the creation of a specific database. Therefore, if you specify the **-v** option together with the **-o** option, you can store the output messages in the file given as a parameter; the messages contain the operation information about the **cubrid createdb** utility and database creation process.

The following example shows how to create a database named *testdb* and display detailed information on the operation onto the screen.

```
cubrid createdb -v testdb en_US
```

#### **Note**

- **temp\_file\_max\_size\_in\_pages** is a parameter used to configure the maximum size of temporary volumes - used for complicated queries or storing arrays - on the disk. With the default value **-1**, the temporary volumes size is only limited by the capacity of the disk specified by the **temp\_volume\_path** parameter. If the value is 0, no temporary volumes can be created. In this case, a permanent volume with temporary data purpose should be added by using the **cubrid addvoldb** utility. For an efficient storage management, it is recommended to use the latter approach.

- By using the **cubrid spacedb** utility, you can check the remaining space of each volume. By using the **cubrid addvoldb** utility, you can add more volumes as needed while managing the database. You are advised to add more volumes when there is less system load. When all preassigned volumes are completely in use, the database system automatically creates new volumes.

The following example shows how to create a database, with additional volumes, including one for temporary data purpose.

```
cubrid createdb --db-volume-size=512M --log-volume-size=256M
cubriddb en_US
cubrid addvoldb -S -n cubriddb_DATA01 --db-volume-size=512M cubriddb
cubrid addvoldb -S -p temp -n cubriddb_TEMP01 --db-volume-size=512M
cubriddb
```

#### Note

##### Creating a database using an existing key file

When the database is created, a key file is created together by default. If you want to use an existing key file when creating a database:

1. Copy the key file with the name **<database-name>\_keys**.
2. Specify the directory path of the copied key file by the system parameter **tde\_keys\_file\_path**.
3. Create a database by using the **createdb utility**.

For more information on the TDE key file, see [File-based Master Key Management](#).

## addvoldb

If you want to micromanage CUBRID storage volumes, addvoldb is the tool for you. You can finely tune each file name, path, purpose, and size. The database system can handle all storage by itself, but it uses default values to configure each new volume.

The command for manually adding a database volume is as follows.

```
cubrid addvoldb [options] database_name
```

- **cubrid**: An integrated utility for CUBRID service and database management.
- **addvoldb**: A command that adds a specified number of pages of the new volume to a specified database.
- *database\_name*: Specifies the name of the database to which a volume is to be added without including the path name to the directory where the database is to be created.

The following example shows how to create a database, with additional multi-purpose volumes.

```
cubrid createdb --db-volume-size=512M --log-volume-size=256M
cubriddb en_US
cubrid addvoldb -S -n cubriddb_DATA01 --db-volume-size=512M cubriddb
cubrid addvoldb -S -p temp -n cubriddb_TEMP01 --db-volume-size=512M
cubriddb
```

The following shows [options] available with the **cubrid addvoldb** utility.

```
--db-volume-size=SIZE      size of additional volume
-n, --volume-name=NAME     NAME of information volume
-F, --file-path=PATH       PATH for adding volume file
--comment=COMMENT          COMMENT for adding volume file
-p, --purpose=PURPOSE      PURPOSE for adding volume file
-S, --SA-mode              stand-alone mode execution
-C, --CS-mode              client-server mode execution
--max-writesize-in-sec=SIZE the amount of volume written per
second
```

#### **--db-volume-size=SIZE**

**--db-volume-size** is an option that specifies the size of the volume to be added to a specified database. If the **--db-volume-size** option is omitted, the value of the system parameter **db\_volume\_size** is used by default. You can set units as K, M, G and T, which stand for kilobytes (KB), megabytes (MB), gigabytes (GB), and terabytes (TB) respectively. If you omit the unit, bytes will be applied. The size of the database is always rounded up to 64 disk sectors, which depends on the size of a page and can be 16M, 32M or 64M for page size 4k, 8k and 16k respectively.

The following example shows how to add a volume for which 256 MB are assigned to the *testdb* database.

```
cubrid addvoldb --db-volume-size=256M testdb
```

**-n, --volume-name=NAME**

This option specifies the name of the volume to be added to a specified database. The volume name must follow the file name protocol of the operating system and be a simple one without including the directory path or spaces. If the **-n** option is omitted, the name of the volume to be added is configured by the system automatically as “database name\_volume identifier”. For example, if the database name is *testdb*, the volume name *testdb\_x001* is automatically configured.

The following example shows how to specify a different name, *testdb\_v1*, to newly added volume.

```
cubrid addvolddb -n testdb_v1 testdb
```

**-F, --file-path=PATH**

This option specifies the directory path where the volume to be added will be stored. If the **-F** option is omitted, the value of the system parameter **volume\_extension\_path** is used by default.

The following example shows how to add a volume in the */dbtemp/addvol* directory. Since the **-n** option is not specified for the volume name, the volume name *testdb\_x001* will be created.

```
cubrid addvolddb -F /dbtemp/addvol/ testdb
```

**--comment COMMENT**

This option facilitates to retrieve information on the added volume by adding such information in the form of comments. It is recommended that the contents of a comment include the name of **DBA** who adds the volume, or the purpose of adding the volume. The comment must be enclosed in double quotes.

The following example shows how to add a volume and inserts a comment with additional information.

```
cubrid addvolddb --comment "Data volume added by cheolsoo kim  
because permanent data space was almost depleted." testdb
```

**-p, --purpose=PURPOSE**

This option specifies the purpose of the volume to be added. The purpose defines the type of files that will be stored in added volume:

- **PERMANENT DATA** to store table rows, indexes and system files.
- **TEMPORARY DATA** to store intermediate and final results of query processing and sorting.

If not specified, the purpose of the volume is by default considered **PERMANENT DATA**. The following example shows how to change it to temporary.

```
cubrid addvoldb -p temp testdb
```

#### Note

PERMANENT DATA volumes used to be classified as generic, data and index. The design of volumes has been changed, and since then the classification no longer exists. In order to avoid invalidating your old scripts, we chose to keep the keywords as valid options, but their effect will be the same. The only remaining option value with a real effect is temp.

For detailed information on each purpose, see [Database Volume Structure](#).

#### **-S, --SA-mode**

This option accesses the database in standalone mode without running the server process. This option has no parameter. If the **-S** option is not specified, the system assumes to be in client/server mode.

```
cubrid addvoldb -S --db-volume-size=256M testdb
```

#### **-C, --CS-mode**

This option accesses the database in client/server mode by running the server and the client separately. There is no parameter. Even when the **-C** option is not specified, the system assumes to be in client/server mode by default.

```
cubrid addvoldb -C --db-volume-size=256M testdb
```

#### **--max-writesize-in-sec=SIZE**

The **--max-writesize-in-sec** is used to limit the impact of system operating when you add a volume to the database. This can limit the maximum writing size per second. The unit of this option is K(kilobytes) and M(megabytes). The minimum value is 160K. If you set this value as less than 160K, it is changed as 160K. It can be used only in client/server mode.

The below is an example to limit the writing size of the 2GB volume as 1MB. Consuming time will be about 35 minutes(= (2048MB/1MB) /60 sec.).

```
cubrid addvoldb -C --db-volume-size=2G --max-writesize-in-sec=1M
testdb
```

## deletedb

The **cubrid deletedb** utility is used to delete a database. You must use the **cubrid deletedb** utility to delete a database, instead of using the file deletion commands of the operating system; a database consists of a few interdependent files.

The **cubrid deletedb** utility also deletes the information on the database from the database location file (**databases.txt**). The **cubrid deletedb** utility must be run offline, that is, in standalone mode when nobody is using the database.

```
cubrid deletedb [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **deletedb**: A command to delete a database, its related data, logs and all backup files. It can be executed successfully only when the database is in a stopped state.
- *database\_name*: Specifies the name of the database to be deleted without including the path name.

The following shows [options] available with the **cubrid deletedb** utility.

```
-o, --output-file=FILE      redirect output messages to FILE
-d, --delete-backup        delete backup volumes
```

### **-o, --output-file=FILE**

This option specifies the file name for writing messages:

```
cubrid deletedb -o deleted_db.out testdb
```

The **cubrid deletedb** utility also deletes the database information contained in the database location file (**databases.txt**). The following message is returned if you enter a utility that tries to delete a non-existing database.

```
cubrid deletedb testdb
Database "testdb" is unknown, or the file "databases.txt" cannot
be accessed.
```

**-d, --delete-backup**

This option deletes database volumes, backup volumes and backup information files simultaneously. If the **-d** option is not specified, backup volume and backup information files are not deleted.

```
cubrid deletedb -d testdb
```

**renamedb**

The **cubrid renamedb** utility renames a database. The names of information volumes, log volumes and control files are also renamed to conform to the new database one.

In contrast, the **cubrid alterdbhost** utility configures or changes the host name of the specified database. In other words, it changes the host name configuration in the **databases.txt** file.

```
cubrid renamedb [options] src_database_name dest_database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **renamedb**: A command that changes the existing name of a database to a new one. It executes successfully only when the database is in a stopped state. The names of related information volumes, log volumes and control files are also changed to new ones accordingly.
- **src\_database\_name**: The name of the existing database to be renamed. The path name to the directory where the database is to be created must not be included.
- **dest\_database\_name**: The new name of the database. It must not be the same as that of an existing database. The path name to the directory where the database is to be created must not be included.

The following shows [options] available with the **cubrid renamedb** utility.

```
-E, --extended-volume-path=PATH directory PATH for extended
information volumes
-i, --control-file=FILE          renaming volumes over several
locations written in the control file
-d, --delete-backup             delete backup volumes
```

**-E, --extended-volume-path=PATH**

This option renames an extended volume created in a specific directory path (e.g. /dbtemp/addvol/), and then moves the volume to a new directory. This specifies a new directory path (e.g. /dbtemp/newaddvols/) where the renamed extended volume will be moved.

If it is not specified, the extended volume is only renamed in the existing path without being moved. If a directory path outside the disk partition of the existing database volume or an invalid one is specified, the rename operation is not executed. This option cannot be used together with the **-i** option.

```
cubrid renamedb -E /dbtemp/newaddvols/ testdb testdb_1
```

### **-i, --control-file=FILE**

The option specifies an input file in which directory information is stored to change all database name of volumes or files and assign different directory at once. To perform this work, the **-i** option is used. The **-i** option cannot be used together with the **-E** option.

```
cubrid renamedb -i rename_path testdb testdb_1
```

The following are the syntax and example of a file that contains the name of each volume, the current directory path and the directory path where renamed volumes will be stored.

```
valid source_fullvolname dest_fullvolname
```

- *valid*: An integer that is used to identify each volume. It can be checked in the database volume control file (database\_name\_vinf).
- *source\_fullvolname*: The current directory path to each volume.
- *dest\_fullvolname*: The target directory path where renamed volumes will be moved. If the target directory path is invalid, the database rename operation is not executed.

```
-5 /home1/user/testdb_vinf      /home1/CUBRID/databases/
testdb_1_vinf
-4 /home1/user/testdb_lginf     /home1/CUBRID/databases/
testdb_1_lginf
-3 /home1/user/testdb_bkvinf    /home1/CUBRID/databases/
testdb_1_bkvinf
-2 /home1/user/testdb_lgat      /home1/CUBRID/databases/
testdb_1_lgat
 0 /home1/user/testdb           /home1/CUBRID/databases/
testdb_1
 1 /home1/user/backup/testdb_x001/home1/CUBRID/databases/backup/
testdb_1_x001
```

### **-d, --delete-backup**

This option renames the *testdb* database and at once forcefully delete all backup volumes and backup information files that are in the same location as *testdb*. Note that you cannot

use the backup files with the old names once the database is renamed. If the **-d** option is not specified, backup volumes and backup information files are not deleted.

```
cubrid renamedb -d testdb testdb_1
```

## alterdbhost

The **cubrid alterdbhost** utility sets or changes the host name of the specified database. It changes the host name set in the **databases.txt** file.

```
cubrid alterdbhost [option] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management
- **alterdbhost**: A command used to change the host name of the current database

The following shows the option available with the **cubrid alterdbhost** utility.

### **-h, --host=HOST**

The **-h** option specifies the host name to be changed. When this option is omitted, specifies the host name to localhost.

## copydb

The **cubrid copydb** utility copy or move a database to another location. As arguments, source and target name of database must be given. A target database name must be different from a source database name. When the target name argument is specified, the location of target database name is registered in the **databases.txt** file.

The **cubrid copydb** utility can be executed only offline (that is, state of a source database stop).

```
cubrid copydb [options] src-database-name dest-database-name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **copydb**: A command that copy or move a database from one to another location.
- *src-database-name*: The names of source and target databases to be copied or moved.
- *dest-database-name*: A new (target) database name.

If options are omitted, a target database is copied into the same directory of a source database.

The following shows [options] available with the **cubrid copydb** utility.

```

--server-name=HOST      server's HOST name
-F, --file-path=PATH    directory PATH for database volumes
-L, --log-path=PATH     directory PATH for log volumes
-E, --extended-volume-path=PATH directory PATH for extended
information volumes
-i, --control-file=FILE  copying volumes over several
locations written in the control file
-r, --replace           replace an existing database
-d, --delete-source     delete a source database
--copy-lob-path         copy external storage PATH for LOB
data from the source database. By default, the LOB path is not copied
-B, --lob-base-path=PATH base directory PATH for external LOB
data

```

#### **--server-name=HOST**

The **--server-name** option specifies a host name of new database. The host name is registered in the **databases.txt** file. If this option is omitted, a local host is registered.

```
cubrid copydb --server-name=cub_server1 demodb new_demodb
```

#### **-F, --file-path=PATH**

The **-F** option specifies a specific directory path where a new database volume is stored with an **-F** option. It represents specifying an absolute path. If the specified directory does not exist, an error is displayed. If this option is omitted, a new database volume is created in the current working directory. And this information is specified in **vol-path** of the **databases.txt** file.

```
cubrid copydb -F /home/usr/CUBRID/databases demodb new_demodb
```

#### **-L, --log-path=PATH**

The **-L** option specifies a specific directory path where a new database volume is stored with an **-L** option. It represents specifying an absolute path. If the specified directory does not exist, an error is displayed. If this option is omitted, a new database volume is created in the current working directory. And this information is specified in **log-path** of the **databases.txt** file.

```
cubrid copydb -L /home/usr/CUBRID/databases/logs demodb
new_demodb
```

#### **-E, --extended-volume-path=PATH**

The **-E** option specifies a specific directory path where a new database extended volume is stored with an **-E**. If this option is omitted, a new database extended volume is created in the location of a new database volume or in the registered path of controlling file. The **-i** option cannot be used with this option.

```
cubrid copydb -E /home/usr/CUBRID/databases/extvols demodb
new_demodb
```

### **-i, --control-file=FILE**

The **-i** option specifies an input file where a new directory path information and a source volume are stored to copy or move multiple volumes into a different directory, respectively. This option cannot be used with the **-E** option. An input file named `copy_path` is specified in the example below.

```
cubrid copydb -i copy_path demodb new_demodb
```

The following is an example of input file that contains each volume name, current directory path, and new directory and volume names.

```
# valid    source_fullvolname    dest_fullvolname
0 /usr/databases/demodb          /drive1/usr/databases/new_demodb
1 /usr/databases/demodb_data1    /drive1/usr/databases/
new_demodb_data1
2 /usr/databases/ext/demodb_ext1 /drive2//usr/databases/
new_demodb_ext1
3 /usr/databases/ext/demodb_ext2 /drive2/usr/databases/
new_demodb_ext2
```

- *valid*: An integer that is used to identify each volume. It can be checked in the database volume control file (**database\_name\_vinf**).
- *source\_fullvolname*: The current directory path to each source database volume.
- *dest\_fullvolname*: The target directory path where new volumes will be stored. You should specify a valid path.

### **-r, --replace**

If the **-r** option is specified, a new database name overwrites the existing database name if it is identical, instead of outputting an error.

```
cubrid copydb -r -F /home/usr/CUBRID/databases demodb new_demodb
```

### **-d, --delete-source**

If the **-d** option is specified, a source database is deleted after the database is copied. This execution brings the same the result as executing **cubrid deletedb** utility after copying a database. Note that if a source database contains LOB data, LOB file directory path of a source database is copied into a new database and it is registered in the **lob-base-path** of the **databases.txt** file.

```
cubrid copydb -d -F /home/usr/CUBRID/databases demodb new_demodb
```

### **--copy-lob-path**

Sets the LOB directory location of the target database to be the same as the source database's LOB directory location. If this option is omitted, the default location will be **<target\_database\_directory>/lob**. Note that this option does not copy LOB files and cannot be used together with the **-B** option ::

```
cubrid copydb --copy-lob-path demodb new_demodb
```

### **-B, --lob-base-path=PATH**

If the **-B** option is specified, a specified directory is specified as for LOB files of a new database and a source database is copied. This option cannot be used with the **--copy-lob-path** option.

```
cubrid copydb -B /home/usr/CUBRID/databases/new_lob demodb  
new_demodb
```

## installdb

The **cubrid installdb** utility is used to register the information of a newly installed database to **databases.txt**, which stores database location information. The execution of this utility does not affect the operation of the database to be registered.

```
cubrid installdb [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **installdb**: A command that registers the information of a moved or copied database to **databases.txt**.
- *database\_name*: The name of database to be registered to **databases.txt**.

If no [options] are used, the command must be executed in the directory where the corresponding database exists.

The following shows [options] available with the **cubrid installdb** utility.

```
--server-name=HOST      server HOST name
-F, --file-path=PATH    directory PATH for database volumes
-L, --log-path=PATH     directory PATH for log volumes
```

### --server-name=HOST

This option registers the server host information of a database to **databases.txt** with a specific host name. If this is not specified, the current host information is registered.

```
cubrid installdb --server-name=cub_server1 testdb
```

### -L, --log-path=PATH

This option registers the absolute directory path of a database log volume to **databases.txt** by using the **-L** option. If this option is not specified, the directory path of a volume is registered.

```
cubrid installdb -L /home/cubrid/CUBRID/databases/logs/testdb
testdb
```

## backupdb

A database backup is the procedure of storing CUBRID database volumes, control files and log files, and it is executed by using the **cubrid backupdb** utility or the CUBRID Manager. **DBA** must regularly back up the database so that the database can be properly restored in the case of storage media or file errors. The restore environment must have the same operating system and the same version of CUBRID as the backup environment. For this reason, you must perform a backup in the new environment immediately after migrating a database to a new version. However, because LOB (Large Object) data in CUBRID is stored as external files separate from database volumes, it is not included in backups performed by the backupdb utility. Therefore, database administrators must manually back up the directory containing LOB files during database backup operations. When restoring the database, the LOB files must also be restored to their original directory to ensure data consistency.

To recover all database pages, control files and the database to the state at the time of backup, the **cubrid backupdb** utility copies all necessary log records.

```
cubrid backupdb [options] database_name[@hostname]
```

- **@hostname**: It is omitted when you do backup in standalone mode. If you do backup on the HA environment, specify "**@hostname**" after the database name. *hostname* is a name specified in \$CUBRID\_DATABASES/databases.txt. If you want to setup a local server, you can specify it as "**@localhost**".

The following shows options available with the **cubrid backupdb** utility (options are case sensitive).

```
-D, --destination-path=PATH  store backup volumes to directory PATH
-r, --remove-archive         delete unnecessary log-archives
-l, --level=LEVEL           backup level
-o, --output-file=FILE       print detailed backup messages to FILE
-S, --SA-mode               stand-alone mode execution
-C, --CS-mode               client-server mode execution
    --no-check              don't check a consistency of the
database
-t, --thread-count=COUNT   number of threads
    --no-compress           don't compress backup volumes
    --sleep-msecs=N        sleep N millisecond per 1M read
-k, --separate-keys         keys file (_keys) for TDE is not
included in the backup volume, but is separated into a file instead
```

### **-D, --destination-path=PATH**

The following shows how to use the **-D** option to store backup files in the specified directory. The backup file directory must be specified before performing this job. If the **-D** option is not specified, backup files are stored in the log directory specified in the **databases.txt** file which stores database location information.

```
cubrid backupdb -D /home/cubrid/backup demodb
```

The following shows how to store backup files in the current directory by using the **-D** option. If you enter a period (.) following the **-D** option as an argument, the current directory is specified.

```
cubrid backupdb -D . demodb
```

### **-r, --remove-archive**

Writes an active log to a new archive log file when the active log is full. If a backup is performed in such a situation and backup volumes are created, backup logs created before the backup will not be used in subsequent backups. The **-r** option is used to remove archive log files that will not be used anymore in subsequent backups after the current one is complete. The **-r** option only removes unnecessary archive log files that were created before backup, and does not have any impact on backup; however, if an administrator removes the archive log file after a backup, it may become impossible to restore everything. For this reason, archive logs should be removed only after careful consideration.

If you perform an incremental backup (backup level 1 or 2) with the **-r** option, there is the risk that normal recovery of the database will be impossible later on. Therefore, it is recommended that the **-r** option only be used when a full backup is performed.

```
cubrid backupdb -r demodb
```

### **-l, --level=LEVEL**

The following shows how to execute an incremental backup of the level specified by using the **-l** option. If the **-l** option is not specified, a full backup is performed. For details on backup levels, see [Incremental Backup](#).

```
cubrid backupdb -l 1 demodb
```

### **-o, --output-file=FILE**

The following shows how to write the progress of the database backup to the info\_backup file by using the **-o** option.

```
cubrid backupdb -o info_backup demodb
```

The following shows the contents of the info\_backup file. You can check the information on the number of threads, compression method, backup start time, the number of permanent volumes, backup progress and backup end time.

```
[ Database(demodb) Full Backup start ]
- num-threads: 1
- compression method: NONE
- backup start time: Mon Jul 21 16:51:51 2008
- number of permanent volumes: 1
- backup progress status
-----
-----
volume name          | # of pages | backup progress
status      | done
-----
-----
demodb_keys          |           1 |
##### | done
demodb_vinf          |           1 |
##### | done
demodb               |        25000 |
##### | done
demodb_lginf         |           1 |
##### | done
demodb_lgat          |        25000 |
##### | done
-----
-----
# backup end time: Mon Jul 21 16:51:53 2008
[Database(demodb) Full Backup end]
```

**-S, --SA-mode**

The following shows how to perform backup in standalone mode (that is, backup offline) by using the **-S** option. If the **-S** option is not specified, the backup is performed in client/server mode.

```
cubrid backupdb -S demodb
```

**-C, --CS-mode**

The following shows how to perform backup in client/server mode by using the **-C** option and the *demodb* database is backed up online. If the **-C** option is not specified, a backup is performed in client/server mode.

```
cubrid backupdb -C demodb
```

**--no-check**

The following shows how to execute backup without checking the consistency of the database by using the **--no-check** option.

```
cubrid backupdb --no-check demodb
```

**-t, --thread-count=COUNT**

The following shows how to execute parallel backup with the number of threads specified by the administrator by using the **-t** option. Even when the argument of the **-t** option is not specified, a parallel backup is performed by automatically assigning as many threads as CPUs in the system.

```
cubrid backupdb -t 4 demodb
```

**--no-compress**

By default, CUBRID compresses the target database in order to reduce the size of the backup volume and then saves it. If a user wants to eliminate the CPU usage by the compression, they can set the **--no-compress** option not to compress the backup volume.

```
cubrid backupdb --no-compress demodb
```

**--sleep-msecs=NUMBER**

This option allows you to specify the interval of idle time during the database backup. The default value is 0 in milliseconds. The system becomes idle for the specified amount of time whenever it reads 1 MB of data from a file. This option is used to reduce the performance degradation of an active server during a live backup. The idle time will prevent excessive disk I/O operations.

```
cubrid backupdb --sleep-msecs=5 demodb
```

### **-k, --separate-keys**

This option is used to exclude the key file from the backup volume. The excluded key file is separated into a file named **<database\_name>\_bk<backup\_level>\_keys**. If this option is not given, the key file is included in the backup volume by default. For a detailed description of key file separation, see [Backup Encryption](#).

```
cubrid backupdb -k demodb
```

#### **Note**

The key file manages an auxiliary key used to encrypt and decrypt the master key of TDE stored within the database. When using the TDE feature, the key file should not be backed up together with the backup volume or stored on the same storage media. Instead, it is recommended to manage it separately using a secure method. If the key file is lost or exposed, data protected by the TDE feature may become inaccessible or may lead to a security incident. Therefore, it is recommended to establish clear policies for the secure storage and management of the key file.

## Backup Strategy and Method

The following must be considered before performing a backup:

### **• Selecting the data to be backed up**

- Determine whether it is valid data worth being preserved.
- Determine whether to back up the entire database or only part of it.
- Check whether there are other files to be backed up along with the database.

### **• Choosing a backup method**

- Choose the backup method from one of incremental and online backups. Also, specify whether to use compression backup, parallel backup, and mode.
- Prepare backup tools and devices available.

### **• Determining backup time**

- Identify the time when the least usage in the database occur.
- Check the size of the archive logs.

- Check the number of clients using the database to be backed up.

## Online Backup

An online backup (or a hot backup) is a method of backing up a currently running database. It provides a snapshot of the database image at a certain point in time. Because the backup target is a currently running database, it is likely that uncommitted data will be stored and the backup may affect the operation of other databases.

To perform an online backup, use the **cubrid backupdb -C** command.

## Offline Backup

An offline backup (or a cold backup) is a method of backing up a stopped database. It provides a snapshot of the database image at a certain point in time.

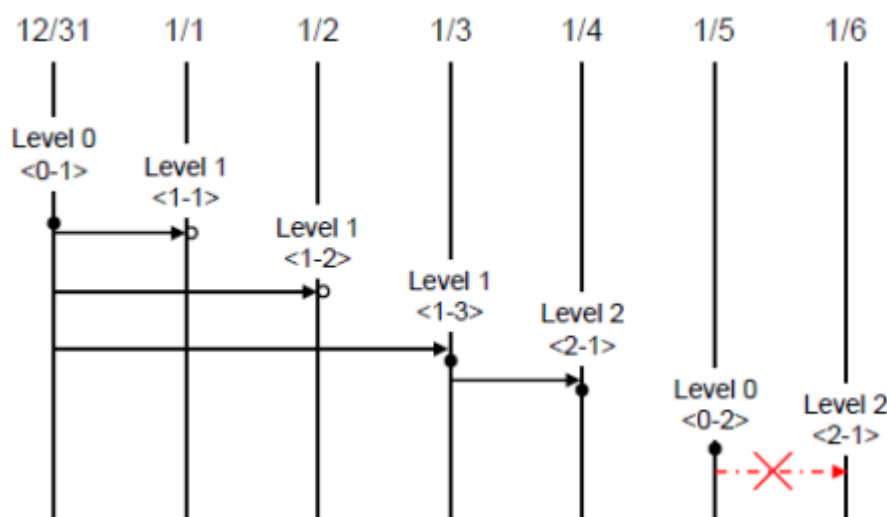

To perform an offline backup, use the **cubrid backupdb -S** command.

## Incremental Backup

An incremental backup, which is dependent upon a full backup, is a method of only backing up data that have changed since the last backup. This type of backup has an advantage of requiring less volume and time than a full backup. CUBRID supports backup levels 0, 1 and 2. A higher level backup can be performed sequentially only after a lower level backup is complete.

To perform an incremental backup, use the **cubrid backupdb -l LEVEL** command.

The following example shows incremental backup. Let's example backup levels in details.

- **Full backup (backup level 0)** : Backup level 0 is a full backup that includes all database pages.

The level of a backup which is attempted first on the database naturally becomes a 0 level. **DBA** must perform full backups regularly to prepare for restore situations. In the example, full backups were performed on December 31st and January 5th.

- **First incremental backup (backup level 1)** : Backup level 1 is an incremental backup that only stores changes since the level 0 full backup, and is called a “first incremental backup.”

Note that the first incremental backups are attempted sequentially such as <1-1>, <1-2> and <1-3> in the example, but they are always performed based on the level 0 full backup.

Suppose that backup files are created in the same directory. If the first incremental backup <1-1> is performed on January 1st and then the first incremental backup <1-2> is attempted again on January 2nd, the incremental backup file created in <1-1> is overwritten. The final incremental backup file is created on January 3rd because the first incremental backup is performed again on that day.

Since there can be a possibility that the database needs to be restored the state of January 1st or January 2nd, it is recommended for **DBA** to store the incremental backup files <1-1> and <1-2> separately in storage media before overwriting with the final incremental file.

- **Second incremental backup (backup level 2)** : Backup level 2 is an incremental backup that only stores data that have changed since the first incremental backup, and is called a “second incremental backup.”

A second incremental backup can be performed only after the first incremental backup. Therefore, the second incremental backup attempted on January fourth succeeds; the one attempted on January sixth fails.

Backup files created for backup levels 0, 1 and 2 may all be required for database restore. To restore the database to its state on January fourth, for example, you need the second incremental backup generated at <2-1>, the first incremental backup file generated at <1-3>, and the full backup file generated at <0-1>. That is, for a full restore, backup files from the most recent incremental backup file to the earliest created full backup file are required.

## Compress Backup

A compress backup is a method of backing up the database by compressing it. This type of backup reduces disk I/O costs and stores disk space because it requires less backup volume.

From version 11.2 of CUBRID, compress backup is used by default.

## Parallel Backup Mode

A parallel or multi-thread backup is a method of performing as many backups as the number of threads specified. In this way, it reduces backup time significantly. Basically, threads are given as many as the number of CPUs in the system.

To perform a parallel backup, use the **cubrid backupdb -t | --thread-count** command.

## Managing Backup Files

One or more backup files can be created in sequence based on the size of the database to be backed up. A unit number is given sequentially (000, 001-0xx) to the extension of each backup file based in the order of creation.

## Managing Disk Capacity during the Backup

During the backup process, if there is not enough space on the disk to store the backup files, a message saying that the backup cannot continue appears on the screen. This message contains the name and path of the database to be backed up, the backup file name, the unit number of backup files and the backup level. To continue the backup process, the administrator can choose one of the following options:

- Option 0: An administrator enters 0 to discontinue the backup.
- Option 1: An administrator inserts a new disk into the current device and enters 1 to continue the backup.
- Option 2: An administrator changes the device or the path to the directory where backup files are stored and enters 2 to continue the backup.

```
*****
Backup destination is full, a new destination is required to
continue:
Database Name: /local1/testing/demodb
Volume Name: /dev/rst1
Unit Num: 1
Backup Level: 0 (FULL LEVEL)
Enter one of the following options:
Type
- 0 to quit.
- 1 to continue after the volume is mounted/loaded. (retry)
- 2 to continue after changing the volume's directory or device.
*****
```

## Managing Archive Logs

You must not delete archive logs by using the file deletion command such as **rm** or **del** by yourself; the archive logs should be deleted by system configuration or the **cubrid backupdb** utility. In the following three cases, archive logs can be deleted.

- In non-HA environment (ha\_mode=off):

If you configure the **force\_remove\_log\_archives** value to yes, archive logs are kept only the number specified in **log\_max\_archives** value; and the left logs are automatically deleted. However, if there is an active transaction in the oldest archive log file, this file is not deleted until the transaction is completed.

- In an HA environment (ha\_mode=on):

If you configure the **force\_remove\_log\_archives** values to no and specify the number specified in **log\_max\_archives** value, archive logs are automatically deleted after replication is applied.

#### Note

If you set **force\_remove\_log\_archives** as yes when “ha\_mode=on”, unapplied archive logs can be deleted; therefore, this setting is not recommended. However, if keeping disk space is prior to keeping replication, set **force\_remove\_log\_archives** as yes and set **log\_max\_archives** as a proper value.

- Use **cubrid backupdb -r** and run this command then archive logs are deleted; note that **-r** option should not be used in an HA environment.

If you want to delete logs as much as possible while operating a database, configure the value of **log\_max\_archives** to a small value or 0 and configure the value of **force\_remove\_log\_archives** to yes. Note that in an HA environment, if the value of **force\_remove\_log\_archives** is yes, archive logs that have not replicated in a slave node are deleted, which can cause replication errors. Therefore, it is recommended that you configure it to no. Although the value of **force\_remove\_log\_archives** is set to no, files that are complete for replication can be deleted by HA management process.

## restoredb

A database restore is the procedure of restoring the database to its state at a certain point in time by using the backup files, active logs and archive logs which have been created in an environment of the same CUBRID version. To perform a database restore, use the **cubrid restoredb** utility or the CUBRID Manager.

The **cubrid restoredb** utility restores the database from the database backup by using the information written to all the active and archive logs since the execution of the last backup.

```
cubrid restoredb [options] database_name
```

If no option is specified, a database is restored to the point of the last commit by default. If no active/archive log files are required to restore to the point of the last commit, the database is restored only to the point of the last backup.

```
cubrid restoredb demodb
```

The following table shows options available with the **cubrid restoredb** utility (options are case sensitive).

|                                               |                                                                                          |
|-----------------------------------------------|------------------------------------------------------------------------------------------|
| <code>-d, --up-to-date=DATE</code>            | restore the database up to its condition at given DATE                                   |
| <code>--list</code>                           | display a list of backup volumes without restoring                                       |
| <code>-B, --backup-file-path=PATH</code>      | PATH is a directory of backup volumes to be restored                                     |
| <code>-l, --level=LEVEL</code>                | LEVEL of backup to be restored; see backup usage                                         |
| <code>-p, --partial-recovery</code>           | perform partial recovery if any log archive is absent                                    |
| <code>-o, --output-file=FILE</code>           | redirect output messages to FILE                                                         |
| <code>-u, --use-database-location-path</code> | restore the database and log volumes to the path specified in the database location file |
| <code>-k, --keys-file-path</code>             | Path of key file (_keys) for TDE to be used during restoring                             |

#### **-d, --up-to-date=DATE**

A database can be restored to the given point by the date-time specified by the **-d** option. The user can specify the restoration point manually in the dd-mm-yyyy:hh:mi:ss (e.g. 14-10-2008:14:10:00) format. If no active log/archive log files are required to restore to the point specified, the database is restored only to the point of the last backup.

```
cubrid restoredb -d 14-10-2008:14:10:00 demodb
```

If the user specifies the restoration point by using the **backuptime** keyword, it restores a database to the point of the last backup.

```
cubrid restoredb -d backuptime demodb
```

#### **--list**

This option displays information on backup files of a database; restoration procedure is not performed. This option is available even if the database is working, from CUBRID 9.3.

```
cubrid restoredb --list demodb
```

The following example shows how to display backup information by using the **--list** option. You can specify the path to which backup files of the database are originally stored as well as backup levels.

```
*** BACKUP HEADER INFORMATION ***
Database Name: /local1/testing/demodb
  DB Creation Time: Mon Oct 1 17:27:40 2008
  Pagesize: 4096
Backup Level: 1 (INCREMENTAL LEVEL 1)
  Start_lsa: 513|3688
  Last_lsa: 513|3688
Backup Time: Mon Oct 1 17:32:50 2008
  Backup Unit Num: 0
Release: 8.1.0
  Disk Version: 8
Backup Pagesize: 4096
Zip Method: 0 (NONE)
  Zip Level: 0 (NONE)
Previous Backup Level: 0
  Time: Mon Oct 1 17:31:40 2008
  (start_lsa was -1|-1)
Database Volume Name: /local1/testing/demodb_keys
  Volume Identifier: -6, Size: 65 bytes (1 pages)
Database Volume Name: /local1/testing/demodb_vinf
  Volume Identifier: -5, Size: 308 bytes (1 pages)
Database Volume Name: /local1/testing/demodb
  Volume Identifier: 0, Size: 2048000 bytes (500 pages)
Database Volume Name: /local1/testing/demodb_lginf
  Volume Identifier: -4, Size: 165 bytes (1 pages)
Database Volume Name: /local1/testing/demodb_bkvinf
  Volume Identifier: -3, Size: 132 bytes (1 pages)
```

With the backup information displayed by using the **--list** option, you can check that backup files have been created at the backup level 1 as well as the point where the full backup of backup level 0 has been performed. Therefore, to restore the database in the example, you must prepare backup files for backup levels 0 and 1.

### **-B, --backup-file-path=PATH**

You can specify the directory where backup files are to be located by using the **-B** option. If this option is not specified, the system retrieves the backup information file (*dbname\_bkvinf*) generated upon a database backup; the backup information file is located in the **log-path** directory specified in the database location information file (**databases.txt**). And then it searches the backup files in the directory path specified in the backup information file. However, if the backup information file has been damaged or the location information of the backup files has been deleted, the system will not be able to find the backup files. Therefore, the administrator must manually specify the directory where the backup files are located by using the **-B** option.

```
cubrid restoredb -B /home/cubrid/backup demodb
```

If the backup files of a database is in the current directory, the administrator can specify the directory where the backup files are located by using the **-B** option.

```
cubrid restoredb -B . demodb
```

### **-l, --level=LEVEL**

You can perform restoration by specifying the backup level of the database to 0, 1, or 2. For details on backup levels, see [Incremental Backup](#).

```
cubrid restoredb -l 1 demodb
```

### **-p, --partial-recovery**

You can perform partial restoration without requesting for the user's response by using the **-p** option. If active or archive logs written after the backup point are not complete, by default the system displays a request message informing that log files are needed and prompting the user to enter an execution option. The partial restoration can be performed directly without such a request message by using the **-p** option. Therefore, if the **-p** option is used when performing restoration, data is always restored to the point of the last backup.

```
cubrid restoredb -p demodb
```

When the **-p** option is not specified, the message requesting the user to select the execution option is as follows:

```
*****
Log Archive /home/cubrid/test/log/demodb_lgar002
is needed to continue normal execution.
Type
- 0 to quit.
- 1 to continue without present archive. (Partial recovery)
- 2 to continue after the archive is mounted/loaded.
- 3 to continue after changing location/name of archive.
*****
```

- Option 0: Stops restoring
- Option 1: Performing partial restoration without log files.
- Option 2: Performing restoration after locating a log to the current device.
- Option 3: Resuming restoration after changing the location of a log

**-o, --output-file=FILE**

The following syntax shows how to write the restoration progress of a database to the info\_restore file by using the **-o** option.

```
cubrid restoredb -o info_restore demodb
```

**-u, --use-database-location-path**

This option restores a database to the path specified in the database location file(**databases.txt**). The **-u** option is useful when you perform a backup on server A and store the backup file on server B.

```
cubrid restoredb -u demodb
```

**-k, --keys-file-path=PATH**

This option specifies the path of a key file required to restore the database. If the valid key file is not given, it could fail to restore. If this option is not given, the appropriate key file is searched automatically according to a priority. For more information on this, refer to [Backup Encryption](#).

```
cubrid restoredb -k /home/cubrid/backup_keys/demodb_bk1_keys  
demodb
```

NOTIFICATION messages, log recovery starting time and ending time are written into the server error log file or the restoredb error log file when database server is started or backup volume is restored; so you can check the elapsed time of these operations. In this message, the number of log records to be applied(redo) and the number of log pages are written together.

```
Time: 06/14/13 21:29:04.059 - NOTIFICATION *** file ../../src/  
transaction/log_recovery.c, line 748 CODE = -1128 Tran = -1, EID = 1  
Log recovery is started. The number of log records to be applied:  
96916. Log page: 343 ~ 5104.  
.....  
Time: 06/14/13 21:29:05.170 - NOTIFICATION *** file ../../src/  
transaction/log_recovery.c, line 843 CODE = -1129 Tran = -1, EID = 4  
Log recovery is finished.
```

## Restoring Strategy and Procedure

You must consider the following before restoring databases.

- **Preparing backup files**

- Identify the directory where the backup and log files are to be stored.

- If the database has been incrementally backed up, check whether an appropriate backup file for each backup level exists.
- Check whether the backed-up CUBRID database and the CUBRID database to be backed up are the same version.

#### • **Choosing restore method**

- Determine whether to perform a partial or full restore.
- Determine whether or not to perform a restore using incremental backup files.
- Prepare restore tools and devices available.

#### • **Determining restore point**

- Identify the point in time when the database server was terminated.
- Identify the point in time when the last backup was performed before database failure.
- Identify the point in time when the last commit was made before database failure.

### **Database Restore Procedure**

The following procedure shows how to perform backup and restoration described in the order of time.

1. Performs a full backup of *demodb* which stopped running at 2008/8/14 04:30.
2. Performs the first incremental backup of *demodb* running at 2008/8/14 10:00.
3. Performs the first incremental backup of *demodb* running at 2008/8/14 15:00. Overwrites the first incremental backup file in step 2.
4. A system failure occurs at 2008/8/14 15:30, and the system administrator prepares the restore of *demodb*. Sets the restore time as 15:25, which is the time when the last commit was made before database failure
5. The system administrator prepares the full backup file created in Step 1 and the first incremental backup file created in Step 3, restores the *demodb* database up to the point of 15:00, and then prepares the active and archive logs to restore the database up to the point of 15:25.

| Time            | Command                   | Description                |
|-----------------|---------------------------|----------------------------|
| 2008/8/14 04:25 | cubrid server stop demodb | Shuts down <i>demodb</i> . |

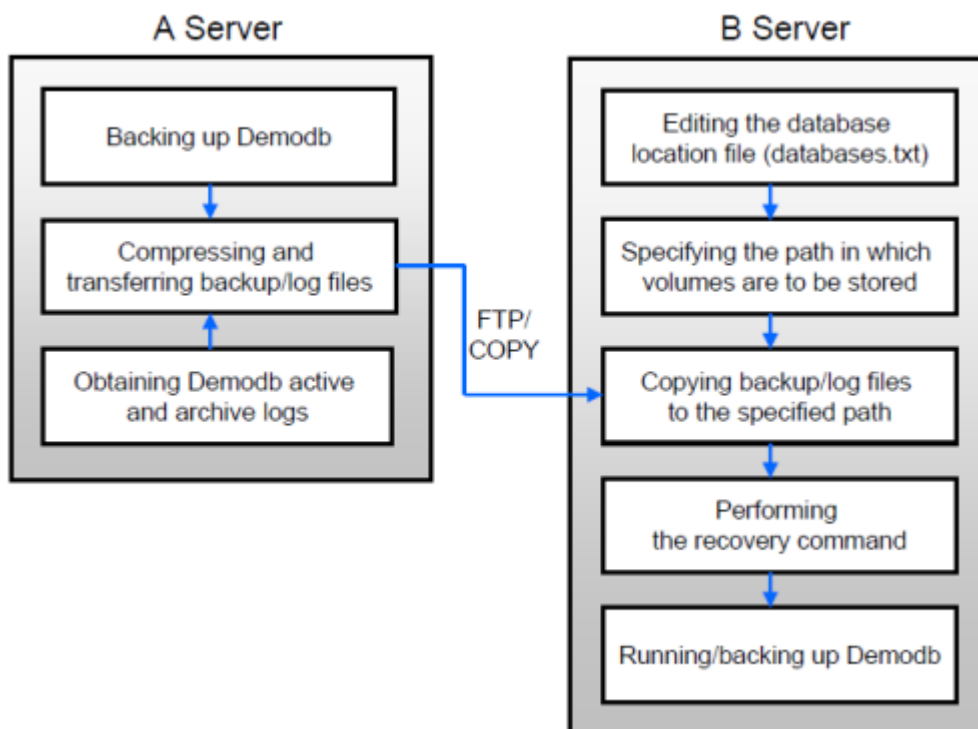

| Time            | Command                                                          | Description                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2008/8/14 04:30 | <code>cubrid backupdb -S -D /home/backup -l 0 demodb</code>      | Performs a full backup of <i>demodb</i> in offline mode and creates backup files in the specified directory.                                                                                                                                   |
| 2008/8/14 05:00 | <code>cubrid server start demodb</code>                          | Starts <i>demodb</i> .                                                                                                                                                                                                                         |
| 2008/8/14 10:00 | <code>cubrid backupdb -C -D /home/backup -l 1 demodb</code>      | Performs the first incremental backup of <i>demodb</i> online and creates backup files in the specified directory.                                                                                                                             |
| 2008/8/14 15:00 | <code>cubrid backupdb -C -D /home/backup -l 1 demodb</code>      | Performs the first incremental backup of <i>demodb</i> online and creates backup files in the specified directory. Overwrites the first incremental backup file created at 10:00.                                                              |
| 2008/8/14 15:30 |                                                                  | A system failure occurs.                                                                                                                                                                                                                       |
| 2008/8/14 15:40 | <code>cubrid restoredb -l 1 -d 08/14/2008:15:25:00 demodb</code> | Restores <i>demodb</i> based on the full backup file, first incremental backup file, active logs and archive logs. The database is restored to the point of 15:25 by the full and first incremental backup files, the active and archive logs. |

## Restoring Database to Different Server

The following shows how to back up *demodb* on server *A* and restore it on server *B* with the backed up files.

### Backup and Restore Environments

Suppose that *demodb* is backed up in the `/home/cubrid/db/demodb` directory on server *A* and restored into `/home/cubrid/data/demodb` on server *B*.

#### 1. Backing up on server A

Back up *demodb* on server *A*. If a backup has been performed earlier, you can perform an incremental backup for data only that have changed since the last backup. The directory where the backup files are created, if not specified in the **-D** option, is created by default in the location where the log volume is stored. The following is a backup command with recommended options. For details on the options, see [backupdb](#).

```
cubrid backupdb -z demodb
```

#### 2. Editing the database location file on Server B

Unlike a general scenario where a backup and restore are performed on the same server, in a scenario where backup files are restored using a different server, you need to add the location information on database restore in the database location file (**databases.txt**) on server *B*. In the diagram above, it is supposed that *demodb* is restored in the `/home/cubrid/data/demodb`

directory on server *B* (hostname: *pmlinux*); edit the location information file accordingly and create the directory on server *B*.

Put the database location information in one single line. Separate each item with a space. The line should be written in [database name]. [data volume path] [host name] [log volume path] format; that is, write the location information of *demodb* as follows:

```
demodb /home/cubrid/data/demodb pmlinux /home/cubrid/data/demodb
```

### 3. Transferring backup files to server B

For a restore, you must prepare backup files. Therefore, transfer a backup file (e.g. *demodb\_bk0v000*) from server *A* to server *B*. That is, a backup file must be located in a directory (e.g. */home/cubrid/temp*) on server *B*.

#### Note

If you want to restore until the current time after the backup, logs after backup, that is, an active log (e.g. *demodb\_lgat*) and archive logs (e.g. *demodb\_lgar000*) are additionally required to copy.

An active log and archive logs should be located to the log directory of the database to be restored; that is, the directory of log files specified in *\$CUBRID/databases/databases.txt*. (e.g. *\$CUBRID/databases/demodb/log*)

Also, if you want to apply the added logs after backup, archive logs should be copied before they are removed. By the way, the default of *log\_max\_archives*, which is a system parameter related to delete archive logs, is 0; therefore, archive logs after backup can be deleted. To prevent this situation, the value of *log\_max\_archives* should be big enough. See [log\\_max\\_archives](#).

### 4. Restoring the database on server B

Perform database restore by calling the **cubrid restoredb** utility from the directory into which the backup files which were transferred to server *B* had been stored. With the **-u** option, *demodb* is restored in the directory path from the **databases.txt** file.

```
cubrid restoredb -u demodb
```

To call the **cubrid restoredb** utility from a different path, specify the directory path to the backup file by using the **-B** option as follows:

```
cubrid restoredb -u -B /home/cubrid/temp demodb
```

## unloaddb

The purposes of loading/unloading databases are as follows:

- To rebuild databases by volume reconfiguration
- To migrate database in different system environments
- To migrate database in different versions

```
cubrid unloaddb [options] database_name
```

**cubrid unloaddb** utility creates the following files:

- Schema file(*database-name***\_schema**): A file that contains information on the schema defined in the database.
- Object file(*database-name***\_objects**): A file that contains information on the records in the database.
- Index file(*database-name***\_indexes**): A file that contains information on the indexes defined in the database.
- Trigger file(*database-name***\_trigger**): A file that contains information on the triggers defined in the database. If you don't want triggers to be running while loading the data, load the trigger definitions after the data loading has completed.
- Split schema files (*database-name***\_schema\_objecttype**): When using the **--split-schema-files** option, the schema information defined in the database is split into object units and These files contain only object information. For a list of split files, see the **--split-schema-files** option.
- Schema list file (*database-name***\_schema\_info**): When using the **--split-schema-files** option, this file contains a list of split schema information files.

The schema, object, index, and trigger files are created in the same directory.

The following is [options] used in **cubrid unloaddb**.

```
-u, --user=ID          user ID for database access
-p, --password=PASS    user password
-i, --input-class-file=FILE input FILE of table names
  --include-reference    include referenced tables
  --input-class-only     include specified class only
```

```

--estimated-size=NUMBER estimated NUMBER of instances
--cached-pages=NUMBER  NUMBER of cached pages
-O, --output-path=PATH  PATH of output directory
-s, --schema-only      dump schema only
-d, --data-only        dump objects only
--output-prefix=PREFIX PREFIX for output files
--hash-file=FILE       FILE for hash
--latest-image         when dumping objects, it dumps the
latest image of objects in data volumes.
-t, --thread-count=COUNT number of threads; default: 1 maximum:
127
--enhanced-estimates  obtain the exact number of records in
the table to unload; default: disabled
-v, --verbose         enable verbose status messages
--use-delimiter       use '"' where an identifier begins and
ends
-S, --SA-mode         stand-alone mode execution
-C, --CS-mode         client-server mode execution
--datafile-per-class  create a object file for each class
--split-schema-files  split schema information by object and
generate each file
--skip-index-detail   Do not print the specified WITH clause
options when creating the index
--as-dba              If the login user is a member of the DBA
group, extract the same schema file as the DBA.

```

#### **-u, --user=ID**

Specify a user account of a database to be unloaded. If this is not specified, the default is **DBA**.

```
cubrid unloaddb -u dba -i table_list.txt demodb
```

#### **-p, --password=PASS**

Specify a user's password of a database to be unloaded. If this is not specified, it is regarded as the empty string is entered.

```
cubrid unloaddb -u dba -p dba_pwd -i table_list.txt demodb
```

#### **-i, --input-class-file FILE**

Unload all schema and index of all tables; however, only the data of specified tables in this file are unloaded. If the to-be-unloaded schema (See the -u option) of the user and the schema of the table are different, the table name must be prefixed with the schema name.

```
cubrid unloaddb -i table_list.txt demodb
```

The following example shows an input file (table\_list.txt).

```
table_1
table_2
..
table_n
```

If this option is used together with the **--input-class-only** option, it creates schema, index, and data files of tables only specified in the input file of **-i** option.

```
cubrid unloaddb --input-class-only -i table_list.txt demodb
```

If this option is used together with the **--include-reference** option, it unloads the referenced tables as well.

```
cubrid unloaddb --include-reference -i table_list.txt demodb
```

#### **--include-reference**

This option is used together with the **-i** option, and also unloads the referenced tables.

#### **--input-class-only**

This option is used together with the **-i** option, and creates only a schema file of tables specified in the input file of **-i** option.

#### **--estimated-size=NUMBER**

This option allows you to assign hash memory to store records of the database to be unloaded. If the **--estimated-size** option is not specified, the number of records of the database is determined based on recent statistics information. This option can be used if the recent statistics information has not been updated or if a large amount of hash memory needs to be assigned. Therefore, if the number given as the argument for the option is too small, the unload performance deteriorates due to hash conflicts.

```
cubrid unloaddb --estimated-size=1000 demodb
```

#### **--cached-pages=NUMBER**

CUBRID supports object-oriented features that allow a specific class (table) to be defined as a data type of another class. In such a structure, OID (Object Identifier) references occur, where a specific record directly points to another record to represent relationships between data. The **--cached-pages** option allows you to specify the number of pages allocated to a hash table in order to efficiently process object references (OID references) that occur during data extraction. Each page is 4,096 bytes in size, and the administrator

can adjust this value considering system memory capacity and performance requirements. If this option is not specified, the default value is 100 pages.

```
cubrid unloaddb --cached-pages 500 demodb
```

#### **-O, --output-path=PATH**

This option specifies the directory in which to create schema and object files. If this is not specified, files are created in the current directory.

```
cubrid unloaddb -O ./CUBRID/Databases/demodb demodb
```

If the specified directory does not exist, the following error message will be displayed.

```
unloaddb: No such file or directory.
```

#### **-s, --schema-only**

This option specifies that only the schema file will be created from amongst all the output files which can be created by the unload operation.

```
cubrid unloaddb -s demodb
```

#### **-d, --data-only**

This option specifies that only the data file will be created from amongst all of the output files which can be created by the unload operation.

```
cubrid unloaddb -d demodb
```

#### **--output-prefix=PREFIX**

This option specifies the prefix for the names of schema and object files created by the unload operation. Once the example is executed, the schema file name becomes *abcd\_schema* and the object file name becomes *abcd\_objects*. If the **--output-prefix** option is not specified, the name of the database to be unloaded is used as the prefix.

```
cubrid unloaddb --output-prefix abcd demodb
```

#### **--hash-file=FILE**

This option specifies the name of the hash file.

#### **--latest-image**

This option makes it to unload the latest image of objects in data volumes when unloading instances (the MVCC version is ignored and it does not refer to the log volumes). It may include uncommitted data and deleted data that has not been vacuumed.

### **-t, --thread-count=COUNT**

This option sets the number of threads to be used in the unload process. It is performed in parallel using as many threads as the specified COUNT value, which must be in the range of 0 to 127. If this setting is omitted, it is the same as specifying COUNT as 1. If specified as 0, unloaddb does not operate in thread mode. Even if thread mode is specified, if a table contains an Object type or a Set, MultiSet, or Sequence (List) type that contains an Object type, it will not operate in thread mode for that table.

```
cubrid unloaddb -t 4 demodb
```

### **--enhanced-estimates**

The -v option must be specified together. When determining the number of records in the target table, this option obtains the actual number of records instead of relying on statistical information. Using this option may increase the execution time of unloaddb because doing so adds the time needed to calculate the number of records. Therefore, this option should be used with caution.

```
cubrid unloaddb --enhanced-estimates demodb
```

### **-v, --verbose**

This option displays detailed information on the database tables and records being unloaded while the unload operation is under way.

```
cubrid unloaddb -v demodb
```

### **--use-delimiter**

This option writes the double quote(") on the beginning and end of an identifier. The default is not to write the double quote("").

### **-S, --SA-mode**

The **-S** option performs the unload operation by accessing the database in standalone mode.

```
cubrid unloaddb -S demodb
```

### **-C, --CS-mode**

The **-C** option performs the unload operation by accessing the database in client/server mode.

```
cubrid unloaddb -C demodb
```

### --datafile-per-class

This option specifies that the output file generated through unload operation creates a data file per each table. The file name is generated as *<Database Name>\_<Table Name>\_objects* for each table. However, all column values in object types are unloaded as NULL and %id class\_name class\_id part is not written in the unloaded file (see [How to Write Files to Load Database](#)).

```
cubrid unloaddb --datafile-per-class demodb
```

### --split-schema-files

Schema information is splited and created in object units, and a file containing a list of splited files is also created. For details, see to [loaddb](#) 's `-schema-file-list=FILE`. If this option is not specified, a single schema file containing all objects is created.

```
cubrid unloaddb --split-schema-files demodb
```

List of files created by splitting schema information into object units

```
demodb_schema_user  
demodb_schema_class  
demodb_schema_vclass  
demodb_schema_synonym  
demodb_schema_serial  
demodb_schema_procedure  
demodb_schema_server  
demodb_schema_pk  
demodb_schema_fk  
demodb_schema_uk  
demodb_schema_grant  
demodb_schema_vclass_query_spec
```

Filename containing a list of splited schema files

```
demodb_schema_info
```

### --as-dba

If the user is a member of the DBA group, create a schema file with the same contents as for the DBA user.

```
cubrid unloaddb -u u1_dba_group --as-dba demodb
```

### --skip-index-detail

This option doesn't output of the WITH clause options specified when creating the index. The default operation of unloaddb is to always print the WITH clause options regardless of the **print\_index\_detail** setting. If this option is specified, options of indexes in the WITH clause are omitted and printed. Affected output files are schema file (*database-name\_schema*) and index file (*database-name\_indexes*). If this option is omitted, even if *deduplicate level* is **0**, it will always be output explicitly.

```
cubrid unloaddb --skip-index-detail demodb
```

In the example below, you can see the difference whether this option is specified or not.

Schema file

--skip-index-detail not specified

```
ALTER CLASS [dba].[ts] ADD CONSTRAINT
[fk_ts_fid] FOREIGN KEY([fid]) WITH
DEDUPLICATE=0 REFERENCES [dba].[tm]
ON DELETE RESTRICT ON UPDATE
RESTRICT ;
```

--skip-index-detail specified

```
ALTER CLASS [dba].[ts] ADD CONSTRAINT
[fk_ts_fid] FOREIGN KEY([fid])
REFERENCES [dba].[tm] ON DELETE
RESTRICT ON UPDATE RESTRICT ;
```

Index file

--skip-index-detail not specified

```
CREATE INDEX [idx_val] ON [dba].[ts]
([val]) WITH DEDUPLICATE=0;
```

--skip-index-detail specified

```
CREATE INDEX [idx_val] ON [dba].[ts]
([val]);
```

**Note**

To shorten the execution time of the `unloaddb`, it is possible to run multiple '**cubrid unloaddb**' processes concurrently for groups of different tables. (or you can use **unloaddb.sh**, refer [unloaddb.sh script](#)).

## loaddb

You can load a database by using the **cubrid loaddb** utility in the following situations:

- Migrating previous version of CUBRID database to new version of CUBRID database
- Migrating a third-party DBMS database to a CUBRID database
- Inserting massive amount of data faster than using the **INSERT** statement

In general, the **cubrid loaddb** utility uses files (schema definition, object input, and index definition files) created by the **cubrid unloaddb** utility.

```
cubrid loaddb [options] database_name
```

### Input Files

- Schema file(*database-name***\_schema**): A file generated by the unload operation; it contains schema information defined in the database.
- Object file(*database-name***\_objects**): A file created by an unload operation. It contains information on the records in the database.
- Index file(*database-name***\_indexes**): A file created by an unload operation. It contains information on the indexes defined in the database.
- Trigger file(*database-name***\_trigger**): A file created by an unload operation. It contains information on the triggers defined in the database.
- User-defined object file(*user\_defined\_object\_file*): A file in table format written by the user to enter mass data. (For details, see [How to Write Files to Load Database](#).)
- Schema list file (*database-name***\_schema\_info**): A file created by unloading with the **--split-schema-files** option. This is a file that has a list of files in which schema information defined in the database is split into object units.(For details, see [unloaddb --split-schema-files](#).)

### Execution order of input files

The **cubrid loaddb** utility follows a specific order of parsing and executing input files, ensuring both correctness and optimized performance. The order is as follows:

1. Load schema file (including primary keys)
2. Load object file
3. Load index file (secondary keys and foreign keys)
4. Load trigger file

### Loading modes

The **cubrid loaddb** utility provides two modes of loading the data into a database.

- **Stand-alone** mode loads the data offline, within a single thread environment. CUBRID 10.1 and older versions run only in this mode.
- **Client-server** mode connects to a server and loads the data online and in parallel. **Client-server** mode can be much faster, but object references and class/shared attributes are not supported in this mode and they can only be loaded in **stand-alone** mode

The following table shows [options] available with the **cubrid loaddb** utility.

|                                            |                                                                                                    |
|--------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>-u, --user=ID</code>                 | user ID <b>for</b> database access                                                                 |
| <code>-p, --password=PASS</code>           | user password                                                                                      |
| <code>-S, --SA-mode</code>                 | standalone mode execution                                                                          |
| <code>-C, --CS-mode</code>                 | client-server mode execution                                                                       |
| <code>--data-file-check-only</code>        | check syntax <b>for</b> data file without load                                                     |
| <code>-l, --load-only</code>               | load data file without prior syntax checking                                                       |
| <code>--estimated-size=NUMBER</code>       | estimated NUMBER of instances                                                                      |
| <code>-v, --verbose</code>                 | enable verbose status messages                                                                     |
| <code>-c, --periodic-commit=COUNT</code>   | insertion COUNT <b>for</b> periodic commit                                                         |
| <code>--no-oid</code>                      | don't use OID                                                                                      |
| <code>--no-statistics</code>               | do <b>not</b> update the statistics <b>while</b> loading                                           |
| <code>-s, --schema-file=FILE[:LINE]</code> | create schema <b>from</b> LINE <b>with</b> FILE                                                    |
| <code>-i, --index-file=FILE[:LINE]</code>  | create index <b>from</b> LINE <b>with</b> FILE                                                     |
| <code>-d, --data-file=FILE</code>          | load data <b>with</b> FILE                                                                         |
| <code>-t, --table=TABLE</code>             | table name that <b>is</b> substituted <b>for</b> missing <b>class</b> header <b>in</b> data file   |
| <code>--error-control-file=FILE</code>     | FILE to control error(s) during loading                                                            |
| <code>--ignore-class-file=FILE</code>      | input file of <b>class</b> names that skip load                                                    |
| <code>--trigger-file=FILE[:LINE]</code>    | create trigger <b>from</b> LINE <b>with</b> FILE                                                   |
| <code>--no-user-specified-name</code>      | Find classes, serials, <b>and</b> triggers by their <b>object</b> names without their owner names. |

```
--schema-file-list=FILE    The content of this file is a list of
schema file names to be used in loaddb.
```

**-u, --user=ID**

This option specifies the user account of a database where records are loaded. If the option is not specified, the default value is **PUBLIC**.

```
cubrid loaddb -u admin -d demodb_objects newdb
```

**-p, --password=PASS**

This option specifies the password of a database user who will load records. If the option is not specified, you will be prompted to enter the password.

```
cubrid loaddb -u dba -p pass -d demodb_objects newdb
```

**-S, --SA-MODE**

This option loads data into a database in **stand-alone** mode. This is the default loading mode of **loaddb** and it is fully compatible with CUBRID 10.1 and older database versions.

```
cubrid loaddb -S -u dba -d demodb_objects newdb
```

**-C, --CS-MODE**

This option connects to a running server process. Unlike the **stand-alone** mode, the **client-server** mode loads the data using multiple threads, leading to greater performance for large amounts of data. Multiple **loaddb** sessions may run at the same time. Object references and class/shared attributes are not supported in this mode.

```
cubrid loaddb -C -u dba -d demodb_objects newdb
```

**Note**

When in **client-server** mode (-C, --CS-MODE) on the **HA** (High Availability), only the -d option (data loading) is available.

**--data-file-check-only**

This option checks only the syntax of the data contained in demodb\_objects, and does not load the data to the database.

```
cubrid loaddb --data-file-check-only -d demodb_objects newdb
```

### **-l, --load-only**

**Stand-alone** mode does, by default, one prior syntax check on the whole data file before actually loading the data into the database. If a syntax error occurs, no data is loaded and the error is reported.

Using the **-l** option, the prior syntax check is skipped, thus increasing the loading speed. Syntax is still checked before loading each row into the database. Loading is stopped if a syntax error occurs, but data may be partially loaded.

**Client-server mode** doesn't do the prior syntax check, so this option has no effect.

```
cubrid loaddb -l -d demodb_objects newdb
```

### **--estimated-size=NUMBER**

This option can be used to improve loading performance when the number of records to be unloaded exceeds the default value of 5,000. You can improve the load performance by assigning large hash memory for record storage with this option.

```
cubrid loaddb --estimated-size 8000 -d demodb_objects newdb
```

### **-v, --verbose**

This option shows how to display detailed information on the tables and records of the database being loaded while the database loading operation is performed. You can check the detailed information such as the progress, the class being loaded and the number of records to be entered.

```
cubrid loaddb -v -d demodb_objects newdb
```

### **-c, --periodic-commit=COUNT**

This option commits periodically every time COUNT records are entered into the database. If this option is not specified, all records included in demodb\_objects are loaded to the database before the transaction is committed. If this option is used together with the **-s** or **-i** option, commit is performed periodically every time 100 DDL statements are loaded.

The recommended commit interval varies depending on the data to be loaded. It is recommended that the parameter of the **-c** option be configured to 50 for schema loading and 1 for index loading. For record loading, the recommended and default value is 10240.

The previous versions of **CUBRID**, like 10.1 or older, did not have a default value for **--periodic-commit** and would commit the transaction only after loading the whole data. With

the current approach, if you want to use the replicate the same behavior, you have to set the **--periodic-commit** argument to a very high value, so that the commit is done after loading all the data.

```
cubrid loaddb -c 100 -d demodb_objects newdb
```

### **--no-oid**

The following is a command that loads records into newdb ignoring the OIDs in demodb\_objects.

```
cubrid loaddb --no-oid -d demodb_objects newdb
```

### **--no-statistics**

The following is a command that does not update the statistics information of newdb after loading demodb\_objects. It is useful especially when small data is loaded to a relatively big database; you can improve the load performance by using this command.

```
cubrid loaddb --no-statistics -d demodb_objects newdb
```

### **-s, --schema-file=FILE[:LINE]**

This option loads the schema information defined in the schema file, from the LINE-th. You can load the actual records after loading the schema information first by using the **-s** option.

On the following example, demodb\_schema is a file created by the unload operation and contains the schema information of the unloaded database.

```
cubrid loaddb -u dba -s demodb_schema newdb
```

```
Start schema loading.
```

```
Total      86 statements executed.
```

```
Schema loading from demodb_schema finished.
```

```
Statistics for Catalog classes have been updated.
```

The following loads the triggers defined in \*demodb\* into the newly created newdb database. demodb\_trigger is a file created by the unload operation and contains the trigger information of the unloaded database. It is recommended to load the schema information after loading the records. ::

```
cubrid loaddb -u dba -s demodb_trigger newdb
```

### **-i, --index-file=FILE[:LINE]**

The following loads the index information defined in the index file, from the LINE-th. On the following example, demodb\_indexes is a file created by the unload operation and contains the index information of the unloaded database. You can create indexes with the **-i** option, after loading records with the **-d** option.

```
cubrid loaddb -c 100 -d demodb_objects newdb
cubrid loaddb -u dba -i demodb_indexes newdb
```

#### **-d, --data-file=FILE**

This option loads the record information into newdb by specifying the data file or the user-defined object file. demodb\_objects is either an object file created by the unload operation or a user-defined object file written by the user for mass data loading.

```
cubrid loaddb -u dba -d demodb_objects newdb
```

#### **-t, --table=TABLE**

This option specifies the table name if a table name header is omitted in the data file to be loaded. The table name must be prefixed with the schema name.

```
cubrid loaddb -u dba -d demodb_objects -t tbl_name newdb
```

#### **--error-control-file=FILE**

This option specifies the file that describes how to handle specific errors occurring during database loading.

```
cubrid loaddb --error-control-file=error_test -d demodb_objects
newdb
```

For the server error code name, see the **\$CUBRID/include/dbi.h** file.

For error messages by error code (error number), see the number under \$set 5 MSGCAT\_SET\_ERROR in the **\$CUBRID/msg/<character set name>/cubrid.msg** file.

```
vi $CUBRID/msg/en_US/cubrid.msg

$set 5 MSGCAT_SET_ERROR
1 Missing message for error code %1$d.
2 Internal system failure: no more specific information is
available.
3 Out of virtual memory: unable to allocate %1$d memory bytes.
4 Has been interrupted.
...
670 Operation would have caused one or more unique constraint
```

```
violations.
...
```

The format of a file that details specific errors is as follows:

- `-<error code>`: Configures to ignore the error that corresponds to the `<error code>` (**loaddb** is continuously executed even when an error occurs while it is being executed).
- `+<error code>`: Configures not to ignore the error that corresponds to the `<error code>` (**loaddb** is stopped when an error occurs while it is being executed).
- `+DEFAULT`: Configures not to ignore errors from 24 to 33.

If the file that details errors is not specified by using the **--error-control-file** option, the **loaddb** utility is configured to ignore errors from 24 to 33 by default. As a warning error, it indicates that there is no enough space in the database volume. If there is no space in the assigned database volume, a generic volume is automatically created.

The following example shows a file that details errors.

- The warning errors from 24 to 33 indicating DB volume space is insufficient are not ignored by configuring `+DEFAULT`.
- The error code 2 is not ignored because `+2` has been specified later, even when `-2` has been specified first.
- `-670` has been specified to ignore the error code 670, which is a unique violation error.
- `#-115` has been processed as a comment since `#` is added.

```
vi error_file

+DEFAULT
-2
-670
#-115 --> comment
+2
```

### **--ignore-class-file=FILE**

You can specify a file that lists classes to be ignored during loading records. All records of classes except ones specified in the file will be loaded.

```
cubrid loaddb --ignore-class-file=skip_class_list -d
demodb_objects newdb
```

### **--trigger-file=FILE[:LINE]**

This option loads the trigger information defined in the trigger file, from the LINE-th.

```
cubrid loaddb --trigger-file=demodb_triggers -d demodb_objects  
newdb
```

### **--no-user-specified-name**

Files unloaded in a version older than 11.2 can be loaded in version 11.2 only if the **--no-user-specified-name** option is used.

This option works if **DBA** is specified as the user account of the database with the -u option.

```
cubrid loaddb -u dba -s demodb_schema -d demodb_objects --no-  
user-specified-name demodb
```

#### **Warning**

The **--no-user-specified-name** option must not be used to load a file unloaded in version 11.2 or after version 11.2.

### **--schema-file-list=FILE**

This option loads all schema files included in the list at once. There must be a list of schema files, and they are loaded sequentially from the top schema file to the bottom of this list file. This option and the -s option cannot be used together.

This list file is automatically created when using the **--split-schema-files** option in unloaddb.

```
cubrid loaddb -u dba --schema-file-list=demodb_schema_info
```

#### **Warning**

You can change the order of schema files written in this file, but loading errors may occur if the order is wrong. For example, an error may occur if the PK file is loaded first while the file with CLASS information is not loaded. Therefore, in the list, the file name for loading CLASS information must be higher than the file for loading PK.

#### **Warning**

The **--no-logging** option enables to load data file quickly when **loadddb** is executed by not storing transaction logs; however, it has risk, which data cannot be recovered in case of errors occurred such as incorrect file format or system failure. In this case, you must rebuild database to solve the problem. Thus, in general, it is not recommended to use this option exception of building a new database which does not require data recovery. If you use this option, **loadddb** does not check the errors like unique violation. To use this option, you should consider these issues.

#### Warning

When running **loadddb**, foreign key constraints are not checked to ensure performance for loading large amounts of data and to minimize dependencies between loaded data. So, the data inconsistencies with the master node may occur because foreign key constraints are checked during the replication process of the slave or replica node in the HA environment if the **-C** option is used.

## How to Write Files to Load Database

You can add mass data to the database more rapidly by writing the object input file used in the **cuprid loadddb** utility. An object input file is a text file in simple table form that consists of comments and command/data lines.

### Comment

In CUBRID, a comment is represented by two hyphens (--).

```
-- This is a comment!
```

### Command Line

A command line begins with a percent character (%) and consists of **%class** and **%id** commands; the former defines classes, and the latter defines aliases and identifiers used for class identification.

#### • Assigning an Identifier to a Class

You can assign an identifier to class reference relations by using the **%id** command.

```
%id [schema_name.]class_name class_id
schema_name:
    identifier
class_name:
    identifier
class_id:
    integer
```

The *class\_name* specified by the **%id** command is the class name defined in the database, and *class\_id* is the numeric identifier which is assigned for object reference. The *class\_name* uses the *schema\_name* as a prefix and the *schema\_name* is the name of the schema in which the class is defined. The *schema\_name* can be omitted, and if the *schema\_name* is omitted, the user name of the database specified with the -u option is used as the schema name.

```
%id [employee] 21
%id [office] 22
%id [project] 23
%id [phone] 24
```

The *schema\_name* and *class\_name* must be enclosed in square brackets ([ ]). Each of *schema\_name* and *class\_name* or together can be enclosed in square brackets.

```
%id [public].[employee] 21
%id [public].[office] 22
%id [public].[project] 23
%id [public].[phone] 24
```

```
%id [public.employee] 21
%id [public.office] 22
%id [public.project] 23
%id [public.phone] 24
```

- Specifying the Class and Attribute

You can specify the classes (tables) and attributes (columns) upon loading data by using the **%class** command. The data line should be written based on the order of attributes specified. When a class name is provided by using the **-t** option while executing the **cubrid loaddb** utility, you don't have to specify the class and attribute in the data file. However, the order of writing data must comply with the order of the attribute defined when creating a class.

```
%class [schema_name.]class_name (attr_name [attr_name...])
schema_name:
    identifier
class_name:
```

```
    identifier
attr_name:
    identifier
```

The class must be pre-defined in the database to be loaded.

The *class\_name* specified by the **%class** command is the class name defined in the database and the *schema\_name* is the name of the schema in which the class is defined. The *attr\_name* is the name of the attribute defined. The method of writing *schema\_name* and *class\_name* is the same as above.

The following example shows how to specify a class and three attributes by using the **%class** command to enter data into a class named *employee*. Three pieces of data should be entered on the data lines after the **%class** command. For this, see [Configuring Reference Relation](#).

```
%class [public].[employee] (name age department)
```

## Data Line

A data line comes after the **%class** command line. Data loaded must have the same type as the class attributes specified by the **%class** command. The data loading operation stops if these two types are different.

Data for each attribute must be separated by at least one space and be basically written as a single line. However, if the data to be loaded takes more than one line, you should specify the plus sign (+) at the end of the first data line to enter data continuously on the following line. Note that no space is allowed between the last character of the data and the plus sign.

### • Loading an Instance

As shown below, you can load an instance that has the same type as the specified class attribute. Each piece of data is separated by at least one space.

```
%class [public].[employee] (name)
'jordan'
'james'
'garnett'
'malone'
```

### • Assigning an Instance Number

You can assign a number to a given instance at the beginning of the data line. An instance number is a unique positive number in the specified class. Spaces are not allowed between the number and the colon (:). Assigning an instance number is used to configure the reference relation for later.

```
%class [public].[employee] (name)
1: 'jordan'
2: 'james'
3: 'garnett'
4: 'malone'
```

#### • Configuring Reference Relation

You can configure the object reference relation by specifying the reference class after an “at sign (@)” and the instance number after the “vertical line (|).”

```
@class_ref | instance_no
class_ref:
    [schema_name.]class_name
    class_id
```

Specify a class name or a class id after the @ sign, and an instance number after a vertical line (|). Spaces are not allowed before and after a vertical line (|). The method of writing *class\_ref* is the same as the method of writing *schema\_name* and *class\_name* in the [Command Line](#). However, enclosing each of *schema\_name* and *class\_name* in square brackets ([ ]) is not allowed.

The following example shows how to load class instances into the *paycheck* class. The *name* attribute references an instance of the *employee* class. As in the last line, data is loaded as **NULL** if you configure the reference relation by using an instance number not specified earlier.

```
%class [public].[paycheck] (name department salary)
@[public.employee]|1    'planning'    8000000
@[public.employee]|2    'planning'    6000000
@[public.employee]|3    'sales'       5000000
@[public.employee]|4    'development'  4000000
@[public.employee]|5    'development'  5000000
```

Since the id 21 was assigned to the *employee* class by using the **%id** command in the [Assigning an Identifier to a Class](#) section, the above example can be written as follows:

```
%class [public].[paycheck] (name department salary)
@21|1    'planning'    8000000
@21|2    'planning'    6000000
@21|3    'sales'       5000000
@21|4    'development'  4000000
@21|5    'development'  5000000
```

## Migrating Database

To use a new version of CUBRID database, you may need to migrate an existing data to a new one. For this purpose, you can use the “Export to an ASCII text file” and “Import from an ASCII text file” features provided by CUBRID.

The following section explains migration steps using the **cubrid unloaddb** and **cubrid loaddb** utilities.

### Recommended Scenario and Procedures

The following steps describes migration scenario that can be applied while the existing version of CUBRID is running. For database migration, you should use the **cubrid unloaddb** and **cubrid loaddb** utilities. For details, see [unloaddb](#) and [loaddb](#).

#### 1. Stop the existing CUBRID service

Execute **cubrid service stop** to stop all service processes running on the existing CUBRID and then check whether all CUBRID-related processes have been successfully stopped.

To verify whether all CUBRID-related processes have been successfully stopped, execute **ps -ef | grep cub\_** in Linux. If there is no process starting with cub\_, all CUBRID-related processes have been successfully stopped. In Windows, press the <Ctrl+Alt+Delete> key and select [Start Task Manager]. If there is no process starting with cub\_ in the [Processes] tab, all CUBRID-related processes have been successfully stopped. In Linux, when the related processes remain even after the CUBRID service has been terminated, use **kill** command to forcibly terminate them, and use **ipcs -m** command to check and release the memory shard by CUBRID broker. To forcibly terminate related processes in Windows, go to the [Processes] tab of Task Manager, right-click the image name, and then select [End Process].

#### 2. Back up the existing database

Perform backup of the existing version of the database by using the **cubrid backupdb** utility. The purpose of this step is to safeguard against failures that might occur during the database unload/load operations. For details on the database backup, see [backupdb](#).

#### 3. Unload the existing database

Unload the database created for the existing version of CUBRID by using the **cubrid unloaddb** utility. For details on unloading a database, see [unloaddb](#).

#### 4. Store the existing CUBRID configuration files

Store the configurations files such as **cubrid.conf**, **cubrid\_broker.conf** and **cm.conf** **\*\* in the \*\*CUBRID/conf** directory. The purpose of this step is to conveniently apply parameter values for the existing CUBRID database environment to the new one.

#### 5. Install a new version of CUBRID

Once backing up and unloading of the data created by the existing version of CUBRID have been completed, delete the existing version of CUBRID and its databases and then install the new version of CUBRID. For details on installing CUBRID, see [Getting Started](#).

#### 6. Configure the new CUBRID environment

Configure the new version of CUBRID by referring to configuration files of the existing database stored in the step 3, “ **Store the existing CUBRID configuration files** .” For details on configuring new environment, see [Installing and Running CUBRID](#) in “Getting Started.”

#### 7. Load the new database

Create a database by using the **cubrid createdb** utility and then load the data which had previously been unloaded into the new database by using the **cubrid loaddb** utility. Please see [createdb](#) for creating a database and [loaddb](#) for loading a database.

#### 8. Back up the new database

Once the data has been successfully loaded into the new database, back up the database created for the new version of CUBRID by using the **cubrid backupdb** utility. The reason for this step is because you cannot restore the data backed up in the existing version of CUBRID when using the new version. For details on backing up the database, see [backupdb](#) .

#### Warning

Even if the version is identical, the 32-bit database volume and the 64-bit database volume are not compatible for backup and recovery. Therefore, it is not recommended to recover a 32-bit database backup on the 64-bit CUBRID or vice versa.

#### Warning

When using the TDE feature in CUBRID 11, it does not provide backward compatibility. So, the unloaded file in CUBRID 11 cannot be loaded into a lower version if more the one TDE table exists.

## spacedb

The **cubrid spacedb** utility is used to check how much space of database volumes is being used. The tool can show brief aggregated information on database space usage, or detailed descriptions of all volumes and files in use, based on its options. Information returned by the **cubrid spacedb** utility includes the volume ID's, names, purpose and total/free space of each volume.

```
cubrid spacedb [options] database_name
```

- **cubrid** : An integrated utility for the CUBRID service and database management.
- **spacedb** : A command that checks the space in the database. It executes successfully only when the database is in a stopped state.
- *database\_name* : The name of the database whose space is to be checked. The path-name to the directory where the database is to be created must not be included.

The following shows [options] available with the **cubrid spacedb** utility.

```
-o, --output-file=FILE      redirect output messages to FILE
-S, --SA-mode              stand-alone mode execution
-C, --CS-mode              client-server mode execution
    --size-unit={PAGE|M|G|T|H} set the display unit (page, mega,
giga, tera, human readable)
-s, --summarize             display only a summary for each volume
purpose
-p, --purpose               display the used size of each
purpose(data/index/temp) of each volume
```

### -o FILE

This option stores the result of checking the space information of *testdb* to a file named *db\_output*.

```
cubrid spacedb -o db_output testdb
```

### -S, --SA-mode

This option is used to access a database in standalone, which means it works without processing server; it does not have an argument. If **-S** is not specified, the system recognizes that a database is running in client/server mode.

```
cubrid spacedb --SA-mode testdb
```

### **-C, --CS-mode**

This option is used to access a database in client/server mode, which means it works in client/server process respectively; it does not have an argument. If **-C** is not specified, the system recognize that a database is running in client/server mode by default.

```
cubrid spacedb --CS-mode testdb
```

### **--size-unit={PAGE|M|G|T|H}**

This option specifies the size unit of the space information of the database to be one of PAGE, M(MB), G(GB), T(TB), H(print-friendly). The default value is **H**. If you set the value to H, the unit is automatically determined as follows: M if 1 MB = DB size < 1024 MB, G if 1 GB = DB size < 1024 GB.

```
$ cubrid spacedb --size-unit=H testdb
```

```
Space description for database 'testdb' with pagesize 16.0K.
(log pagesize: 16.0K)
```

| type      | purpose        | volume_count |
|-----------|----------------|--------------|
| used_size | free_size      | total_size   |
| PERMANENT | PERMANENT DATA | 2            |
| 61.0 M    | 963.0 M        | 1.0 G        |
| PERMANENT | TEMPORARY DATA | 1            |
| 12.0 M    | 500.0 M        | 512.0 M      |
| TEMPORARY | TEMPORARY DATA | 1            |
| 40.0 M    | 88.0 M         | 128.0 M      |
| -         | -              | 4            |
| 113.0 M   | 1.5 G          | 1.6 G        |

```
Space description for all volumes:
```

| valid              | type      | purpose         |
|--------------------|-----------|-----------------|
| used_size          | free_size | total_size      |
| volume_name        |           |                 |
| 0                  | PERMANENT | PERMANENT DATA  |
| 60.0 M             | 452.0 M   | 512.0 M /home1/ |
| cubrid/testdb      |           |                 |
| 1                  | PERMANENT | PERMANENT DATA  |
| 1.0 M              | 511.0 M   | 512.0 M /home1/ |
| cubrid/testdb_x001 |           |                 |
| 2                  | PERMANENT | TEMPORARY DATA  |

```

12.0 M          500.0 M          512.0 M          /home1/
cubrid/testdb_x002
32766          TEMPORARY          TEMPORARY DATA
40.0 M          88.0 M          128.0 M          /home1/
cubrid/testdb_t32766

LOB space description file:/home1/cubrid/lob

```

### **-s, --summarize**

This option aggregates volume count, used size, free size and total size by volume types and purposes. There are three classes of volumes: permanent volumes with permanent data, permanent volumes with temporary data and temporary volume with temporary data; no temporary volumes with permanent data. Last row shows the total values for all types of volumes.

```

$ cubrid spacedb -s testdb

Space description for database 'testdb' with pagesize 16.0K.
(log pagesize: 16.0K)

type           purpose           volume_count
used_size      free_size      total_size
PERMANENT      PERMANENT DATA      2
61.0 M         963.0 M         1.0 G
PERMANENT      TEMPORARY DATA      1
12.0 M         500.0 M         512.0 M
TEMPORARY      TEMPORARY DATA      1
40.0 M         88.0 M          128.0 M
-              -                  4
113.0 M        1.5 G           1.6 G

```

### **-p, --purpose**

This option shows detailed information on the purpose of stored data. The information includes number of files, used size, size of file tables, reserved sectors size and total size.

```

Space description for database 'testdb' with pagesize 16.0K.
(log pagesize: 16.0K)

Detailed space description for files:

## compactdb

The **cubrid compactdb** utility is used to secure unused space of the database volume. In case the database server is not running (offline), you can perform the job in standalone mode. In case the database server is running, you can perform it in client-server mode.

### Note

The **cubrid compactdb** utility secures the space being taken by OIDs of deleted objects and by class changes. When an object is deleted, the space taken by its OID is not immediately freed because there might be other objects that refer to the deleted one.

Therefore, when you make a table to reuse OIDs, it is recommended to use a REUSE\_OID option as below.

```
CREATE TABLE tbl REUSE_OID
(
  id INT PRIMARY KEY,
  b VARCHAR
);
```

However, a table with a REUSE\_OID option cannot be referred by the other table. That is, this table cannot be used as a type of the other table.

```
CREATE TABLE reuse_tbl (a INT PRIMARY KEY) REUSE_OID;
CREATE TABLE tbl_1 ( a reuse_tbl);
```

```
ERROR: The class 'reuse_tbl' is marked as REUSE_OID and is non-
referable. Non-referable classes can't be the domain of an
attribute and their instances' OIDs cannot be returned.
```

To see details of REUSE\_OID, please refer to [REUSE\\_OID](#).

Reference to the object deleted during compacting is displayed as **NULL**, which means this can be reused by OIDs.

```
cubrid compactdb [options] database_name [schema_name.class_name [{,
schema_name.class_name}]]
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **compactdb**: A command that compacts the space of the database so that OIDs assigned to deleted data can be reused.
- *database\_name*: The name of the database whose space is to be compacted. The path name to the directory where the database is to be created must not be included.
- *class\_name\_list*: You can specify the list of tables names that you want to compact space after a database name; the **-i** option cannot be used together. The table name must be prefixed with the schema name. If you use the lists on client/server mode, it skips securing space taken by objects such as catalog, delete files and tracker, etc.

**-l, -c, -d, -p** options are applied in client/server mode only.

The following shows [options] available with the **cubrid compactdb** utility.

```
-v, --verbose           enable verbose status messages
-S, --SA-mode          stand-alone mode execution
-C, --CS-mode          client-server mode execution
-i, --input-class-file=FILE input FILE of table names
-p, --pages-committed-once=NUMBER maximum number of pages to commit once
-d, --delete-old-repr  delete old class representations
from catalog
-I, --Instance-lock-timeout timeout for instance lock
-c, --class-lock-timeout timeout for class lock
```

### **-v, --verbose**

You can output messages that shows which class is currently being compacted and how many instances have been processed for the class by using the **-v** option.

```
cubrid compactdb -v testdb
```

### **-S, --SA-mode**

This option specifies to compact used space in standalone mode while database server is not running; no argument is specified. If the **-S** option is not specified, system recognizes that the job is executed in client/server mode.

```
cubrid compactdb --SA-mode testdb
```

**-C, --CS-mode**

This option specifies to compact used space in client/server mode while database server is running; no argument is specified. Even though this option is omitted, system recognizes that the job is executed in client/server mode.

**-i, --input-class-file=FILE**

You can specify an input file name that contains the table name with this option. Write one table name in a single line; invalid table name is ignored. The table name must be prefixed with the schema name. Note that you cannot specify the list of the table names after a database name in case of you use this option. If you use this option on client/server mode, it skips securing space taken by objects such as catalog, delete files and tracker, etc.

The following options can be used in client/server mode only.

**-p, --pages-committed-once=NUMBER**

You can specify the number of maximum pages that can be committed once with this option. The default value is 10, the minimum value is 1, and the maximum value is 10. The less option value is specified, the more concurrency is enhanced because the value for class/instance lock is small; however, it causes slowdown on operation, and vice versa.

```
cubrid compactdb --CS-mode -p 10 testdb public.tbl1,  
public.tbl2, public.tbl5
```

**-d, --delete-old-repr**

You can delete an existing table representation (schema structure) from catalog with this option. Generally you'd better keep the existing table representation because schema updating cost will be saved when you keep the status as referring to the past schema for the old records.

**-l, --Instance-lock-timeout=NUMBER**

You can specify a value of instance lock timeout with this option. The default value is 2 (seconds), the minimum value is 1, and the maximum value is 10. The less option value is specified, the more operation speeds up. However, the number of instances that can be processed becomes smaller, and vice versa.

**-c, --class-lock-timeout=NUMBER**

You can specify a value of instance lock timeout with this option. The default value is 10 (seconds), the minimum value is 1, and the maximum value is 10. The less option value is specified, the more operation speeds up. However, the number of tables that can be processed becomes smaller, and vice versa.

## optimizedb

Updates statistical information such as the number of objects, the number of pages to access, and the distribution of attribute values.

```
cubrid optimizedb [<option>] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **optimizedb**: Updates the statistics information, which is used for cost-based query optimization of the database. If the option is specified, only the information of the specified class is updated.
- *database\_name*: The name of the database whose cost-based query optimization statistics are to be updated.

The following shows <option> available with the **cubrid optimizedb** utility.

### **-n, --class-name**

The following example shows how to update the query statistics information of the given class by using the **-n** option. The table name must be prefixed with the schema name.

```
cubrid optimizedb -n public.event_table testdb
```

The following example shows how to update the query statistics information of all classes in the database.

```
cubrid optimizedb testdb
```

## plandump

The **cubrid plandump** utility is used to display information on the query plans stored (cached) on the server.

```
cubrid plandump [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **plandump**: A utility that displays the query plans stored in the current cache of a specific database.
- *database\_name*: The name of the database where the query plans are to be checked or dropped from its server cache.

The following shows [options] available with the **cubrid plandump** utility.

```
-d, --drop           drop all plans in the server's cache
-o, --output-file=FILE  redirect output messages to FILE
-s, --sha1=SHA1       drop a specific plan using its SHA1
                        hash from the server's cache
```

#### **-d, --drop**

This option drops the query plans stored in the cache.

```
cubrid plandump -d testdb
```

#### **-o, --output-file=FILE**

This option stores the results of the query plans stored in the cache to a file.

```
cubrid plandump -o output.txt testdb
```

#### **-s, --sha1=SHA1**

This option drops specific query plans identified by their SHA1 hashes from the server's cache.

```
$ cubrid plandump testdb

Entries:

  XASL_ID = {
    sha1 = { da9cab5d 597f2fe4 48aa8ae8 66b87d81
49fdd7ca },
    time_stored = 1718614753 sec, 257499 usec
  }
sql info:
  SQL_ID = 4dfa6d901e048
  sql user text = select * from game where host_year > '2004'
  sql plan text = Sequential scan(public.game dba.game)

cubrid plandump -s 'da9cab5d 597f2fe4 48aa8ae8 66b87d81
49fdd7ca' demodb
```

By default, it examines the query plans stored in the plan cache if no options are specified.

```
cubrid plandump testdb
```

```

```

CUBRID supports the reuse of SQL execution plans through the Plan Cache feature. The Plan Cache is managed on the server side and operates through cooperation between the Common Application Server (CAS) and the database server. The main processing steps are as follows:

1. Query Analysis (Parsing and Rewrite) : When an SQL query is sent from the client, it is first parsed and rewritten by the CAS. During this step, the query is analyzed and internally transformed for optimization and normalization purposes.
2. XASL\_ID Generation : Based on the rewritten query, a XASL\_ID is generated. This XASL\_ID serves as a unique identifier for the query and is used to check whether the corresponding execution plan (XASL) is already stored in the server's Plan Cache.
3. Plan Cache Lookup : Using the generated XASL\_ID, the CAS queries the server to determine if a matching XASL (Execution Plan) already exists in the Plan Cache.
  - If the XASL is found: The server uses the existing plan to execute the query.
  - If the XASL is not found: The CAS generates a new Tree(Execution Plan) and sends it to the server, which may then decide whether or not to store it in the Plan Cache.

#### Note

The Plan Cache improves performance by reusing XASL(execution plan).

The following describes **the detailed fields** included in the output of plandump:

- **XASL\_ID**The SQL hash text is converted into a SHA1 hash string, which is then used as the key for the plan cache.
  - time\_stored: The timestamp indicating when the plan was saved in the plan cache. It is represented as a Unix timestamp and can be converted to a human-readable format using the date command.
  - ex) \$> date -d @1750657813.784232 (Mon Jun 23 14:50:13 KST 2025)
- fix\_count : Number of concurrently used threads
- **cache flags**Status information of the cache entry
  - 8000000 : mark\_deleted
  - 4000000 : to be recompiled
  - 2000000 : was recompiled

- 0800000 : clean up
- 0400000 : recomiled requested
- reference count: The number of times the execution plan has been referenced (i.e., reused) by queries.
- **time second last used: The UNIX timestamp indicating when this plan was last used. You can convert it to human-readable format using: `date -d @<timestamp>`**
  - ex) `$> date -d @1750657814` (Mon Jun 23 14:50:14 KST 2025)
- clone count: The number of clone instances created from this plan. When an execution plan is stored in memory as a stream format, it must be converted to an XASL (eXtended Access Specification Language) structure before execution. To reduce this transformation cost, a clone cache is used. The clone cache holds reusable XASL structures. If a thread requests a clone and none are available, a new clone is created and added to the cache. Each time this happens, the clone count increases.
- **SQL\_ID: A unique identifier generated from the original SQL statement using the MD5 hash function. From the resulting 32-character hexadecimal hash, the last 13 hexadecimal characters are used as the SQL\_ID.**
  - If the MD5 hash value is `e1faffb3e614e6c2fba74296962386b7`, the corresponding SQL ID is the last 13 characters of the hash: `74296962386b7`.
- sql user text : The original SQL query submitted by the user.
- sql hash text : The rewritten form of the SQL statement used for caching and plan reuse.
- sql plan text : The text representation of the execution plan generated for the SQL.
- OID\_LIST : A list of Object ID for database objects (e.g., tables, serials) referenced by this execution plan.

#### Note

- You can convert a Unix timestamp to a human-readable date and time format using the `date` command.

## statdump

**cubrid statdump** utility checks statistics information processed by the CUBRID database server. The statistics information mainly consists of the following: File I/O, Page buffer, Logs, Transactions, Concurrency/Lock, Index, and Network request.

You can also use CSQL's session commands to check the statistics information only about the CSQL's connection. For details, see [Dumping CSQL execution statistics information](#).

```
cubrid statdump [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **statdump**: A command that dumps the statistics information on the database server execution.
- *database\_name*: The name of database which has the statistics data to be dumped.

The following shows [options] available with the **cubrid statdump** utility.

```
-i, --interval=S          print stats every S secs  
-o, --output-file=FILE    redirect output message to FILE  
-c, --cumulative          print cumulative stats  
-s, --substr=STRING       print stat item only that match the  
substring
```

#### **-i, --interval=SECOND**

This option specifies the periodic number of Dumping statistics as seconds.

The following outputs the accumulated values per second.

```
cubrid statdump -i 1 -c demodb
```

The following outputs the accumulated values during 1 second, as starting with 0 value per every 1 second.

```
cubrid statdump -i 1 demodb
```

The following outputs the last values which were executed with **-i** option.

```
cubrid statdump demodb
```

The following outputs the same values with the above. **-c** option doesn't work if it is not used with **-i** option together.

```
cubrid statdump -c demodb
```

The following outputs the values per every 5 seconds.

```
$ cubrid statdump -i 5 -c testdb
```

```
Mon November 11 23:44:36 KST 2019

The following are the explanation about the above statistical information. You can find the statistic category (database module), the name, the stat type and a brief description for each statistic.

There are several types of statistic, based on how they are collected:

- Accumulator: The stat values are incremented whenever the tracked action happens.
- Counter/timer: The stat tracks both the number and the duration of an action. Also biggest and average duration are tracked.
- Snapshot: The stat is peeked from database.
- Complex: The stat tracks multiple values for an action, separated by various attributes.

Most statistics are accumulators (they are incremented when an action happens). Other statistics can be counter/timers (they track both number of actions and their duration), some are peeked from database (snapshot) and some are computed based on other values. Lastly, there are several complex statistics which track detailed information on some operations.

### File I/O

| Stat name        | Stat type   | Description                 |
|------------------|-------------|-----------------------------|
| Num_file_removes | Accumulator | The number of files removed |
| Num_file_creates | Accumulator | The number of files created |
| Num_file_ireads  | Accumulator | The number of files read    |

|                        |               |                                           |
|------------------------|---------------|-------------------------------------------|
| Num_file_iowrites      | Accumulator   | The number of files stored                |
| Num_file_iosynches     | Accumulator   | The number of file synchronization        |
| ..file_iosync_all      | Counter/timer | The number and duration of sync all files |
| Num_file_page_allocs   | Accumulator   | The number of page allocations            |
| Num_file_page_deallocs | Accumulator   | The number of page deallocations          |

### Page Buffer

| Stat name                   | Stat type   | Description                                                                                           |
|-----------------------------|-------------|-------------------------------------------------------------------------------------------------------|
| Num_data_page_fetches       | Accumulator | The number of fetched pages                                                                           |
| Num_data_page_dirties       | Accumulator | The number of dirty pages                                                                             |
| Num_data_page_ioreads       | Accumulator | The number of pages read from disk<br>(more means less efficient, it correlates with lower hit ratio) |
| Num_data_page_iowrites      | Accumulator | The number of pages write to disk (more means less efficient)                                         |
| Num_data_page_private_quota | Snapshot    | The target number of pages for private LRU lists                                                      |

|                                |          |                                                     |
|--------------------------------|----------|-----------------------------------------------------|
| Num_data_page_private_count    | Snapshot | The actual number of pages for private LRU lists    |
| Num_data_page_fixed            | Snapshot | The number of fixed pages in data buffer            |
| Num_data_page_dirty            | Snapshot | The number of dirty pages in data buffer            |
| Num_data_page_lru1             | Snapshot | The number of pages in LRU1 zone in data buffer     |
| Num_data_page_lru2             | Snapshot | The number of pages in LRU2 zone in data buffer     |
| Num_data_page_lru3             | Snapshot | The number of pages in LRU3 zone in data buffer     |
| Num_data_page_victim_candidate | Snapshot | The number of victim candidate pages in data buffer |

### Logs

| Stat name             | Stat type   | Description                     |
|-----------------------|-------------|---------------------------------|
| Num_log_page_fetches  | Accumulator | The number of fetched log pages |
| Num_log_page_ioreads  | Accumulator | The number of log pages read    |
| Num_log_page_iowrites | Accumulator | The number of log pages stored  |

|                                       |             |                                                                                   |
|---------------------------------------|-------------|-----------------------------------------------------------------------------------|
| Num_log_append_records                | Accumulator | The number of log records appended                                                |
| Num_log_archives                      | Accumulator | The number of logs archived                                                       |
| Num_log_start_checkpoints             | Accumulator | The number of started checkpoints                                                 |
| Num_log_end_checkpoints               | Accumulator | The number of ended checkpoints                                                   |
| Num_log_wals                          | Accumulator | The number of log flushes requested to write a data page.                         |
| Num_log_page_iowrites_for_replacement | Accumulator | The number of log data pages written to disk due to replacements (should be zero) |
| Num_log_page_replacements             | Accumulator | The number of log data pages discarded due to replacements                        |

|                            |             |                                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_prior_lsa_list_size    | Accumulator | <p>Current size of the prior LSA(Log Sequence Address) list.</p> <p>CUBRID write the order of writing into the prior LSA list, before writing operation from the log buffer to the disk; this list is used to raise up the concurrency by reducing the waiting time of the transaction from writing to disk</p> |
| Num_prior_lsa_list_maxed   | Accumulator | <p>The count of the prior LSA list being reached at the maximum size.</p> <p>The maximum size of the prior LSA list is <math>\text{log\_buffer\_size} * 2</math>.</p> <p>If this value is big, we can assume that log writing jobs happen a lot at the same time</p>                                            |
| Num_prior_lsa_list_removed | Accumulator | <p>The count of LSA being moved from prior LSA list into log buffer.</p> <p>We can assume that the commits have happened at the similar count with this value</p>                                                                                                                                               |
| Log_page_buffer_hit_ratio  | Computed    | <p>Hit ratio of log page buffers</p> $\frac{(\text{Num\_log\_page\_fetches} - \text{Num\_log\_page\_ioreads}) * 100}{\text{Num\_log\_page\_fetches}}$                                                                                                                                                           |

### Concurrency/lock

| Stat name                         | Stat type   | Description                                                    |
|-----------------------------------|-------------|----------------------------------------------------------------|
| Num_page_locks_acquired           | Accumulator | The number of locked pages acquired                            |
| Num_object_locks_acquired         | Accumulator | The number of locked objects acquired                          |
| Num_page_locks_converted          | Accumulator | The number of locked pages converted                           |
| Num_object_locks_converted        | Accumulator | The number of locked objects converted                         |
| Num_page_locks_re-requested       | Accumulator | The number of locked pages requested                           |
| Num_object_locks_re-requested     | Accumulator | The number of locked objects requested                         |
| Num_page_locks_waits              | Accumulator | The number of locked pages waited                              |
| Num_object_locks_waits            | Accumulator | The number of locked objects waited                            |
| Num_object_locks_time_waited_usec | Accumulator | The time in microseconds spent on waiting for all object locks |
| Time_obj_lock_acquire_time        | Complex     | Time consumer for locking objects classified by lock mode      |

## Transactions

| Stat name                          | Stat type   | Description                                                                                                                                                         |
|------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_tran_commits                   | Accumulator | The number of commits                                                                                                                                               |
| Num_tran_rollbacks                 | Accumulator | The number of rollbacks                                                                                                                                             |
| Num_tran_savepoints                | Accumulator | The number of savepoints                                                                                                                                            |
| Num_tran_start_topops              | Accumulator | The number of top operations started                                                                                                                                |
| Num_tran_end_topops                | Accumulator | The number of top operations stopped                                                                                                                                |
| Num_tran_interrupts                | Accumulator | The number of interruptions                                                                                                                                         |
| Num_tran_postpone_cache_hits       | Accumulator | The number of cache hits when executing transaction postpone ops                                                                                                    |
| Num_tran_postpone_cache_miss       | Accumulator | The number of cache misses when executing transaction postpone ops<br>Cache misses may degrade performance of transaction commits and may impact all log operations |
| Num_tran_topop_postpone_cache_hits | Accumulator | The number of cache hits when executing top operations postpone ops                                                                                                 |
| Num_tran_topop_postpone_cache_miss | Accumulator | The number of cache misses when executing top operations postpone                                                                                                   |

Cache misses may degrade performance of top operations commits and may impact all log operations

## Index

| Stat name                         | Stat type   | Description                                                                                                   |
|-----------------------------------|-------------|---------------------------------------------------------------------------------------------------------------|
| Num_btree_inserts                 | Accumulator | The number of nodes inserted                                                                                  |
| Num_btree_deletes                 | Accumulator | The number of nodes deleted                                                                                   |
| Num_btree_updates                 | Accumulator | The number of nodes updated                                                                                   |
| Num_btree_covered                 | Accumulator | The number of cases in which an index includes all data upon query execution                                  |
| Num_btree_noncovered              | Accumulator | The number of cases in which an index includes some or no data upon query execution                           |
| Num_btree_resumes                 | Accumulator | The exceeding number of index scan specified due to too many results                                          |
| Num_btree_multirange_optimization | Accumulator | The number of executions on multi-range optimization for the WHERE ... IN ... LIMIT condition query statement |

|                     |               |                                                                       |
|---------------------|---------------|-----------------------------------------------------------------------|
| Num_btree_splits    | Accumulator   | The number of B-tree split-operations                                 |
| Num_btree_merges    | Accumulator   | The number of B-tree merge-operations                                 |
| Num_btree_get_stats | Accumulator   | The number of B-tree get stat calls                                   |
| ..bt_leaf           | Counter/timer | The number and duration of all operations in index leaves             |
| ..bt_find_unique    | Counter/timer | The number and duration of B-tree 'find-unique' operations            |
| ..btrange_search    | Counter/timer | The number and duration of B-tree 'range-search' operations           |
| ..bt_insert_obj     | Counter/timer | The number and duration of B-tree 'insert object' operations          |
| ..bt_delete_obj     | Counter/timer | The number and duration of B-tree 'physical delete object' operations |
| ..bt_mvcc_delete    | Counter/timer | The number and duration of B-tree 'mvcc delete' operations            |

|                       |               |                                                                     |
|-----------------------|---------------|---------------------------------------------------------------------|
| ..bt_mark_delete      | Counter/timer | The number and duration of B-tree mark delete operations            |
| ..bt_undo_insert      | Counter/timer | The number and duration of B-tree 'undo insert' operations          |
| ..bt_undo_delete      | Counter/timer | The number and duration of B-tree 'undo physical delete' operations |
| ..bt_undo_mvcc_delete | Counter/timer | The number and duration of B-tree 'undo mvcc delete' operations     |
| ..bt_vacuum           | Counter/timer | The number and duration of B-tree vacuum deleted object operations  |
| ..bt_vacuum_insid     | Counter/timer | The number and duration of vacuum operations on B-tree 'insert id'  |
| ..bt_fix_ovf_oids     | Counter/timer | The number and duration of B-tree overflow page fixes               |
| ..bt_unique_rlocks    | Counter/timer | The number and duration of blocked read locks on unique indexes     |
| ..bt_unique_wlocks    | Counter/timer | The number and duration of blocked write locks on unique indexes    |

|                            |               |                                                                       |
|----------------------------|---------------|-----------------------------------------------------------------------|
| ..bt_traverse              | Counter/timer | The number and duration of B-tree traverse                            |
| ..bt_find_unique_traverse  | Counter/timer | The number and duration of B-tree traverse for 'find unique'          |
| ..bt_range_search_traverse | Counter/timer | The number and duration of B-tree traverse for 'range search'         |
| ..bt_insert_traverse       | Counter/timer | The number and duration of B-tree traverse for 'insert'               |
| ..bt_delete_traverse       | Counter/timer | The number and duration of B-tree traverse for 'physical delete'      |
| ..bt_mvcc_delete_traverse  | Counter/timer | The number and duration of B-tree traverse for 'mvcc delete'          |
| ..bt_mark_delete_traverse  | Counter/timer | The number and duration of B-tree traverse for 'mark delete'          |
| ..bt_undo_insert_traverse  | Counter/timer | The number and duration of B-tree traverse for 'undo physical insert' |
| ..bt_undo_delete_traverse  | Counter/timer | The number and duration of B-tree traverse for 'undo physical delete' |
|                            | Counter/timer |                                                                       |

|                                |  |                                                              |
|--------------------------------|--|--------------------------------------------------------------|
| ..bt_undo_mvcc_delete_traverse |  | The number and duration of B-tree traverse for 'undo delete' |
|--------------------------------|--|--------------------------------------------------------------|

|                      |               |                                                                      |
|----------------------|---------------|----------------------------------------------------------------------|
| ..bt_vacuum_traverse | Counter/timer | The number and duration of B-tree traverse for vacuum deleted object |
|----------------------|---------------|----------------------------------------------------------------------|

|                            |               |                                                                   |
|----------------------------|---------------|-------------------------------------------------------------------|
| ..bt_vacuum_insid_traverse | Counter/timer | The number and duration of B-tree traverse for vacuum 'insert id' |
|----------------------------|---------------|-------------------------------------------------------------------|

### Load Index Online

| Stat name | Stat type | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                     |               |                                                                   |
|---------------------|---------------|-------------------------------------------------------------------|
| ..btree_online_load | Counter/timer | The number and duration of B-tree online index loading statements |
|---------------------|---------------|-------------------------------------------------------------------|

|                            |               |                                                               |
|----------------------------|---------------|---------------------------------------------------------------|
| ..btree_online_insert_task | Counter/timer | The number and duration of batch insert tasks by index loader |
|----------------------------|---------------|---------------------------------------------------------------|

|                             |               |                                                                   |
|-----------------------------|---------------|-------------------------------------------------------------------|
| ..btree_online_prepare_task | Counter/timer | The number and duration of preparing (sorting) index loader tasks |
|-----------------------------|---------------|-------------------------------------------------------------------|

|                            |               |                                                                                                                                |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| ..btree_online_insert_leaf | Counter/timer | The number and duration of leaf pages processed by index loader (multiple keys may be inserted while a leaf page is processed) |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------|

|                          |             |                                           |
|--------------------------|-------------|-------------------------------------------|
| Num_btree_online_inserts | Accumulator | The number of key inserts by index loader |
|--------------------------|-------------|-------------------------------------------|

|                                         |             |                                                                                                                              |
|-----------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------|
| Num_btree_online_inserts_same_page_hold | Accumulator | The number of successive inserts by index loader in same leaf page (loader optimization to avoid expensive index traversals) |
| Num_btree_online_inserts_retry          | Accumulator | The number of restarted inserts because successive keys do not belong to same leaf or because there is not enough space      |
| Num_btree_online_inserts_retry_nice     | Accumulator | The number of restarted inserts to let others access leaf page                                                               |

### Query

| Stat name         | Stat type   | Description                                |
|-------------------|-------------|--------------------------------------------|
| Num_query_selects | Accumulator | The number of SELECT query execution       |
| Num_query_inserts | Accumulator | The number of INSERT query execution       |
| Num_query_deletes | Accumulator | The number of DELETE query execution       |
| Num_query_updates | Accumulator | The number of UPDATE query execution       |
| Num_query_scans   | Accumulator | The number of sequential scans (full scan) |

|                            |             |                                                       |
|----------------------------|-------------|-------------------------------------------------------|
| Num_query_iscans           | Accumulator | The number of index scans                             |
| Num_query_lscans           | Accumulator | The number of LIST scans                              |
| Num_query_setscans         | Accumulator | The number of SET scans                               |
| Num_query_methscans        | Accumulator | The number of METHOD scans                            |
| Num_query_nljoins          | Accumulator | The number of nested loop joins                       |
| Num_query_mjoins           | Accumulator | The number of parallel joins                          |
| Num_query_objfetches       | Accumulator | The number of fetch objects                           |
| Num_query_holdable_cursors | Snapshot    | The number of holdable cursors in the current server. |

## Sort

| Stat name           | Stat type   | Description                                                                                |
|---------------------|-------------|--------------------------------------------------------------------------------------------|
| Num_sort_io_pages   | Accumulator | The number of pages fetched on the disk during sorting<br>(more means less efficient)      |
| Num_sort_data_pages | Accumulator | The number of pages found on the page buffer during sorting<br>(more means less efficient) |

**Network**

| Stat name            | Stat type   | Description                     |
|----------------------|-------------|---------------------------------|
| Num_network_requests | Accumulator | The number of network requested |

**Heap**

| Stat name                      | Stat type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_heap_stats_sync_best space | Accumulator | <p>The updated number of the “best page” list.</p> <p>“Best pages” means that the data pages of which the free space is more than 30% in the environment of multiple INSERTs and DELETEs.</p> <p>Only some information of these pages are saved as the “best page” list. In the “best page” list, the information of a million pages is saved at once. This list is searched when INSERTing a record, and then this list is updated when there are no free space to store this record on the pages. If there are still no free space to store this record even this list is updated for several times, this record is stored into a new page.</p> |
| Num_heap_home_inserts          | Accumulator |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                              |             |                                                                              |
|------------------------------|-------------|------------------------------------------------------------------------------|
|                              |             | The number of inserts in heap HOME type records                              |
| Num_heap_big_inserts         | Accumulator | The number of inserts in heap BIG type records                               |
| Num_heap_assign_inserts      | Accumulator | The number of inserts in heap ASSIGN type records                            |
| Num_heap_home_deletes        | Accumulator | The number of deletes from heap HOME type records in non-MVCC mode           |
| Num_heap_home_mvcc_deletes   | Accumulator | The number of deletes from heap HOME type records in MVCC mode               |
| Num_heap_home_to_rel_deletes | Accumulator | The number of deletes from heap HOME to RELOCATION type records in MVCC mode |
| Num_heap_home_to_big_deletes | Accumulator | The number of deletes from heap HOME to BIG type records in MVCC mode        |
| Num_heap_rel_deletes         | Accumulator | The number of deletes from heap RELOCATION type records in non-MVCC mode     |
| Num_heap_rel_mvcc_deletes    | Accumulator | The number of deletes from heap RELOCATION type records in MVCC mode         |

|                              |             |                                                                                    |
|------------------------------|-------------|------------------------------------------------------------------------------------|
| Num_heap_rel_to_home_deletes | Accumulator | The number of deletes from heap RELOCATION to HOME type records in MVCC mode       |
| Num_heap_rel_to_big_deletes  | Accumulator | The number of deletes from heap RELOCATION to BIG type records in MVCC mode        |
| Num_heap_rel_to_rel_deletes  | Accumulator | The number of deletes from heap RELOCATION to RELOCATION type records in MVCC mode |
| Num_heap_big_deletes         | Accumulator | The number of deletes from heap BIG type records in non-MVCC mode                  |
| Num_heap_big_mvcc_deletes    | Accumulator | The number of deletes from heap BIG type records in MVCC mode                      |
| Num_heap_home_updates        | Accumulator | The number of updates in place of heap HOME type records in non-MVCC mode(*)       |
| Num_heap_home_to_rel_updates | Accumulator | The number of updates of heap HOME to RELOCATION type records in non-MVCC mode(*)  |
| Num_heap_home_to_big_updates | Accumulator | The number of updates of heap HOME to BIG type records in non-MVCC mode(*)         |
| Num_heap_rel_updates         | Accumulator |                                                                                    |

|                              |             |                                                                                         |
|------------------------------|-------------|-----------------------------------------------------------------------------------------|
|                              |             | The number of updates of heap RELOCATION type records in non-MVCC mode(*)               |
| Num_heap_rel_to_home_updates | Accumulator | The number of updates of heap RELOCATION to HOME type records in non-MVCC mode(*)       |
| Num_heap_rel_to_rel_updates  | Accumulator | The number of updates of heap RELOCATION to RELOCATION type records in non-MVCC mode(*) |
| Num_heap_rel_to_big_updates  | Accumulator | The number of updates of heap RELOCATION to BIG type records in non-MVCC mode(*)        |
| Num_heap_big_updates         | Accumulator | The number of updates of heap BIG type records in non-MVCC mode(*)                      |
| Num_heap_home_vacuums        | Accumulator | The number of vacuumed heap HOME type records                                           |
| Num_heap_big_vacuums         | Accumulator | The number of vacuumed heap BIG type records                                            |
| Num_heap_rel_vacuums         | Accumulator | The number of vacuumed heap RELOCATION type records                                     |
| Num_heap_insid_vacuums       | Accumulator | The number of vacuumed heap newly inserted records                                      |
|                              | Accumulator |                                                                                         |

|                         |               |                                                            |
|-------------------------|---------------|------------------------------------------------------------|
| Num_heap_remove_vacuums |               | The number of vacuum operations that remove heap records   |
| ..heap_insert_prepare   | Counter/timer | The number and duration of preparing heap insert operation |
| ..heap_insert_execute   | Counter/timer | The number and duration of executing heap insert operation |
| ..heap_insert_log       | Counter/timer | The number and duration of logging heap insert operation   |
| ..heap_delete_prepare   | Counter/timer | The number and duration of preparing heap delete operation |
| ..heap_delete_execute   | Counter/timer | The number and duration of executing heap delete operation |
| ..heap_delete_log       | Counter/timer | The number and duration of logging heap delete operation   |
| ..heap_update_prepare   | Counter/timer | The number and duration of preparing heap update operation |
| ..heap_update_execute   | Counter/timer | The number and duration of executing heap update operation |

|                       |               |                                                            |
|-----------------------|---------------|------------------------------------------------------------|
| ..heap_update_log     | Counter/timer | The number and duration of logging heap update operation   |
| ..heap_vacuum_prepare | Counter/timer | The number and duration of preparing heap vacuum operation |
| ..heap_vacuum_execute | Counter/timer | The number and duration of executing heap vacuum operation |
| ..heap_vacuum_log     | Counter/timer | The number and duration of logging heap vacuum operation   |

### Query plan cache

| Stat name             | Stat type   | Description                                  |
|-----------------------|-------------|----------------------------------------------|
| Num_plan_cache_add    | Accumulator | The number of entries added to query cache   |
| Num_plan_cache_lookup | Accumulator | The number of lookups in query cache         |
| Num_plan_cache_hit    | Accumulator | The number of hits in query cache            |
| Num_plan_cache_miss   | Accumulator | The number of misses in query cache          |
| Num_plan_cache_full   | Accumulator | The number of times query cache becomes full |

|                                |             |                                                                 |
|--------------------------------|-------------|-----------------------------------------------------------------|
| Num_plan_cache_delete          | Accumulator | The number of entries deleted from query cache                  |
| Num_plan_cache_invalid_xasl_id | Accumulator | The number of failed attempts of retrieving entries by XASL ID. |
| Num_plan_cache_entries         | Snapshot    | The current number of entries in query cache                    |

### High Availability

| Stat name                 | Stat type   | Description                     |
|---------------------------|-------------|---------------------------------|
| Time_ha_replication_delay | Accumulator | Replication latency time (sec.) |

### Vacuuming

| Stat name                              | Stat type   | Description                                                                                                                                                        |
|----------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_vacuum_log_pages_vacuumed          | Accumulator | The number of log data pages processed by vacuum workers.                                                                                                          |
| Num_vacuum_log_pages_to_vacuum         | Accumulator | The number of log data pages to be vacuumed by vacuum workers.<br>(if value is much bigger than Num_vacuum_log_pages_vacuumed, it means vacuum system lags behind) |
| Num_vacuum_prefetch_requests_log_pages | Accumulator |                                                                                                                                                                    |

|                                    |               |                                                                                                                                                                                                                                                                                  |
|------------------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |               | The number of requests to prefetch buffer for log pages from vacuum                                                                                                                                                                                                              |
| Num_vacuum_prefetch_hits_log_pages | Accumulator   | The number of hits to prefetch buffer for log pages from vacuum                                                                                                                                                                                                                  |
| ..vacuum_master                    | Counter/timer | The number and duration of vacuum master iterations.                                                                                                                                                                                                                             |
| ..vacuum_job                       | Counter/timer | The number and duration of vacuum jobs                                                                                                                                                                                                                                           |
| ..vacuum_worker_process_log        | Counter/timer | The number and duration of process log tasks                                                                                                                                                                                                                                     |
| ..vacuum_worker_execute            | Counter/timer | The number and duration of execute vacuum tasks                                                                                                                                                                                                                                  |
| Vacuum_data_page_buffer_hit_ratio  | Computed      | Hit ratio of vacuuming data page buffers                                                                                                                                                                                                                                         |
| Vacuum_page_efficiency_ratio       | Computed      | Ratio between number of page unfix of vacuum with dirty flag and total number of page unfix of vacuum. Ideally, the vacuum process performs only write operations since it cleans up all unused records. Even with an optimized vacuum process, 100% efficiency is not possible. |

|                         |          |                                                                   |
|-------------------------|----------|-------------------------------------------------------------------|
| Vacuum_page_fetch_ratio | Computed | Ratio (percentage) of page unfix from vacuum module versus total. |
|-------------------------|----------|-------------------------------------------------------------------|

|                             |          |                                                               |
|-----------------------------|----------|---------------------------------------------------------------|
| Num_data_page_avoid_dealloc | Snapshot | The number of data pages that cannot be deallocated by vacuum |
|-----------------------------|----------|---------------------------------------------------------------|

### Heap Bestspace

| Stat name | Stat type | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                             |               |                                                                 |
|-----------------------------|---------------|-----------------------------------------------------------------|
| ..heap_stats_sync_bestspace | Counter/timer | The number and duration of bestspace synchronization operations |
|-----------------------------|---------------|-----------------------------------------------------------------|

|                                  |             |                                                                  |
|----------------------------------|-------------|------------------------------------------------------------------|

### Page buffer fix

| Stat name                            | Stat type | Description                                                                               |
|--------------------------------------|-----------|-------------------------------------------------------------------------------------------|
| Data_page_fix_lock_acquire_time_msec | Computed  | Time waiting for other transaction to load page from disk                                 |
| Data_page_fix_hold_acquire_time_msec | Computed  | Time to obtain page latch                                                                 |
| Data_page_fix_acquire_time_msec      | Computed  | Total time to fix page                                                                    |
| Data_page_allocate_time_ratio        | Computed  | Ratio of time necessary for page loading from disk versus the total time of fixing a page |
| Data_page_total_promote_success      | Computed  | Number of successful page latch promotions from shared to exclusive                       |
| Data_page_total_promote_fail         | Computed  | Number of failed page latch promotions                                                    |

|                                   |             |                                                                                                                                                                                                                                                                          |
|-----------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data_page_total_promote_time_msec | Computed    | Time for promoting page latches                                                                                                                                                                                                                                          |
| Num_data_page_hash_anchor_waits   | Accumulator | Number of waits on page buffer hash bucket                                                                                                                                                                                                                               |
| Time_data_page_hash_anchor_wait   | Accumulator | Total wait time on page buffer hash bucket                                                                                                                                                                                                                               |
| Num_data_page_fix_ext             | Complex     | Number of data page fixes classified by: <ul style="list-style-type: none"> <li>- module (system, worker, vacuum)</li> <li>- page type</li> <li>- page fetch/found mode</li> <li>- page latch mode</li> <li>- page latch condition</li> </ul>                            |
| Time_data_page_lock_acquire_time  | Complex     | Time consumed waiting for other thread to load data page from disk: <ul style="list-style-type: none"> <li>- module (system, worker, vacuum)</li> <li>- page type</li> <li>- page fetch/found mode</li> <li>- page latch mode</li> <li>- page latch condition</li> </ul> |
| Time_data_page_hold_acquire_time  | Complex     | Time consumed waiting for data page latch: <ul style="list-style-type: none"> <li>- module (system, worker, vacuum)</li> <li>- page type</li> <li>- page fetch/found mode</li> <li>- page latch mode</li> </ul>                                                          |
| Time_data_page_fix_acquire_time   | Complex     | Time consumed fixing data page: <ul style="list-style-type: none"> <li>- module (system, worker, vacuum)</li> <li>- page type</li> </ul>                                                                                                                                 |

- page fetch/found mode
- page latch mode
- page latch condition

Num\_data\_page\_promote\_ext      Complex

Number of data page promotions classified by:

- module (system, worker, vacuum)
- page type
- promote latch condition
- holder latch mode
- successful/failed promotion

Num\_data\_page\_promote\_time\_ext      Complex

Time consumed for data page promotions classified by:

- module (system, worker, vacuum)
- page type
- promote latch condition
- holder latch mode
- successful/failed promotion

### Page buffer unfix

#### Stat name

#### Stat type

#### Description

Num\_unfix\_void\_to\_private\_top      Accumulator

Unfix newly loaded data page and add to top of private LRU list

Num\_unfix\_void\_to\_private\_mid      Accumulator

Unfix newly loaded data page and add to middle of private LRU list

Num\_unfix\_void\_to\_shared\_mid      Accumulator

Unfix newly loaded data page and add to middle of shared LRU list

|                                      |             |                                                                       |
|--------------------------------------|-------------|-----------------------------------------------------------------------|
| Num_unfix_lru1_private_to_shared_mid | Accumulator | Unfix data page and move from zone 1 of private list to shared middle |
| Num_unfix_lru2_private_to_shared_mid | Accumulator | Unfix data page and move from zone 2 of private list to shared middle |
| Num_unfix_lru3_private_to_shared_mid | Accumulator | Unfix data page and move from zone 3 of private list to shared middle |
| Num_unfix_lru2_private_keep          | Accumulator | Unfix data page and keep it in zone 2 of private list                 |
| Num_unfix_lru2_shared_keep           | Accumulator | Unfix data page and keep it in zone 2 of shared list                  |
| Num_unfix_lru2_private_to_top        | Accumulator | Unfix data page and boost it from zone 2 of private list to its top   |
| Num_unfix_lru2_shared_to_top         | Accumulator | Unfix data page and boost it from zone 2 of shared list to its top    |
| Num_unfix_lru3_private_to_top        | Accumulator | Unfix data page and boost it from zone 3 of private list to its top   |
| Num_unfix_lru3_shared_to_top         | Accumulator | Unfix data page and boost it from zone 3 of shared list to its top    |

|                                      |             |                                                                                    |
|--------------------------------------|-------------|------------------------------------------------------------------------------------|
| Num_unfix_lru1_private_keep          | Accumulator | Unfix data page and keep it in zone 1 of private list                              |
| Num_unfix_lru2_shared_keep           | Accumulator | Unfix data page and keep it in zone 2 of shared list                               |
| Num_unfix_void_to_private_mid_vacuum | Accumulator | Unfix newly loaded data page and add to middle of private LRU list (vacuum thread) |
| Num_unfix_lru1_any_keep_vacu         | Accumulator | Unfix data page and keep it in zone 1 of private/shared list (vacuum thread)       |
| Num_unfix_lru2_any_keep_vacu         | Accumulator | Unfix data page and keep it in zone 2 of private/shared list (vacuum thread)       |
| Num_unfix_lru3_any_keep_vacu         | Accumulator | Unfix data page and keep it in zone 3 of private/shared list (vacuum thread)       |
| Num_unfix_void_aout_found            | Accumulator | Newly loaded data page was found in AOUT list                                      |
| Num_unfix_void_aout_not_found        | Accumulator | Newly loaded data page was not found in AOUT list                                  |
| Num_unfix_void_aout_found_vacu       | Accumulator | Newly loaded data page was found in AOUT list (vacuum thread)                      |

|                                      |             |                                                                                                                                                                                                                                              |
|--------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_unfix_void_aout_not_found_vacuum | Accumulator | Newly loaded data page was not found in AOUT list (vacuum thread)                                                                                                                                                                            |
| Num_data_page_unfix_ext              | Complex     | Number of data page unfixes classified by: <ul style="list-style-type: none"> <li>- module (system, worker, vacuum)</li> <li>- page type</li> <li>- dirty or not</li> <li>- dirtied by holder or not</li> <li>- holder latch mode</li> </ul> |

### Page buffer I/O

| Stat name                    | Stat type     | Description                                                                                                                                           |
|------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data_page_buffer_hit_ratio   | Computed      | Hit ratio of data page buffers<br>$\frac{(\text{Num\_data\_page\_fetches} - \text{Num\_data\_page\_ioreads}) * 100}{\text{Num\_data\_page\_fetches}}$ |
| Num_adaptive_flush_pages     | Accumulator   | The number of data pages requested from adaptive flush controller.                                                                                    |
| Num_adaptive_flush_log_pages | Accumulator   | The number of log data pages requested from adaptive flush controller                                                                                 |
| Num_adaptive_flush_max_pages | Accumulator   | The total number of page tokens assigned by adaptive flush controller                                                                                 |
| ..compensate_flush           | Counter/timer |                                                                                                                                                       |

|                                   |               |                                                                                   |
|-----------------------------------|---------------|-----------------------------------------------------------------------------------|
|                                   |               | The number and duration of flush compensations force by adaptive flush controller |
| ..assign_direct_bcb               | Counter/timer | The number and duration of assigning bcb's directly to waiters                    |
| ..wake_flush_waiter               | Counter/timer | The number and duration of waking up a thread waiting for bcb                     |
| ..flush_collect                   | Counter/timer | The number and duration of flush thread collecting BCB sets                       |
| ..flush_flush                     | Counter/timer | The number and duration of flush thread flushing BCB sets                         |
| ..flush_sleep                     | Counter/timer | The number and duration of flush thread pauses                                    |
| ..flush_collect_per_page          | Counter/timer | The number and duration of flush thread collecting one BCB                        |
| ..flush_flush_per_page            | Counter/timer | The number and duration of flush thread flushing one BCB                          |
| Num_data_page_writes              | Accumulator   | The total number of data pages flushed to disk                                    |
| Num_data_page_dirty_to_post_flush | Accumulator   |                                                                                   |

|                                             |             |                                                                                                          |
|---------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------|
|                                             |             | Number of flushed pages sent to post-flush thread for processing                                         |
| Num_data_page_skipped_flush                 | Accumulator | The total number of BCB's that flush thread skipped                                                      |
| Num_data_page_skipped_flush_need_wal        | Accumulator | The number of BCB's that flush thread skipped because it required log data pages be flushed first        |
| Num_data_page_skipped_flush_already_flushed | Accumulator | The number of BCB's that flush thread skipped because they have been flushed already                     |
| Num_data_page_skipped_flush_fixed_or_hot    | Accumulator | The number of BCB's that flush thread skipped because they are fixed or have been fixed since collected. |

### Page buffer victimization

| Stat name   | Stat type     | Description                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ..alloc_bcb | Counter/timer | <p>The number and duration of BCB allocation to store new data page.</p> <p>When a database is just started, the page buffer has available BCB's ready to be picked. However, once page buffer becomes full all BCB's are in use, one must be victimized. The time tracked here</p> |

|                                          |               |                                                                                                |
|------------------------------------------|---------------|------------------------------------------------------------------------------------------------|
|                                          |               | includes BCB victimization and loading from disk.                                              |
| ..alloc_bcb_search_victim                | Counter/timer | The number and duration of searches through all LRU lists for victims                          |
| ..alloc_bcb_cond_wait_high_prio          | Counter/timer | The number and duration of direct victim waits in high-priority queue                          |
| ..alloc_bcb_cond_wait_low_prio           | Counter/timer | The number and duration of direct victim waits in low-priority queue                           |
| Num_alloc_bcb_prioritize_vacuum          | Accumulator   | The number of vacuum direct victim waits in high-priority queue                                |
| Num_alloc_bcb_wait_threads_high_priority | Snapshot      | The current number of direct victim waiters in high-priority queue                             |
| Num_alloc_bcb_wait_threads_low_priority  | Snapshot      | The current number of direct victim waiters in low-priority queue                              |
| Num_flushed_bcbs_wait_for_direct_victim  | Snapshot      | The current number of BCB's waiting for post-flush thread to process them and assign directly. |
| Num_victim_use_invalid_bcb               | Accumulator   | The number of BCB's allocated from invalid list                                                |

|                                                   |               |                                                                                                                                     |
|---------------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| ..alloc_bcb_get_victim_search_own_private_list    | Counter/timer | The number and duration of getting a victim from own private list                                                                   |
| ..alloc_bcb_get_victim_search_others_private_list | Counter/timer | The number and duration of getting a victim from other private lists                                                                |
| ..alloc_bcb_get_victim_search_shared_list         | Counter/timer | The number and duration of getting a victim from a shared list                                                                      |
| Num_data_page_avoid_victim                        | Accumulator   | The number of BCB's that cannot be victimized because they are in process of being flushed to disk                                  |
| Num_victim_assign_direct_vacuum_void              | Accumulator   | The number of direct victims assigned from void zone by vacuum worker                                                               |
| Num_victim_assign_direct_vacuum_lru               | Accumulator   | The number of direct victims assigned from LRU zone 3 by vacuum worker                                                              |
| Num_victim_assign_direct_flush                    | Accumulator   | The number of direct victims assigned by flush thread                                                                               |
| Num_victim_assign_direct_panic                    | Accumulator   | The number of direct victims assigned by panicked LRU searches. If there are a lot of waiters for victims, threads that found other |

victims while searching LRU list, will also try to assign more directly.  
Page buffer maintenance thread assignments are also counted here

Num\_victim\_assign\_direct\_a  
djust\_lru

Accumulator

The number of direct victims assigned when BCB falls to LRU zone 3

Num\_victim\_assign\_direct\_a  
djust\_lru\_to\_vacuum

Accumulator

The number of BCB's falling to LRU zone 3 **not** assigned as direct victims because a vacuum thread is expected to access it

Num\_victim\_assign\_direct\_s  
earch\_for\_flush

Accumulator

The number of direct victims assigned by flush thread while collecting BCB sets for flush

Num\_victim\_shared\_lru\_suc  
cess

Accumulator

The number of successful victim searches in shared LRU lists

Num\_victim\_own\_private\_lr  
u\_success

Accumulator

The number of successful victim searches in own private LRU lists

Num\_victim\_other\_private\_l  
ru\_success

Accumulator

The number of successful victim searches in other private LRU lists

|                                   |             |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Num_victim_shared_lru_fail        | Accumulator | The number of failed victim searches in shared LRU lists                                                                                                                                                                                                                                                                                    |
| Num_victim_own_private_lru_fail   | Accumulator | The number of failed victim searches in own private LRU lists                                                                                                                                                                                                                                                                               |
| Num_victim_other_private_lru_fail | Accumulator | The number of failed victim searches in other private LRU lists                                                                                                                                                                                                                                                                             |
| Num_victim_all_lru_fail           | Accumulator | <p>The number of unlucky streaks to find victims in the sequence:</p> <ol style="list-style-type: none"> <li>1. Own private LRU list (if over quota)</li> <li>2. Other private LRU list (if own private is over quota)</li> <li>3. Shared LRU list</li> </ol> <p>(this is simplified explanation, see <i>pgbuf_get_victim</i> function)</p> |
| Num_victim_get_from_lru           | Accumulator | The total number of victim searches in any LRU list                                                                                                                                                                                                                                                                                         |
| Num_victim_get_from_lru_was_empty | Accumulator | The number of victim searches in any LRU list that stop immediately because candidate count is zero                                                                                                                                                                                                                                         |
| Num_victim_get_from_lru_failed    | Accumulator | The number of failed victim searches in any LRU list although the candidate count was not zero                                                                                                                                                                                                                                              |

|                                      |             |                                                                                                                                       |
|--------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Num_victim_get_from_lru_b<br>ad_hint | Accumulator | The number of failed victim searches in any LRU list because victim was wrong                                                         |
| Num_lfcq_prv_get_total_calls         | Accumulator | The number of victim searches in non-zero candidate private LRUs queue                                                                |
| Num_lfcq_prv_get_empty               | Accumulator | The number of times non-zero candidate private LRUs queue was empty                                                                   |
| Num_lfcq_prv_get_big                 | Accumulator | The number of victim searches in only very big non-zero candidate private LRUs queue (in this context, very big means way over quota) |
| Num_lfcq_shr_get_total_calls         | Accumulator | The number of victim searches in non-zero candidate shared LRUs queue                                                                 |
| Num_lfcq_shr_get_empty               | Accumulator | The number of times non-zero candidate shared LRUs queue was empty                                                                    |
| Num_lfcq_big_private_lists           | Snapshot    | The current number of very big non-zero candidate private LRU lists                                                                   |
| Num_lfcq_private_lists               | Snapshot    | The current number of non-zero candidate private LRU lists                                                                            |

|                       |          |                                                           |
|-----------------------|----------|-----------------------------------------------------------|
| Num_lfcq_shared_lists | Snapshot | The current number of non-zero candidate shared LRU lists |
|-----------------------|----------|-----------------------------------------------------------|

### Double write buffer

| Stat name                       | Stat type     | Description                                                            |
|---------------------------------|---------------|------------------------------------------------------------------------|
| ..DWB_flush_block               | Counter/timer | The number of blocks flushed and total writing duration                |
| ..DWB_file_sync_helper          | Counter/timer | The number and duration of files synchronized by DWB helper            |
| ..DWB_flush_block_cond_wait     | Counter/timer | The number and duration of DWB thread waits                            |
| ..DWB_flush_block_sort          | Counter/timer | The number and duration of sorting pages for flush                     |
| ..DWB_decache_pages_after_write | Counter/timer | The number and duration of removing pages from DWB cache after flush   |
| ..DWB_wait_flush_block          | Counter/timer | The number and duration of waiting for block to be flush to add a page |
| ..DWB_wait_file_sync_helper     | Counter/timer | The number and duration of waiting for DWB helper to sync file         |
| ..DWB_flush_force               | Counter/timer |                                                                        |

The number and duration of forced full DWB flushes

Num\_dwb\_flushed\_block\_volumes

Complex

A histogram of number of files synchronized by each block flush  
(last value is for ten or more files)

### MVCC Snapshot

**Stat name**

**Stat type**

**Description**

Time\_get\_snapshot\_acquire\_time:

Accumulator

Total time consumed by all transactions to get a snapshot

Count\_get\_snapshot\_retry:

Accumulator

The number of retries to acquire MVCC snapshot

Time\_tran\_complete\_time:

Accumulator

Time spent to invalidate snapshot and MVCCID on commit/rollback

Time\_get\_oldest\_mvcc\_acquire\_time:

Accumulator

Time spend to acquire "global oldest MVCC ID"

Count\_get\_oldest\_mvcc\_retry:

Accumulator

The number of retries to acquire "global oldest MVCC ID"

Num\_mvcc\_snapshot\_ext

Complex

Number of data page fixes classified by:  
- snapshot type  
- insert/delete MVCCID's status  
- visible/invisible

## Thread workers

Statistics collected by thread worker pools:

| Stat name             | Stat type     | Description                                                                                              |
|-----------------------|---------------|----------------------------------------------------------------------------------------------------------|
| ..start_thread        | Counter/timer | The number and duration of starting new threads                                                          |
| ..create_context      | Counter/timer | The number and duration of creating thread context                                                       |
| ..execute_task        | Counter/timer | The number and duration of executed tasks                                                                |
| ..retire_task         | Counter/timer | The number and duration of retiring task objects                                                         |
| ..found_task_in_queue | Counter/timer | The number of tasks found in queue and the duration of claiming from queue after finishing previous task |
| ..wakeup_with_task    | Counter/timer | The number of tasks assigned to threads on standby and the duration to wakeup thread                     |
| ..recycle_context     | Counter/timer | The number and duration of thread context recyclings between task executions                             |
| ..retire_context      | Counter/timer | The number and duration of retired thread contexts                                                       |

Statistics are collected from two worker pools:

- **Thread\_stats\_counters\_timers:** statistics for workers executing client requests.
- **Thread\_loaddb\_stats\_counters\_timers:** statistics for workers loading data into database (using **loaddb** command). *At least one load session must be active to see these statistics.*

### Thread daemons

Statistics collected by background daemon threads:

| Stat name             | Stat type   | Description                                                  |
|-----------------------|-------------|--------------------------------------------------------------|
| ..daemon_loop_count   | Accumulator | The number of loops executed by daemon thread                |
| ..daemon_execute_time | Accumulator | The total duration spent by daemon thread on execution       |
| ..daemon_pause_time   | Accumulator | The total duration spent by daemon thread between executions |
| ..looper_sleep_count  | Accumulator | The number of times thread looper was put to sleep           |
| ..looper_sleep_time   | Accumulator | The total duration thread looper spent on sleep              |
| ..looper_reset_count  | Accumulator | The number of times an incremental looper is reset by wakeup |

|                            |             |                                                                     |
|----------------------------|-------------|---------------------------------------------------------------------|
| ..waiter_wakeup_count      | Accumulator | The number of wakeup requests on daemon thread                      |
| ..waiter_lock_wakeup_count | Accumulator | The number of wakeup requests on daemon thread that required lock   |
| ..waiter_sleep_count       | Accumulator | The number of times daemon thread went to sleep                     |
| ..waiter_timeout_count     | Accumulator | The number of daemon thread waits ended with timeout                |
| ..waiter_no_sleep_count    | Accumulator | The number of times daemon thread spins with no wait                |
| ..waiter_awake_count       | Accumulator | The number of times daemon thread is awoken by other thread request |
| ..waiter_wakeup_delay_time | Accumulator | The total duration of awaking daemon thread                         |

Statistics are collected for next daemon threads:

| Daemon name                   | Description                                       |
|-------------------------------|---------------------------------------------------|
| Page_flush_daemon_thread      | Background thread that flushes data pages to disk |
| Page_post_flush_daemon_thread |                                                   |

|                                  |                                                                                      |
|----------------------------------|--------------------------------------------------------------------------------------|
|                                  | Background thread that may reclaim memory space occupied by flushes data pages       |
| Page_flush_control_daemon_thread | Background thread that controls data flush rate                                      |
| Page_maintenance_daemon_thread   | Background thread that recalculates quotas for private LRU lists                     |
| Deadlock_detect_daemon_thread    | Background thread that looks for deadlocks and chooses victims to unblock the system |
| Log_flush_daemon_thread          | Background thread that flushes log data to disk                                      |

### Note

(\*) : These statistics measure the non-MVCC operations or MVCC operations which are performed in-place (decided internally)

### **-o, --output-file=FILE**

**-o** options is used to store statistics information of server processing for the database to a specified file.

```
cubrid statdump -o statdump.log testdb
```

### **-c, --cumulative**

You can display the accumulated operation statistics information of the target database server by using the **-c** option.

Num\_data\_page\_fix\_ext, Num\_data\_page\_unfix\_ext, Time\_data\_page\_hold\_acquire\_time, Time\_data\_page\_fix\_acquire\_time information can be output only when this option is specified; however, these informations will be omitted because they are for CUBRID Engine developers.

By combining this with the **-i** option, you can check the operation statistics information at a specified interval.

```
cubrid statdump -i 5 -c testdb
```

### **-s, --substr=STRING**

You can display statistics about items, the names of which include the specified string by using **-s** option.

The following example shows how to display statistics about items, the names of which include “data”.

```
cubrid statdump -s data testdb

*** SERVER EXECUTION STATISTICS ***

**Note**

Each status information consists of 64-bit INTEGER data and the corresponding statistics information can be lost if the accumulated value exceeds the limit (highly unlikely though).

**Note**

Some sets of performance statistics are activated/deactivated by **extended\_statistics\_activation** system parameter. Each set is represented by a value power of two. To be activated, it needs to be present in the base-2 representation of the system parameter. This is the lists of sets that can be manipulated:

| Value | Name                  | Active Default | Description                                                                                                                                                                                                                                        |
|-------|-----------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## lockdb

The **cubrid lockdb** utility is used to check the information on the lock being used by the current transaction in the database.

```
cubrid lockdb [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **lockdb**: A command used to check the information on the lock being used by the current transaction in the database.
- *database\_name*: The name of the database where lock information of the current transaction is to be checked.

The following example shows how to display lock information of the *testdb* database on a screen without any option.

```
cubrid lockdb testdb
```

The following shows [options] available with the **cubrid lockdb** utility.

### -o, --output-file=FILE

The **-o** option displays the lock information of the *testdb* database as a output.txt.

```
cubrid lockdb -o output.txt testdb
```

### **-c, --contention**

The **-c** option displays information on locks that are in contention.

```
cubrid lockdb -c testdb
```

## Output Contents

The output contents of **cubrid lockdb** are divided into three logical sections.

- Server lock settings
- Clients that are accessing the database
- The contents of an object lock table

### Server lock settings

The first section of the output of **cubrid lockdb** is the database lock settings.

```
*** Lock Table Dump ***  
Lock Escalation at = 100000, Run Deadlock interval = 0
```

The lock escalation level is 100,000 records, and the interval to detect deadlock is set to 0 seconds.

For a description of the related system parameters, **lock\_escalation** and **deadlock\_detection\_interval**, see [Concurrency/Lock-Related Parameters](#).

### Clients that are accessing the database

The second section of the output of **cubrid lockdb** includes information on all clients that are connected to the database. This includes the transaction index, program name, user ID, host name, process ID, isolation level and lock timeout settings of each client.

```
Transaction (index 1, csql, dba@cubridb|12854)  
Isolation COMMITTED READ  
Timeout_period : Infinite wait
```

Here, the transaction index is 1, the program name is csql, the user ID is dba, the host name is cubridb, the client process identifier is 12854, the isolation level is COMMITTED READ and the lock timeout is unlimited.

A client for which transaction index is 0 is the internal system transaction. It can obtain the lock at a specific time, such as the processing of a checkpoint by a database. In most cases, however, this transaction will not obtain any locks.

Because **cubrid lockdb** utility accesses the database to obtain the lock information, the **cubrid lockdb** is an independent client and will be output as such.

### Object lock table

The third section of the output of the **cubrid lockdb** includes the contents of the object lock table. It shows which client has the lock for which object in which mode, and which client is waiting for which object in which mode. The first part of the result of the object lock table shows how many objects are locked and how many lock objects are allocated to memory. CUBRID reuses lock objects for performance, but if the number of locks exceeds the value of **lock\_escalation**, the lock objects are freed from memory at the end of the transaction. For more details, see [Concurrency/Lock-Related Parameters](#).

#### Object lock Table:

```
Current number of objects which are locked = 100
Current number of objects which are allocated = 1000
Current size of objects which are allocated = 242K
```

**cubrid lockdb** outputs the OID, object type and table name of each object that obtained lock. In addition, it outputs the number of transactions that hold lock for the object (*Num holders*), the number of transactions (*Num blocked-holders*) that hold lock but are blocked since it could not convert the lock to the upper lock (e.g., conversion from **SCH\_S\_LOCK** to **SCH\_M\_LOCK**), and the number of different transactions that are waiting for the lock of the object (*Num waiters*). It also outputs the list of client transactions that hold lock, blocked client transactions and waiting client transactions. For rows, but not class, MVCC information is also shown.

The example below shows an object in which the object type is a class, that will be blocked because the class OID( 0| 62| 5 ) that has **IX\_LOCK** for transaction 1 and **SCH\_S\_LOCK** for transaction 2 cannot be converted into **SCH\_M\_LOCK**. It also shows that transaction 3 is blocked because transaction 2 is waiting for **SCH\_M\_LOCK** even when transaction 3 is only waiting for **SCH\_S\_LOCK**.

```
OID = 0| 62| 5
Object type: Class = athlete.
Num holders = 1, Num blocked-holders= 1, Num waiters = 1
LOCK HOLDERS :
    Tran_index = 1, Granted_mode = IX_LOCK, Count = 1, Nsubgranules
= 1
BLOCKED LOCK HOLDERS :
    Tran_index = 2, Granted_mode = SCH_S_LOCK, Count = 1,
Nsubgranules = 0
    Blocked_mode = SCH_M_LOCK
```

```

                                Start_waiting_at = Wed Feb 3 14:44:31 2016
                                Wait_for_secs = -1
LOCK WAITERS :
    Tran_index = 3, Blocked_mode = SCH_S_LOCK
                                Start_waiting_at = Wed Feb 3 14:45:14 2016
                                Wait_for_secs = -1

```

The next example shows an instance of class, object OID( 2| 50| 1 ), that was inserted by transaction 1 which holds **X\_LOCK** on the object. The class has a unique index and the key of inserted instance is about to be modified by transaction 2, which is blocked until transaction 1 is completed. The **-c** option displays only the information on locks that are involved in contention.

```

OID = 2|50|1
Object type: instance of class ( 0| 62| 5) = athlete.
MVCC info: insert ID = 6, delete ID = missing.
Num holders = 1, Num blocked-holders= 1, Num waiters = 1
LOCK HOLDERS :
    Tran_index = 1, Granted_mode = X_LOCK, Count = 1
LOCK WAITERS :
    Tran_index = 2, Blocked_mode = X_LOCK
                                Start_waiting_at = Wed Feb 3 14:45:14 2016
                                Wait_for_secs = -1

```

*Granted\_mode* refers to the mode of the obtained lock, and *Blocked\_mode* refers to the mode of the blocked lock. *Start\_waiting\_at* refers to the time at which the lock was requested, and *Wait\_for\_secs* refers to the waiting time of the lock. The value of *Wait\_for\_secs* is determined by **lock\_timeout**, a system parameter.

When the object type is a class (table), *Nsubgranules* is displayed, which is the sum of the record locks and the key locks obtained by a specific transaction in the table.

```

OID = 0| 62| 5
Object type: Class = athlete.
Num holders = 2, Num blocked-holders= 0, Num waiters= 0
LOCK HOLDERS:
Tran_index = 3, Granted_mode = IX_LOCK, Count = 2, Nsubgranules = 0
Tran_index = 1, Granted_mode = IX_LOCK, Count = 3, Nsubgranules = 1
Tran_index = 2, Granted_mode = IX_LOCK, Count = 2, Nsubgranules = 1

```

## tranlist

The **cubrid tranlist** is used to check the transaction information of the target database.

```
cubrid tranlist [options] database_name
```

If you omit the [options], it displays the total information about each transaction.

“cubrid tranlist demodb” outputs the similar result with “cubrid killtran -q demodb”, but tranlist outputs more items; “User name” and “Host name”. “cubrid tranlist -s demodb” outputs the same result with “cubrid killtran -d demodb”.

The following shows what information is displayed when you run “cubrid tranlist demodb”.

```
$ cubrid tranlist demodb
```

| Tran index   | User name  | Host name | Process id |
|--------------|------------|-----------|------------|
| Program name | Query time | Tran time | Wait for   |
| lock holder  | SQL_ID     | SQL Text  |            |

```
-----
-----
1(ACTIVE)          public      test-server          1681
broker1_cub_cas_1  0.00
0.00              -1          *** empty ***
2(ACTIVE)          public      test-server          1682
broker1_cub_cas_2  0.00
0.00              -1          *** empty ***
3(ACTIVE)          public      test-server          1683
broker1_cub_cas_3  0.00
0.00              -1          *** empty ***
4(ACTIVE)          public      test-server          1684
broker1_cub_cas_4  1.80          1.80
3, 2, 1      e5899a1b76253  update ta set a = 5 where a > 0
5(ACTIVE)          public      test-server          1685
broker1_cub_cas_5  0.00
0.00              -1          *** empty ***
-----
-----
-----
```

```
SQL_ID: e5899a1b76253
```

```
Tran index : 4
```

```
update ta set a = 5 where a > 0
```

In the above example, when each three transaction is running INSERT statement, UPDATE statement is tried to run in the other transaction. In the above, UPDATE statement with “Tran index” 4 waits for the transactions 3,2,1, which are found in “Wait for lock holder”, to be ended.

“SQL Text” is SQLs which are stored into the query plan cache; this is printed out as **empty** when this query’s execution is terminated.

Each column’s meaning is as following.

- Tran index : the index of transaction

- User name: database user's name
- Host name: host name of CAS which running this transaction
- Process id : client's process id
- Program name : program name of a client
- Query time : total execution time for the running query (unit: second)
- Tran time : total run time for the current transaction (unit: second)
- Wait for lock holder : the list of transactions which own the lock when the current transaction is waiting for a lock
- SQL\_ID: an ID for SQL Text
- SQL Text : running SQL text (maximum 30 characters)

Transaction status messages, which are shown on "Tran index", are as follows.

- ACTIVE : active state
- RECOVERY : recovering transaction
- COMMITTED : transaction which is already committed and will be ended soon.
- COMMITTING : transaction which is committing
- ABORTED : transaction which is rolled back and will be ended soon.
- KILLED : transaction which is forcefully killed by the server.

The following shows [options] available with the **cubrid tranlist** utility.

```
-s, --summary          print summarized information of
transaction
--sort-key=COLUMN_NUMBER column number to be sorted
--reverse              reverse the sort result
```

#### **-s, --summary**

This option outputs only summarized information(it omits query execution information or locking information).

```
$ cubrid tranlist -s demodb
```

```
Tran index      User name      Host name      Process
id      Program name
-----
```

```

-----
1(ACTIVE)                public    test-server    1681
broker1_cub_cas_1
2(ACTIVE)                public    test-server    1682
broker1_cub_cas_2
3(ACTIVE)                public    test-server    1683
broker1_cub_cas_3
4(ACTIVE)                public    test-server    1684
broker1_cub_cas_4
5(ACTIVE)                public    test-server    1685
broker1_cub_cas_5
-----
-----

```

### --sort-key=NUMBER

This option outputs the ascending values sorted by the NUMBERth column. If the type of the column is the number, it is sorted by the number; if not, it is sorted by the string. If this option is omitted, the output is sorted by "Tran index".

The following is an example which outputs the sorted information by specifying the "Process id", the 4th column.

```

$ cubrid tranlist --sort-key=4 demodb

Tran index      User name      Host name      Process id
Program name    Query time    Tran time      Wait for
lock holder     SQL_ID        SQL Text
-----
-----
1(ACTIVE)       public        test-server    1681
broker1_cub_cas_1
0.00            -1            *** empty ***
2(ACTIVE)       public        test-server    1682
broker1_cub_cas_2
0.00            -1            *** empty ***
3(ACTIVE)       public        test-server    1683
broker1_cub_cas_3
0.00            -1            *** empty ***
4(ACTIVE)       public        test-server    1684
broker1_cub_cas_4
1.80            3, 1, 2      e5899a1b76253  update ta set
a = 5 where a > 0
5(ACTIVE)       public        test-server    1685
broker1_cub_cas_5
0.00            -1            *** empty ***
-----
-----
-----

```

```
SQL_ID: e5899a1b76253
Tran index : 4
update ta set a = 5 where a > 0
```

### --reverse

This option outputs the reversely sorted values.

The following is an example which outputs the reversely sorted values by the “Tran index”.

```
Tran index      User name      Host name      Process id
Program name    Query time     Tran time      Wait for
lock holder     SQL_ID         SQL Text
-----
5(ACTIVE)      public         test-server    1685
broker1_cub_cas_5 0.00
0.00           -1            *** empty ***
4(ACTIVE)      public         test-server    1684
broker1_cub_cas_4 1.80          1.80
3, 2, 1        e5899a1b76253 update ta set a = 5 where a > 0
3(ACTIVE)      public         test-server    1683
broker1_cub_cas_3 0.00
0.00           -1            *** empty ***
2(ACTIVE)      public         test-server    1682
broker1_cub_cas_2 0.00
0.00           -1            *** empty ***
1(ACTIVE)      public         test-server    1681
broker1_cub_cas_1 0.00
0.00           -1            *** empty ***
-----
-----
-----

SQL_ID: e5899a1b76253
Tran index : 4
update ta set a = 5 where a > 0
```

## killtran

The **cubrid killtran** is used to check transactions or abort specific transaction. Only a **DBA** can use options for killing a transaction.

```
cubrid killtran [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management

- **killtran**: A utility that manages transactions for a specified database
- *database\_name*: The name of database whose transactions are to be killed

Some [options] refer to killing specified transactions; others refer to print active transactions. If no option is specified, **-d** is specified by default so all transactions are displayed on the screen.

```
cubrid killtran demodb
```

| Tran index<br>name | User name | Host name | Process id | Program |
|--------------------|-----------|-----------|------------|---------|
| 1(ACTIVE)          | dba       | myhost    | 664        |         |
| cub_cas            |           |           |            |         |
| 2(ACTIVE)          | dba       | myhost    | 6700       |         |
| csql               |           |           |            |         |
| 3(ACTIVE)          | dba       | myhost    | 2188       |         |
| cub_cas            |           |           |            |         |
| 4(ACTIVE)          | dba       | myhost    | 696        |         |
| csql               |           |           |            |         |
| 5(ACTIVE)          | public    | myhost    | 6944       |         |
| csql               |           |           |            |         |

The following shows [options] available with the **cubrid killtran** utility.

```
-i, --kill-transaction-index=INDEX kill transaction with transaction
INDEX
    --kill-user-name=ID            kill all transactions with user ID
    --kill-host-name=HOST         kill all transactions with client
HOST
    --kill-program-name=NAME      kill all transactions with client
program NAME
    --kill-sql-id=SQL_ID          kill all transactions with SQL_ID
-p, --dba-password=PASS          password of the DBA user
-q, --query-exec-info            display information about query
execution information of active transactions
-d, --display-information        display information about active
transactions
-f, --force                      kill the transaction without a
prompt for verification
```

#### **-i, --kill-transaction-index=ID1,ID2,ID3**

This option kills transactions in a specified index. Several transaction indexes can be specified by separating with comma(.). If there is an invalid transaction ID among several IDs, it is ignored.

```
$ cubrid killtran -i 1 demodb
Ready to kill the following transactions:
```

| Tran index<br>id | Program name | User name | Host name | Process |
|------------------|--------------|-----------|-----------|---------|
| 1(ACTIVE)        |              | DBA       | myhost    |         |
| 15771            | csql         |           |           |         |
| 2(ACTIVE)        |              | DBA       | myhost    |         |
| 2171             | csql         |           |           |         |

```

Do you wish to proceed ? (Y/N)y
Killing transaction associated with transaction index 1
Killing transaction associated with transaction index 2

```

**--kill-user-name=ID**

This option kills transactions for a specified OS user ID.

```
cubrid killtran --kill-user-name=os_user_id demodb
```

**--kill-host-name=HOST**

This option kills transactions of a specified client host.

```
cubrid killtran --kill-host-name=myhost demodb
```

**--kill-program-name=NAME**

This option kills transactions for a specified program.

```
cubrid killtran --kill-program-name=cub_cas demodb
```

**--kill-sql-id=SQL\_ID**

This option kills transactions for a specified SQL ID.

```
cubrid killtran --kill-sql-id=5377225ebc75a demodb
```

**-p, --dba-password=PASSWORD**

This option can only be used, if using killing option such as **-i** and **--kill** options. A value followed by the **-p** option is a password of the **DBA**, and should be entered in the prompt.

**-q, --query-exec-info**

The difference with the output of “cubrid tranlist” command is that there are no “User name” column and “Host name” column. See [tranlist](#).

### **-d, --display-information**

This is the default option and it displays the summary of transactions. Its output is the same as the output of “cubrid tranlist” with **-s** option. See [tranlist -s](#)

### **-f, --force**

This option omits a prompt to check transactions to be stopped.

```
cubrid killtran -f -i 1 demodb
```

## checkdb

The **cubrid checkdb** utility is used to check the consistency of a database. You can use **cubrid checkdb** to identify data structures that are different from indexes by checking the internal physical consistency of the data and log volumes. If the **cubrid checkdb** utility reveals any inconsistencies, you must try automatic repair by using the **--repair** option.

```
cubrid checkdb [options] database_name [schema_name.table_name [{,
schema_name.table_name}]]
```

- **cubrid**: An integrated utility for CUBRID service and database management.
- **checkdb**: A utility that checks the data consistency of a specific database.
- *database\_name*: The name of the database whose consistency status will be either checked or restored.
- *schema\_name*: The schema name of the table.
- *table\_name*: List the table names for consistency check or recovery

The following shows [options] available with the **cubrid checkdb** utility.

```
-S, --SA-mode      stand-alone mode execution
-C, --CS-mode      client-server mode execution
-r, --repair        repair when inconsistency is found
  --check-prev-link check only previous links of indices
  --repair-prev-link repair previous links of indices
-i, --input-class-file=FILE input FILE of class names
  --check-file-tracker check all allocated pages of file
  --check-heap       check all pages of heap files
  --check-catalog     check catalog consistency
  --check-btree       check all btree indices
```

```
--check-class-name      check class name consistency  
--check-btree-entries  check entries of btree consistency  
-I, --index-name=INDEX_NAME  index name that will be checked only
```

### **-S, --SA-mode**

This option is used to access a database in standalone, which means it works without processing server; it does not have an argument. If **-S** is not specified, the system recognizes that a database is running in client/server mode.

```
cubrid checkdb -S demodb
```

### **-C, --CS-mode**

This option is used to access a database in client/server mode, which means it works in client/server process respectively; it does not have an argument. If **-C** is not specified, the system recognize that a database is running in client/server mode by default.

```
cubrid checkdb -C demodb
```

### **-r, --repair**

This option is used to restore an issue if a consistency error occurs in a database.

```
cubrid checkdb -r demodb
```

### **--check-prev-link**

This option is used to check if there are errors on previous links of an index.

```
$ cubrid checkdb --check-prev-link demodb
```

### **--repair-prev-link**

This option is used to restore if there are errors on previous links of an index.

```
$ cubrid checkdb --repair-prev-link demodb
```

### **-i, --input-class-file=FILE**

You can specify tables to check the consistency or to restore, by specifying the **-i FILE** option or listing the table names after a database name. Both ways can be used together. If a target is not specified, entire database will be a target of consistency check or restoration.

```
cubrid checkdb demodb public.table_1 public.table_2  
cubrid checkdb -r demodb public.table_1 public.table_2
```

```
cubrid checkdb -r -i table_list.txt demodb public.table_1
public.table_2
```

Empty string, tab, carriage return and comma are separators among table names in the table list file specified by **-i** option. The following example shows the table list file; from t1 to t10, it is recognized as a table for consistency check or restoration.

```
t1 t2 t3,t4 t5
t6, t7 t8 t9

t10
```

**--check-file-tracker**

Check about all pages of all files in file-trackers.

**--check-heap**

Check about all heap-files.

**--check-catalog**

Check the consistency about catalog information.

**--check-btree**

Check the validity about all B-tree indexes.

**--check-class-name**

Check the identical between the hash table of a class name and the class information(oid) brought from a heap file.

**--check-btree-entries**

Check the consistency of all B-tree entries.

**-I, --index-name=INDEX\_NAME**

Check if the index specified with this option about checking table. If you use this option, there is no heap validation check. Only one table and one index are permitted when you use this option; if you don't input a table name or input two tables, an error occurs.

## diagdb

You can check various pieces of internal information on the database with the **cubrid diagdb** utility. Information provided by **cubrid diagdb** is helpful in diagnosing the current status of the database or figuring out a problem.

## cubrid diagdb options database\_name

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **diagdb**: A command that is used to check the current storage state of the database by Dumping the information contained in the binary file managed by CUBRID in text format. It normally executes only when the database is in a stopped state. You can check the whole database or the file table, file size, heap size, class name or disk bitmap selectively by using the provided option.
- *database\_name*: The name of the database whose internal information is to be diagnosed.

The following shows [options] available with the **cubrid diagdb** utility.

```
-d, --dump-type=TYPE      TYPE of dump
-o, --output-file=FILE    redirect output messages to FILE
--emergency               emergency restart
```

### -d, --dump-type=TYPE

This option specifies the output range when you display the information of all files in the *demodb* database. If any option is not specified, the default value of -1 is used.

```
cubrid diagdb -d 1 demodb
```

The utility has 9 types of **-d** options as follows:

| Type | Description                          |
|------|--------------------------------------|
| -1   | Displays all database information.   |
| 1    | Displays file table information.     |
| 2    | Displays file capacity information.  |
| 3    | Displays heap capacity information.  |
| 4    | Displays index capacity information. |

|   |                                   |
|---|-----------------------------------|
| 5 | Displays class name information.  |
| 6 | Displays disk bitmap information. |
| 7 | Displays catalog information.     |
| 8 | Displays log information.         |
| 9 | Displays heap information.        |

### **-o, --output-file=FILE**

The **-o** option is used to store information of the parameters used in the server/client process of the database into a specified file. The file is created in the current directory. If the **-o** option is not specified, the message is displayed on a console screen.

```
cubrid diagdb -d8 -o logdump_output demodb
```

### **--emergency**

Use **--emergency** option to suppress recovery. **This option is meant ONLY for debugging, if there are recovery issues. It is recommended to backup your database before using this option.**

## paramdump

The **cubrid paramdump** utility outputs parameter information used in the server/client process.

```
cubrid paramdump [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management
- **paramdump**: A utility that outputs parameter information used in the server/client process
- *database\_name*: The name of the database in which parameter information is to be displayed.

The following shows [options] available with the **cubrid paramdump** utility.

```
-o, --output-file=FILE    redirect output message to FILE
-b, --both                dump both client and server parameters
```

|                      |                              |
|----------------------|------------------------------|
| <b>-S, --SA-mode</b> | stand-alone mode execution   |
| <b>-C, --CS-mode</b> | client-server mode execution |

**-o, --output-file=FILE**

The **-o** option is used to store information of the parameters used in the server/client process of the database into a specified file. The file is created in the current directory. If the **-o** option is not specified, the message is displayed on a console screen.

```
cubrid paramdump -o db_output demodb
```

**-b, --both**

The **-b** option is used to display parameter information used in server/client process on a console screen. If the **-b** option is not specified, only server-side information is displayed.

```
cubrid paramdump -b demodb
```

**-S, --SA-mode**

This option displays parameter information of the server process in standalone mode.

```
cubrid paramdump -S demodb
```

**-C, --CS-mode**

This option displays parameter information of the server process in client/server mode.

```
cubrid paramdump -C demodb
```

## tde

The **cubrid tde** utility is used to manage the TDE encryption of the database and can only be executed by the **DBA** user. With **cubrid tde** utility, you can change the key set on the database, add a new key, or remove a key in the key file stably. Also, you can inquire about the keys added to the key file and the key set on the database. For more information, see [TDE \(Transparent Data Encryption\)](#).

```
cubrid tde <operation> [option] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **tde**: A utility that manages TDE encryption applied to the database.

- *operation*: There are four types of operation: key addition, key deletion, key change, and showing keys' information. One operation must be set, and they are exclusive.
- *database\_name*: The name of the database on which TDE administration operations to be performed.

The following table shows <operation> available with the cubrid tde utility.

```
-s, --show-keys          print key information set on the
                        database and the key file (_keys)
-n, --generate-new-key  generate a new key in the key file
                        (_keys)
-d, --delete-key=KEY_INDEX delete a key in the key file (_keys)
-c, --change-key=KEY_INDEX change the key set on the database for
                        another key in the key file (_keys)
```

### **-s, --show-keys**

This option displays information about the keys set on the database and keys in the key file (\_keys).

```
$ cubrid tde -s testdb
Key File: /home/usr/CUBRID/databases/testdb/testdb_keys

The current key set on testdb:
Key Index: 2
Created on Fri Nov 27 11:14:54 2020
Set      on Fri Nov 27 11:15:30 2020

Keys Information:
Key Index: 0 created on Fri Nov 27 11:11:27 2020
Key Index: 1 created on Fri Nov 27 11:14:47 2020
Key Index: 2 created on Fri Nov 27 11:14:54 2020
Key Index: 3 created on Fri Nov 27 11:14:55 2020

The number of keys: 4
```

**The current key** section shows the information on the key set on the current database, which displays the index for the key in the key file, the creation time, and the set time. The set key can be identified by the key index and creation time, and a key change plan can be established with the set time.

**Keys Information** section shows the keys added and being managed in the key file, through which the key indexes and creation time of them is checked.

### **-n, --generate-new-key**

This option is used to add a new key to the key file (up to 128). If it is successful, the index of the added key is displayed, and this index is used to identify the key when changing or removing the key later. Information of added keys can be checked by **--show-keys**.

```
$ cubrid tde -n testdb
Key File: /home/usr/CUBRID/databases/testdb/testdb_keys

SUCCESS: A new key has been generated - key index: 1 created on
Tue Dec 1 11:30:47 2020
```

#### **-d, --delete-key=KEY\_INDEX**

This option is used to remove a key specified by index from the key file. The key currently set on the database cannot be removed.

```
$ cubrid tde -d 1 testdb
Key File: /home/usr/CUBRID/databases/testdb/testdb_keys

SUCCESS: The key (index: 1) has been deleted
```

#### **-c, --change-key=KEY\_INDEX**

This option is used to change the key set on the database to another key existing in the key file. When changing, both the previously set key and the new key to be set must exist.

```
$ cubrid tde -c 2 testdb
Key File: /home/usr/CUBRID/databases/testdb/testdb_keys

Trying to change the key from the key (index: 0) to the key
(index: 2)..
SUCCESS: The key has been changed from the key (index: 0) to the
key (index: 2)
```

To change the key set on the database, a user must first create a key to be set by the **--generate-new-key** option. The user can create a new key to change, or create multiple keys in advance for changing the key according to their own security plans.

The following table shows [options] available with the cubrid tde utility.

#### **-p, --dba-password=PASSWORD**

This option specifies the password of the DBA.

## vacuumdb

The **cubrid vacuumdb** utility is used to vacuum deleted records and unnecessary mvcc related information from records in the database. And it is also used to get the status information about the vacuum.

```
cubrid vacuumdb [options] database_name
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **vacuumdb**: A utility that vacuum deleted records and unnecessary mvcc related information from records in the database.
- *database\_name*: The name of the database to vacuum.

The following shows [options] available with the **cubrid vacuumdb** utility.

```
-o, --output-file=FILE      redirect output messages to FILE
--dump                      dump current state of vacuum
-S, --SA-mode              stand-alone mode execution
-C, --CS-mode              client-server mode execution
```

### **-o, --output-file=FILE**

This option is used to store the status information about the vacuum in a specified file. The file is created in the current directory. If the **-o** option is not specified, the message is displayed on a console screen.

```
cubrid vacuumdb -o db_output demodb
```

### **--dump**

This option is used to display the status information about the vacuum. It currently displays the first log page ID referenced by the vacuum and the log volume name in which it resides. Users can check the progress of the vacuum operation through the change of the first log page ID and they can know the minimum log volume to keep for the vacuum operation. It can be used with both the standalone mode and the client/server mode. If specified together with the **-C** option, information on indexes that have read more **leaf's overflow pages** than the threshold is also displayed, when the index is vacuumed. The related system parameters are **vacuum\_ovfp\_check\_duration** and **vacuum\_ovfp\_check\_threshold**.

```
cubrid vacuumdb --dump demodb
```

```
$ cubrid vacuumdb -C --dump demodb

*** Vacuum Dump ***
First log page ID referenced = 85653 (in demodb_lgar013)

*** Exceeding read threshold (1000 pages) for OID overflow pages
(OVFP), Since 09/04/23 08:53:50 ***
  Class name          Index name          Count          Num
of OVFP recent read  Max num of OVFP read
=====
=====
  dba.tm              v_idx              272451
1089 (09/04/23 10:49:52) 1478 (09/04/23 10:28:46)
  dba.tbl             idx              322728
1023 (09/04/23 09:53:47) 1475 (09/04/23 09:29:29)

$
```

- Exceeding read threshold (**1000** pages) : Shows vacuum\_ovfp\_check\_threshold parameter.
- Since **09/04/23 08:53:50** : Shows the time information when OVFP monitoring started
- Class name: Class name(table name), included the owner's name.
- Index name: Index name
- Count: The number of times an index's overflow pages were read by exceeding the threshold (vacuum\_ovfp\_check\_threshold) during index vacuum operation.
- Num of OVFP recent read: The latest time an index's overflow page was read by exceeded the threshold (vacuum\_ovfp\_check\_threshold) during index vacuum operation.
- Max num of OVFP read: The latest time an index's overflow page was maximally read by exceeding the threshold (vacuum\_ovfp\_check\_threshold) during index vacuum operation.

### **-S, --SA-mode**

This option performs vacuuming the database in standalone mode.

```
cubrid vacuumdb -S demodb
```

### **-C, --CS-mode**

This option performs vacuuming the database in client/server mode. But it is not currently supported to vacuum in this mode.

```
cubrid vacuumdb -C demodb
```

## flashback

The **cubrid flashback** utility is used to get SQL statements to rewind a specific committed transaction, and can only be executed by the **DBA** user. The system parameter **supplemental\_log** must be turned on, and flashback is supported only for DML executed after the **supplemental\_log** is set. This utility can only be performed in client/server mode and cannot be executed more than once simultaneously.

```
cubrid flashback [options] database_name owner_name.class_name1
[owner_name.class_name2, ...]
```

- **cubrid**: An integrated utility for the CUBRID service and database management.
- **flashback**: A utility that provides statements to rewind a specific transaction.
- *database\_name*: The name of the database whose transaction is to be rewound.
- *owner\_name.class\_name*: The classes to rewind. When specifying the class\_name, it must be specified along with the owner name.

The following shows what information is displayed when a user runs “cubrid flashback demodb dba.tbl”.

```
$ csql -u dba demodb

csql> CREATE TABLE tbl (a INT);
csql> INSERT INTO tbl VALUES (10);

$ cubrid flashback demodb dba.tbl

Flashback Summary
Number of Transaction: 1
Start date - End date: 03-05-2022:10:52:56 - 03-05-2022:11:02:56
Transaction id  User name          Start
time           End time           Num_insert  Num_update
Num_delete  Table
          135  DBA
03-05-2022:11:02:40  03-05-2022:11:02:41          1
0              0  dba.tbl
Enter transaction id (press -1 to quit): 135

delete from [dba.tbl] where [a] = 10 limit 1;
```

In the above example, when the flashback is executed, it displays information about transactions performed within the specified time period. If users do not specify a period, the transaction history up to 10 minutes before the current time is displayed. When the user selects a transaction ID, SQL statements are provided to execute the flashback on DML executed within the selected

transaction. The user must enter the transaction ID within 300 seconds which can be adjusted using the system parameter `flashback_timeout`.

Each column's meaning in the **Flashback Summary** is as following.

- Transaction id : The identifier of the transaction
- User name : Transaction user
- Start time : Transaction start time (approximate time)
- End time : Transaction end time
- Num\_insert : Number of insert operations executed within the transaction
- Num\_update : Number of update operations executed within the transaction
- Num\_delete : Number of delete operations executed within the transaction
- Table : List of tables for which DMLs have been performed within the transaction

#### Note

If users attempt to rewind a table on which a trigger is created, unintended results may be obtained. Users are recommended to disable triggers on the table before executing the flashback. For more information, see [ALTER TRIGGER](#).

#### Note

The flashback utility does not support complex data types such as SET, MULTiset, LIST, and JSON. When performing flashback on a class that includes columns with unsupported data types, those columns are displayed as having null values. In addition, for LOB type columns, only the location information of the file(LOB locator) is displayed, not the data itself.

The following shows [options] available with the **cubrid flashback** utility.

```
-o, --output-file=FILE      redirect output message to FILE
-u, --user=ID              specify the user who executed the SQL
statement to flashback
-p, --dba-password         password of the DBA user
-s, --start-date=DATE      specify starting DATE for flashback
-e, --end-date=DATE        specify end DATE for the flashback
--detail                   output a detailed information for each
```

SQL statement.

```
--oldest flashback is performed in
chronological order for SQL statements executed from start time to
end time;
```

### **-o, --output-file=FILE**

This option is used to store the SQL statements that can rewind a specific transaction in a specified file. If the **-o** option is not specified, the message is displayed on a console screen.

```
cubrid flashback -o db_output demodb dba.tbl
```

### **-u, --user=ID**

This option is used to specify the user who executed the SQL statements. If the **-u** option is not specified, then it searches for statements executed by all users.

```
$ csql -u public demodb

csql> CREATE TABLE tbl (a int);
csql> INSERT INTO tbl VALUES (10);

csql> CALL login ('dba', '') ON CLASS db_user;

csql> INSERT INTO public.tbl VALUES (20);

$ cubrid flashback -u public demodb dba.tbl

Flashback Summary
Number of Transaction: 1
Start date - End date: 03-05-2022:10:52:56 - 03-05-2022:11:02:56
Transaction id  User name          Start
time           End time           Num_insert  Num_update
Num_delete  Table
          135  PUBLIC
03-05-2022:11:02:40  03-05-2022:11:02:41          1
0              0 public.tbl
Enter transaction id (press -1 to quit): 135

delete from [public.tbl] where [a] = 10 limit 1;
```

### **-p, --dba-password=PASSWORD**

This option specifies the password of the dba. If the **-p** option is not specified, then the password should be entered in the prompt.

### **-s, --start-date=DATE**

This option specifies the start date in the dd-mm-yyyy:hh:mi:ss (e.g. 28-04-2022:14:10:00) format. It finds transactions that started after the specified time or are in progress at the specified time among committed transactions.

```
cubrid flashback -s 28-04-2022:14:10:00 demodb dba.tbl
```

### **-e, --end-date=DATE**

This option specifies the end date in the dd-mm-yyyy:hh:mi:ss (e.g. 28-04-2022:14:10:00) format. It finds transactions that have committed before the specified time.

If no start date is specified, the start date is set to the value of 10 minutes before the end date. Also, if an end date is not specified, the end date is set to 10 minutes after the start date. If neither start date nor end date is set, transactions performed up to 10 minutes before the current time are searched for.

```
cubrid flashback -e 28-04-2022:14:10:00 demodb dba.tbl
```

### **--detail**

This option is used to display the detailed information for each SQL statement. Transaction ID, transaction user, and original SQL statements are displayed with the SQL statements for flashback. The original SQL statement is not the exact syntax user executed. It simply represents the user-executed statement as INSERT/UPDATE/DELETE statements that are executed row-by-row. For example, An INSERT ... SELECT statement is expressed as multiple INSERT statements. If the **--detail** option is not specified, only the SQL statements for flashback is displayed.

```
cubrid flashback --detail demodb dba.tbl
```

Flashback Summary

Number of Transaction: 1

Start date - End date: 03-05-2022:10:52:56 - 03-05-2022:11:02:56

| Transaction id | User name | Start time          | End time            | Num_insert | Num_update |
|----------------|-----------|---------------------|---------------------|------------|------------|
| 135            | DBA       | 03-05-2022:11:02:40 | 03-05-2022:11:02:41 | 1          | 0          |

0 dba.tbl

Enter transaction id (press -1 to quit): 135

[TRANSACTION ID] 135

[USER] DBA

[ORIGINAL] insert into [dba.tbl] values (10);

[FLASHBACK] delete from [dba.tbl] where [a] = 10 limit 1;

### **--oldest**

This option is used to display the SQL statements executed within the specified transaction in chronological order. If the **--oldest** is not specified, the SQL statements executed within the transaction are displayed in reverse chronological order.

```
cubrid flashback --oldest demodb dba.tbl
```

## memmon

The **cubrid memmon** utility prints the heap memory usage currently allocated to the server process. When the system parameter **enable\_memory\_monitoring** is set to *yes*, the server memory monitoring module tracks and manages the total usage of heap memory and detailed memory allocation information based on the CUBRID source code and the line information where memory allocation occurs. This allows users to check the current state of the server's heap memory usage at the time the utility is executed.

```
cubrid memmon [option] database_name
```

- **cubrid**: Integrated utility for CUBRID service and database management.
- **memmon**: A utility that provides information of heap memory usage on the server process.
- *database\_name*: The name of the database to check the heap memory usage status.

The following example shows the result of executing “cubrid memmon demodb”.

```
=====cubrid memmon=====
Server Name: demodb
Total Memory Usage: 935240660 Bytes (for meta info: 470300 Bytes)
-----
      File
Name
|      Memory Usage(Ratio)
      storage/page_buffer.c:
4977
|      525315320 Bytes( 56%)
      transaction/log_page_buffer.c:
584
|      262147560 Bytes( 28%)
      ...
```

When **cubrid memmon** is executed, it displays the following information: the name of the database server, the total amount of heap memory in use, and the amount of heap memory used to store meta information for tracking and managing allocated heap memory. Detailed items include the memory usage and usage ratio for each file and line [ *file:line* ] at which heap

memory allocation occurred, sorted by usage. If the system parameter **enable\_memory\_monitoring** sets to no or the `-disable-force` option is used to forcibly stop the memory monitoring feature, an error message will be displayed.

The information output by the **cubrid memmon** utility has the following meanings.

- Server name : The name of database
- Total Memory Usage : The total amount of heap memory in use
  - for meta info : The memory usage of the metadata used to track and manage the total heap memory usage
- File Name : The name of the CUBRID source code file and the line number where the heap memory allocation occurred
- Memory Usage(Ratio) : Heap memory usage (ratio compared to the total heap memory usage)

#### Note

To record the history of heap memory allocations, the point at which heap memory is deallocated and the current memory usage becomes 0 is also included in the output of **cubrid memmon**.

The following are the [option] used by **cubrid memmon**.

#### **-o, --output-file=FILE**

Option to save the result of the utility execution to a specified file. If the **-o** option is not specified, messages will be displayed on the console screen.

```
cubrid memmon -o memory_usage_output demodb
```

#### **--disable-force**

Option to forcibly disable the memory monitoring feature. If the memory monitoring feature is forcibly disabled, the **cubrid memmon** utility will not display the server's heap memory usage. To resume tracking memory usage, the server must be restarted.

```
cubrid memmon --disable-force demodb
```

## HA Commands

**cubrid changemode** utility prints or changes the HA mode.

**cubrid applyinfo** utility prints the information of applied transaction logs in the HA environment.

For more details, see [Registering HA to cubrid service](#).

## Locale Commands

**cubrid genlocale** utility compiles the locale information to use. This utility is executed in the **make\_locale.sh** script ( **.bat** for Windows).

**cubrid dumplocale** utility dumps the compiled binary locale (CUBRID locale library) file as a human-readable format on the console. It is better to save the output as a file by output redirection.

**cubrid synccolldb** utility checks if the collations between database and locale library are consistent or not, and synchronize them.

For more detailed usage, see [Locale Setting](#).

## Timezone Commands

**cubrid gen\_tz** utility has two modes:

- **new** mode when it compiles the IANA timezone data stored in the tzdata folder into a C source code file. This file is then converted into a .so shared library for Linux or .dll library for Windows using the **make\_tz.sh** (Linux) / **make\_tz.bat** (Windows) scripts.
- **extend** mode is similar to new but is used when you want to update your timezone data to a different version and ensure backward compatibility with the old data. It is always used with a database name argument. In some situations, when it is impossible to ensure backward compatibility just by merging the two versions of timezone data, an update of the data in the tables of the database is done. It is executed using **make\_tz.sh -g extend** for Linux and **make\_tz.bat /extend** for Windows.

**cubrid dump\_tz** utility dumps the compiled CUBRID timezone library file as a human-readable format on the console. It is better to save the output as a file by output redirection.

## System Parameters

This chapter provides information about configuring system parameters that can affect the system performance. System parameters determine overall performance and operation of the

system. This chapter explains how to use configuration files for database server and broker as well as a description of each parameter.

This chapter covers the following topics:

- Configuring the database server
- Configuring the broker
- HA Configuration
- SHARD Configuration

## Configuring the Database Server

### Scope of Database Server Configuration

CUBRID consists of the database server, the broker and the CUBRID Manager. Each component has its configuration file. The system parameter configuration file for the database server is **cubrid.conf** located in the **\$CUBRID/conf** directory. System parameters configured in **cubrid.conf** affect overall performance and operation of the database system. Therefore, it is very important to understand the database server configuration.

The CUBRID database server has a client/server architecture. To be more specific, it is divided into a database server process linked to the server library and the broker process linked to the client library. The server process manages the database storage structure and provides concurrency and transaction functionalities. The client process prepares for query execution and manages object/schema.

System parameters for the database server, which can be set in the **cubrid.conf** file, are classified into a client parameter, a server parameter and a client/server parameter according to the range to which they are applied. A client parameter is only applied to client processes such as the broker. A server parameter affects the behaviors of the server processes. A client/server parameter must be applied to both server and client.

#### Note

##### Location of cubrid.conf File and How It Works

The **cubrid.conf** file is located on the **\$CUBRID/conf** directory. For setting by database, it divides into a section in the **cubrid.conf** file.

## Changing Database Server Configuration

### Editing the Configuration File

You can add/delete parameters or change parameter values by manually editing the system parameter configuration file (**cubrid.conf**) in the **\$CUBRID/conf** directory.

The following parameter syntax rules are applied when configuring parameters in the configuration file:

- Parameter names are not case-sensitive.
- The name and value of a parameter must be entered in the same line.
- An equal sign (=) can be to configure the parameter value. Spaces are allowed before and after the equal sign.
- If the value of a parameter is a character string, enter the character string without quotes. However, use quotes if spaces are included in the character string.

### Using SQL Statements

You can configure a parameter value by using SQL statements in the CSQL Interpreter or CUBRID Manager's Query Editor. Note that you cannot change every parameter. For updatable parameters, see [cubrid.conf Configuration File and Default Parameters](#).

```
SET SYSTEM PARAMETERS 'parameter_name=value [{; name=value}...]'
```

*parameter\_name* is the name of a client parameter whose value is editable. In this syntax, *value* is the value of the given parameter. You can change multiple parameter values by separating them with a semicolon(;). You should be careful when you change a parameter.

The following example shows how to retrieve the result of an index scan in OID order and configure the number of queries to be stored in the history of the CSQL Interpreter to 70.

```
SET SYSTEM PARAMETERS 'index_scan_in_oid_order=1;  
csql_history_num=70';
```

**DEFAULT** for *value* will reset the parameter to its default value with an exception of **call\_stack\_dump\_activation\_list** parameter.

```
SET SYSTEM PARAMETERS 'lock_timeout=DEFAULT';
```

## Using Session Commands of the CSQL Interpreter

You can configure system parameter values by using session commands (;SET) in the CSQL Interpreter. Note that you cannot change every parameter. For updatable parameters, see [cubrid.conf Configuration File and Default Parameters](#).

The following example shows how to configure the block\_ddl\_statement parameter to yes so that execution of DDL statements is not allowed.

```
csql> ;set block_ddl_statement=yes
=== Set Param Input ===
block_ddl_statement=yes
```

## cubrid.conf Configuration File and Default Parameters

CUBRID consists of the database server, the broker and the CUBRID Manager. The name of the configuration file for each component is as follows. These files are all located in the **\$CUBRID/conf** directory.

- Database server configuration file: **cubrid.conf**
- Broker configuration file: **cubrid\_broker.conf**
- CUBRID Manager server configuration file: **cm.conf**

**cubrid.conf** is a configuration file that sets system parameters for the CUBRID database server and determines overall performance and operation of the database system. In the **cubrid.conf** file, some important parameters needed for system installation are provided, having their default values.

## Database Server System Parameters

The following are database server system parameters that can be used in the **cubrid.conf** configuration file. On the following table, “Applied” column’s “client parameter” means that they are applied to CAS, CSQL, **cubrid** utilities. Its “server parameter” means that they are applied to the DB server (cub\_server process). For the scope of **client** and **server parameters**, see [Scope of Database Server Configuration](#).

You can change the parameters that are capable of changing dynamically the setting value through the **SET SYSTEM PARAMETERS** statement or a session command of the CSQL Interpreter, For more semantics on **;set** see [Viewing Query Plan](#) . **;set** while running the DB. If you are a DBA, you can change parameters regardless of the applied classification. However, if you are not a DBA, you can only change “session” parameters. (on the below table, a parameter of which “session” item’s value is O.)

On the below table, if “Applied” is “server parameter”, that parameter affects to cub\_server process; If “client parameter”, that parameter affects to CAS, CSQL or “cubrid” utilities which run on client/server mode (--CS-mode). “Client/server parameter” affects to all of cub\_server, CAS, CSQL and “cubrid” utilities.

“Dynamic Change” and “Session or not” are marked on the below table. The affected range of the parameter which “Dynamic Change” is “available” depends on “Applied” and “Session” items.

- If “Dynamic Change” is “available” and “Applied” is “server parameter”, that parameter’s changed value is applied to DB server. Then applications use the changed value of the parameter until the DB server is restarted.
- If “Dynamic Change” is “available” and “Applied” is “client parameter”, this belongs to the “session” parameter and that parameter’s changed value is applied only to that DB session. In other words, the changed value is only applied to the application which requested to change that value. For example, if **block\_ddl\_statement** parameter’s value is changed into **yes**, then only the application requested to change that parameter cannot use DDL statements.
- If “Dynamic Change” is “available”, “Applied” is “client parameter” and;
  - this belongs to the “session” parameter, that parameter’s changed value is applied only to that DB session. In other words, the changed value is only applied to the application requested to change that value. For example, if **add\_column\_update\_hard\_default** parameter’s value is changed into **yes**, then only the application requested to change that parameter lets the newly added column with NOT NULL constraint have hard default value.
  - this does not belong to the “session” parameter, the values of “client” side and “server” side are changed. For example, **error\_log\_level** parameter is applied to each of “server” side and “client” side; if this value is changed from “ERROR” into “WARNING”, this is applied only to “server” (cub\_server process) and “client” (CAS or CSQL) which requested to change this value. Other “clients” keeps the value of “ERROR”.

#### Note

If you want to change the value of a parameter permanently, restart all of DB server and broker after changing configuration values of cubrid.conf.

| Category | Parameter Name | Applied | Session | Type | Default Value | Dynamic Change |
|----------|----------------|---------|---------|------|---------------|----------------|
|          |                |         |         | int  | 1523          |                |

|          | deduplicate_key_level              | client/server parameter |         | int    | -1            |                |
|          | print_index_detail                 | client/server parameter | 0       | bool   | no            | available      |
|          | enable_memory_monitoring           | client/server parameter | 0       | bool   | no            | available      |
|          |                                    |                         |         | int    | 300           |                |

| Category | Parameter Name    | Applied          | Session | Type | Default Value | Dynamic Change |
|----------|-------------------|------------------|---------|------|---------------|----------------|
|          | flashback_timeout | client parameter |         |      |               |                |

- **log\_page\_size**: A log volume page size specified by **--log-page-size** option when you are **creating database**. Default: 16KB. log page related parameter's value is rounded off by page unit. For example, the value of checkpoint\_every\_size is divided by 16KB and its decimal point is dropped, then it is multiplied by 16KB.
- **db\_page\_size**: A DB volume page size specified by **--db-page-size** option when you are **creating database**. Default: 16KB. DB page related parameter's value is rounded off by page unit. For example, the value of data\_buffer\_size is divided by 16KB and its decimal point is dropped, then it is multiplied by 16KB.

## Section by Parameter

Parameters specified in **cubrid.conf** have the following four sections:

- Used when the CUBRID service starts: [service] section
- Applied commonly to all databases: [common] section
- Applied individually to each database: [@<database>] section
- Used only when the cubrid utilities are run with stand-alone mode(--SA-mode): [standalone] section

Where <database> is the name of the database to which each parameter applies. If a parameter configured in [common] is the same as the one configured in [@<database>], the one configured in [@<database>] is applied.

```
.....
[common]
.....
sort_buffer_size=2M
.....
[standalone]

sort_buffer_size=256M
.....
```

Configuration defined in [standalone] is used only when cubrid utilities started with “cubrid” are run with stand-alone mode. For example, on the above configuration, if DB is started with --CS-mode(default)(cubrid databases start db\_name), “sort\_buffer\_size=2M” is applied. However, if DB is stopped and “cubrid loaddb --SA-mode” is executed, “sort\_buffer\_size=256M” is applied. If you run “cubrid loaddb --SA-mode”, bigger size of sort buffer will be required during index creation; therefore, increasing sort buffer size will be better for the performance of “loaddb” execution.

## Default Parameters

**cubrid.conf**, a default database configuration file created during the CUBRID installation, includes some default database server parameters that must be changed. You can change the value of a parameter that is not included as a default parameter by manually adding or editing one.

The following is the content of the **cubrid.conf** file.

```
# Copyright (C) 2008 Search Solution Corporation. All rights
reserved by Search Solution.
#
# $Id$
#
# cubrid.conf#

# For complete information on parameters, see the CUBRID
# Database Administration Guide chapter on System Parameters

# Service section - a section for 'cubrid service' command
[service]

# The list of processes to be started automatically by 'cubrid
service start' command
# Any combinations are available with server, broker and manager.
service=server,broker,manager

# The list of database servers in all by 'cubrid service start'
command.
# This property is effective only when the above 'service' property
contains 'server' keyword.
#server=demodb,testdb

# Common section - properties for all databases
# This section will be applied before other database specific
sections.
[common]

# Read the manual for detailed description of system parameters
# Manual > System Configuration > Database Server Configuration >
Default Parameters

# Size of data buffer are using K, M, G, T unit
```

```
data_buffer_size=512M

# Size of log buffer are using K, M, G, T unit
log_buffer_size=256M

# Size of sort buffer are using K, M, G, T unit
# The sort buffer should be allocated per thread.
# So, the max size of the sort buffer is sort_buffer_size *
max_clients.
sort_buffer_size=2M

# The maximum number of concurrent client connections the server
will accept.
# This value also means the total # of concurrent transactions.
max_clients=100

# TCP port id for the CUBRID programs (used by all clients).
cubrid_port_id=1523
```

If you want to set **data\_buffer\_size** as 128M and **max\_clients** as 10 only on *testdb*, set as follows.

```
[service]

service=server,broker,manager

[common]

data_buffer_size=512M
log_buffer_size=256M
sort_buffer_size=2M
max_clients=100

# TCP port id for the CUBRID programs (used by all clients).
cubrid_port_id=1523

[@testdb]
data_buffer_size=128M
max_clients=10
```

## Connection-Related Parameters

The following are parameters related to the database server. The type and value range for each parameter are as follows:

| Parameter Name   | Type   | Default | Min | Max  |
|------------------|--------|---------|-----|------|
| cubrid_port_id   | int    | 1523    | 1   |      |
| check_peer_alive | string | both    |     |      |
| db_hosts         | string | NULL    |     |      |
| max_clients      | int    | 100     | 10  | 4000 |
| tcp_keepalive    | bool   | yes     |     |      |
| use_user_hosts   | bool   | off     |     |      |

### cubrid\_port\_id

**cubrid\_port\_id** is a parameter to configure the port to be used by the master process. The default value is **1523**. If port 1523 is already being used on the server where CUBRID is installed or is blocked by a firewall, an error message is displayed indicating that the master server is not connected because the master process cannot run properly. If such a port conflict occurs, the administrator must change the value of **cubrid\_port\_id** considering the server environment.

### check\_peer\_alive

**check\_peer\_alive** is a parameter to decide whether you execute the function checking that the client/server processes work well. The default is **both**.

The client processes connecting with a server process are the broker application server(cub\_cas) process, the process copying replication logs(copylogdb), the process applying replication logs. (applylogdb), CSQL interpreter(csql), etc. The server process and the client process which connected with it wait each other's response. But if one of them cannot get the data for a long time(example: exceeding 5 sec), it will check or not if the other works well based on the configuration of check\_peer\_alive parameter. During this processes, if it is judged that the process doesn't work properly, it disconnect forcibly.

The values and the working methods are as follows.

- **both**: As the server process accesses to the client process by ECHO(7) port, it checks if the client process works well. The client process also does the same thing to the server process(The default value).
- **server\_only**: Only the server process checks whether the client process works well.
- **client\_only**: Only the client process checks whether the server process works well.
- **none**: None of the server and client processes check whether the other process works well.

Specially, if ECHO(7) port is blocked by the firewall configuration, each process can mistake that the other process was exited. Therefore, you should avoid this problem by setting this parameter's value as none.

## db\_hosts

**db\_hosts** is a parameter to configure a list of the database server hosts to which clients can connect, and the connection order. The server host list consists of multiple server host names, and host names are separated by spaces or colons (:). Duplicate or non-existent names are ignored.

The following example shows the values of the **db\_hosts** parameter. In this example, connections are attempted in the order of **host1 > host2 > host3**.

```
db_hosts="hosts1:hosts2:hosts3"
```

To connect to the server, the client first tries to connect to the specified server host referring to the database location file (**databases.txt**). If the connection fails, the client then tries to connect to the first one of the secondarily specified server hosts by referring to the value of the **db\_hosts** parameter in the database configuration file (**cubrid.conf**).

## max\_clients

**max\_clients** is a parameter to configure the maximum number of clients (usually broker application processes (CAS)) which allow concurrent connections to the database server. The **max\_clients** parameter refers to the number of concurrent transactions per database server process. The default value is **100**.

To guarantee performance while increasing the number of concurrent users in CUBRID environment, you need to make the appropriate value of the **max\_clients** (**cubrid.conf**) parameter and the **MAX\_NUM\_APPL\_SERVER** (**cubrid\_broker.conf**) parameter. That is, you are required to configure the number of concurrent

connections allowed by databases with the **max\_clients** parameter. You should also configure the number of concurrent connections allowed by brokers with the **MAX\_NUM\_APPL\_SERVER** parameter.

For example, in the **cubrid\_broker.conf** file, two node of a broker where the **MAX\_NUM\_APPL\_SERVER** value of [%query\_editor] is 50 and the **MAX\_NUM\_APPL\_SERVER** value of [%BROKER1] is 50 is trying to connect one database server, the concurrent connections (**max\_clients** value) allowed by the database server can be configured as follows:

- (the maximum number of 50 by each node of a broker) \* (two node of a broker) + (10 spare for database server connections of internal CUBRID process such as database server connection of CSQL Interpreter or HA log replication process) = 110

Especially, in HA environment, the value must be greater than the sum specified in **MAX\_NUM\_APPL\_SERVER** of every broker node which connects to the same database.

Note that the memory usage is affected by the value specified in **max\_clients**. That is, if the number of value is high, the memory usage will increase regardless of whether or not the clients actually access the database.

#### Note

In Linux system, **max\_clients** parameter is related to “ulimit -n” command, which specifies the maximum number of file descriptors which a process can use. File descriptor includes not only a file, but also a network socket. Therefore, the number of “ulimit -n” should be greater than the number of **max\_clients**.

## tcp\_keealive

**tcp\_keealive** is a parameter which specifies if you apply SO\_KEEPAIVE option to TCP network protocol or not. The default is **yes**. If this value is **no**, DB server-side connection can be disconnected when transaction logs are not copied for a long time in the firewall environment between master and slave.

## use\_user\_hosts

**use\_user\_hosts** is a system parameter that is used to select the host look up between **hostname** and **IP address**, required by the CUBRID service from the services below. The default value is **OFF**.

- The host/IP address look-up library that **OS** provides. (**glibc**, Linux)
- **The host/IP address look-up library** that **CUBRID** provides.

use\_user\_hosts=off (default)

- Looks up between IP address and hostname using the system library.
- In general, provides /etc/hosts host look-up, DNS Query commonly

use\_user\_hosts=on

- Looks up between IP address and hostname using CUBRID host look-up library.
- Uses **\$CUBRID/conf/cubrid\_hosts.conf** file to look up between IP address and hostname.
- executes regardless of the read permission of /etc/hosts, /etc/nsswitch.conf file.

#### Warning

If **use\_user\_hosts** parameter is changed during service operation, CUBRID service cannot terminate normally. So, the user must change the parameter after CUBRID service terminates.

- The format of **\$CUBRID/conf/cubrid\_hosts.conf** is same as **/etc/hosts** but there are some restrictions as follows.
  - Allow **IPv4** format address only. (Not allow **IPv6** format address)
  - Not allow **alias**.

```
172.31.0.1 host1 alias1 alias2
```

- If there are multiple IP addresses, the top of information ,{ip, hostname}, is used except others.

```
172.31.0.1 host1
172.31.0.1 alias1
172.31.0.1 alias2
```

- If you use the same hostname for more than one IP, only the topmost IP will be applied.

```
172.31.0.1 host1
178.31.0.2 host1
```

- The following is an example of \$CUBRID/conf/cubrid\_hosts.conf.

```
#
# hosts file for CUBRID user specific host service
#
127.0.0.1      localhost
172.31.0.1     node1
192.168.0.31   node4.kr      # Seoul
192.168.2.31   node5.gov.or.kr # Daejeon
```

#### Warning

You must change \$CUBRID/conf/cubrid\_hosts.conf after terminating all CUBRID processes, and **the changes will be applied after restarting**. In addition, you must write including **localhost** and **'hostname'** (The output of hostname command by among Linux commands) in the cubrid\_hosts.conf.

#### Warning

The hostname adheres the following format in the \$CUBRID/conf/cubrid\_hosts.conf (The Linux hostname naming rule).

- Only English letters, numbers (0 to 9), hyphen ('-'), and dot (".") characters can be used for the hostname.
- The first character of the hostname must be an English letter.
- The last character of the hostname must be an English letter and a number.
- FQDN (Fully Qualified Domain Name) format hostname can be used (Example: www.cubrid.com).

Allow the following hostname.

```
cubrid-dev1
CUB2.dev
```

## Memory-Related Parameters

The following are parameters related to the memory used by the database server or client. The type and value range for each parameter are as follows:

| Parameter Name             | Type | Default                  | Min                     | Max                                                |
|----------------------------|------|--------------------------|-------------------------|----------------------------------------------------|
| data_buffer_size           | byte | 32,768<br>db_page_size * | 1,024<br>db_page_size * | 2G(32bit),<br>INT_MAX<br>db_page_size<br>(64bit) * |
| index_scan_oid_buffer_size | byte | 4<br>db_page_size *      | 0.05<br>db_page_size *  | 16<br>db_page_size *                               |
| max_agg_hash_size          | byte | 2,097,152(2M)            | 32,768(32K)             | 134,217,728(128MB)                                 |
| max_hash_list_scan_size    | byte | 8,388,608(8M)            | 0                       | 128MB                                              |
| max_parallel_workers       | int  | 100                      | 0                       | 1000                                               |
| parallelism                | int  | 4                        | 0                       | MIN(32, system cores)                              |
| max_subquery_cache_size    | byte | 2,097,152(2M)            | 0                       | 16,777,216(16M)                                    |
| sort_buffer_size           | byte | 128<br>db_page_size *    | 1<br>db_page_size *     | 2G(32bit),<br>INT_MAX<br>db_page_size<br>(64bit) * |
|                            | int  | 4                        | 0                       | 20                                                 |

| Parameter Name                 | Type | Default   | Min    | Max |
|--------------------------------|------|-----------|--------|-----|
| temp_file_memory_size_in_pages |      |           |        |     |
| thread_stacksize               | byte | 1,048,576 | 65,536 |     |

### data\_buffer\_size

**data\_buffer\_size** is a parameter to configure the size of data buffer to be cached in the memory by the database server. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is  $32,768 * db\_page\_size$  (**512M** when `db_page_size` is 16K), and the minimum value is  $1,024 * db\_page\_size$  (**16M** when `db_page_size` is 16K). The maximum value in 64-bit CUBRID is `INT_MAX * db_page_size`. Note that the maximum value in 32-bit CUBRID is **2G**.

The greater the value of the **data\_buffer\_size** parameter, the more data pages to be cached in the buffer, thus providing the advantage of decreased disk I/O cost. However, if this parameter is too large, the buffer pool can be swapped out by the operating system because the system memory is excessively occupied. It is recommended to configure the **data\_buffer\_size** parameter in a way the required memory size is less than two-thirds of the system memory size.

- Required memory size = data buffer size (**data\_buffer\_size**)

### index\_scan\_oid\_buffer\_size

**index\_scan\_oid\_buffer\_size** is a parameter to configure the size of buffer where the OID list is to be temporarily stored during the index scan. You can set unit K, which stands for KB (kilobytes). If you omit the unit, bytes will be applied. The default value is  $4 * db\_page\_size$  (**64K** when `db_page_size` is 16K), and the minimum value is  $0.05 * db\_page\_size$  (about **1K** when `db_page_size` is 16K).

The size of the OID buffer tends to vary in proportion to the value of the **index\_scan\_oid\_buffer\_size** parameter and the page size set when the database was created. In addition, the bigger the size of such OID buffer, the more the index scan cost. You can set the value of the **index\_scan\_oid\_buffer\_size** by considering these factors.

### max\_agg\_hash\_size

**max\_agg\_hash\_size** is a parameter to configure the maximum memory per transaction allocated for hashing the tuple groups in a query containing aggregation. The default is **2,097,152**(2M), the minimum size is 32,768(32K), and the maximum size is 134,217,728(128MB).

If **NO\_HASH\_AGGREGATE** hint is specified, hash aggregate evaluation will not be used. As a reference, see [agg\\_hash\\_respect\\_order](#).

### **max\_hash\_list\_scan\_size**

**max\_hash\_list\_scan\_size** is a parameter to configure the maximum memory per transaction allocated for building hash table in a query containing subqueries. The default is 8MB, the minimum size is 0, and the maximum size is 128MB.

If this parameter is set to 0 or If **NO\_HASH\_LIST\_SCAN** hint is specified, hash list scan will not be used.

### **max\_parallel\_workers**

**max\_parallel\_workers** is a parameter that sets the maximum number of parallel query worker threads that can be executed simultaneously across the entire server. The default value is **100**, the minimum value is **0**, and the maximum value is **1000**.

If this parameter is set to **0**, the parallel query feature is disabled. When set to **2 or higher**, various parallel processing features such as Parallel Heap Scan, Parallel Subquery Execution, Parallel Hash Join, and Parallel Sort can be used.

The server manages parallel query execution through a **global worker pool**. Even when multiple sessions simultaneously request parallel queries or complex parallel operations are performed within a single session, the total number of active parallel workers across the entire server cannot exceed the **max\_parallel\_workers** value.

Each server thread reserves the required number of workers through the **parallel query worker manager** before query execution, and releases them immediately upon task completion. If reservation fails due to insufficient available workers, the query is executed in the normal single-threaded manner.

For more details on parallel query execution, see [Parallel Execution](#).

The following example allows up to 200 parallel workers.

```
max_parallel_workers=200
```

#### **Note**

Parallel queries are effective in environments with sufficient CPU cores and memory. If the **max\_parallel\_workers** value is excessively large compared to the actual number of physical cores, performance may degrade due to system resource contention.

#### **Note**

Each worker thread in parallel queries uses independent resources (such as memory), so the overall server memory usage increases as the number of parallel workers used grows.

#### **Note**

If all queries are executed in parallel, excessive server resource usage may cause overall system performance degradation. To prevent this, the optimizer applies **throughput rules** to selectively allow parallel execution only for queries with high parallel processing efficiency.

## **parallelism**

**parallelism** is a parameter that sets the upper limit of the **degree of parallelism** that can be allocated to a single parallel operation. The default value is **4**, the minimum value is **0**, and the maximum value is **MIN(32, number of system CPU cores)**.

If this parameter is set to **0** or **1**, all queries without the **PARALLEL** hint are executed in single-threaded mode. When set to **2 or higher**, the optimizer automatically applies parallel execution to operations (scan, hash join, sort, subquery, etc.) where parallel processing is determined to be efficient.

The actual degree of parallelism applied during query execution follows these rules:

When the **PARALLEL(N)** hint is used, it ignores this parameter value and attempts to allocate N workers. However, it cannot exceed the maximum allowed value (the smaller of 32 or the number of system cores).

Without hints, the number of workers allocated to individual parallel operations cannot exceed this parameter value. However, if a single query has a structure that performs multiple parallel operations simultaneously, the total number of parallel workers used by that query may exceed this parameter value. The total number of

parallel workers across the entire server cannot exceed the `max_parallel_workers` value.

You can redefine the degree of parallelism for each query using the **PARALLEL ( degree )** hint. For more details, see [Parallel Execution](#).

The following example sets the default degree of parallelism to 8.

```
parallelism=8
```

#### Note

The **parallelism** parameter sets the upper limit for individual parallel operations, but the actual parallel execution and its degree for an entire query are determined by throughput rules, table size, `max_parallel_workers` settings, and other factors.

#### Note

Setting a high degree of parallelism may improve individual query performance, but excessively high values can degrade overall system performance due to resource contention.

#### Note

The maximum value of this parameter is automatically limited to the smaller of the number of physical cores and 32, preventing individual parallel operations from excessively occupying server resources and ensuring overall system stability.

## **max\_subquery\_cache\_size**

**max\_subquery\_cache\_size** is a parameter used to set the size of the subquery cache (correlated). You can set a unit as B, K or M, which stand for bytes, kilobytes (KB), and megabytes (MB), respectively. If you omit the unit, bytes will be applied. The default value is **2,097,152** (2M) bytes, the minimum value is **0**, and the maximum value is **16,777,216** (16M) bytes. The subquery cache is allocated for the number of subqueries in a query and is deallocated when the main query is completed.

If `max_subquery_cache_size` is set to 0, the `NO_SUBQUERY_CACHE` hint is specified, or there is insufficient memory space, the subquery cache optimization is not enabled.

### **sort\_buffer\_size**

**sort\_buffer\_size** is a parameter to configure the size of buffer to be used when a query is processing sorting. The server assigns one sort buffer for each client's sorting-request, and releases the assigned buffer memory when sorting is complete. A sorting query includes not only SELECT sorting query, but also index-creating query.

You can set a unit as B, K, M, G or T, which stand for bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), and terabytes (TB) respectively. If you omit the unit, bytes will be applied. The default value is  $128 * \text{db\_page\_size}$  (**2M** when `db_page_size` is 16K), and the minimum value is  $1 * \text{db\_page\_size}$  (**16K** when `db_page_size` is 16K).

### **temp\_file\_memory\_size\_in\_pages**

**temp\_file\_memory\_size\_in\_pages** is a parameter to configure the number of buffer pages to cache temporary result of a query. The default value is **4** and the maximum value is 20.

- Required memory size = the number of temporary memory buffer pages (**temp\_file\_memory\_size\_in\_pages** \* **page size**)
- The number of temporary memory buffer pages = the value of the **temp\_file\_memory\_size\_in\_pages** parameter
- Page size = the value of the page size specified by the **-s** option of the **cubrid createdb** utility during the database creation

The spaces to store the temporary result are as follows.

- Cache buffer to store the temporary result (acquired by **temp\_file\_memory\_size\_in\_pages** parameter)
- Permanent volumes with the purpose of storing temporary data.
- Temporary volumes

If the previous space is exhausted, then the next space is used as the following order: Cache buffer for storing temporary result -> Permanent volumes -> Temporary volumes.

### **thread\_stacksize**

**thread\_stacksize** is a parameter to configure the stack size of a thread. The default value is **1048576** bytes. The value of the **thread\_stacksize** parameter must not exceed the stack size allowed by the operating system.

## Disk-Related Parameters

The following are disk-related parameters for defining database volumes and storing files. The type and value range for each parameter are as follows:

| Parameter Name              | Type   | Default        | Min | Max              |
|-----------------------------|--------|----------------|-----|------------------|
| db_volume_size              | byte   | 512M           | 0   | 20G              |
| dont_reuse_heap_file        | bool   | no             |     |                  |
| log_volume_size             | byte   | 512M           | 20M | 4G               |

### db\_volume\_size

**db\_volume\_size** is a parameter to configure the following values. You can set a unit as B, K, M, G or T, which stand for bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), and terabytes (TB) respectively. If you omit the unit, bytes will be applied. The default value is **512M**.

- The default database volume size when **cubrid createdb** and **cubrid addvoldb** utility is used without **--db-volume-size** option.
- The default size of volume that is maximum size of an automatically added volume when the database is full. (The auto-added volume is incrementally increased by the needed amount, and another volume is created when the volume exceeds db\_volume\_size.)

#### Note

The actual volume size will always be rounded up to a multiple of the size of 64 sectors. Sector size depends on page size, therefore 64 sectors size is 16M, 32M or 64M for page size 4k, 8k or 16k respectively.

### **dont\_reuse\_heap\_file**

**dont\_reuse\_heap\_file** is a parameter to configure whether or not heap files, which are deleted when deleting the table (**DROP TABLE**), are to be reused when creating a new table (**CREATE TABLE**). If this parameter is set to no, the deleted heap files can be reused; if it is set to yes, the deleted heap files are not used when creating a new table. The default value is **no**.

### **log\_volume\_size**

**log\_volume\_size** is a parameter to configure the default size of log volume file when the **cubrid createdb** utility is used without **--log-volume-size** option. You can set a unit as B, K, M, G or T, which stand for bytes, kilobytes (KB), megabytes (MB), gigabytes (GB) and terabytes (TB) respectively. If you omit the unit, bytes will be applied. The default value is **512M**.

### **temp\_file\_max\_size\_in\_pages**

**temp\_file\_max\_size\_in\_pages** is a parameter to configure the maximum number of pages to which temporary volumes can be extended. By default, this value is **-1**, which means that temporary volumes can occupy an unlimited disk space. A positive value will set a limit to these values (exceeding it may show an error and cancel some big queries).

If the parameter is configured to **0**, temporary volumes are not created automatically; the administrator must create permanent volumes with the purpose of storing temporary data by using the **cubrid addvoldb** utility.

For more details see [Temporary Volume](#)

### **temp\_volume\_path**

**temp\_volume\_path** is a parameter to configure the directory in which to create temporary volumes used for the execution of complex queries or sorting. The default value is the volume location configured during the database creation.

### **unfill\_factor**

**unfill\_factor** is a parameter to configure the rate of disk space to be allocated in a heap page for data updates. The default value is **0.1**. That is, the rate of free space is configured to 10%. In principle, data in the table is inserted in physical order. However, if the size of the data increases due to updates and there is not enough space for storage in the given page, performance may degrade because updated data must be relocated to another page. To prevent such a problem, you can configure the rate of space for a heap page by using the **unfill\_factor** parameter. The allowable maximum value is 0.3 (30%). In a database where data updates rarely occur, you can configure this parameter to 0.0 so that space will not be allocated in a heap page for data updates. If the value of the **unfill\_factor** parameter is negative or greater than the maximum value, the default value (**0.1**) is used.

### **volume\_extension\_path**

**volume\_extension\_path** is a parameter to configure the directory where automatically extended volumes are to be created. The default value is the volume location configured during the database creation.

### **double\_write\_buffer\_size**

**double\_write\_buffer\_size** is a parameter to configure the memory and disk size of double writer buffer. Double write buffer protection against partial I/O writes can be disabled by setting this size to zero. By default, it is enabled and its size is 2M. The value operates in bytes, and must be set within the range of 2,097,152 bytes (minimum) to 33,554,432 bytes (maximum).

### **data\_file\_os\_advise**

**data\_file\_os\_advise** is a UNIX-only parameter that may be used to boost I/O performance. The parameter value is converted into a *posix\_fadvise()* flag (for details about the flags [see here](#)).

| Parameter Value | posix_fadvise flag    |
|-----------------|-----------------------|
| 0               | 0                     |
| 1               | POSIX_FADV_NORMAL     |
| 2               | POSIX_FADV_SEQUENTIAL |
| 3               | POSIX_FADV_RANDOM     |
| 4               | POSIX_FADV_NOREUSE    |
| 5               | POSIX_FADV_WILLNEED   |
| 6               | POSIX_FADV_DONTNEED   |

#### Warning

Make sure posix\_fadvise flags and how data is accessed are perfectly understood. The parameter can help improve performance but it can also degrade it if misused. In most scenarios it is best to use the default value.

### Error Message-Related Parameters

The following are parameters related to processing error messages recorded by CUBRID. The type and value range for each parameter are as follows:

| Parameter Name                  | Type   | Default |
|---------------------------------|--------|---------|
| call_stack_dump_activation_list | string | DEFAULT |

| Parameter Name                    | Type   | Default                        |
|-----------------------------------|--------|--------------------------------|
| call_stack_dump_deactivation_list | string | NULL                           |
| call_stack_dump_on_error          | bool   | no                             |
| error_log                         | string | cub_client.err, cub_server.err |
| error_log_level                   | string | NOTIFICATION                   |
| error_log_warning                 | bool   | no                             |
| error_log_size                    | int    | 512M                           |

### call\_stack\_dump\_activation\_list

**call\_stack\_dump\_activation\_list** is a parameter to configure a certain error number for which a call stack is to be dumped to a server error log (located in \$CUBRID/log/server directory) as an exception even when you configure that a call stack will not be dumped for any errors. Therefore, the **call\_stack\_dump\_activation\_list** parameter is effective only when **call\_stack\_dump\_on\_error=no**.

If this value is not configured, the default value is “DEFAULT” keyword. This keyword includes below errors. “DEFAULT” keyword can be used together with other error numbers.

| Error Number | Error Message                                                                     |
|--------------|-----------------------------------------------------------------------------------|
| -2           | Internal system failure: no more specific information is available.               |
| -7           | Trying to format disk volume xxx with an incorrect value xxx for number of pages. |

| Error Number | Error Message                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------|
| -13          | An I/O error occurred while reading page xxx of volume xxx.                                                  |
| -14          | An I/O error occurred while writing page xxx of volume xxx.                                                  |
| -17          | Internal error: fetching deallocated pageid xxx of volume xxx.                                               |
| -19          | Internal error: pageptr = xxx of page xxx of volume xxx is not fixed.                                        |
| -21          | Internal error: unknown sector xxx of volume xxx.                                                            |
| -22          | Internal error: unknown page xxx of volume xxx.                                                              |
| -45          | Slot xxx on page xxx of volume xxx is allocated to an anchored record. A new record cannot be inserted here. |
| -46          | Internal error: slot xxx on page xxx of volume xxx is not allocated.                                         |
| -48          | Accessing deleted object xxx xxx xxx.                                                                        |
| -50          | Internal error: relocation record of object xxx xxx xxx may be corrupted.                                    |
| -51          | Internal error: object xxx xxx xxx may be corrupted.                                                         |

| Error Number | Error Message                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| -52          | Internal error: object overflow address xxx xxx xxx may be corrupted.                                                                         |
| -76          | Your transaction (index xxx, xxx@xxx xxx) timed out waiting on xxx on page xxx xxx. You are waiting for user(s) xxx to release the page lock. |
| -78          | Internal error: an I/O error occurred while reading logical log page xxx (physical page xxx) of xxx.                                          |
| -79          | Internal error: an I/O error occurred while writing logical log page xxx (physical page xxx) of xxx.                                          |
| -81          | Internal error: logical log page xxx may be corrupted.                                                                                        |
| -90          | Redo logging is always a page level logging operation. A data page pointer must be given as part of the address.                              |
| -96          | Media recovery may be needed on volume xxx.                                                                                                   |
| -97          | Internal error: unable to find log page xxx in log archives.                                                                                  |
| -313         | Object buffer underflow while reading.                                                                                                        |
| -314         | Object buffer overflow while writing.                                                                                                         |

| Error Number | Error Message                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------|
| -407         | Unknown key xxx referenced in B+tree index {vfid: (xxx, xxx), rt_pgid: xxx, key_type: xxx}.                          |
| -414         | Unknown class identifier: xxx xxx xxx.                                                                               |
| -415         | Invalid class identifier: xxx xxx xxx.                                                                               |
| -416         | Unknown representation identifier: xxx.                                                                              |
| -417         | Invalid representation identifier: xxx.                                                                              |
| -583         | Trying to allocate an invalid number (xxx) of pages.                                                                 |
| -603         | Internal Error: Sector/page table of file VFID xxx xxx seems corrupted.                                              |
| -836         | LATCH ON PAGE(xxx xxx) TIMEDOUT                                                                                      |
| -859         | LATCH ON PAGE(xxx xxx) ABORTED                                                                                       |
| -890         | Partition failed.                                                                                                    |
| -891         | Appropriate partition does not exist.                                                                                |
| -976         | Internal error: Table size overflow (allocated size: xxx, accessed size: xxx) at file table page xxx xxx(volume xxx) |

| Error Number | Error Message                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------|
| -1040        | HA generic: xxx.                                                                                                            |
| -1075        | Descending index scan aborted because of lower priority on B+tree with index identifier: (vfid = (xxx, xxx), rt_pgid: xxx). |

The following example shows how to make error numbers only -115 and -116, perform call-stack dump.

```
call_stack_dump_on_error= no
call_stack_dump_activation_list=-115,-116
```

The following example shows how to make error numbers -115, -116 and "DEFAULT" error numbers, perform call-stack dump.

```
call_stack_dump_on_error= no
call_stack_dump_activation_list=-115,-116, DEFAULT
```

### **call\_stack\_dump\_deactivation\_list**

**call\_stack\_dump\_deactivation\_list** is a parameter to configure a certain error number for which a call stack is not to be dumped when you configure that a call stack will be dumped for any errors. Therefore, the **call\_stack\_dump\_deactivation\_list** parameter is effective only when **call\_stack\_dump\_on\_error** is set to **yes**.

The following example shows how to configure the parameter so that call stacks will be dumped for any errors, except the ones whose numbers are -115 and -116.

```
call_stack_dump_on_error= yes
call_stack_dump_deactivation_list=-115,-116
```

### **call\_stack\_dump\_on\_error**

**call\_stack\_dump\_on\_error** is a parameter to configure whether or not to dump a call stack when an error occurs in the database server. If this parameter is set to **no**, a

call stack for any errors is not dumped. If it is set to **yes**, a call stack for all errors is dumped. The default value is **no**.

### error\_log

**error\_log** is a server/client parameter to configure the name of the error log file when an error occurs in the database server. The name of the error log file must be in the form of `<database_name>_<date>_<time>.err`. However, the naming rule of the error log file does not apply to errors for which the system cannot find the database server information. Therefore, error logs are recorded in the **cubrid.err** file. The error log file **cubrid.err** is stored in the **\$CUBRID/log/server** directory.

### error\_log\_level

**error\_log\_level** is a server parameter to configure an error message to be stored based on severity. There are five different levels which range from **WARNING** (lowest level), to **FATAL** (highest level). The inclusion relation in messages is **FATAL < ERROR < SYNTAX < NOTIFICATION < WARNING**. The default is **NOTIFICATION**. If severity of error is **NOTIFICATION**, error messages with **NOTIFICATION**, **SYNTAX**, **ERROR** and **FATAL** levels are written to the log file.

### error\_log\_warning

**error\_log\_warning** is a parameter to configure whether or not error messages with a severity level of **WARNING** are to be displayed. Its default value is **no**. For this reason, you must set **error\_log\_warning** to **yes** to store **WARNING** messages to an error log file.

### error\_log\_size

**error\_log\_size** is a parameter to configure the maximum size per an error log file. The default value is **512M**. If it reaches up to the specified size, the `<database_name>_<date>_<time>.err.bak` file is created.

## Concurrency/Lock-Related Parameters

The following are parameters related to concurrency control and locks of the database server. The type and value range for each parameter are as follows:

| Parameter Name | Type  | Default | Min | Max |
|----------------|-------|---------|-----|-----|
|                | float | 1.0     | 0.1 |     |

| Parameter Name                      | Type | Default | Min        | Max     |
|-------------------------------------|------|---------|------------|---------|
| deadlock_detection_interval_in_secs |      |         |            |         |
| isolation_level                     | int  | 4       | 4          | 6       |
| lock_escalation                     | int  | 100,000 | 5          |         |
| lock_timeout                        | msec | -1(inf) | 0(no wait) | INT_MAX |
| rollback_on_lock_escalation         | bool | no      |            |         |

### deadlock\_detection\_interval\_in\_secs

**deadlock\_detection\_interval\_in\_secs** is a parameter to configure the interval (in seconds) in which deadlocks are detected for stopped transactions. If a deadlock occurs, CUBRID resolves the problem by rolling back one of the transactions. The default value is 1 second and the minimum value is 0.1 second. This value is rounded up by 0.1 sec. unit. For example, if an input value is 0.12 seconds, the value is rounded up to 0.2 seconds. Note that deadlocks cannot be detected if the detection interval is too long.

### isolation\_level

**isolation\_level** is a parameter to configure the isolation level of a transaction. The higher the isolation level, the less concurrency and the less interruption by other concurrent transactions. The **isolation\_level** parameter can be configured to an integer value from 4 to 6, which represent isolation levels, or character strings. The default value is **READ COMMITTED**. For details about each isolation level and parameter values, see [Transaction Isolation Level](#) and the following table.

| Isolation Level | isolation_level Parameter Value |
|-----------------|---------------------------------|
| SERIALIZABLE    | "TRAN_SERIALIZABLE" or 6        |

| Isolation Level | isolation_level Parameter Value                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------|
| REPEATABLE READ | "TRAN_REP_CLASS_REP_INSTANCE" or<br>"TRAN_REP_READ" or 5                                        |
| READ COMMITTED  | "TRAN_REP_CLASS_COMMIT_INSTANCE"<br>or "TRAN_READ_COMMITTED" or<br>"TRAN_CURSOR_STABILITY" or 4 |

- **TRAN\_SERIALIZABLE** : This isolation level ensures the highest level of consistency. For details, see [SERIALIZABLE Isolation Level](#).
- **TRAN\_REP\_READ** : This isolation level prevents dirty reads, non-repeatable reads, and phantom reads due to snapshot isolation. For details, see [REPEATABLE READ Isolation Level](#).
- **TRAN\_READ\_COMMITTED** : This isolation level can incur unrepeatable read. For details, see [READ COMMITTED Isolation Level](#).

#### Note

9.3 or less version supports the below levels additionally. From 10.0, concurrency can be guaranteed more because MVCC method is applied when multiple concurrent transactions are processed; therefore, the below isolation levels are not used anymore.

- **TRAN\_REP\_CLASS\_UNCOMMIT\_INSTANCE** : This isolation level can incur dirty read.
- **TRAN\_COMMIT\_CLASS\_COMMIT\_INSTANCE** : This isolation level can incur unrepeatable read. It allows modification of table schema by current transactions while data is being retrieved.
- **TRAN\_COMMIT\_CLASS\_UNCOMMIT\_INSTANCE** : This isolation level can incur dirty read. It allows modification of table schema by current transactions while data is being retrieved.

**lock\_escalation** is a parameter to configure the maximum number of locks permitted before row level locking is extended to table level locking. The default value is **100,000**. If the value of the **lock\_escalation** parameter is small, the overhead by memory lock management is small as well; however, the concurrency decreases. On the other hand, if the configured value is large, the overhead is large as well; however, the concurrency increases.

### **lock\_timeout**

**lock\_timeout** is a client parameter to configure the lock waiting time. If the lock is not permitted within the specified time period, the given transaction is canceled, and an error message is returned. If the parameter is configured to **-1**, which is the default value, the waiting time is infinite until the lock is permitted. If it is configured to **0**, there is no waiting for locks.

You can set a unit as s, min or h, which stands for seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied, and it is rounded up to seconds. For example, 1ms will be 1s, and 1001ms will be 2s.

### **rollback\_on\_lock\_escalation**

It specifies rolling back the transaction or not when the lock escalation occurs. The default is **no**.

If this parameter is specified with **yes**, the error log is written without lock escalation on the lock-escalating time and this lock escalation request is failed with rolling back the transaction. If it is specified with **no**, the lock escalation is performed and the transaction is continued.

When the lock escalation occurs, record locks are transformed into a table lock and lock-releasing time can take long, so other transaction's access to the table can be impossible. However, if you specify the value of **lock\_escalation** parameter(it specifies the number of record locks occurring the lock escalation) bigger, the system can overuse the memory resource.

## Logging-Related Parameters

The following are parameters related to logs used for database backup and restore. The types and value range for each parameter are as follows:

| Parameter Name            | Type | Default                 | Min                    | Max                        |
|---------------------------|------|-------------------------|------------------------|----------------------------|
| adaptive_flush_control    | bool | yes                     |                        |                            |
| background_archiving      | bool | yes                     |                        |                            |
| checkpoint_every_size     | byte | 10,000<br>log_page_size | * 10<br>log_page_size  | * log_page_size            |
| checkpoint_interval       | msec | 6min                    | 1min                   | 35,791,394min              |
| checkpoint_sleep_msecs    | msec | 1                       | 0                      |                            |
| force_remove_log_archives | bool | yes                     |                        |                            |
| log_buffer_size           | byte | 16k<br>log_page_size    | * 128<br>log_page_size | * INT_MAX<br>log_page_size |
| log_max_archives          | int  | INT_MAX                 | 0                      | INT_MAX                    |
| log_trace_flush_time      | int  | 0                       | 0                      | INT_MAX                    |
| max_flush_size_per_second | byte | 10,000<br>db_page_size  | * 1<br>db_page_size    | * INT_MAX<br>db_page_size  |
|                           | sec  | 0                       | 0                      |                            |

| Parameter Name                         | Type | Default             | Min                 | Max                       |
|----------------------------------------|------|---------------------|---------------------|---------------------------|
| remove_log_archive_interval_in_seconds |      |                     |                     |                           |
| sync_on_flush_size                     | byte | 200<br>db_page_size | * 1<br>db_page_size | * INT_MAX<br>db_page_size |
| ddl_audit_log                          | bool | no                  |                     |                           |
| ddl_audit_log_size                     | byte | 10M                 | 10M                 | 2G                        |

### adaptive\_flush\_control

**adaptive\_flush\_control** is a parameter used automatically to adjust the flush capacity at every 50 ms depending on the current status of the flushing operation. The default value is **yes**. That is, this capacity is increased if a large number of **INSERT** or **UPDATE** operations are concentrated at a certain point of time and the number of flushed pages reaches the **max\_flush\_size\_per\_second** parameter value; and is decreased otherwise. In the same way, you can distribute the I/O load by adjusting the flush capacity on a regular basis depending on the workload.

### background\_archiving

**background\_archiving** is a parameter used to create temporary archive logs periodically at a specific time. It is useful when balancing disk I/O load which has been caused by archiving logs. The default is **yes**.

### checkpoint\_every\_size

**checkpoint\_every\_size** is a parameter to configure checkpoint interval by log page. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is **10,000 \* log\_page\_size (156.25M** when log\_page\_size is 16K).

You can distribute disk I/O overload at the checkpoint by specifying lower size in the **checkpoint\_every\_size** parameter, especially in the environment where **INSERT** / **UPDATE** are heavily loaded at a specific time.

Checkpoint is a job to record every modified page except for the temp page in data buffers to database volumes (disk) at a specific point. Checkpoint can shrink a restore time after the database failure because this makes the transaction logs which have been generated previously than the checkpoint time needless when the restore is processed. However, an efficient checkpoint interval should be properly considered because this job can occur a lot of disk I/O.

#### Note

There are three ways to run checkpoint in CUBRID. The following two ways are provided by the setting of cubrid.conf.

- **checkpoint\_interval**: After the previous checkpoint is done, checkpoint is periodically processed at every time after the term of this parameter value.
- **checkpoint\_every\_size**: Checkpoint is periodically processed at every time after the transaction log size of this parameter value.

If one condition on the above parameters is satisfied, checkpoint is processed.

The following two ways are provided by a user's command.

- If you run “;checkpoint” command in the CSQL interpreter, which is run with a “DBA” user, checkpoint is processed.

As a reference, if you run backup command during checkpoint, backup command is blocked until checkpoint is ended.

### **checkpoint\_interval**

**checkpoint\_interval** is a parameter to configure execution period of checkpoint. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied, and it is rounded up to seconds. For example, 1ms will be 1s, and 1001ms will be 2s. The default value is **6min** and the minimum value is 1min.

### **checkpoint\_sleep\_msecs**

**checkpoint\_sleep\_msecs** is a parameter to let the job which flushes a buffer's data into a disk process slowly. The default is **1** (millisecond).

## force\_remove\_log\_archives

**force\_remove\_log\_archives** is a parameter to configure whether to allow the deletion of the files other than the recent log archive files whose number is specified by **log\_max\_archives**. The default value is **yes**.

If the value is set to **yes**, the files will be deleted other than the recent log archive files for which the number is specified by **log\_max\_archives**.

If it is set to **no**, the log archive files will not be deleted. Exceptionally, if **ha\_mode** is set to **on**, the files other than the log archive files required for the HA-related processes and the recent log archive files of which the number is specified by **log\_max\_archives** will be deleted.

For setting up the CUBRID HA environment, see [Environment Configuration](#).

## log\_buffer\_size

**log\_buffer\_size** is a parameter to configure the size of log buffer to be cached in the memory. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is 16k \* **log\_page\_size** (**256M** when **log\_page\_size** is 16K).

If the value of the **log\_buffer\_size** parameter is large, performance can be improved (due to the decrease in disk I/O) in an environment where transactions are long and numerous. Moreover, CUBRID Multiversion Concurrency Control system relies on log to access previous row versions and to vacuum invisible versions from database. It is recommended to configure an appropriate value considering the memory size and operations of the system where CUBRID is installed.

- Required memory size = the size of log buffer (**log\_buffer\_size**)

## log\_max\_archives

**log\_max\_archives** is a parameter to configure the maximum number of archive log files. The minimum value is 0 and default value is **INT\_MAX** (2,147,483,647). Its operations can differ depending on the configuration of **force\_remove\_log\_archives**. For example, when **log\_max\_archives** is 3 and **force\_remove\_log\_archives** is **yes** in the cubrid.conf file, the most recent three archive log files are recorded and when a fourth archiving log file is generated, the oldest archive log file is automatically deleted; the information about the deleted archive logs are recorded in the **\*\_lginf** file. When a user sets **ha\_mode=off** and **force\_remove\_log\_archives=n**, the system automatically assigns the value of **INT\_MAX** (2,147,483,647) to **log\_max\_archives** instead of the value entered by the user.

However, if an active transaction still refers to an existing archive log file, the archive log file will not be deleted. That is, if a transaction starts at the point that the first archive log file is generated, and it is still active until the fifth archive log is generated, the first archive log file cannot be deleted.

Also, if the information of archive logs is not applied to database volumes, these are not deleted. (Archive logs after which a checkpoint has occurred keep the information of modified pages of a data buffer; therefore, they are required to restore a database.)

If you change the value of **log\_max\_archives** dynamically during database operation, changed value will be applied when a new log archive file is created. For example, if you change this value from 10 to 5, old 5 files will be deleted when a new log archive file is created.

For setting up the CUBRID HA environment, see [Environment Configuration](#).

#### Note

In 2008 R4.3 or lower and in 9.1, **log\_max\_archives** was also used for specifying the maximum number of keeping replication log files in HA environment. From 2008 R4.4 and 9.2, **ha\_copy\_log\_max\_archives** of cubrid\_ha.conf is in charge of this role.

## log\_trace\_flush\_time

When the log flushing time takes more time than the time you set in this parameter, this event is recorded in the log of the database server.

The example of written information is as below.

```
03/18/14 10:20:45.889 - LOG_FLUSH_THREAD_WAIT
total flush count: 1 page(s)
total flush time: 310 ms
time waiting for log writer: 308 ms
last log writer info
  client: DBA@cdb037.cub|copylogdb(15312)
  time spent by log writer: 308 ms
```

- LOG\_FLUSH\_THREAD\_WAIT: Event name
- total flush count: The number of flushed pages when the event occurs
- total flush time: Total spent time when the log is flushed

- time waiting for log writer: The time LFT(Log Flushing Thread) has been waiting for LWT(Log Writer Thread)
- last log writer info
  - `DBA@cubs037.cub|copylogdb(15312)`: copylogdb information related to LWT which let LFT wait `<user@host_name|client_name(pid)>`
  - time spent by log writer: Time spend by LWT measured in LWT; in general, this value is the same as the value of “time waiting for log writer”)

### **max\_flush\_size\_per\_second**

**max\_flush\_size\_per\_second** is a parameter to configure the maximum flush capacity when the flushing operation is performed from a buffer to a disk. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is  $10,000 * \text{db\_page\_size}$  (**156.25M** when db\_page\_size is 16K). That is, you can prevent concentration of I/O load at a certain point of time by configuring this parameter to control the maximum flush capacity per second.

If a large number of **INSERT** or **UPDATE** operations are concentrated at a certain point of time, and the flush capacity reaches the maximum capacity set by this parameter, only log pages are flushed to the disk, and data pages are no longer flushed. Therefore, you must set an appropriate value for this parameter considering the workload of the service environment.

### **remove\_log\_archive\_interval\_in\_secs**

Archive logs which exceed the specified number in the **log\_max\_archives** are removed when checkpoint occurs. By the way, many archive logs can be removed at once frequently after being piled up when jobs such as data migration or big data batch processing are performed. If files are removed at once like these, I/O overhead of database server is rapidly risen; therefore, we need to decrease this burden.

**remove\_log\_archive\_interval\_in\_secs** parameter lets archive logs delete slowly to shrink this burden. The default is **0** (second). In the situations which jobs like big data batch processing occur frequently, it is recommended to set the deletion interval as a 60 seconds if the disk space is enough.

### **sync\_on\_flush\_size**

**sync\_on\_flush\_size** is a parameter to configure the interval in pages between after data and log pages are flushed from buffer and before they are synchronized with FILE I/O of operating system. The default value is  $200 * \text{db\_page\_size}$  (**3.125M** when db\_page\_size is 16K). That is, the CUBRID Server performs synchronization with the

FILE I/O of the operating system whenever 200 pages have been flushed. This is also a parameter related to I/O load.

### **ddl\_audit\_log**

**ddl\_audit\_log** is a parameter to turn on/off DDL logging facility. The default value is no. If this value is set to yes, all DDL executed will be logged into the logfile. The path of log files is \$CUBRID/log/ddl\_audit, and refer to :doc:/admin/ddl\_audit for each DDL AUDIT log file name and description of log files in detail.

### **ddl\_audit\_log\_size**

**ddl\_audit\_log\_size** specifies the maximum size of the DDL AUDIT log file. If the ddl audit log file is larger than the specified size, that ddl audit log file is backed up with the name of .bak appended to the ddl audit log file, and new recording will be started with the file from the beginning of the file. You can set the size with a size unit as B, K, M, or G, which stand for bytes, kilobytes (KB), megabytes (MB), and gigabytes (GB) respectively. If you omit the size unit, bytes will be applied. The default is 10M, and it can be set up to 2G.

## Transaction Processing-Related Parameters

The following are parameters for improving transaction commit performance. The type and value range for each parameter are as follows:

| Parameter Name                 | Type | Default | Min | Max |
|--------------------------------|------|---------|-----|-----|
| async_commit                   | bool | no      |     |     |
| group_commit_interval_in_msecs | msec | 0       | 0   |     |

### **async\_commit**

**async\_commit** is a parameter used to activate the asynchronous commit functionality. If the parameter is set to **no**, which is the default value, the asynchronous commit is not performed; if it is set to **yes**, the asynchronous commit is executed. The asynchronous commit is a functionality that improves commit performance by completing the commit for the client before commit logs are flushed on the disk and having the log flush thread (LFT) perform log flushing in the background. Note that already committed transactions cannot be restored if a failure occurs on the database server before log flushing is performed.

## group\_commit\_interval\_in\_msecs

**group\_commit\_interval\_in\_msecs** is a parameter to configure the interval (in milliseconds), at which the group commit is to be performed. If the parameter is configured to **0**, which is the default value, the group commit is not performed. The group commit is a functionality that improves commit performance by combining multiple commits that occurred in the specified time period into a group so that commit logs are flushed on the disk at once.

## dblink\_auto\_commit

**dblink\_auto\_commit** is a setting that affects the commit behavior of queries executed through dblink during distributed transactions. The default value is **yes**.

- When this parameter is set to **yes**, queries executed via dblink are automatically committed immediately upon execution.
- Conversely, if it is set to **no**, the queries on the remote server connected through dblink are committed only when the entire transaction, including the dblink, is committed.

In distributed transactions, the system attempts to commit the dblink queries first. If any of these commits fail, the entire transaction is rolled back.

### Warning

- If some dblink queries have already been committed and the overall transaction commit later fails, those prior commits cannot be rolled back.
- Savepoints are not supported in dblink transactions.

## Statement/Type-Related Parameters

The following are parameters related to SQL statements and data types supported by CUBRID. The type and value range for each parameter are as follows:

| Parameter Name                 | Type | Default | Min | Max       |
|--------------------------------|------|---------|-----|-----------|
| add_column_update_hard_default | bool | no      |     |           |
| alter_table_change_type_strict | bool | yes     |     |           |
| allow_truncated_string         | bool | no      |     |           |
| ansi_quotes                    | bool | yes     |     |           |
| block_ddl_statement            | bool | no      |     |           |
| block_nowhere_statement        | bool | no      |     |           |
| compat_numeric_division_scale  | bool | no      |     |           |
| create_table_reuse_id          | bool | yes     |     |           |
| cte_max_recurSIONs             | int  | 2,000   | 2   | 1,000,000 |
| default_week_format            | int  | 0       |     |           |
| group_concat_max_len           | byte | 1,024   | 4   | INT_MAX   |

| Parameter Name                | Type   | Default | Min   | Max       |
|-------------------------------|--------|---------|-------|-----------|
| intl_check_input_string       | bool   | no      |       |           |
| intl_collation                | string |         |       |           |
| intl_date_lang                | string |         |       |           |
| intl_number_lang              | string |         |       |           |
| json_max_array_idx            | int    | 65,536  | 1,024 | 1,048,576 |
| max_query_per_tan             | int    | 100     | 1     | 32,767    |
| no_backslash_escapes          | bool   | yes     |       |           |
| only_full_group_by            | bool   | no      |       |           |
| oracle_compat_number_behavior | bool   | no      |       |           |
| oracle_style_empty_string     | bool   | no      |       |           |
| pipes_as_concat               | bool   | yes     |       |           |
| plus_as_concat                | bool   | yes     |       |           |

| Parameter Name                       | Type | Default   | Min | Max        |
|--------------------------------------|------|-----------|-----|------------|
| require_like_escape_character        | bool | no        |     |            |
| return_null_on_function_errors       | bool | no        |     |            |
| stored_procedure_return_numeric_size | list | 38,15     | 1,0 | 38,38      |
| string_max_size_bytes                | byte | 1,048,576 | 64  | 33,554,432 |
| unicode_input_normalization          | bool | no        |     |            |
| unicode_output_normalization         | bool | no        |     |            |
| update_use_attribute_references      | bool | no        |     |            |

### add\_column\_update\_hard\_default

**add\_column\_update\_hard\_default** is a parameter to configure whether or not to provide the hard default value as the input value for a column when you add a new column to the **ALTER TABLE ... ADD COLUMN** clause.

When there is **NOT NULL** constraint and no **DEFAULT** constraint, if a value of this parameter is set to **yes**, the value of newly added column will be inserted as hard default value; if it is set to **no**, CUBRID returns an error. For the hard default for each type, see the **CHANGE/MODIFY Clauses** of the **ALTER TABLE** statement.

```
SET SYSTEM PARAMETERS 'add_column_update_hard_default=yes';
```

```
CREATE TABLE tbl (i int);
INSERT INTO tbl VALUES (1),(2);
ALTER TABLE tbl ADD COLUMN j INT NOT NULL;

SELECT * FROM tbl;
```

| i | j |
|---|---|
| 1 | 0 |
| 2 | 0 |

```
SET SYSTEM PARAMETERS 'add_column_update_hard_default=no';

CREATE TABLE tbl (i INT);
INSERT INTO tbl VALUES (1),(2);
ALTER TABLE tbl ADD COLUMN j INT NOT NULL;
```

```
ERROR: Cannot add NOT NULL constraint for attribute "j":
there are existing NULL values for this attribute.
```

### alter\_table\_change\_type\_strict

**alter\_table\_change\_type\_strict** is a parameter to configure whether to allow the conversion of column values according to the type change, and the default value is **yes**. If a value for this parameter is set to **no**, the value may be changed when you change the column types or when you add **NOT NULL** constraints; if it is set to **yes**, the value does not change. For details, see [CHANGE Clause in the CHANGE/MODIFY Clauses](#).

### allow\_truncated\_string

**allow\_truncated\_string** is a parameter to configure whether to allow the truncation of string values according to the string manipulation operations used in insert or update query, and the default value is **no**. If the value for this parameter is set to **no**, the string value is not allowed to be truncated when you do operation for any string related to insert or update query; however the string related to select query may be truncated regardless of this configuration. If it is set to **yes**, the string value may be truncated regardless of the type of (INSERT/UPDATE/SELECT) query.

### ansi\_quotes

**ansi\_quotes** is a parameter used to enclose symbols and character string to handle identifiers. The default value is **yes**. If this parameter value is set to **yes**, double quotations are handled as identifier symbols and single quotations are handled as

character string symbols. If it is set to **no**, both double and single quotations are handled as character string symbols.

### **block\_ddl\_statement**

**block\_ddl\_statement** is a parameter used to limit the execution of DDL (Data Definition Language) statements by the client. If the parameter is set to **no**, the given client is allowed to execute DDL statements. If it is set to **yes**, the client is not permitted to execute DDL statements. If set to **Yes**, update statistics may also be restricted. The default value is **no**.

### **block\_nowhere\_statement**

**block\_nowhere\_statement** is a parameter used to limit the execution of **UPDATE** / **DELETE** statements without a condition clause (**WHERE**) by the client. If the parameter is set to **no**, the given client is allowed to execute **UPDATE** / **DELETE** statements without a condition clause. If it is set to **yes**, the client is not permitted to execute **UPDATE** / **DELETE** statements without a condition clause. The default value is **no**.

### **compat\_numeric\_division\_scale**

**compat\_numeric\_division\_scale** is a parameter to configure the scale to be displayed in the result (quotient) of a division operation. If the parameter is set to **no**, the scale of the quotient is 9, if it is set to **yes**, the scale is determined by that of the operand. The default value is **no**.

### **create\_table\_reuseoid**

**create\_table\_reuseoid** is a parameter to specify whether to use the **REUSE\_OID** or **DONT\_REUSE\_OID** option when creating a table without table option. If it is set to **yes**, the table is created with **REUSE\_OID** option. The default value is **yes**.

For detail, see [REUSE\\_OID](#) and [DONT\\_REUSE\\_OID](#).

### **cte\_max\_recursions**

**cte\_max\_recursions** is a parameter to limit the maximum number of iterations when executing the recursive part of the CTE (Common Table Expressions) statement. This avoids infinite loop and potential issues produced by the size of temporary lists.

### **default\_week\_format**

**default\_week\_format** is a parameter to configure default value for the *mode* attribute of the `WEEK()` function. The default value is **0**. For details, see `WEEK()`.

### **intl\_check\_input\_string**

**intl\_check\_input\_string** is a parameter to determine whether or not to check that string entered is correctly corresponded to character set used. The default value is **no**. If this value is **no** and character set is UTF-8 and incorrect data is enter which violate UTF-8 byte sequence, it can show abnormal behavior or database server and applications can be terminated abnormally. However, if it is guaranteed this problem does not happen, it has advantage in performance not to do it.

UTF-8 and EUC-KR can be checked; ISO-8859-1 is one-byte encoding so it does not have to be checked because every byte is valid.

### **group\_concat\_max\_len**

**group\_concat\_max\_len** is a parameter used to limit the return value size of the `GROUP_CONCAT()` function. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is **1,024**. The minimum value is 4 and the maximum value is INT\_MAX (about 2G) bytes.

This function is affected by **string\_max\_size\_bytes** parameter; if the value of **group\_concat\_max\_len** is greater than the value **string\_max\_size\_bytes** and the result size of **GROUP\_CONCAT** exceeds the value of **string\_max\_size\_bytes**, an error occurs.

### **intl\_check\_input\_string**

**intl\_check\_input\_string** is a parameter to determine whether or not to check that string entered is correctly corresponded to character set used. The default value is **no**. If this value is no and character set is UTF-8 and incorrect data is enter which violate UTF-8 byte sequence, it can show abnormal behavior or database server and applications can be terminated abnormally. However, if it is guaranteed this problem does not happen, it has advantage in performance not to do it.

UTF-8 and EUC-KR can be checked; ISO-8859-1 is one-byte encoding so it does not have to be checked because every byte is valid.

### **intl\_collation**

**intl\_collation** is a parameter which specifies a collation name about a specific application client. Specifying this parameter is the same as changing a collation of application client by using "SET NAMES" statement. Specifying a collation includes a charset.

The following two statements behave the same.

```
SET NAMES utf8;  
SET SYSTEM PARAMETERS 'intl_collation=utf8_bin';
```

For an available value of **intl\_collation**, see [Collation](#).

## intl\_date\_lang

**intl\_date\_lang** is a parameter used to input/output the values of **TIME**, **DATE**, **DATETIME**, and **TIMESTAMP**. If language name is omitted, it specifies a locale format of string of localized calendar (month, weekday, and AM/PM).

The values allowed are as follows: Note that to use all values, locale library should be configured except built-in locale. For configuring locale, see [Locale Setting](#).

| Language   | Locale Name of Language |
|------------|-------------------------|
| English    | en_US                   |
| German     | de_DE                   |
| Spanish    | es_ES                   |
| French     | fr_FR                   |
| Italian    | it_IT                   |
| Japanese   | ja_JP                   |
| Cambodian  | km_KH                   |
| Korean     | ko_KR                   |
| Turkish    | tr_TR                   |
| Vietnamese | vi_VN                   |
| Chinese    | zh_CN                   |

| Language | Locale Name of Language |
|----------|-------------------------|
| Romanian | ro_RO                   |

The function recognizing input string based on calendar format of specified language is as follows:

- `TO_DATE()`
- `TO_TIME()`
- `TO_DATETIME()`
- `TO_TIMESTAMP()`
- `STR_TO_DATE()`

The function outputting string based on calendar format of specified language is as follows:

- `TO_CHAR()`
- `DATE_FORMAT()`
- `TIME_FORMAT()`

## intl\_number\_lang

**intl\_number\_lang** is a parameter used to specify locale applied when numeric format is assigned to input/output string in the function where a string is converted to number or number is converted to string. A delimiter and decimal symbol are used for numeric localization. In general, a comma and period are used; however, it can be changeable based on locale. For example, while number 1000.12 is written as 1,000.12 in most locale, it is written as 1.000,12 in tr\_TR locale.

The function recognizing input string based on calendar format of specified language is as follows:

- `TO_NUMBER()`

The function outputting string based on calendar format of specified language is as follows:

- `FORMAT()`
- `TO_CHAR()`

## json\_max\_array\_idx

**json\_max\_array\_idx** is a parameter used by JSON functions to set a limit on the size of arrays after changes.

If a very large index is fed to functions like **JSON\_ARRAY\_INSERT** by accident, the JSON document will occupy a lot of memory and disk space. Use this parameter to limit the risks.

The limit is not applied to arrays generated by parsing strings.

## max\_query\_per\_tran

**max\_query\_per\_tran** is a parameter used to set the maximum number of queries (unclosed queries) that can be held per transaction.

The default setting is 100, the minimum value is 1, and the maximum value is 32,767. Be careful not to set this value too high, as it may increase memory usage and affect overall system performance.

## no\_backslash\_escapes

**no\_backslash\_escapes** is a parameter to configure whether or not to use backslash (\) as an escape character, and the default value is **yes**. If a value for this parameter is set to **no**, backslash (\) will be used as an escape character; if it is set to **yes**, backslash (\) will be used as a normal character. For example, if this value is set to **no**, “\n” means a newline character. For details, see [Escape Special Characters](#).

## only\_full\_group\_by

**only\_full\_group\_by** is a parameter to configure whether or not to use extended syntax about using **GROUP BY** statement.

If this parameter value is set to **no**, an extended syntax is applied thus, a column that is not specified in the **GROUP BY** statement can be specified in the **SELECT** column list. If it is set to **yes**, a column that is only specified in the **GROUP BY** statement can be the **SELECT** column list.

The default value is **no**. Therefore, specify the **only\_full\_group\_by** parameter value to **yes** to execute queries by SQL standards. Because the extended syntax is not applied in this case, an error below is displayed.

```
ERROR: Attributes exposed in aggregate queries must also
appear in the group by clause.
```

## oracle\_compat\_number\_behavior

**oracle\_compat\_number\_behavior** is a parameter used to improve compatibility with other DBMS (Database Management Systems); for NUMERIC type, DOUBLE and FLOAT types, it does not display decimal point trailing 0, and in case of DOUBLE and FLOAT, it does not display the exponent. For example, if this parameter setting value is **no**, the result of a query that searches the a\_double table composed of DOUBLE types is displayed in the form of an exponent as shown below, but if the parameter setting value is **yes**, only decimal point is displayed.

```
csql> ;get oracle_compat_number_behavior

=== Get Param Input ===

oracle_compat_number_behavior=n

SELECT a FROM a_double;
```

```

                                a
=====
1.234567890123457e+19
1.234567890123457e-08
1.2300000000000000e-08
1.0000000000000000e+00
1.2000000000000000e+00
-4.9390303000000000e-03
-1.293934894993939e+18
-1.938943893939394e+16
```

```
csql> ;get oracle_compat_number_behavior

=== Get Param Input ===

oracle_compat_number_behavior=y

SELECT a FROM a_double;
```

```

                                a
=====
12345678901234570000
0.00000001234567890123457
0.0000000123

1.2
-0.0049390303
-1293934894993939000
-19389438939393940
```

Also, when **oracle\_compat\_number\_behavior** is set to **yes**, the type of division operation for integer numbers becomes a real number type (that is, a NUMERIC type) not an integer type. In the example below, if this parameter is **yes**, affected integer types are INT, SHORT and BIGINT.

```
csql> ;get oracle_compat_number_behavior

=== Get Param Input ===

oracle_compat_number_behavior=y

SELECT 1/2;
```

```
      1/2
=====
      0.5
```

#### Note

The following JDBC/CCI functions are affected by the oracle\_compat\_number\_behavior setting:

#### JDBC

##### **getString(int columnIndex), getString(String columnLabel)**

• Data Types Affected: NUMERIC, DOUBLE, FLOAT

##### **getObject(int columnIndex), getObject(String columnLabel)**

• Data Types Affected: NUMERIC

#### CCI

##### **cci\_get\_data(CCI\_A\_TYPE\_STR as type), Example) cci\_get\_data(req, i, CCI\_A\_TYPE\_STR, &data, &ind)**

• Data Types Affected: NUMERIC, DOUBLE, FLOAT

## oracle\_style\_empty\_string

**oracle\_style\_empty\_string** is a parameter used to improve compatibility with other DBMS (Database Management Systems); it specifies to process empty string and **NULL** as the same value. The default is **no**. If the **oracle\_style\_empty\_string** parameter is set to **no**, the character string is processed as a valid string; if it is set to **yes**,

according to each function, the empty string is processed as **NULL** or **NULL** is processed as the empty string.

#### Note

Other functions except below functions are not affected by **oracle\_style\_empty\_string** parameter.

• Functions processing an empty string and NULL into NULL when **oracle\_style\_empty\_string=yes**.

- ASCII()
- CONCAT\_WS()
- ELT()
- FIELD()
- FIND\_IN\_SET()
- FROM\_BASE64()
- INSERT()
- INSTR()
- LOWER()
- LEFT()
- LOCATE()
- LPAD()
- LTRIM()
- MID()
- POSITION()
- REPEAT()
- REVERSE()
- RIGHT()

- RPAD()
  - RTRIM()
  - SPACE()
  - STRCMP()
  - SUBSTR()
  - SUBSTRING()
  - SUBSTRING\_INDEX()
  - TO\_BASE64()
  - TRANSLATE()
  - TRIM()
  - UPPER()
- Functions processing an empty string and NULL into an empty string when **oracle\_style\_empty\_string=yes**.
- CONCAT()
  - REPLACE()

#### Note

**REPLACE()** function has the different behavior in the previous versions of 10.0 when **oracle\_style\_empty\_string=yes**.

```
SELECT REPLACE ('abc', 'a', '');
```

In the above query, the version of 10.0 or more return 'bc' because it processes the input of an empty string as an empty string; the previous version of 10.0 returns NULL because it processes the input of an empty string as NULL.

**pipes\_as\_concat** is a parameter to configure how to handle a double pipe symbol. The default value is **yes**. If this parameter value is set to **yes**, a double pipe symbol is handled as a concatenation operator if **no**, it is handled as the **OR** operator.

### plus\_as\_concat

**plus\_as\_concat** is a parameter to configure the plus (+) operator, and the default value is **yes**. If a value for this parameter is set to **yes**, the plus (+) operator will be interpreted as a concatenation operator; if it is set to **no**, the operator will be interpreted as a numeric operator.

```
-- plus_as_concat = yes
SELECT '1'+'1';
```

```
      '1'+'1'
=====
      '11'
```

```
SELECT '1'+'a';
```

```
      '1'+'a'
=====
      '1a'
```

```
-- plus_as_concat = no
SELECT '1'+'1';
```

```
      '1'+'1'
=====
2.0000000000000000e+000
```

```
SELECT '1'+'a';
```

```
ERROR: Cannot coerce 'a' to type double.
```

### require\_like\_escape\_character

**require\_like\_escape\_character** is parameter to configure whether or not to use an ESCAPE character in the **LIKE** clause, and the default value is **no**. If a value for this

parameter is set to **yes** and a value for **no\_backslash\_escapes** is set to **no**, backslash (\) will be used as an ESCAPE character in the strings of the LIKE clause, otherwise you should specify an ESCAPE character by using the **LIKE ... ESCAPE** clause. For details, see [LIKE](#).

## **return\_null\_on\_function\_errors**

**return\_null\_on\_function\_errors** is a parameter used to define actions when errors occur in some SQL functions, and the default value is **no**. If a value for this parameter is set to **yes**, **NULL** is returned; if it is set to **no**, an error is returned when the error occurs in functions, and the related message is displayed.

The following SQL functions are affected by this system parameter.

### **Date/Time functions**

- `ADDDATE()`
- `ADDTIME()`
- `DATEDIFF()`
- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `FROM_DAYS()`
- `FROM_UNIXTIME()`
- `HOUR()`
- `LAST_DAY()`
- `MAKEDATE()`
- `MAKETIME()`
- `MINUTE()`
- `MONTH()`
- `QUARTER()`
- `SEC_TO_TIME()`

- `SECOND()`
- `TIME()`
- `TIME_TO_SEC()`
- `TIMEDIFF()`
- `TO_DAYS()`
- `WEEK()`
- `WEEKDAY()`
- `YEAR()`

## String functions

- `ASCII()`
- `BIN()`
- `BIT_LENGTH()`
- `CHR()`

## Numeric functions

- `ABS()`
- `ACOS()`
- `ASIN()`
- `ATAN()`
- `ATAN2()`
- `CEIL()`
- `CONV()`
- `COS()`
- `COT()`
- `DEGREES()`
- `EXP()`
- `FLOOR()`

- `LN()`
- `LOG2()`
- `LOG10()`
- `MOD()`
- `POW()`
- `RADIANS()`
- `SIGN()`
- `SIN()`
- `SQRT()`
- `TAN()`
- `TRUNC()`
- `WIDTH_BUCKET()`

```
SET SYSTEM PARAMETERS 'return_null_on_function_errors=no';
SELECT YEAR('12:34:56');
```

```
ERROR: Conversion error in time format.
```

```
SET SYSTEM PARAMETERS 'return_null_on_function_errors=yes';
SELECT YEAR('12:34:56');
```

```
year('12:34:56')
=====
NULL
```

### **stored\_procedure\_return\_numeric\_size**

**stored\_procedure\_return\_numeric\_size** is a parameter that sets the precision and scale of values returned as the NUMERIC type in a stored procedure. The setting is specified as a list of positive integers, with the precision and scale designated respectively. For example, to set the precision to 15 and the scale to 10, specify it as 15,10. The default value is 38,15, and the valid range is from 1 to 38 for precision and from 0 to 38 for scale. Additionally, the scale value cannot exceed the precision value.

## string\_max\_size\_bytes

**string\_max\_size\_bytes** is a parameter to define the maximum byte allowable in string functions or operators. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is **1,048,576**(1M). The minimum value is 64 and the maximum value is 33,554,432(32M). If the maximum value is exceeded, REPEAT and SPACE functions return NULL, while other functions return an error.

The functions and operators affected by this parameter are as follows:

- **SPACE()**
- **CONCAT()**
- **CONCAT\_WS()**
- '+': Operand of string
- **REPEAT()**
- **GROUP\_CONCAT()**: This function is affected not only by **string\_max\_size\_bytes** parameter, but also by **group\_concat\_max\_len**.
- **INSERT()** function

## unicode\_input\_normalization

**unicode\_input\_normalization** is a parameter to determine whether or not to input unicode stored in system level or not. The default value is **no**.

In general, unicode text can be stored in “fully composed” or “fully decomposed”. When character ‘Ä’ has 00C4 (if it is encoded in UTF-8, it becomes 2 bytes of C3 84) which is only one code point. In “fully decomposed” mode, it has two code points/characters. It is 0041 (character “A”) and 0308(COMBINING DIAERESIS). In case of UTF-8 encoding, it becomes 3 bytes of 41 CC 88.

CUBRID can work with fully composed unicode. For clients which have fully decomposed texts, configure the value of **unicode\_input\_normalization** to yes so that it can be converted to fully composed mode; and then it can be reverted to fully decomposed mode. For normalization of unicode encapsulation of CUBRID, compatibility equivalence is not applied. In general, normalization of unicode is not possible to revert after composition, CUBRID supports revert for characters as many as possible, and it applies normalization of unicode encapsulation. The characteristics of CUBRID normalization are as follows:

- In case of language specific, normalization does not depend on locale.

If one or more locale can be used, this means every CAS/CSQL process, not CUBRID server. The **unicode\_input\_normalization** system parameter determines whether composition of input codes by normalization in system level. The **unicode\_output\_normalization** system parameter determines whether composition of output codes by normalization in system level.

- Collation and normalization does not have direct relationship.

Even though the value of **unicode\_input\_normalization** is no, the string of extensible collation (utf8\_de\_exp, utf8\_jap\_exp, utf8\_km\_exp) is properly sorted fully decomposed mode, it is not intended; it is side-effect of UCA(Unicode Collation Algorithm). The extensible collation is implemented only with fully composed texts.

- In CUBRID, composition and decomposition for normalization does not work separately.

It is generally used when **unicode\_input\_normalization** and **unicode\_output\_normalization** are yes. In this case, codes entered from clients are stored in composed mode and output in decomposed mode.

If the application client sends the decomposed text data into CUBRID, let CUBRID deal with the composed code, by setting **unicode\_input\_normalization** as **yes**.

If the application client can deal with the decomposed text data only, let CUBRID always send the decomposed code, by setting **unicode\_output\_normalization** as **yes**.

If the application client knows both of input and output, leave the setting **unicode\_input\_normalization** and **unicode\_output\_normalization** as **no**.

For more details, see [An Overview of Globalization](#).

## **unicode\_output\_normalization**

**unicode\_output\_normalization** is a parameter to determine whether or not to output unicode stored in system level. The default value is **no**. For details, see the above **unicode\_input\_normalization** description.

## **update\_use\_attribute\_references**

**update\_use\_attribute\_references** is a parameter whether a value X of a column to be updated in an **UPDATE** statement affects to another column's update which uses X. The default is **no**.

The below result of an **UPDATE** statement is dependent on the value of **update\_use\_attribute\_references** parameter.

```
CREATE TABLE tbl(a INT, b INT);
INSERT INTO tbl values (10, NULL);

UPDATE tbl SET a=1, b=a;
```

If this parameter's value is **yes**, the updated value of the column “b” will be “1” which is affected by “a=1”.

```
SELECT * FROM tbl;
```

```
1, 1
```

If this parameter's value is **no**, the updated value of the column “b” will be “NULL”, which is affected by the value of “a” stored in the record, not by “a=1”.

```
SELECT * FROM tbl;
```

```
1, NULL
```

## Thread-Related Parameters

Thread management can be configured by threads parameters. The type and value range for each parameter are as follows:

| Parameter Name                    | Type | Default | Min | Max  |
|-----------------------------------|------|---------|-----|------|
| thread_connection_pooling         | bool | true    |     |      |
| thread_connection_timeout_seconds | int  | 300     | -1  | 3600 |
| thread_worker_pooling             | bool | true    |     |      |

| Parameter Name                | Type | Default          | Min | Max  |
|-------------------------------|------|------------------|-----|------|
| thread_core_count             | int  | # of system core | 1   | 1024 |
| thread_worker_timeout_seconds | int  | 300              | -1  | 3600 |
| loaddb_worker_count           | bool | 8                | 2   | 64   |

### thread\_connection\_pooling

If **thread\_connection\_pooling** parameter is true, all threads used for client connection management are pooled on server boot.

### thread\_connection\_timeout\_seconds

**thread\_connection\_timeout\_seconds** is a parameter that configures wait time before stopping for threads handling connection management. After closing a connection, the thread will wait the value of the parameter expressed in seconds to be assigned a new connection. If no connection is assigned and the wait time expires, the thread stops. Another thread may be started the next time a connection comes. If parameter value is **-1**, threads never stop. They sleep until they are given a new assignment.

### thread\_worker\_pooling

If **thread\_worker\_pooling** parameter is true, all threads used for client requests execution are pooled on server boot.

### thread\_core\_count

The number of groups of pooled threads is configured according to the **thread\_core\_count** parameter. The default value is set to the number of system cores. If the number of threads in a group does not reach 3 or more according to the parameter value, the system adjusts this value so that at least 3 threads belong to each group.

### thread\_worker\_timeout\_seconds

**thread\_worker\_timeout\_seconds** is a parameter that configures wait time before stopping for threads handling client requests. After executing a request, the thread

will wait the value of the parameter expressed in seconds to be assigned a request. If no client request is assigned and the wait time expires, the thread stops. Another thread may be started the next time a client request comes. If parameter value is **-1**, threads never stop. They sleep until they are given a new assignment.

### **loaddb\_worker\_count**

**loaddb\_worker\_count** is a parameter that configures the maximum number of threads that can be dedicated for **loaddb** sessions. If a single **loaddb** session runs, it may use all threads. If multiple **loaddb** sessions run concurrently, the total number of threads of all sessions cannot exceed the parameter's value.

### Timezone Parameter

The following are the parameters related to timezone. The type and the value range for each parameter are as follows:

| Parameter Name             | Type   | Default             | Min | Max |
|----------------------------|--------|---------------------|-----|-----|
| server_timezone            | string | OS timezone         |     |     |
| timezone                   | string | server_timezon<br>e |     |     |
| tz_leap_second_s<br>upport | bool   | no                  |     |     |

#### • **timezone**

Specifies a timezone for a session. The default is a value of **server\_timezone**. This value can be specified by a timezone offset (e.g. +01:00, +02) or a timezone region name (e.g. Asia/Seoul). This value can be changed during operating database.

#### • **server\_timezone**

Specifies a timezone for a server. The default is a OS timezone. To apply the changed value, database should be restarted. The timezone of operating system is read depending on the operating system and information found in operating system configuration files:

- on Windows, the API tzset() function and tzname[0] variable are used to retrieve an Windows style timezone name. This name is translated into IANA/CUBRID style name using the CUBRID mapping data (the mapping file is %CUBRID%\timezones\tzdata\windowsZones.xml).
- on Linux, CUBRID attempts to read and parse the file “/etc/sysconfig/clock”. If this file is not available, then the value of link “/etc/localtime” is read and used.
- on AIX, the value of “TZ” operating system environment variable is used.

On all operating systems, if the server\_timezone is not specified, and the value for timezone from operating system cannot be read, then “Asia/Seoul” zone is used as server timezone.

#### • tz\_leap\_second\_support

Specifies to support a leap second or not as yes or no. The default is **no**.

A leap second is a one-second adjustment that is occasionally applied to Coordinated Universal Time (UTC) in order to keep its time of day close to the mean solar time.

To apply the changed value, database should be restarted.

### Query Plan Cache-Related Parameters

The following are parameters related to the query plan cache functionality. The type and value range for each parameter are as follows:

| Parameter Name         | Type | Default | Min | Max |
|------------------------|------|---------|-----|-----|
| max_plan_cache_entries | int  | 1,000   |     |     |
| max_plan_cache_clones  | int  | 1,000   |     |     |
|                        | int  | 360     |     |     |

| Parameter Name                                    | Type | Default | Min | Max |
|---------------------------------------------------|------|---------|-----|-----|
| <code>xasl_cache_time_threshold_in_minutes</code> |      |         |     |     |
| <code>max_filter_pred_cache_entries</code>        | int  | 1,000   |     |     |

### **max\_plan\_cache\_entries**

**max\_plan\_cache\_entries** is a parameter to configure the maximum number of query plans to be cached in the memory. If the **max\_plan\_cache\_entries** parameter is configured to -1 or 0, generated query plans are not stored in the memory cache; if it is configured to an integer value equal to 0 or greater than 1, a specified number of query plans are cached in the memory.

The following example shows how to cache up to 1,000 queries.

```
max_plan_cache_entries=1000
```

### **max\_plan\_cache\_clones**

The plan cache stores the XASL for a query in a serializable form. When executing the query, the XASL is converted back into its deserialized form, populated with values, and then executed. The clone cache stores deserialized XASL to reuse it instead of discarding. The **max\_plan\_cache\_clones** is a parameter that sets the maximum number of cloned cache entries a single plan can hold, and its default value is set to 1000. When a plan is deleted, its clones are also deleted.

### **xasl\_cache\_time\_threshold\_in\_minutes**

It is a parameter that determines the time threshold for deciding whether to recompile (clean-up) a cached plan. It is also used when searching for a candidate plan to remove when there is no space in the plan cache. This parameter can be set in minutes, with a default value of 360 minutes.

### **max\_filter\_pred\_cache\_entries**

**max\_filter\_pred\_cache\_entries** is a parameter used to specify the maximum number of filtered index expressions. The filtered index expressions are stored with them compiled and can be immediately used in server. If it is not stored in cache, the

process is required which filtered index expressions are fetched from database schema and interpreted.

### Query Cache-Related Parameters

The following are the parameters related to the query cache functionality. The type and value range for each parameter are as follows:

| Parameter Name            | Type | Default | Min | Max     |
|---------------------------|------|---------|-----|---------|
| max_query_cache_entries   | int  | 0       | 0   | INT_MAX |
| query_cache_size_in_pages | int  | 0       | 0   | INT_MAX |

If one of the parameters is set to 0 or negative value, the query cache is disabled regardless using the query hint **QUERY\_CACHE**.

#### max\_query\_cache\_entries

**max\_query\_cache\_entries** is a parameter to configure the maximum number of query to be cached. If it is configured to an integer value equal to 0 or greater than 1, a specified number of queries are cached with the result.

The following example shows how to cache up to 500 queries.

```
max_query_cache_entries=500
```

#### query\_cache\_size\_in\_pages

**query\_cache\_size\_in\_pages** is a parameter to configure the maximum page of result to be cached. If it is configured to an integer value equal to 0 or greater than 1, specified pages in results are cached as temp files.

The following example shows how to cache up to 4,000 pages.

```
query_cache_size_in_pages=4000
```

## Utility-Related Parameters

The following are parameters related to utilities used in CUBRID. The type and value range for each parameter are as follows:

| Parameter Name               | Type | Default | Min | Max |
|------------------------------|------|---------|-----|-----|
| backup_volume_max_size_bytes | byte | 0       | 32K |     |
| communication_histogram      | bool | no      |     |     |
| compactdb_page_reclaim_only  | int  | 0       |     |     |
| csql_history_num             | int  | 50      | 1   | 200 |

### backup\_volume\_max\_size\_bytes

**backup\_volume\_max\_size\_bytes** is a parameter to configure the size of the backup volume file created by the **cubrid backupdb** utility in byte unit. You can set a unit as B, K, M, G or T, which stands for bytes, kilobytes(KB), megabytes(MB), gigabytes(GB) or terabytes(TB) respectively. If you omit the unit, bytes will be applied. The default value is **0**, and the minimum value is 32K.

If the parameter is configured to **0**, which is the default value, the created backup volume is not partitioned; if it is configured to a value greater than 0, the backup volume is partitioned as much as it is specified size.

### communication\_histogram

**communication\_histogram** is a parameter associated with [Session Commands “;h”](#) of the CSQL Interpreter and the default value is **no**. For details, see [Dumping CSQL execution statistics information](#).

### compactdb\_page\_reclaim\_only

**compactdb\_page\_reclaim\_only** is a parameter to configure the **compactdb** utility, which compacts the storage of already deleted objects to reuse OIDs of the already assigned storage. Storage optimization with the **compactdb** utility can be divided into

three steps. The optimization steps can be selected through the **compactdb\_page\_reclaim\_only** parameter. If the parameter is configured to **0**, which is the default value, step 1, 2 and 3 are all performed, so the storage is optimized in data, table and file units. If it is configured to 1, step 1 is skipped to have the storage optimized in table and file units. If it is configured to 2, steps 1 and 2 are skipped to have the storage optimized only in file units.

- Step 1: Optimizes the storage only in data unit.
- Step 2: Optimizes the storage in table unit.
- Step 3: Optimizes the storage in file (heap file) unit.

### **csql\_history\_num**

**csql\_history\_num** is a parameter to configure the CSQL Interpreter and the number of SQL statements to be stored in the history of the CSQL Interpreter. The default value is **50**.

## HA-Related Parameters

The following are HA-related parameters. The type and value range for each parameter are as follows:

| Parameter Name | Type   | Default Value |
|----------------|--------|---------------|
| ha_mode        | string | off           |

### **ha\_mode**

The **ha\_mode** parameter is used to set CUBRID HA, and the default value is **off**.

- off : CUBRID HA is not used.
- on : CUBRID HA is used using the configured node as a node for failover.
- replica : CUBRID HA is used without using the configured node as a node for failover.

To use the CUBRID HA feature, you should set HA-related parameters in the **cubrid\_ha.conf** file in addition to the **ha\_mode** parameter. For details, see [CUBRID HA](#).

## Other Parameters

The following are other parameters. The type and value range for each parameter are as follows:

| Parameter Name            | Type   | Default | Min | Max   |
|---------------------------|--------|---------|-----|-------|
| access_ip_control         | bool   | no      |     |       |
| access_ip_control_file    | string |         |     |       |
| agg_hash_respect_order    | bool   | yes     |     |       |
| auto_restart_server       | bool   | yes     |     |       |
| enable_string_compression | bool   | yes     |     |       |
| index_scan_in_order       | bool   | no      |     |       |
| index_unfill_factor       | float  | 0.05    | 0   | 0.5   |
| stored_procedure          | bool   | yes     |     |       |
| stored_procedure_uds      | bool   | yes     |     |       |
| stored_procedure_port     | int    | 0       | 0   | 65535 |
|                           | string |         |     |       |

| Parameter Name                 | Type   | Default          | Min          | Max                   |
|--------------------------------|--------|------------------|--------------|-----------------------|
| stored_procedure_vm_options    |        |                  |              |                       |
| multi_range_optimization_limit | int    | 100              | 0            | 10,000                |
| optimizer_enable_merge_join    | bool   | no               |              |                       |
| use_stat_estimation            | bool   | no               |              |                       |
| server                         | string |                  |              |                       |
| service                        | string |                  |              |                       |
| session_state_timeout          | sec    | 21,600 (6 hours) | 60(1 minute) | 31,536,000 (1 year)   |
| sort_limit_max_count           | int    | 1000             | 0            | INT_MAX               |
| sql_trace_slow                 | msec   | -1(inf)          | 0            | 86,400,000 (24 hours) |
| sql_trace_execution_plan       | bool   | no               |              |                       |
| use_orderby_sort_limit         | bool   | yes              |              |                       |

| Parameter Name                      | Type   | Default | Min | Max     |
|-------------------------------------|--------|---------|-----|---------|
| vacuum_prefetch_log_mode            | int    | 1       | 0   | 1       |
| vacuum_prefetch_log_buffer_size     | int    | 50M     | 25M | INT_MAX |
| data_buffer_neighbor_flush_pages    | int    | 8       | 0   | 32      |
| data_buffer_neighbor_flush_nondirty | bool   | no      |     |         |
| tde_keys_file_path                  | string | NULL    |     |         |
| tde_default_algorithm               | string | AES     |     |         |
| recovery_progress_logging_interval  | int    | 0 (off) | 0   | 3600    |
| supplemental_logging                | int    | 0 (off) | 0   | 2       |
| regexp_engine                       | string | re2     |     |         |
| vacuum_ovfp_checkpoint_threshold    | int    | 1000    | 2   | INT_MAX |

| Parameter Name             | Type | Default | Min | Max    |
|----------------------------|------|---------|-----|--------|
| vacuum_ovfp_check_duration | int  | 45000   | 1   | 600000 |
| deduplicate_key_level      | int  | -1      | -1  | 14     |
| print_index_detail         | bool | no      |     |        |
| enable_memory_monitoring   | bool | no      |     |        |
| flashback_timeout          | int  | 300     | 0   | 3600   |

### access\_ip\_control

**access\_ip\_control** is a parameter to configure whether to use feature limiting the IP addresses that allow server access. The default value is **no**. For details, see [Limiting Database Server Access](#).

### access\_ip\_control\_file

**access\_ip\_control\_file** is a parameter to configure the file name in which the list of IP addresses allowed by servers is stored. If **access\_ip\_control** value is set to **yes**, database server allows the list of IP addresses only stored in the file specified by this parameter. For details, see [Limiting Database Server Access](#).

### agg\_hash\_respect\_order

**agg\_hash\_respect\_order** is a parameter to configure whether the groups in an aggregate function will be returned ordered or not. The default is **yes**. As a reference, see [max\\_agg\\_hash\\_size](#).

If all the groups (keys and accumulators) can fit into hash memory, then “agg\_hash\_respect\_order=no” will skip sorting them before writing to output, so it is fair to assume that the order cannot be guaranteed in this case. However, when

overflows occur, then a sort step must be performed and you will get the results in-order even with “agg\_hash\_respect\_order=no”.

### **auto\_restart\_server**

**auto\_restart\_server** is a parameter used to configure whether to restart the process when it terminates abnormally due to fatal errors occurring in the database server process (cub\_server). The default value is **yes**.

If this parameter is set to **yes**, the master process (cub\_master) detects the abnormal termination of the server process and automatically restarts it. However, if the server process, which was restarted by this functionality, abnormally terminates again within 120 seconds, the system will not attempt another restart to prevent potential issues caused by repeated abnormal terminations. Additionally, server processes that have been stopped through a normal process (**cubrid server stop** command) will not be automatically restarted.

This parameter only operates in Linux environments and affects server processes that are not configured for HA. It will not function properly if the master process is not running.

### **enable\_string\_compression**

**enable\_string\_compression** is a parameter to configure whether string compression should be used when storing variable string type value into heap, index or list. If **enable\_string\_compression** value is set to **yes**, and the string is at least 255 bytes in size and the compressed string requires less size than original string, then the string is stored in compressed form.

### **index\_scan\_in\_oid\_order**

**index\_scan\_in\_oid\_order** is a parameter to configure the result data to be retrieved in OID order after the index scan. If the parameter is set to **no**, which is the default value, results are retrieved in data order; if it is set to **yes**, they are retrieved in OID order.

### **index\_unfill\_factor**

If there is no free space because index pages are full when the **INSERT** or **UPDATE** operation is executed after the first index is created, the split of index page nodes occurs. This substantially affects the performance by increasing the operation time. **index\_unfill\_factor** is a parameter to configure the percent of free space defined for each index page node when an index is created. The **index\_unfill\_factor** value is applied only when an index is created for the first time. The percent of free space defined for the page is not maintained dynamically. Its value ranges between 0 and 0.5. The default value is **0.05**.

If an index is created without any free space for the index page node (**index\_unfill\_factor** is set to 0), the split of index page nodes occurs every time an additional insertion is made. This may degrade the performance.

If the value of **index\_unfill\_factor** is large, a large amount of free space is available when an index is created. Therefore, better performance can be obtained because the split of index nodes does not occur for a relatively long period of time until the free space for the nodes is filled after the first index is created.

If this value is small, the amount of free space for the nodes is small when an index is created. Therefore, it is likely that the index nodes are split by **INSERT** or **UPDATE** because free space for the index nodes is filled in a short period of time.

### stored\_procedure

**stored\_procedure** is a parameter to enable the use of stored procedures by running the cub\_pl process. The default value is **yes**. If set to **no**, the cub\_pl process will not run, and stored procedures cannot be used.

### stored\_procedure\_uds

**stored\_procedure\_uds** is a parameter to use a Unix domain socket connection between the cub\_pl process and the cub\_server process when calling stored procedures. The default value is **yes**. If set to **no** or on Windows, the connection operates using a TCP socket regardless of the parameter value.

#### Note

For information on the **CUBRID\_TMP** environment variable that specifies the Unix domain socket file path for the cub\_pl process, see [Configuring Environment Variables](#).

### stored\_procedure\_port

**stored\_procedure\_port** is a parameter to set the TCP port number for calling stored procedures on the database server. This value must be less than 65,536. The default value is **0**, which means the port number is automatically assigned from an ephemeral port range. This parameter is only applicable when the **stored\_procedure** parameter is set to **yes**. Note that configuring this parameter in the [common] section of cubrid.conf will result in an error.

```
.....  
[common]  
.....
```

```
# an error occurs. remove the following line.
stored_procedure_port=4333
.....
[@testdb]
.....
# the parameter is configured successfully for testdb
stored_procedure_port=4334
.....
```

### stored\_procedure\_vm\_options

**stored\_procedure\_vm\_options** is a parameter to configure the virtual machine settings of Procedural Language Server where stored procedures are executed. Each option string should be separated by spaces. The default is an empty string. If the parameter is set in the [@<database>] section, the options set in the [common] section do not apply to that database.

#### Note

The cub\_pl process internally uses the Java Virtual Machine (JVM), so JVM options can be specified. There are standard, non-standard, and advanced JVM options. Non-standard and advanced options are not guaranteed to be supported by all JVM implementations.

```
.....
[common]
.....
stored_procedure_vm_options="-Xms1024m -Xmx1024m -
XX:PermSize=512m -XX:MaxPermSize=512m"
.....
[@testdb]
.....

# Note that -XX:PermSize=512m and -XX:MaxPermSize=512m will
not be applied for testdb, even though they are specified
in the [common] section.
stored_procedure_vm_options="-Xms2048m -Xmx2048m"
.....
```

### multi\_range\_optimization\_limit

If the number of rows specified by the **LIMIT** clause in the query, which has multiple ranges (col IN (?, ?, ... ?)) and is available to use an index, is within the number

specified in the **multi\_range\_optimization\_limit** parameter, the optimization for the way of index sorting will be performed. The default value is **100**.

For example, if a value for this parameter is set to 50, LIMIT 10 means that it is within the value specified by this parameter, so that the values that meet the conditions will be sorted to produce the result. If LIMIT is 60, it means that it exceeds the parameter configuration value, so that it gets and sorts out all values that meet the conditions.

Depending on the setting value, the differences are made between collecting the result with on-the-fly sorting of the intermediate values and sorting the result values after collecting them, and the bigger value could make more unfavorable performance.

### **optimizer\_enable\_merge\_join**

**optimizer\_enable\_merge\_join** is a parameter to specify whether to include sort merge join plan as a candidate of query plans or not. The default is **no**. Regarding sort merge join, see [Using SQL Hint](#).

### **use\_stat\_estimation**

**use\_stat\_estimation** is a parameter to specify whether to use the estimated information in calculating statistics or not. The default is **no**. The estimated information generated by the heap manager while processing DML is associated with the number of added objects. it is relatively accurate for the number of total objects, NOT for the number of distinct values.

### **server**

**server** is a parameter used to register the name of database server process which will run automatically when CUBRID server starts.

### **service**

**service** is a parameter to configure process that starts automatically when the CUBRID service starts. There are four types of processes: **server**, **broker**, **manager**, and **heartbeat**. Three processes are usually registered as in **service=server,broker,manager**.

- If the parameter is set to **server**, the database process specified by the **@server** parameter gets started.
- If the parameter is set to **broker**, the broker process gets started.
- If the parameter is set to **manager**, the manager process gets started.
- If the parameter is set to **heartbeat**, the HA-related processes get started.

## session\_state\_timeout

**session\_state\_timeout** is a parameter used to define how long the CUBRID session data will be kept. The session data will be deleted when the driver terminates the connection or the session time expires. The session time will expire after the specified time if a client terminates abnormally.

Custom variables defined by **SET** and **PREPARE** statements can be deleted by **DROP / DEALLOCATE** statements before session timeout.

The default value is **21,600** seconds(6 hours), and this parameter's unit is second.

## sort\_limit\_max\_count

Regarding SORT-LIMIT optimization which can be applied when top-N rows are sorted by "ORDER BY ... LIMIT N" statement, this parameter specifies the LIMIT count to limit applying this optimization. When the value of *N* is smaller than a value of **sort\_limit\_max\_count**, SORT-LIMIT optimization is applied. The default is 1000, the minimum is 0(which means that this optimization is disabled), and the maximum is INT\_MAX.

For more details, see [SORT-LIMIT optimization](#).

## sql\_trace\_slow

**sql\_trace\_slow** is a parameter to configure the execution time of a query which will be judged as a long time execution. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied. The default value is -1 and the maximum value is 86,400,000 msec (24 hour). -1 means that the infinite time, so any queries will not be judged as a long duration query. For details, see the below **sql\_trace\_execution\_plan**.

### Note

The system parameter **sql\_trace\_slow** judges the query execution time based on the server, but the broker parameter **MAX\_QUERY\_TIMEOUT** judges the query execution time based on the broker.

## sql\_trace\_execution\_plan

**sql\_trace\_execution\_plan** is a parameter to configure if the query plan of the long running query is written to the log or not. The default value is **no**.

If it is set to yes, a long running SQL, a query plan and the output of cubrid statdump command are written to the server error log file(located on \$CUBRID/log/server directory) and CAS log file(located on \$CUBRID/log/broker/sql\_log directory) .

If it is set to no, only a long running SQL is written to the server error log file and CAS log file.

For example, if you want to write the execution plan of the slow query to the log file, and specify the query which executes more than 5 seconds as the slow query, then configure the value of the **sql\_trace\_slow** parameter as 5000(ms) and configure the value of the **sql\_trace\_execution\_plan** parameter as yes.

But, on the server error log file, the related information is written only when the value of error\_log\_level is NOTIFICATION.

### **use\_orderby\_sort\_limit**

**use\_orderby\_sort\_limit** is a parameter to configure whether to keep the intermediate result of sorting and merging process in the statement including the **ORDER BY ... LIMIT row\_count** clause as many as *row\_count*. If it is set to **yes**, you can decrease unnecessary comparing and merging processes because as many as intermediate results will be kept as the value of *row\_count*. The default value is **yes**.

### **vacuum\_prefetch\_log\_mode**

**vacuum\_prefetch\_log\_mode** is a parameter to configure the prefetch mode of log pages on behalf of vacuum.

In mode 0, the vacuum master thread prefetch the required log pages in a shared buffer. In mode 1 (default), each vacuum worker prefetches the required log pages in its own buffer. Mode 0 also requires that **vacuum\_prefetch\_log\_buffer\_size** system parameter is configured, in mode 0 this parameter is ignored and each vacuum worker prefetches an entire vacuum log block (default 32 log pages).

### **vacuum\_prefetch\_log\_buffer\_size**

**vacuum\_prefetch\_log\_buffer\_size** is a parameter to configure the log prefetch buffer size of vacuum (it is used only if **vacuum\_prefetch\_log\_mode** is set to 0).

### **data\_buffer\_neighbor\_flush\_pages**

**data\_buffer\_neighbor\_flush\_pages** is a parameter to control the number of neighbor pages to be flushed with background flush (victim candidates flushing). When is less or equal to 1, the neighbor flush feature is considered deactivated.

### **data\_buffer\_neighbor\_flush\_nondirty**

**data\_buffer\_neighbor\_flush\_nondirty** is a parameter to control the flushing of non-dirty neighbor pages. When victim candidates pages are flushed, and neighbor flush is activated (**data\_buffer\_neighbor\_flush\_pages** is greater than 1), than single non-dirty pages which completes a chain of neighbor (dirty) pages are also flushed.

### **tde\_keys\_file\_path**

**tde\_keys\_file\_path** is a parameter to configure the path of the key file for TDE. The key file's name is fixed as <database\_name>\_keys, and the directory where the key file exists is designated. If this system parameter is not set, the key file is searched in the same location as the database volume. For a detailed description of the key file, see [File-based Master Key Management](#).

### **tde\_default\_algorithm**

**tde\_default\_algorithm** is a parameter that configures the default algorithm used when creating the TDE encryption table. Log and temporary data are always encrypted using the algorithm set with this parameter when they have to be encrypted. **AES** or **ARIA** can be set. For more information on encryption algorithms, refer to [Encryption Algorithm](#).

### **recovery\_progress\_logging\_interval**

**recovery\_progress\_logging\_interval** is a parameter to decide whether the details of recovery are printed and configure its period in seconds. If it is set bigger than 0, the total works and remained works to do of the three phases of recovery: Analysis, Redo and Undo are printed. When this is set smaller than 5, it is set to 5.

### **supplemental\_log**

**supplemental\_log** is a parameter to determine whether information needed to support the CDC (Change Data Capture) or [flashback](#) is written to the log volume. CDC and flashback must be able to see how transactions logically changed the database through the physical logs. Any additional information required to interpret the physical logs is saved as **supplemental\_log**. Setting this parameter bigger than 0 affects performance and log space because more logs are created and stored in addition to the existing transaction logs. If this parameter is set to 1, the information necessary to interpret DML and DDL executed by the user is logged. If it is set to 2, only information necessary to interpret the DML is logged.

### **regexp\_engine**

**regexp\_engine** is a parameter to choose a library in which regular expression operators and functions will perform. **cppstd** or **re2** can be set and the default value is **re2**. For more information on regular expression functionalities, refer to [Regular Expressions Functions and Operators](#).

## **vacuum\_ovfp\_check\_threshold**

**vacuum\_ovfp\_check\_threshold** collects index information when the number of leaf's overflow pages to be read is greater than the value, when index vacuum is performed. The default is 1000 pages.

## **vacuum\_ovfp\_check\_duration**

**vacuum\_ovfp\_check\_duration** specifies the duration for which data related to the count of index overflow pages, gathered by vacuum threads, is retained. Data that remains unchanged within the specified duration will be automatically removed. The unit of it's value is minutes.

## **deduplicate\_key\_level**

**deduplicate\_key\_level** determines the automatic inclusion and value setting of the WITH DEDUPLICATE statement within the index creation statement. For details on DEDUPLICATE, see [DEDUPLICATE](#). The default is -1(which means that the WITH DEDUPLICATE is not included implicitly).

### Note

- If **deduplicate\_key\_level** is set to **-1**, even if the *deduplicate level* is explicitly specified in the CREATE INDEX statement, it is ignored.

## **print\_index\_detail**

It specifies whether option information in the **WITH** clause is displayed when index syntax information is displayed, such as in the SHOW CREATE TABLE statement. Default is NO. However, the unloaddb tool is not affected by this setting.

## **enable\_memory\_monitoring**

**enable\_memory\_monitoring** specifies whether to monitor the server's heap memory usage. The default value is NO. To apply any modifications to this value, a server restart is required. Setting the value to YES activates the server's memory monitoring feature, which continuously tracks and manages the server's heap memory usage. Heap memory usage is tracked based on the file and line where dynamic memory allocation occurs in the CUBRID source code. If multiple memory allocations occur at the same location, the memory usage is accumulated. When the tracked memory is deallocated, the amount of deallocated memory is subtracted from the accumulated total, continuously tracking the real-time heap memory usage. The monitored heap memory usage can be checked using the [memmon](#) utility.

**Note**

- This feature is only supported on Linux.
- The memory monitoring feature incurs additional overhead as it tracks usage every time memory is allocated on the server. In an HA environment, this can lead to performance issues, particularly for slave nodes, which experience a high proportion of memory allocations while processing logs from the master node. Therefore, it is not recommended to use this feature on slave nodes.
- The memory usage tracked by CUBRID may differ from the memory usage displayed by commands like `pmap -d` and `htop`. This is because the memory monitoring feature in CUBRID does not track memory allocations occurring within header files and glibc internals, to prevent conflicts that arise from automating the feature at the code level. Additionally, there are a few notable differences:
  - The heap memory usage of a process in `pmap -d` can be identified through the `writable/private` section. However, this metric reflects the memory occupancy of the process based on the memory management policies of the OS. As a result, there may be differences between the memory usage shown by CUBRID's memory monitoring feature and what is displayed in `pmap -d`.
  - `htop` provides the memory usage of a process through the `RES(Resident Size)` section. However, since this shows the physical memory usage of a process, it cannot be used to check only the heap memory usage of a process.

**flashback\_timeout**

It specifies the timeout for entering a transaction identifier in the flashback utility. If a transaction to be rewind is not entered within the specified timeout, an error message will be displayed, and the flashback utility will terminate. If there is no timeout, it may cause an issue where the archive log volumes required by the flashback utility are not deleted. Therefore, a method to remove the timeout is not provided. The default value is 300 seconds.

## Broker Configuration

### cubrid\_broker.conf Configuration File and Default Parameters

#### Broker System Parameters

The following table shows the broker parameters available in the broker configuration file (**cubrid\_broker.conf**). For details, see [Common Parameters](#) and [Parameter by Broker](#). You can temporarily change the parameter of which configuration values can be dynamically changed by using the **broker\_changer** utility. To apply configuration values even after restarting all brokers with **cubrid broker restart**, you should change the values in the **cubrid\_broker.conf** file.

| Category            | Use                        | Parameter Name                | Type   | Default Value                | Dynamic Changes |
|---------------------|----------------------------|-------------------------------|--------|------------------------------|-----------------|
| Common Parameters   | Access                     | ACCESS_CONTROL                | bool   | no                           |                 |
|                     |                            | ACCESS_CONTROL_FILE           | string |                              |                 |
|                     |                            | ACCESS_CONTROL_DEFAULT_POLICY | bool   | DENY                         |                 |

## Default Parameters

The **cubrid\_broker.conf** file, the default broker configuration file created when installing CUBRID, includes some parameters that must be modified by default. If you want to modify the values of parameters that are not included in the configuration file by default, you can add or modify one yourself.

The following is the content of the **cubrid\_broker.conf** file provided by default.

```

[broker]
MASTER_SHM_ID           =30001
ADMIN_LOG_FILE           =log/broker/cubrid_broker.log

[%query_editor]
SERVICE                 =ON
BROKER_PORT               =30000
MIN_NUM_APPL_SERVER      =5
MAX_NUM_APPL_SERVER      =40
APPL_SERVER_SHM_ID       =30000
LOG_DIR                   =log/broker/sql_log
ERROR_LOG_DIR             =log/broker/error_log
SQL_LOG                   =ON
TIME_TO_KILL              =120
SESSION_TIMEOUT           =300
KEEP_CONNECTION           =AUTO

[%BROKER1]
SERVICE                 =ON
BROKER_PORT               =33000
MIN_NUM_APPL_SERVER      =5
MAX_NUM_APPL_SERVER      =40
APPL_SERVER_SHM_ID       =33000
LOG_DIR                   =log/broker/sql_log
ERROR_LOG_DIR             =log/broker/error_log
SQL_LOG                   =ON
TIME_TO_KILL              =120
SESSION_TIMEOUT           =300
KEEP_CONNECTION           =AUTO

```

## Broker Configuration File Related Environment Variables

You can specify the location of broker configuration file (**cubrid\_broker.conf**) file by using the **CUBRID\_BROKER\_CONF\_FILE** variable. The variable is used when executing several brokers with different configuration.

## Common Parameters

The following are parameters commonly applied to entire brokers; it is written under [broker] section.

### Access

#### **ACCESS\_CONTROL**

**ACCESS\_CONTROL** is a parameter used to limit applications which are trying to connect a broker. The default value is **OFF**. For details, see [Limiting Broker Access](#).

### **ACCESS\_CONTROL\_FILE**

**ACCESS\_CONTROL\_FILE** is a parameter to configure the name of a file in which a database name, database user ID, and the list of IPs are stored. List of IPs can be written up to the maximum of 256 lines per `<db_name>:<db_user>` in a broker. For details, see [Limiting Broker Access](#).

### **ACCESS\_CONTROL\_DEFAULT\_POLICY**

If no broker is specified in the **ACCESS\_CONTROL\_FILE** and the value of **ACCESS\_CONTROL\_DEFAULT\_POLICY** is **ALLOW**, access to the broker is permitted for everyone. The default is **DENY**. For more information, see [Limiting Broker Access](#).

#### **Note**

The settings value **ALLOW** or **DENY** for **ACCESS\_CONTROL\_DEFAULT\_POLICY** is valid only when **ACCESS\_CONTROL** is set to **ON**. If it is set to **OFF**, the setting value is not applicable.

## Logging

### **ADMIN\_LOG\_FILE**

**ADMIN\_LOG\_FILE** is a parameter to configure the file in which time of running CUBRID broker is stored. The default value is a **log/broker/cubrid\_broker.log** file.

## Broker Server(cub\_broker)

### **MASTER\_SHM\_ID**

**MASTER\_SHM\_ID** is a parameter used to specify the identifier of shared memory which is used to manage the CUBRID broker. Its value must be unique in the system. The default value is **30001**.

## Parameter by Broker

The following describes parameters to configure the environment variables of brokers; each parameter is located under `[%broker_name]`. The maximum length of `broker_name` is 63 characters in English.

## Access

### ACCESS\_LIST

**ACCESS\_LIST** is a parameter to configure the name of a file where the list of IP addresses of an application which allows access to the CUBRID broker is stored. To allow access by IP addresses access 192.168.10.\* and 192.168.20.\* store them to a file (ip\_lists.txt) and then assign the file name with the value of this parameter.

### ACCESS\_MODE

**ACCESS\_MODE** is a parameter to configure default mode of the broker. The default value is **RW**. For details, see [cubrid\\_broker.conf](#).

### BROKER\_PORT

**BROKER\_PORT** is a parameter to configure the port number of the broker; the value must be unique and smaller than 65,535. The default port value of **query\_editor** broker is **30,000** and the port value of the **broker1** is **33,000**.

### CONNECT\_ORDER

**CONNECT\_ORDER** is a parameter to specify whether a CAS tries to connect to one of hosts in the order or randomly in **\$CUBRID\_DATABASES/databases.txt**, when a CAS decides the order of connecting to a host. The default is **SEQ**; a CAS tries to connect to a host in the order. if this value is **RANDOM**, a CAS tries to connect to a host randomly. If **PREFERRED\_HOSTS** parameter is specified, firstly a CAS tries to connect to one of hosts specified in **PREFERRED\_HOSTS**, then uses db-host values in **\$CUBRID\_DATABASES/databases.txt** only when the connection is failed.

### ENABLE\_MONITOR\_HANG

**ENABLE\_MONITOR\_HANG** is a parameter to configure whether to block the access from the application to the broker or not, when more than a certain ratio of CASes on that broker are hung. If the **ENABLE\_MONITOR\_HANG** parameter value is **ON**, blocking feature is processed. The default value is **OFF**. If it is **OFF**, don't do the behavior.

The broker process judges the CAS as hung if the hanging status of the CAS keeps more than one minute, then block the access from applications to that broker; it brings the behavior which the applications try to access to the alternative hosts(altHosts) configured by the connection URL.

### KEEP\_CONNECTION

**KEEP\_CONNECTION** is a parameter to configure the way of connection between CAS and application clients; it is set to one of the following: **ON** or **AUTO**. If this value is **ON**, it is connected in connection unit. If it is **AUTO** and the number of servers is

more than that of clients, transaction unit is used; in the reverse case, connection unit is used. The default value is **AUTO**.

### **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP**

When almost all DB servers have the delay of replication in the HA environment where multiple DB servers on `db-host` of `databases.txt` are specified, check if the connection is established or not until the number of delayed replication servers; the number is specified in **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP** (whether the delay of replication in the DB server is judged only with the standby hosts; it is determined by the setting of `ref:ha_delay_limit` `<ha_delay_limit>`). See **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP** for further information.

### **PREFERRED\_HOSTS**

**PREFERRED\_HOSTS** is a parameter to specify the order of a host to which a CAS tries to connect in a first priority. If the connection is failed after trying connection in the order specified in **PREFERRED\_HOSTS**, a CAS tries to connect to the one of hosts specified in **\$CUBRID\_DATABASES/databases.txt**. The default value is **NULL**. For details, see `cubrid_broker.conf`.

### **RECONNECT\_TIME**

If the time specified by **RECONNECT\_TIME** is elapsed in a certain status, CAS will try to reconnect to the other DB server. The default of this parameter is **600s(10min)**. You can set a unit as `ms`, `s`, `min` or `h`, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, `s` will be applied.

a certain status which CAS tries to reconnect is as follows.

- when CAS is connected to not a DB server in **PREFERRED\_HOSTS**, but the DB server of `db-host` in `databases.txt`.
- when CAS with “`ACCESS_MODE=RO`”(Read Only) is connected to not the standby DB server, but the active DB server.
- when CAS is connected to the DB server of which replication is delayed.

When **RECONNECT\_TIME** is 0, CAS does not try to reconnect.

### **REPLICA\_ONLY**

If a value of **REPLICA\_ONLY** is **ON**, CAS is connected only to replicas. The default is **OFF**. Even though the value of **REPLICA\_ONLY** is **ON**, when a value of **ACCESS\_MODE** is **RW**, it is possible to write directly to the replica DB. However, the data to be written directly to the replica DB are not replicated.

**Note**

Please note that replication mismatch occurs when you write the data directly to the replica DB.

## Broker App. Server(CAS)

**APPL\_SERVER\_MAX\_SIZE**

**APPL\_SERVER\_MAX\_SIZE** is a parameter to configure the maximum size of the process memory usage handled by CAS. You can set a unit as B, K, M or G, which stands for bytes, kilobytes(KB), megabytes(MB) or gigabytes(GB) respectively. If you omit the unit, M will be applied.

Specifying this parameter makes transactions terminate (commit or rollback) only when it is executed by a user. In contrast to this, specifying **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** makes transactions forcibly terminate (rollback) and restart CAS.

Note that the default values of Windows and Linux are different from each other.

For 32-bit Windows, the default value is **40** MB; for 64-bit Windows, it is **80** MB. The maximum value is the same on Windows and Linux as 2,097,151 MB. When current process size exceeds the value of **APPL\_SERVER\_MAX\_SIZE**, broker restarts the corresponding CAS.

For Linux, the default value of **APPL\_SERVER\_MAX\_SIZE** is **0**; CAS restarts in the following conditions.

- **APPL\_SERVER\_MAX\_SIZE** is zero or negative: At the point when current process size becomes twice as large as initial memory
- **APPL\_SERVER\_MAX\_SIZE** is positive: At the point when it exceeds the value specified in **APPL\_SERVER\_MAX\_SIZE**

**Note**

Be careful not to make the value too small because application servers may restart frequently and unexpectedly. In general, the value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is greater than that of

**APPL\_SERVER\_MAX\_SIZE.** For details, see description of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT.**

## **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT**

**APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is a parameter to configure the maximum size of process memory usage handled by CAS. You can set a unit as B, K, M or G, which stands for bytes, kilobytes(KB), megabytes(MB) or gigabytes(GB) respectively. If you omit the unit, M will be applied. The default value is **1,024** (MB), and the maximum value is 2,097,151 (MB).

Specifying this parameter makes transactions being processed forcibly terminate (rollback) and restart CAS. In contrast to this, specifying **APPL\_SERVER\_MAX\_SIZE** makes transactions terminate only when it is executed by a user.

### **Note**

Be careful not to make the value too small because application servers may restart frequently and unexpectedly. When restarting CAS, **APPL\_SERVER\_MAX\_SIZE** is specified to wait for normal termination of transactions although memory usage increases; **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is specified to forcibly terminate transactions if memory usage exceeds the maximum value allowed. Therefore, in general, the value of **APPL\_SERVER\_MAX\_SIZE\_HARD\_LIMIT** is greater than that of **APPL\_SERVER\_MAX\_SIZE**.

## **APPL\_SERVER\_PORT**

**APPL\_SERVER\_PORT** is a parameter to designate the TCP ports of CAS that communicates with application clients (**Windows only**).

On Linux, an established TCP connection between the BROKER and the client will be passed to the CAS. Therefore, the client can communicate with the CAS without additional TCP connection.

On the other hand, in Windows, all available CASes are waiting for a connection on an independent TCP port, for example, 33001/tcp, 33002/tcp. In these circumstances, when a client connects to a BROKER, the BROKER delivers the TCP port number, for example, 33001/tcp, for connecting to an available CAS to the client. In sequence, the client terminates the current network connection with the BROKER and establishes a new connection with the CAS using the port number received from the BROKER.

If the **APPL\_SERVER\_PORT** parameter is not additionally specified, this value is the value obtained by adding 1 to the value of **BROKER\_PORT**. For example, if the value of **BROKER\_PORT** is 30,000 and the **APPL\_SERVER\_PORT** parameter has not been specified, and if the **MIN\_NUM\_APPL\_SERVER** value is 5, then five CASes use the TCP ports between 30,001 and 30,005, respectively. On the other hand, if the value of **APPL\_SERVER\_PORT** is 35,000 under the same conditions, 5 CASes use TCP ports from 35,000 to 35,004. The maximum number of CAS specified in the **MAX\_NUM\_APPL\_SERVER** parameter in **cubrid\_broker\_conf**; therefore, the maximum number of connection ports is also determined by the value of **MAX\_NUM\_APPL\_SERVER** parameter.

On the Windows system, if a firewall system exists between an application and a CUBRID broker, all TCP ports specified in **BROKER\_PORT** and **APPL\_SERVER\_PORT** must be opened.

#### Note

For the **CUBRID\_TMP** environment variable that specifies the UNIX domain socket file path of **cub\_master** and **cub\_broker** processes, see [Configuring Environment Variables](#).

### **APPL\_SERVER\_SHM\_ID**

**APPL\_SERVER\_SHM\_ID** is a parameter to configure the ID of shared memory used by CAS; the value must be unique within system. The default value is the same as the port value of the broker.

### **AUTO\_ADD\_APPL\_SERVER**

**AUTO\_ADD\_APPL\_SERVER** is a parameter to configure whether CAS increase automatically to the value specified in **MAX\_NUM\_APPL\_SERVER** in case of needed; the value will be either **ON** or **OFF** (default: **ON**).

### **MAX\_NUM\_APPL\_SERVER**

**MAX\_NUM\_APPL\_SERVER** is a parameter to configure the maximum number of simultaneous connections allowed. The default value is **40**.

### **MIN\_NUM\_APPL\_SERVER**

**MIN\_NUM\_APPL\_SERVER** is a parameter to configure the minimum number of CAS even if any request to connect the broker has not been made. The default value is **5**.

### **TIME\_TO\_KILL**

**TIME\_TO\_KILL** is a parameter to configure the time to remove CAS in idle state among CAS added dynamically. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, s will be applied. The default value is **120** (seconds).

An idle state is one in which the server is not involved in any jobs. If this state continues exceeding the value specified in **TIME\_TO\_KILL**, CAS is removed.

The value configured in this parameter affects only CAS added dynamically, so it applies only when the **AUTO\_ADD\_APPL\_SERVER** parameter is configured to **ON**. Note that times to add or remove CAS will be increased more if the **TIME\_TO\_KILL** value is so small.

## Transaction & Query

### **CCI\_DEFAULT\_AUTOCOMMIT**

**CCI\_DEFAULT\_AUTOCOMMIT** is a parameter to configure whether to make application implemented in CCI interface or CCI-based interface such as PHP, OLE DB, Perl, Python, and Ruby commit automatically. The default value is **ON**. This parameter does not affect applications implemented in JDBC.

If the **CCI\_DEFAULT\_AUTOCOMMIT** parameter value is **OFF**, the broker application server (CAS) process is occupied until the transaction is terminated. Therefore, it is recommended to execute commit after completing fetch when executing the **SELECT** statement.

#### Note

The **CCI\_DEFAULT\_AUTOCOMMIT** parameter has been supported from 2008 R4.0, and the default value is **OFF** for the version. Therefore, if you use CUBRID 2008 R4.1 or later versions and want to keep the configuration **OFF**, you should manually change it to **OFF** to avoid auto-commit of unexpected transaction.

#### Warning

In ODBC driver, the setting of **CCI\_DEFAULT\_AUTOCOMMIT** is ignored and worked as **ON**; therefore, you should set the autocommit on or off in the program directly.

### **LONG\_QUERY\_TIME**

**LONG\_QUERY\_TIME** is a parameter to configure execution time of query which is evaluated as long-duration query. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied. The default value is **60** (seconds) and the maximum value is 86,400(1 day). When you run a query and this query's running time takes more than the specified time, a value of LONG-Q, which is printed out from "cubrid broker status" command, is increased 1; this SQL is written to SLOW log file (\$CUBRID/log/broker/sql\_log/\*.slow.log) of CAS. See [SLOW\\_LOG](#).

This value can be valued in milliseconds with a decimal separator. For example, the value can be configured into 0.5 to configure 500 msec.

Note that if a parameter value is configured to **0**, a long-duration query is not evaluated.

### **LONG\_TRANSACTION\_TIME**

**LONG\_TRANSACTION\_TIME** is a parameter to configure execution time of query which is evaluated as long-duration transaction. The default value is **60** (seconds) and the maximum value is 86,400(1 day).

This value can be valued in milliseconds with a decimal separator. For example, the value can be configured into 0.5 to configure 500 msec.

Note that if a parameter value is configured to **0**, a long-duration transaction is not evaluated.

### **MAX\_PREPARED\_STMT\_COUNT**

**MAX\_PREPARED\_STMT\_COUNT** is a parameter used to limit the number of prepared statements by user (application) access. The default value is **2,000** and the minimum value is 1. The problem in which prepared statement exceeding allowed memory is mistakenly generated by system can be prohibited by making users specify the parameter value.

#### **Note**

When you want to change the value of **MAX\_PREPARED\_STMT\_COUNT** dynamically by **broker\_changer** command, this can be changed only when this is bigger than the existing value; this cannot be changed when this is smaller than the existing value.

### **MAX\_QUERY\_TIMEOUT**

**MAX\_QUERY\_TIMEOUT** is a parameter to configure timeout value of query execution. When time exceeds a value specified in this parameter after starting query execution, the query being executed stops and rolls back. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied. The default value is **0** (seconds) and it means infinite waiting. The value range is available from 0 to 86,400 seconds(one day).

The smallest value (except 0) between the **MAX\_QUERY\_TIMEOUT** value and query timeout value of an application is applied if query timeout is configured in an application.

#### **Note**

See the `cci_connect_with_url()` and `cci_set_query_timeout()` functions to configure query timeout of CCI applications. For configuring query timeout of JDBC applications, see the **setQueryTimeout** method.

## **SESSION\_TIMEOUT**

**SESSION\_TIMEOUT** is a parameter to configure timeout value for the session of the broker. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied. The default value is **300** (seconds).

If there is no response to the job request for the specified time period, session will be terminated. If a value exceeds the value specified in this parameter without any action taken after starting transaction, the connections are terminated.

## **STATEMENT\_POOLING**

**STATEMENT\_POOLING** is a parameter to configure whether to use statement pool feature. The default value is **ON**.

CUBRID closes all handles of prepared statement in the corresponding client sessions when transaction commit or rollback is made. If the value of **STATEMENT\_POOLING** is set to **ON**, the handles are reusable because they are maintained in the pool. Therefore, in an environment where libraries, such as general applications reusing prepared statement or DBCP where statement pooling is implemented is applied, the default configuration (**ON**) should be maintained.

If the prepared statement is executed after transaction commit or termination while **STATEMENT\_POOLING** is set to **OFF**, the following message will be displayed.

```
Caused by: cubrid.jdbc.driver.CUBRIDException: Attempt to
access a closed Statement.
```

## JDBC\_CACHE

**JDBC\_CACHE** is a parameter to configure whether to use result-cache feature. The default value is **OFF**.

If the parameter is **ON**, all of SELECT queries from JDBC is cached at client for life time which is configured by **JDBC\_CACHE\_LIFE\_TIME**

## JDBC\_CACHE\_HINT\_ONLY

**JDBC\_CACHE\_HINT\_ONLY** is a parameter to configure whether to use result-cache feature only by query hint `/*+ JDBC_CACHE */`.

It works as if the parameter is **ON** when the query hint is given.

## JDBC\_CACHE\_LIFE\_TIME

**JDBC\_CACHE\_HINT\_ONLY** is a parameter to configure JDBC client's result-cache life time. The default value is 1000 (sec).

For only cache life time, the result-cache is available. After the cache lifetime expired, the prior cached results are no more available and a new result is cached.

The cache life time works only when the parameter **JDBC\_CACHE** or **JDBC\_CACHE\_HINT\_ONLY** is configured to "ON".

## WARNING

**JDBC\_CACHE**, **JDBC\_CACHE\_HINT\_ONLY**, and **JDBC\_CACHE\_LIFE\_TIME** parameters are meaningless

when the query cache-related system parameter both of **max\_query\_cache\_entries** and **query\_cache\_size\_in\_pages** are not set to positive value.

For result cache working, the SELECT query must include query hint `/*+ QUERY_CACHE */` together with these JDBC related parameter setting.

## TRIGGER\_ACTION

Turn on or off of the trigger's action about the broker which specified this parameter. Specify **ON** or **OFF** as a value; The default is **ON**.

## Logging

### ACCESS\_LOG

**ACCESS\_LOG** is a parameter to configure whether to store the access log of the broker. The default value is **OFF**. The name of the access log file for the broker is *broker\_name.access* and the file is stored under **\$CUBRID/log/broker** directory.

### ACCESS\_LOG\_DIR

**ACCESS\_LOG\_DIR** specifies the directory for broker access logging files(**ACCESS\_LOG**) to be created. The default is **log/broker**.

### ACCESS\_LOG\_MAX\_SIZE

**ACCESS\_LOG\_MAX\_SIZE** specifies the maximum size of broker access logging files(**ACCESS\_LOG**); if a broker access logging file is bigger than a specified size, this file is backed up into the name of *broker\_name.access.YYYYMMDDHHMISS*, then logging messages are written to the new file(*broker\_name.access*). The default is 10M and the maximum is 2G. It can be dynamically changed during operating a broker.

### ERROR\_LOG\_DIR

**ERROR\_LOG\_DIR** is a parameter to configure default directory in which error logs about broker is stored. The default value is **log/broker/error\_log**. The log file name for the broker error is *broker\_name\_id.err*.

### LOG\_DIR

**LOG\_DIR** is a parameter to configure the directory where SQL logs are stored. The default value is **log/broker/sql\_log**. The file name of the SQL logs is *broker\_name\_id.sql.log*.

### SLOW\_LOG

**SLOW\_LOG** is a parameter to configure whether to log. The default value is **ON**. If the value is **ON**, long transaction query which exceeds the time specified in **LONG\_QUERY\_TIME** or query where an error occurred is stored in the **SLOW SQL** log file. The name of file created is *broker\_name\_id.slow.log* and it is located under **SLOW\_LOG\_DIR**.

### SLOW\_LOG\_DIR

**SLOW\_LOG\_DIR** is a parameter to configure the location of directory where the log file is generated. The default value is **log/broker/sql\_log**.

### SQL\_LOG

**SQL\_LOG** is a parameter to configure whether to leave logs for SQL statements processed by CAS when CAS handles requests from a client. The default value is **ON**. When this parameter is configured to **ON**, all logs are stored. The log file name becomes *broker\_name\_id.sql.log*. The file is created in the **log/broker/sql\_log** directory under the installation directory. The parameter values are as follows:

- **OFF** : Does not leave any logs.
- **ERROR** : Stores logs for queries which occur an error. only queries where an error occurs.
- **NOTICE** : Stores logs for the long-duration execution queries which exceeds the configured time/transaction, or leaves logs for queries which occur an error.
- **TIMEOUT** : Stores logs for the long-duration execution queries which exceeds the configured time/transaction.
- **ON / ALL** : Stores all logs.

## SQL\_LOG\_MAX\_SIZE

**SQL\_LOG\_MAX\_SIZE** is a parameter to configure the maximum size of the SQL log file. You can set a unit as B, K, M or G, which stands for bytes, kilobytes(KB) or megabytes(MB) or gigabytes(GB) respectively. If you omit the unit, M will be applied. The default value is **10,000\*** (KB).

- If the size of the SQL log file, which is created when the **SQL\_LOG** parameter is configured to **ON**, reaches to the size configured by the parameter, *broker\_name\_id.sql.log.bak* is created.
- If the size of the SLOW SQL log file, which is created when the **SLOW\_LOG** parameter is configured to **ON**, reaches to the size configured by the parameter, *broker\_name\_id.slow.log.bak* is created.

## SHARD

To use SHARD feature, configure the below parameters in **cubrid\_broker.conf** as referring to **cubrid\_broker.conf.shard**.

### SHARD

It specifies to activate/deactivate SHARD feature. You can set this value as **ON** or **OFF**. The default is **OFF**.

## SHARD\_CONNECTION\_FILE

The path of the shard connection file. The shard connection file should be located in **\$CUBRID/conf**. For more information, see the [shard connection file](#).

### SHARD\_DB\_NAME

The name of the shard DB, used to verify the request for connection from an application.

### SHARD\_DB\_PASSWORD

The user password of the backend shard DB, used to connect to the backend DBMS for the CAS process as well as to verify the request for connection from an application. Passwords of all shard DBs should be identical.

The environment variable can be used when you don't want to expose **SHARD\_DB\_PASSWORD** to `cubrid-broker.conf`. The format of this environment variable name is `<broker_name>_SHARD_DB_PASSWORD`, and `<broker_name>` always should be changed as upper cases. For example, if the name of broker is `shard1`, the name of an environment variable which configures the shard DB password will be **SHARD1\_SHARD\_DB\_PASSWORD**. But, if the SHARD feature is restarted by “cubrid broker restart” command, the environment variable of **SHARD\_DB\_PASSWORD** or the value of **SHARD\_DB\_PASSWORD** in `cubrid-broker.conf` must be configured.

```
export SHARD1_SHARD_DB_PASSWORD=shard123
```

#### Note

SHARD\_DB\_USER/SHARD\_DB\_PASSWORD parameters is deprecated. Therefore, it is recommended to deliver the connection information in an application.

### SHARD\_DB\_USER

The name of the backend shard DB user, used to connect to the backend DBMS for the CAS process as well as to verify the request for connection from an application. User names on all shard DBs should be identical.

#### Note

SHARD\_DB\_USER/SHARD\_DB\_PASSWORD parameters is deprecated. Therefore, it is recommended to deliver the connection information in an application.

## SHARD\_IGNORE\_HINT

When this value is **ON**, the hint provided to connect to a specific shard is ignored and the database to connect is selected based on the defined rule. The default value is **OFF**. It can be used to balance the read load while all databases are copied with the same data. For example, to give the load of an application to only one node among several replication nodes, the proxy automatically determines the node (database) with one connection to a specific shard.

## SHARD\_KEY\_FILE

The path of the shard key configuration file. The shard key configuration file should be located in **\$CUBRID/conf**. For more information, see the [shard key configuration file](#).

## SHARD\_KEY\_FUNCTION\_NAME

The parameter to specify the name of the user hash function for shard key. For more information, see [Setting User-Defined Hash Function](#).

## SHARD\_KEY\_LIBRARY\_NAME

Specify the library path loadable at runtime to specify the user hash function for the shard key. If the **SHARD\_KEY\_LIBRARY\_NAME** parameter is set, the **SHARD\_KEY\_FUNCTION\_NAME** parameter should also be set. For more information, see [Setting User-Defined Hash Function](#).

## SHARD\_KEY\_MODULAR

The parameter to specify the range of results of the default shard key hash function. The result of the function is `shard_key(integer) % SHARD_KEY_MODULAR`. The minimum value is 1, and the maximum value is 256. For related issues, see [shard key configuration file](#) and [Setting User-Defined Hash Function](#).

## SHARD\_MAX\_CLIENTS

The number of applications that can be concurrently connected by using the proxy. The default value is 256 and the maximum value is 10,000 per proxy.

## SHARD\_MAX\_PREPARED\_STMT\_COUNT

The maximum size of statement pool managed by proxy. The default is 10,000.

## SHARD\_NUM\_PROXY

The number of proxy processes.

## SHARD\_PROXY\_CONN\_WAIT\_TIMEOUT

If there is no request anymore during the time specified in this parameter, CAS disconnect with DB. The default is **8h**. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, second(s) will be applied. CAS which has a previous password should be exit because it cannot be used anymore; this feature protects that CAS is still kept unnecessarily.

## SHARD\_PROXY\_LOG

The proxy log level. It can be set to one of the following values:

Proxy log level policy: Setting the higher level leaves all the lower logs.

- Example) When SCHEDULE is set, ERROR | TIMEOUT | NOTICE | SHARD | SCHEDULE log is left.
- **ALL** : All logs
- **ON** : All logs
- **SHARD** : Logs for selecting and processing shard DBs.
- **SCHEDULE** : Logs for scheduling tasks.
- **NOTICE** : Logs for key notices.
- **TIMEOUT** : Logs for timeouts.
- **ERROR** : Logs for errors.
- **NONE** : No logs recorded.
- **OFF** : No logs recorded.

## SHARD\_PROXY\_LOG\_DIR

The directory path where the proxy logs will be saved.

## SHARD\_PROXY\_LOG\_MAX\_SIZE

The maximum size of the proxy log file. You can set a unit as B, K, M or G, which stands for bytes, kilobytes(KB) or megabytes(MB) or gigabytes(GB) respectively. If you omit the unit, K will be applied. The maximum value is 1,000,000(KB).

## SHARD\_PROXY\_SHM\_ID

A parameter to configure the ID of shared memory used by proxy

## SHARD\_PROXY\_TIMEOUT

The maximum waiting time by which the statement is prepared or CAS is available to use. The default value is 30(seconds). If this value is 0, the waiting time is decided by the value of the query\_timeout system parameter; if the value of query\_timeout is also 0, the waiting time is infinite. IF the value SHARD\_PROXY\_TIMEOUT is larger than 0, the maximum value between query\_timeout and SHARD\_PROXY\_TIMEOUT decides the waiting time. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, s will be applied.

### Note

#### Required parameters for configuring proxy

To configure CUBRID proxy, you should specify SHARD\_MAX\_CLIENTS, MAX\_NUM\_APPL\_SERVER and SHARD\_NUM\_PROXY.

- In Linux, the number of file descriptors(fd) per proxy process is limited as follows.
  - “((SHARD\_MAX\_CLIENTS + MAX\_NUM\_APPL\_SERVER) / SHARD\_NUM\_PROXY) + 256” <= 10,000

The following are detail descriptions on above formulas.

- SHARD\_MAX\_CLIENTS is the maximum number of applications which access the SHARD system.
- MAX\_NUM\_APPL\_SERVER is the maximum number of all CASes which can access proxy system.
- SHARD\_NUM\_PROXY is the maximum number of proxy processes which can use on the SHARD system.
- “SHARD\_MAX\_CLIENTS / SHARD\_NUM\_PROXY” is the maximum number of applications which can access per proxy process.
- “MAX\_NUM\_APPL\_SERVER / SHARD\_NUM\_PROXY” is the maximum number of CASes which can access per proxy process.
- 256 is the number of file descriptors which are used internally per process on Linux.

As an example of configuring SHARD parameters in Linux system, if you specify the maximum concurrent access number of applications (SHARD\_MAX\_CLIENTS) as 5,000, the maximum number of CASes(MAX\_NUM\_APPL\_SERVER) as 200 and the maximum number of proxy process(SHARD\_NUM\_PROXY) as 1, then file descriptors per proxy process becomes (5,000 + 200)/1 + 256 = 5,456, and it is less than 10,000; it is possible configuration.

Regarding above, the following is the connection-relationship between each process. “proxy” intermediates a connection between “app. client” and “CAS”.

In the below, [] indicates a process, and -> indicates the requesting direction.

```
[app. client]  --(initial access request)-----> [broker]
(select proxy)
               <--(announce proxy to access)---
               -----> [proxy] --
(select CAS)--> [CAS] ---> [DB server]
               <-----
<-----      <---
               <--(now use the same proxy)----->
<----->      <-->
```

broker is used only once when the application client requires the initial access, and then CUBRID keep connections among “[app. client] - [proxy] - [CAS] - [DB Server]”.

Also, CAS keeps connection with DB server after DB connection is completed.

Etc

## MAX\_STRING\_LENGTH

**MAX\_STRING\_LENGTH** is a parameter to configure the maximum string length for BIT, VARBIT, CHAR and VARCHAR data types. If the value is **-1**, which is the default value, the length defined in the database is used. If the value is **100**, the value acts like 100 being applied even when a certain attribute is defined as VARCHAR(1000).

## SERVICE

**SERVICE** is a parameter to configure whether to run the broker. It can be either **ON** or **OFF**. The default value is **ON**. The broker can run only when this value is configured to **ON**.

## SSL

**SSL** is a parameter to configure whether to apply packet encryption (**SSL**) to the broker. It can be either **ON** or **OFF**. The default value is **OFF**. When this value is configured to **ON**, packet encryption using **TLS** will be applied to the broker/CAS.

 **Warning**

When the broker is configured to do **TLS (SSL=ON)**, clients such as **jdbc** client must connect in encryption mode, otherwise the connection request to the broker will be rejected. The opposite is also true. The connection request of SSL clients to the non-SSL broker will be rejected.

## SOURCE\_ENV

**SOURCE\_ENV** is a parameter used to determine the file where the operating system variable for each broker is configured. The extension of the file must be **env**. All parameters specified in **cubrid.conf** can also be configured by environment variables. For example, the **lock\_timeout** parameter in **cubrid.conf** can also be configured by the **CUBRID\_LOCK\_TIMEOUT** environment variable. As another example, to block execution of DDL statements on broker1, you can configure **CUBRID\_BLOCK\_DDL\_STATEMENT** to 1 in the file specified by **SOURCE\_ENV**.

An environment variable, if exists, has priority over **cubrid.conf**. The default value is **cubrid.env**.

## NET\_BUF\_SIZE

**NET\_BUF\_SIZE** is a parameter used to determine the network buffer size used by **CAS** to transmit results to the client. The result sets will be buffered into the **CAS** network buffer, and are sent to the client when the buffer is full. **NET\_BUF\_SIZE** is the size of the packet that CAS transmits to the client, and it may affect transmission efficiency.

## HA Configuration

Regarding HA configuration, see [Environment Configuration](#).

## SHARD Configuration

Regarding SHARD configuration, see [Configuration](#).

## SystemTap

### Overview

SystemTap is a tool that can be used to dynamically monitor and track the process of running. CUBRID supports SystemTap; therefore, it is possible to find the cause of a performance bottleneck.

The basic idea of SystemTap script is that you can specify the name of the event and grant a handler there. Handler is script statements that specify the action to be performed each time an event occurs.

To monitor the performance of CUBRID using SystemTap, you need to install SystemTap. After installing SystemTap, you can write and run a SystemTap script which is like a C language. With this script, you can monitor the performance of the System.

SystemTap supports only on Linux.

See <https://sourceware.org/systemtap/index.html> for further information and installation.

## Installing SystemTap

### Checking Installation

1. Check if you have group accounts, stapusr and stapdev in /etc/group file. If they don't exist, SystemTap may not be installed.
2. Add CUBRID user account when you install CUBRID into stapusr and stapdev group accounts. Here let's assume the CUBRID user account as "cubrid".

```
$ vi /etc/group

stapusr:x:156:cubrid
stapdev:x:158:cubrid
```

3. To check if SystemTap is runnable, simply run the below command.

```
$ stap -ve 'probe begin { log("hello world") exit() }'
```

### Version

To execute SystemTap scripts in CUBRID, you should use SystemTap 2.2 or higher.

The below is an example to install SystemTap in CentOS 6.3. Checking version and installing SystemTap can be different among Linux distributors.

1. Check the current version of the installed SystemTap.

```
$ sudo yum list|grep systemtap
systemtap.x86_64
1.7-5.el6_3.1 @update
```

```
systemtap-client.x86_64
1.7-5.el6_3.1 @update
systemtap-devel.x86_64
1.7-5.el6_3.1 @update
systemtap-runtime.x86_64
1.7-5.el6_3.1 @update
systemtap-grapher.x86_64
1.7-5.el6_3.1 update
systemtap-initscript.x86_64
1.7-5.el6_3.1 update
systemtap-sdt-devel.i686
1.7-5.el6_3.1 update
systemtap-sdt-devel.x86_64
1.7-5.el6_3.1 update
systemtap-server.x86_64
1.7-5.el6_3.1 update
systemtap-testsuite.x86_64
1.7-5.el6_3.1 update
```

2. If the lower version of SystemTap than 2.2 version is installed, remove it.

```
$ sudo yum remove systemtap-runtime
$ sudo yum remove systemtap-devel
$ sudo yum remove systemtap
```

3. Install the RPM distributed package of SystemTap 2.2 or higher. You can find the RPM distributed package in <http://rpmfind.net/linux/rpm2html/>.

```
$ sudo rpm -ivh systemtap-devel-2.3-3.el6.x86_64.rpm
$ sudo rpm -ivh systemtap-runtime-2.3-3.el6.x86_64.rpm
$ sudo rpm -ivh systemtap-client-2.3-3.el6.x86_64.rpm
$ sudo rpm -ivh systemtap-2.3-3.el6.x86_64.rpm
```

## Related Terms

### Marker

A marker placed in code provides a hook to call a function (probe) that you can provide at runtime. The function you provide is called each time the marker is executed, in the execution context of the caller. When the function provided ends its execution, it returns to the caller.

The function a user provides, the probe can be used for tracing and performance accounting.

## Probe

Probe is a kind of function to define the behavior when a certain event occurs; it is separated into an event and a handler.

SystemTap script defines a specific event, that is, the behavior when a marker occurs.

SystemTap script is able to have several probes; a handler of the probe is called as probe body.

SystemTap script accepts the insertion of the probing code without recompiling codes and gives more flexibility for handlers. Events are executed as triggers as handlers can be run. Handler can write data and be specified as the action to print out the data.

For CUBRID's markers, see [CUBRID markers](#).

## Asynchronous Events

Asynchronous events are defined internally; it is not dependent on special jobs or locations on the code. These kinds of probing events are mainly counter and timer, etc.

Examples of asynchronous events are as follows.

- begin

The start of SystemTap session.

e.g. The moment the SystemTap starts.

- end

The end of SystemTap.

- timer events

The event specifying the handler works periodically

e.g. The below prints "hello world" per 5 seconds.

```
probe timer.s(5)
{
    printf("hello world\n")
}
```

## Using SystemTap in CUBRID

### Building CUBRID source

SystemTap can be used only on Linux.

To use SystemTap by building CUBRID source, **ENABLE\_SYSTEMTAP** is **ON** which is set by default.

This option is already included in the release build, a user not building the CUBRID source but installing CUBRID with the installation package can also use SystemTap script.

The below is an example of building the CUBRID source.

```
build.sh -m release
```

### Running SystemTap script

Examples of SystemTap scripts in CUBRID are located in `$CUBRID/share/systemtap` directory.

The below is an example of running `buffer_access.stp` file.

```
cd $CUBRID/share/systemtap/tapset/scripts  
stap -k buffer_access.stp -o result.txt
```

### Printing Results

When you run a certain script, it displays the requested result to the console by the script code. With “`-o filename`” option, it writes the requested result to the *filename*.

The below is the result of the above example.

```
Page buffer hit count: 172  
Page buffer miss count: 172  
Miss ratio: 50
```

### CUBRID markers

A very useful feature of SystemTap is the possibility of placing markers in the user source code (CUBRID code) and writing probes that triggers when these markers are reached. Below is the list of CUBRID markers and their meaning.

## Connection markers

We might be interested in gathering information helpful for an analysis related to connection activity (number of connections, duration of individual connections, average duration of a connection, maximum number of connections achieved etc.) during a period of time. In order for such monitoring scripts to be written, we must provide at least two helpful markers: connection-start and connection-end.

### `conn_start(connection_id, user)`

This marker is triggered when the query execution process on the server has begun.

#### Parameters:

- **connection\_id** – an integer containing the connection ID.
- **user** – The username used by this connection.

### `conn_end(connection_id, user)`

This marker is triggered when the query execution process on the server has ended.

#### Parameters:

- **connection\_id** – an integer containing the connection ID.
- **user** – The username used by this connection.

## Query markers

Markers for query execution related events can prove very useful in monitor tasks, although they do not contain global information related to the entire system. At least two markers are essential: those corresponding to the start of the execution of a query and the end of the execution.

### `query_exec_start(query_string, query_id, connection_id, user)`

This marker is triggered after the query execution has begun on the server.

#### Parameters:

- **query\_string** – string representing the query to be executed
- **query\_id** – Query identifier
- **connection\_id** – Connection ID
- **user** – The username used by this connection

**query\_exec\_end(*query\_string*, *query\_id*, *connection\_id*, *user*, *status*)**

This marker is triggered when the query execution process on the server has ended.

**Parameters:**

- **query\_string** – string representing the query to be executed
- **query\_id** – Query identifier
- **connection\_id** – Connection ID
- **user** – The username used by this connection
- **status** – The status returned by the query execution (Success, Error)

**Object operation markers**

Operations involving the storage engine are critical and probing updates in a table at object level can greatly help monitor database activity. Markers will be triggered for each object inserted/updated/deleted, which may bring performance drawbacks on both the monitoring scripts and the server.

**obj\_insert\_start(*table*)**

This marker is triggered before an object is inserted.

**Parameters:**

- **table** – Target table of the operation

**obj\_insert\_end(*table*, *status*)**

This marker is triggered after an object has been inserted.

**Parameters:**

- **table** – Target table of the operation
- **status** – Value showing whether the operation ended with success or not

**obj\_update\_start(*table*)**

This marker is triggered before an object is updated.

Parameters:

**table** – Target table of the operation

`obj_update_end(table, status)`

This marker is triggered after an object has been updated

Parameters:

- **table** – Target table of the operation
- **status** – Value showing whether the operation ended with success or not

`obj_deleted_start(table)`

This marker is triggered before an object is deleted.

Parameters:

**table** – Target table of the operation

`obj_delete_end(table, status)`

This marker is triggered after an object has been deleted.

Parameters:

- **table** – Target table of the operation
- **status** – Value showing whether the operation ended with success or not

## Index operation markers

The object operation markers presented above are table-related, but below are index-related markers.

Indexes and their misuse can be the cause of many problems in a system and the possibility of monitoring them can be very helpful. The proposed markers are similar to those used for tables, since indexes support the same operations.

`idx_insert_start(classname, index_name)`

This marker is triggered before an insertion in the B-Tree.

Parameters:

- **classname** – Name of the class having the target index
- **index\_name** – Target index of the operation

`idx_insert_end(classname, index_name, status)`

This marker is triggered after an insertion in the B-Tree.

Parameters:

- **classname** – Name of the class having the target index
- **index\_name** – Target index\_name of the operation
- **status** – Value showing whether the operation ended with success or not

`idx_update_start(classname, index_name)`

This marker is triggered before an update in the B-Tree.

Parameters:

- **classname** – Name of the class having the target index
- **index\_name** – Target index\_name of the operation

`idx_update_end(classname, index_name, status)`

This marker is triggered after an update in the B-Tree.

Parameters:

- **classname** – Name of the class having the target index
- **index\_name** – Target index\_name of the operation
- **status** – Value showing whether the operation ended with success or not

`idx_delete_start(classname, index_name)`

This marker is triggered before a deletion in the B-Tree.

**Parameters:**

- **classname** – Name of the class having the target index
- **index\_name** – Target index\_name of the operation

**idx\_delete\_end(classname, index\_name, status)**

This marker is triggered after a deletion in the B-Tree.

**Parameters:**

- **classname** – Name of the class having the target index
- **index\_name** – Target index\_name of the operation
- **status** – Value showing whether the operation ended with success or not

**Locking markers**

Markers that involve locking events are perhaps the most important for global monitoring tasks. The locking system has a deep impact on the server performance and a comprehensive analysis on lock waiting times and count, number of deadlocks and aborted transactions is very useful in finding problems.

**lock\_acquire\_start(OID, table, type)**

This marker is triggered before a lock is requested.

**Parameters:**

- **OID** – Target object of the lock request.
- **table** – Table holding the object
- **type** – Lock type (X\_LOCK, S\_LOCK etc.)

**lock\_acquire\_end(OID, table, type, status)**

This marker is triggered after a lock request has been completed.

**Parameters:**

- **OID** – Target object of the lock request.
- **table** – Table holding the object

- **type** – Lock type (X\_LOCK, S\_LOCK etc.)
- **status** – Value showing whether the request has been granted or not.

#### `lock_release_start(OID, table, type)`

This marker is triggered before a lock is released.

##### Parameters:

- **OID** – Target object of the lock request.
- **table** – Table holding the object
- **type** – Lock type (X\_LOCK, S\_LOCK etc.)

#### `lock_release_end(OID, table, type)`

This marker is triggered after a lock release operation has been completed.

##### Parameters:

- **OID** – Target object of the lock request
- **table** – Table holding the object
- **type** – Lock type(X\_LOCK, S\_LOCK etc)

### Transaction markers

Another interesting measure in server monitoring is transaction activity. A simple example: the number of transactions aborted is closely related to the number of deadlocks occurred, a very important performance indicator. Another straightforward use of such markers is the availability of a simple method of gathering system performance statistics such as TPS by using a simple SystemTap script.

#### `tran_commit(tran_id)`

This marker is triggered after a transaction completes successfully.

##### Parameters:

- **tran\_id** – Transaction identifier.

#### `tran_abort(tran_id, status)`

This marker is triggered after a transaction has been aborted.

Parameters:

- **tran\_id** – Transaction identifier.
- **status** – Exit status.

**tran\_start(*tran\_id*)**

This marker is triggered after a transaction is started.

Parameters:

**tran\_id** – Transaction identifier.

**tran\_deadlock()**

This marker is triggered when a deadlock has been detected.

I/O markers

I/O access is the main bottleneck of a RDBMS and we should provide markers that allow the monitoring of I/O performance. The markers should be placed in a manner that will make it possible for user scripts to measure I/O page access time and aggregate various and complex statistics based on this measure.

**pgbuf\_hit()**

This marker is triggered when a requested page was found in the page buffer and there is no need to retrieve it from disk.

**pgbuf\_miss()**

This marker is triggered when a requested page was not found in the page buffer and it must be retrieved from disk.

**io\_write\_start(*query\_id*)**

This marker is triggered when a the process of writing a page onto disk has begun.

Parameters:

**query\_id** – Query identifier

**io\_write\_end(*query\_id*, *size*, *status*)**

This marker is triggered when a the process of writing a page onto disk has ended.

#### Parameters:

- **query\_id** – Query identifier
- **size** – number of bytes written
- **status** – Value showing whether the operation ended successfully or not

#### `io_read_start(query_id)`

This marker is triggered when a the process of reading a page from disk has begun.

#### Parameters:

- query\_id** – Query identifier

#### `io_read_end(query_id, size, status)`

This marker is triggered when a the process of reading a page from disk has ended.

#### Parameters:

- **query\_id** – Query identifier
- **size** – number of bytes read
- **status** – Value showing whether the operation ended successfully or not

### Other markers

#### `sort_start()`

This marker is triggered when a sort operation is started.

#### `sort_end(nr_rows, status)`

This marker is triggered when a sort operation has been completed.

#### Parameters:

- **nr\_rows** – number of rows sorted
- **status** – Value showing whether the operation ended successfully or not

## cubrid scripts

### unloaddb.sh script

To shorten the execution time of **unloaddb** of a large size database, it is possible to run **cubrid unloaddb** processes concurrently over groups of different tables. **unloaddb.sh** is a shell script that automates this process and can be found in the `$CUBRID/share/scripts` directory.

To evenly distribute unloaddb load over multiple child processes, the **unloaddb.sh** gets the size information of the tables to be unloaded from the system catalog (this requires dba privileges).

Tables to be unloaded are allocated to each child process based on the table size, and each child process simultaneously unloads the allocated tables.

#### Warning

##### restrictions:

- Require Linux Environments
- Only users with **DBA privileges** can run this script

The following is [options] used in **unloaddb.sh**.

#### **-u user**

Specify a user account of a database to be unloaded. If this is not specified, the default is **DBA** (The **user** must have **DBA privileges**).

```
sh unloaddb.sh -u dba demodb
```

#### **-t no-process**

Number of child processes to run concurrently (default: 8, maximum 16)

```
sh unloaddb.sh -t 4 demodb
```

#### **-i input-class-file**

Unload schemas, indexes and data of specified tables in the file. (default: all tables in the database)

```
sh unloaddb.sh -i table_list.txt demodb
```

The following example shows an input file (table\_list.txt).

```
public.table_1  
public.table_2  
..  
public.table_n
```

### **-D output-directory**

Specifies the directory in which to create schema and object files. If it is not specified, files are created in the current directory.

```
sh unloaddb.sh -D /tmp demodb
```

### **-s**

Specifies only the schema file will be created (**schema only**).

```
sh unloaddb.sh -s demodb
```

### **-d**

Specifies only the data file will be created (**data only**).

```
sh unloaddb.sh -d demodb
```

### **-v**

Verbose mode. Show additional information during process (for example size of tables) (**verbose mode**).

```
sh unloaddb.sh -v demodb
```

### **Files/Directory created by unloaddb.sh**

- single schema file for all tables unloaded: **{database name}\_schema**
- **object files (as many as the number of child processes, suffix starts from 0)**
  - {database name}\_0\_objects, {database name}\_1\_objects, ..., {database name}\_n-1\_objects
- **LOG files / Directory:**
  - **{database name}\_unloaddb.log** will be created.

- Various log-files will be created here.

### unloaddb.sh example

```
sh unloaddb.sh -t 4 demodb
```

**Files/Directory** created by the result of this command:

```
* demodb_schema: schema file for all tables unloaded
* demodb_0_objects: object files unloaded by the 1st child process
* demodb_1_objects: object files unloaded by the 2nd child process
* demodb_2_objects: object files unloaded by the 3rd child process
* demodb_3_objects: object files unloaded by the 4th child process
* demodb_unloaddb.log/demodb_0.files: table names unloaded by 1st
child process
* demodb_unloaddb.log/demodb_0.pid: process id of 1st child process
* demodb_unloaddb.log/demodb_0_unloaddb.log: 'cubrid unloaddb' log
of the 1st child process
* demodb_unloaddb.log/demodb_0.status: execution result of the 1st
child process (success/fail)
```

#### Note

- If the interrupt key (**CTRL-C**) is pressed before termination of **unloaddb.sh**, all in-progress unloaddb **object files** will be **deleted** (object files that unload completed will not be deleted).

## restore\_to\_newdb.sh script

When data recovery is required due to user errors or system failures, the recovery process typically involves restoring a backup to the production server. This often requires additional steps such as creating new user accounts or installing database engines, making the process cumbersome.

The restore\_to\_newdb.sh script allows you to restore a backup and create a new database instance under a new database name without any additional setup, using the existing CUBRID environment. The script can be found in the \$CUBRID/share/scripts directory.

#### Warning

**Restrictions:**

- Only available on Linux environments.
- The backup files for the target database must exist.
- The new database name must differ from the original database name.
- The new database name must not already be registered in \$CUBRID/databases.txt.

**Basic Usage**

```
sh restore_to_newdb.sh [options] backed-database-name new-database-name
```

- **restore\_to\_newdb.sh** : A script that restores a backup and creates a new DBMS instance.
- **backed-database-name** : Name of the backed-up database to be restored.
- **new-database-name** : Name of the newly created database after restoration.

**[Options] for restore\_to\_newdb.sh****-F path**

Specifies the absolute path for the new database. If not specified, the current path is used by default.

```
sh restore_to_newdb.sh -F /home/cubrid/newdbpath backed-database-name new-database-name
```

**-B path**

Specifies the absolute path where the backup files are located. If not specified, the current path is used by default.

```
sh restore_to_newdb.sh -B /home/cubrid/backupdbpath backed-database-name new-database-name
```

**-d date**

Restores the database up to a specific point in time. The format must be *dd-mm-yyyy:hh:mi:ss* (e.g., 14-10-2008:14:10:00).

This option works the same as the *-d* option in *cubrid restoredb*.

```
sh restore_to_newdb.sh backed-up-database-name new-database-name -
F /home/cubrid -B /home/cubrid/DB/backupdbpath -d 30-10-2025:12:
20:00
```

### **-l level**

Specifies the backup level (0, 1, or 2) to restore from. This option function the same as the *-l* option in *cubrid restoredb*.

```
sh restore_to_newdb.sh -B /home/cubrid/DB/backupdbpath -l 1
backed-up-database-name new-database-name
```

### **-p**

Performs a partial restore when log archives are unavailable. Refer to the *-p* option in *cubrid restoredb* for more details.

```
sh restore_to_newdb.sh -B /home/cubrid/DB/backupdbpath -p
backed-up-database-name new-database-name
```

### **-k path**

Specifies the path of the key file required for restoration. Refer to the *-k* option in *cubrid restoredb* for more details.

```
sh restore_to_newdb.sh -B /home/cubrid/DB/backupdbpath -k /home/
cubdev/DB/backupdbpath/backupdb_bk1_keys backed-up-database-name
new-database-name
```

### **Example of Running restore\_to\_newdb.sh**

```
sh restore_to_newdb.sh -B /home/cubrid/DB/backupdbpath backed-
database-name new-database-name
```

```
Validation passed: newdb_path and vol-path are different.
Validation passed: 'new-database-name' does not exist in /home/
cubrid/CUBRID-11.4-Linux.x86_64/databases/databases.txt.
```

```
Confirmed: Files found for pattern (/home/cubrid/DB/backupdbpath/
backed-up-database-name_bk0v*).
```

```
file: /home/cubrid/DB/backupdbpath/backed-up-database-name_bk0v*
```

```
Warning: /home/cubrid/CUBRID-11.4-Linux.x86_64/databases/
databases.txt already exists.
```

```
Existing databases.txt backed up as databases.txt.bak.
```

```
Restoring... /
```

CUBRID 11.4

```
Restoring... |Updated CUBRID-11.4-Linux.x86_64/databases/  
databases.txt  
successfully.  
database restoration completed successfully.
```

Once the database is successfully restored, start the new DBMS as follows:

```
[cubrid ~]$ cubrid server start new-database-name  
@ cubrid server start: new-database-name
```

This may take a long time depending on the amount of recovery works to do.

CUBRID 11.4

```
++ cubrid server start: success  
Calling java stored procedure is allowed
```

#### Note

- Since the recovery process using this script modifies `$CUBRID_DATABASES`, it is recommended to verify that the newly created database has been properly registered after the script finishes
- It is recommended to delete recovered DBMS instances that are no longer in use using the `deletedb` command.

### Checking the Log File After Running `restore_to_newdb.sh`

After the restoration, a log file named `restoredb_YYYYMMDDhhmiss.log` will be created in the same directory where the script was executed. If any issues occur, you can check this log file to review the restoration history.

```
[cubrid ~]$ cat restoredb_20250411185128.log  
  
[ Database(db1) Restore (level = 0) start ]  
  
- restore start time: Fri Apr 11 18:51:28 2025  
  
- restore steps: 1  
  step 1) restore using (level = 0) backup data
```

```

- restore progress status (using level = 0 backup data)

-----
-----
volume name          | # of pages | restore progress
status | done
-----
-----
dbms_keys            |           1 |
##### | done
dbms_vinf            |           1 |
##### | done
dbms                  |        32768 |
##### | done
dbms_lgar001         |        32768 |
##### | done
dbms_lgar002         |        32768 |
##### | done
dbms_lginf           |           1 |
##### | done
dbms_lgat            |        32768 |
##### | done
-----
-----

- restore end time: Fri Api 11 18:51:30 2025

[ Database(db1) Restore (level = 0) end ]

```

## Troubleshooting

### Checking SQL Log

#### SQL log of CAS

When a specific error occurs, generally you can check SQL logs of broker application server(CAS)

One SQL log file is generated per each CAS; it is hard to find an SQL log in which an error occurred because SQL log files are many when CAS processes are many. However, SQL log file name includes CAS ID in the end part, you can find easily if you know the CAS ID in which an error occurred.

**Note**

SQL log file name in a CAS is <broker\_name>\_<app\_server\_num>.sql.log(see [Broker Logs](#)); <app\_server\_num> is CAS ID.

## Function getting CAS information

`cci_get_cas_info()` function or `cubrid.jdbc.driver.CUBRIDConnection.toString()` method in JDBC prints out the information including the broker host and CAS ID in which the query is executed when the query is run; with this information, you can find an SQL log file of that CAS easily.

```
<host>:<port>,<cas id>,<cas process id>  
e.g. 127.0.0.1:33000,1,12916
```

## Application log

If you specify the connection URL for printing out the log in the application, you can check the CAS ID which brought an error when an error occurs in the specific query. The following are examples that an application log is written when an error occurs.

### JDBC application log

```
Syntax: syntax error, unexpected IdName [CAS INFO - localhost:  
33000,1,30560],[SESSION-16],[URL-jdbc:cubrid:localhost:  
33000:demodb:*****:  
logFile=driver_1.log&logSlowQueries=true&slowQueryThresholdMillis=5].
```

### CCI application log

```
Syntax: syntax error, unexpected IdName [CAS INFO - 127.0.0.1:33000,  
1, 30560].
```

## Slow query

When a slow query occurs, you should find the reason of a slow query by an application log and an SQL log of CAS.

To find where the cause exists when slow query occurs(in the application-broker section? or in the broker-DB section?), you should check application log or SQL log of CAS because CUBRID is composed of 3-tiers; application-broker-DB server.

There is a slow query in the application log but that is not printed as slow query in the SQL log of CAS; then there will be a cause to make the speed low in the application-broker section.

Some examples are as below.

- Check if there is a low speed of the network between application and broker.
- Check if there is a case where CAS was restarted by checking the broker log (located in the **\$CUBRID/log/broker** directory). If it is revealed that the number of CASes is insufficient (please tune for any slow queries first), you should increase the number of CASes. To do so, the value of **MAX\_NUM\_APPL\_SERVER** should be increased appropriately. Also, increase the value of **max\_clients** if needed.

If application log and CAS SQL log show the slow query log together and there is almost no gap between the slow query times of application log and the CAS SQL log, the cause which the query was slow will exist between the broker and DB server. For example, the query execution in the DB server was slow.

There are examples of each application log when a slow query occurs.

### JDBC application log

```
2013-05-09 16:25:08.831|INFO|SLOW QUERY
[CAS INFO]
localhost:33000, 1, 12916
[TIME]
START: 2013-05-09 16:25:08.775, ELAPSED: 52
[SQL]
SELECT * from db_class a, db_class b
```

### CCI application log

```
2013-05-10 18:11:23.023 [TID:14346] [DEBUG][CONHANDLE - 0002][CAS
INFO - 127.0.0.1:33000, 1, 12916] [SLOW QUERY - ELAPSED : 45] [SQL -
select * from db_class a, db_class b]
```

Slow query information in an application and in a broker is stored in each file when the setting is as following.

- The slow query information in application is stored in application log file when the value of **logSlowQueries** property in the connection URL is set to **yes** and the value of **slowQueryThresholdMillis** is set; it is stored to the application logfile specified with the **logFile** property (see `cci_connect_with_url()` and **Configuration Connection**).
- The slow query information in broker is stored in the **\$CUBRID/log/broker/sql\_log** directory when **SLOW\_LOG** of **Broker Configuration** is set to ON and **LONG\_QUERY\_TIME** is set.

## Server Error Log

You can get various information from the server error log by setting **error\_log\_level** parameter in cubrid.conf. The default of **error\_log\_level** is **NOTIFICATION**. For how to set this parameter, see [Error Message-Related Parameters](#).

### Detecting Overflow Keys or Overflow Pages

When overflow keys or overflow pages occur, **NOTIFICATION** messages are written to the server error log. Through this message, users can detect DB performance became slow because of overflow keys or overflow pages. If possible, overflow keys or overflow pages should not appear. That is, it is better not to use the index on the big size column, and not to define the record size largely.

```
Time: 06/14/13 19:23:40.485 - NOTIFICATION *** file ../../src/
storage/btree.c, line 10617 CODE = -1125 Tran = 1, CLIENT =
testhost:csql(24670), EID = 6
Created the overflow key file. INDEX idx(B+tree: 0|131|540) ON CLASS
hoo(CLASS_OID: 0|522|2). key: 'z ..... '(OID: 0|530|1).
.....

Time: 06/14/13 19:23:41.614 - NOTIFICATION *** file ../../src/
storage/btree.c, line 8785 CODE = -1126 Tran = 1, CLIENT =
testhost:csql(24670), EID = 9
Created a new overflow page. INDEX i_foo(B+tree: 0|149|580) ON CLASS
foo(CLASS_OID: 0|522|3). key: 1(OID: 0|572|578).
.....

Time: 06/14/13 19:23:48.636 - NOTIFICATION *** file ../../src/
storage/btree.c, line 5562 CODE = -1127 Tran = 1, CLIENT =
testhost:csql(24670), EID = 42
Deleted an empty overflow page. INDEX i_foo(B+tree: 0|149|580) ON
CLASS foo(CLASS_OID: 0|522|3). key: 1(OID: 0|572|192).
```

### Detecting log recovery time

When DB sever is started or backup volume is restored, you can check the duration of the log recovery by printing out the **NOTIFICATION** messages, the starting time and the ending time of the log recovery, to the server error log or an error log file of restoredb. In these messages, the number of logs and the number of log pages to redo are written together.

```
Time: 06/14/13 21:29:04.059 - NOTIFICATION *** file ../../src/
transaction/log_recovery.c, line 748 CODE = -1128 Tran = -1, EID = 1
Log recovery is started. The number of log records to be applied:
96916. Log page: 343 ~ 5104.
.....
```

```
Time: 06/14/13 21:29:05.170 - NOTIFICATION *** file ../../src/
transaction/log_recovery.c, line 843 CODE = -1129 Tran = -1, EID = 4
Log recovery is finished.
```

## Detecting a Deadlock

Locks related information is written to the server error log. The server error log file is saved in the **\$CUBRID/log/server** directory as named in `<databases>_<date>_<time>.err`.

```
demodb_20160202_1811.err
```

```
...
```

```
Your transaction (index 1, public@testhost|csql(21541)) timed out
waiting on      X_LOCK lock on instance 0|650|3 of class t because of
deadlock. You are waiting for user(s) public@testhost|csql(21529) to
finish.
```

```
...
```

## Detecting the change of HA status

Detecting the change of HA status can be checked in the cub\_master process log. This log file is stored in the **\$CUBRID/log** directory as named in `<host_name>.cub_master.err`.

## Detecting HA split-brain

When there is an abnormal status that two or more nodes are in charge of master role in HA environment, we call it “split-brain”.

To resolve the split-brain status, one of two is dead for itself; cub\_master log file of this node includes the following information.

```
Time: 01/10/25 13:46:34.782 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 873 ERROR CODE = -988, Tran = -1, EID = 35
Node event: [Failback] [Diagnosis] Multiple master nodes
(testhost02, testhost01) are detected.
```

```
Time: 01/10/25 13:46:34.782 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 876 ERROR CODE = -988, Tran = -1, EID = 36
Node event: HA Node Info
```

```
=====
=====
* group_id : hagrps   host_name : testhost02   state : master
-----
-----
```

```

name                priority  state      score      missed
heartbeat
-----
testhost02          2      master    -32766     0
testhost01          1      master    -32767     0
=====

Time: 01/10/25 13:46:34.782 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 889 ERROR CODE = -988, Tran = -1, EID = 37
Node event: HA Ping Host Info
=====
=====
* PING check is enabled
-----
-----
hostname            PING check result
-----
8.8.8.8              SUCCESS
=====
=====

Time: 01/10/25 13:46:34.782 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 1371 ERROR CODE = -988, Tran = -1, EID = 38
Node event: [Failback] [Success] Current node has been successfully
demoted to slave.

```

Above example is the information to print out into the cub\_master log when testhost02 server detects split-brain status and it is dead for itself.

## Detecting Fail-over, Fail-back

If fail-over or fail-back occurs, a node changes its role.

The following is the log file of the cub\_master that changes to a slave node after fail-back or to a master node after fail-over; log messages for fail-over and fail-back are prefixed with [Failover] or [Failback].

The log messages for fail-over and fail-back include both diagnosis and result messages.

A diagnosis message is logged when a fail-over or fail-back is triggered for a specific reason. These messages indicate the reason why the fail-over or fail-back was initiated and are prefixed with [Diagnosis].

A result message is logged when a fail-over or fail-back is either canceled or successfully completed. If the fail-over or fail-back is canceled, the result message logs the reason for the cancellation and is prefixed with [Canceled]. If the fail-over or fail-back is completed successfully,

the result message logs the outcome and is prefixed with [Success]. For details, see [Determine the Cause of Failover](#).

```
Time: 01/09/25 16:14:13.005 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 924 ERROR CODE = -988, Tran = -1, EID = 6
Node event: [Failover] [Diagnosis] The master node (testhost01) has
lost its role due to server process problem, such as disk failure.

Time: 01/09/25 16:14:13.614 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 1179 ERROR CODE = -988, Tran = -1, EID = 7
Node event: [Failover] [Success] Current node has been successfully
promoted to master.

Time: 01/09/25 16:14:13.614 - ERROR *** file ../../src/executables/
master_heartbeat.c, line 1196 ERROR CODE = -988, Tran = -1, EID = 8
Node event: HA Node Info
=====
=====
* group_id : hagrp    host_name : testhost02    state : master
-----
-----
name                priority    state                score                missed
heartbeat
-----
-----
testhost02           2          to-be-master        -4094                0
testhost01           1          unknown             32767                1
=====
=====
```

The above example shows information which is printed in the cub\_master log; it describes the process where the 'testhost02' host changes its role from slave to master during a fail-over because the master node 'testhost01' has lost its role due to server process issue.

## Failure on HA Start

The following is examples that replicated DB volumes' restoration is impossible without user intervention.

- When logs to copy in copylogdb process are deleted from a source node.
- When archive logs to apply from active server are already deleted.
- When a restoration of server is failed.

When replicated DB volumes' restoration is impossible like above cases, **"cubrid heartbeat start"** command is failed; for each case, you should fix it properly.

## Typical Unrestorable Failure

If server process is the cause of the cases that automatic restoration of DB volumes without user intervention is impossible, that cases will be very various, so descriptions for those are omitted. The following describes the error messages when **copylogdb** or **applylogdb** process is the cause.

- When **copylogdb** process is the cause

| Cause                                                         | Error message                                                                             |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| A log not copied yet is already deleted from the target node. | log writer: failed to get log page(s) starting from page id 80.                           |
| Detected as the other DB's log.                               | Log "/home1/cubrid/DB/tdb01_cdb037.cub/tdb01_lgat" does not belong to the given database. |

- When **applylogdb** process is the cause

| Cause                                                                                                                                                          | Error message                                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Archive logs including logs to apply in replication are already deleted.                                                                                       | Internal error: unable to find log page 81 in log archives.<br><br>Internal error: logical log page 81 may be corrupted.              |
| Different between _db_ha_apply_info catalog time and DB creation time in the current replication logs. That is, it's not the previous log to be being applied. | HA generic: Failed to initialize _db_ha_apply_info.                                                                                   |
| Different database locale.                                                                                                                                     | Locale initialization: Active log file(/home1/cubrid/DB/tdb01_cdb037.cub/tdb01_lgat) charset is not valid (iso88591), expecting utf8. |

## How to fix when a Failure on HA start

| Status                                                           | How to fix                                                             |
|------------------------------------------------------------------|------------------------------------------------------------------------|
| When the source node, the cause of failure, is in master status. | Rebuild replication.                                                   |
| When the source node, the cause of failure, is in slave status.  | Initialize replicated logs and _db_ha_apply_info catalog then restart. |

## DDL Audit Log

### Overview

CUBRID has the capability of recording DDL (Data Definition Language) that changes the database system configuration such as create/delete/modify tables as well as changing the access privilege of a table. DDLs issued through CAS, csql, and loaddb could be recorded in log files in addition to the copy of the files executed if required.

The DDL Audit log will be created in the \$CUBRID/log/ddl\_audit directory when ddl\_audit\_log of the system parameter is turned on. Note that the size of each log file cannot exceed the value specified in the ddl\_audit\_log\_size parameter. For parameters related to DDL audit, refer to system parameters of CUBRID Managment [System Parameters](#) .

#### Note

If you use a method from the [System Catalog](#) , the DDL Audit Log will not be created.

### DDL Audit Log file name convention

- cas: {broker\_name}\_{app\_server\_num}\_ddl.log
- csql interactive: csql\_{db\_name}\_ddl.log
- loaddb: loaddb\_{db\_name}\_ddl.log

#### **Additional file name convention:**

- csql from file: csql/{csql\_file}\_{YYYYMMDD}\_{HHMMSS}\_{pid}

- loaddb: loaddb/{loaddb\_file}\_{YYYYMMDD}\_{HHMMSS}\_{pid}

## DDL Audit Logfile format of CAS

- [Time] [ip\_addr][db\_name][user\_name][result][elapsed time][auto commit/rollback][sql\_text]

Description:

- [Time]: Time starting execution of the DDL (e.g. 20-12-18 12:08:32.327)
- [db\_name]: Database name where DDL was executed
- [ip\_addr]: An IP address of an application client (e.g. 172.31.0.70)
- [user\_name]: the database user name who issued DDL
- [result]: statement execution result. OK if successful, otherwise error code (e.g. ERROR:-494)
- [elapsed time]: Elapsed time of statement execution
- [auto commit/rollback]: Automatically committed or rolled back, with the error code of it
- [sql\_text]: executed DDL text

## DDL Audit Logfile format of CSQL

- [Time] [pid][user\_name][result][elapsed time][auto commit/rollback][sql\_text]

Description:

- [Time]: Time starting execution of the DDL (e.g. 20-11-20 13:26:51.765)
- [pid]: csql process id
- [user\_name]: the database user name who issued DDL
- [result]: statement execution result. OK if successful, otherwise error code (e.g. ERROR:-272)
- [elapsed time]: Elapsed time of statement execution
- [auto commit/rollback]: Automatically committed or rolled back, with the error code
- [sql\_text]: executed DDL text or executed csql filename

## DDL Audit Log format of LOADDDB

• [Time] [pid][user\_name][result][log contents][file name]

Description:

- [Time]: Time starting execution of the DDL (e.g. 20-12-18 12:08:32.327)
- [pid]: loadddb process id
- [user\_name]: the database user name who issued DDL
- [result]: Result of loadddb execution, OK if successful, otherwise error code (e.g. ERROR:-494)
- [log contents]: The number of total statements, or the number of commit in case of error and error line
- [file name]: Copy the file loaded from loadddb. At this time, it is the name of the copied file

## Database Error Logs

### Overview of CUBRID Error Messages

CUBRID error messages are provided in both Korean and English in the `$CUBRID/msg` directory. From the perspective of a CUBRID user (DBA), these error messages constitute a core error catalog that systematically classifies major error situations that the CUBRID database may encounter during runtime, such as system issues, transaction/lock problems, log/backup issues, DDL/DML operations, indexes, constraints, authorization, SQL execution, and HA/replication.

The composition of CUBRID error message files and user guidance messages is as follows.

- cubrid.msg: Runtime errors and system messages of the CUBRID database engine
- csqll.msg: Usage instructions, commands, and error messages of the CSQL (CUBRID SQL Interpreter) client tool
- utils.msg: Messages and usage instructions of CUBRID administrative utility tools

### CUBRID Data Model Terminology

CUBRID was developed as an object-relational database (ORDB) and partially supports object concepts such as class (table) inheritance. Because of this, object-based terminology may be used in error messages or internal concepts. Therefore, it is necessary to understand traditional

relational database (RDB) terminology together with object-relational database (ORDB) terminology, as shown below.

| Relational (RDB) Term | Object-Relational (ORDB) |
|-----------------------|--------------------------|
| Table                 | Class                    |
| Column                | Attribute                |
| Record                | Instance                 |
| Data Type             | Domain                   |

### Classification of CUBRID Error Messages

Major database error messages are classified into six categories: system management, SQL queries, database administration, database files, transactions, and CUBRID HA. For each error code and message, descriptions and service impact are organized together.

### System Management Errors

#### **ERROR CODE: -3, 'Out of virtual memory: unable to allocate %1\$zu memory bytes.'**

- This message indicates an error where the CUBRID system attempted to allocate a certain amount of virtual memory from the operating system, but the allocation failed because there was not enough virtual memory available on the system; virtual memory includes physical RAM and disk swap space, and CUBRID uses a large amount of memory for database work (e.g., query execution, buffer cache, transaction management, internal data structures); this message typically occurs when the system has insufficient physical RAM, the swap space is exhausted, or the memory limit assigned to the CUBRID process has been exceeded, and as a result it can interfere with normal database service.

#### **ERROR CODE: -7, 'Trying to format disk volume "%1\$s" with an incorrect value %2\$d for number of pages.'**

- This message indicates an error where the CUBRID system attempted to format a particular disk volume, but the format operation failed because the specified number of pages is invalid or not an allowed value; it mainly occurs in the file-open stage due to incorrect settings, exceeding system limits, or an internal logic error, and it can interfere with database creation or volume expansion operations.

**ERROR CODE: -8, 'Unable to format disk volume "%1\$s" with %2\$d pages (%3\$lld bytes).'**

- This message indicates an error where the CUBRID system attempted to format a particular disk volume to the specified size, but the format operation failed due to a file-system-level problem; it mainly occurs in the file-open stage due to a file system error, a permission problem, a hardware problem, or a volume-file path problem, and it can interfere with database creation or volume expansion operations.

**ERROR CODE: -9, 'Unable to format disk volume "%1\$s" with %2\$d pages (%3\$lld Kbytes) due to insufficient space. Current space available is %4\$d pages (%5\$lld Kbytes).'**

- This message indicates an error where the CUBRID system attempted to format a particular disk volume, but the format operation failed because the available disk space is less than the requested size; it mainly occurs due to insufficient disk space, an error in volume-size configuration, or file-system limits, and it can interfere with database creation or volume expansion operations.

**ERROR CODE: -10, 'Unable to mount disk volume "%1\$s".'**

- This message indicates an error where the CUBRID system attempted to mount a particular disk volume, but the operation failed due to an operating-system or file-system-level problem; it mainly occurs due to file system corruption, a missing volume file, insufficient permissions, or a hardware problem, and it can interfere with normal database startup or recovery operations.

**ERROR CODE: -11, 'Unable to mount disk volume "%1\$s". The database "%2\$s", to which the disk volume belongs, is in use by user %3\$s on process %4\$d of host %5\$s since %6\$s.'**

- This message indicates an error where the CUBRID system attempted to mount a particular disk volume, but the mount failed because the database to which that volume belongs is already in use by another CUBRID process; it is mainly an error that occurs when creating a lock file, and it happens when a lock file has already been created by another process or when the lock file cannot be created; this message typically occurs when two or more CUBRID server instances try to access the same database at the same time, and it is an important mechanism for protecting database consistency.

**ERROR CODE: -12, 'Unable to dismount disk volume "%1\$s".'**

- This message indicates an error where the CUBRID system attempted to dismount a particular volume, but the operation failed due to an operating-system or file-system-level problem; it mainly occurs in the file-close stage due to issues such as file system errors, permission problems, or hardware problems, and it can interfere with safe database shutdown or volume management operations.

**ERROR CODE: -13, 'Unable to read page %1\$d of disk volume "%2\$s".'**

- This message indicates an error where the CUBRID system attempted to read a specific page of a particular volume from disk, but the read operation failed due to an error during the I/O

operation; it mainly occurs due to disk errors, file system problems, permission problems, or hardware problems, and it can affect database stability and can lead to data corruption.

**ERROR CODE: -14, 'Unable to write page %1\$d of disk volume "%2\$s"'**

- This message indicates an error where the CUBRID system attempted to write a specific page of a particular volume to disk, but the write operation failed due to an error during the I/O operation; it mainly occurs due to disk errors, file system problems, permission problems, or hardware problems, and it can affect database stability and can lead to data corruption.

**ERROR CODE: -15, 'Unable to write page %1\$d of disk volume "%2\$s" due to insufficient space.'**

- This message indicates an error where the CUBRID system attempted to write a specific page of a particular volume to disk, but the write operation failed because there was not enough disk space at the operating-system level; it mainly occurs due to a full disk, file-system quota/limits, or improper disk-space management, and it can interfere with normal database operation and volume growth.

**ERROR CODE: -16, 'Unable to rename disk volume "%1\$s" to "%2\$s"'**

- This message indicates an error where the CUBRID system attempted to rename a particular disk volume, but the operation failed due to a file-system-level problem; it mainly occurs due to insufficient permissions, conflicts with an existing target file/directory, the source file being in use, or other file-system issues, and it can interfere with volume management operations such as database maintenance, backup/restore, or storage migration.

**ERROR CODE: -78, 'Internal error: an I/O error occurred while reading logical log page %1\$lld (physical page %2\$lld) of "%3\$s"'**

- This message is an internal error indicating that, when the CUBRID system tried to read a logical log page from a physical page, an I/O (input/output) error occurred on the specified operating-system device and the read operation failed; this mainly occurs due to hardware issues (disk failure), file system corruption, OS-level I/O problems, or driver errors.

**ERROR CODE: -79, 'Internal error: an I/O error occurred while writing logical log page %1\$lld (physical page %2\$lld) of "%3\$s"'**

- This message is an internal error indicating that, when the CUBRID system tried to write a logical log page to a physical page, an I/O (input/output) error occurred on the specified operating-system device and the write operation failed; this mainly occurs due to hardware issues (disk failure), file system corruption, OS-level I/O problems, or driver errors.

**ERROR CODE: -82, 'Unable to mount log volume "%1\$s"'**

- This message indicates an error where the CUBRID database system failed to "mount" or access the specified log disk volume or file; this mainly occurs due to file-system permission

problems, missing or corrupted files, disk-space shortages, or other storage-related I/O problems, and it can interfere with database startup, recovery, and transaction logging.

**ERROR CODE: -101, 'Not a database volume file - %1\$s.'**

- This message indicates an error that occurs when the CUBRID system tries to access or process a particular user file, but the file does not exist, the path is incorrect, or it is a file that the system cannot recognize; it mainly occurs when the file specified in the `createdb` command with the `--more-volume-file` option cannot be found, or when the volume information file (DBname\_vinf) cannot be found.

**ERROR CODE: -102, 'Unexpected EOF in volume information file.'**

- This message is displayed while the CUBRID system reads the volume information (DBname\_vinf) file; it mainly occurs when the file is incomplete or corrupted, or when it has been recorded/entered in a way that does not match the actual database volume information.

**ERROR CODE: -103, 'The first volume in volume information file is not in order.'**

- This message is displayed while the CUBRID system searches for the first volume in the database volume information (DBname\_vinf) file; it means that the entries in the volume information file must be sorted sequentially, but their order has been changed or there are missing entries.

**ERROR CODE: -104, 'The first volume in volume information file is not found.'**

- This message is displayed while the CUBRID system searches for the first volume in the database volume information (DBname\_vinf) file; it may indicate a database integrity issue, file corruption, or that the file has possibly been modified manually.

**ERROR CODE: -105, 'Unable to open backup file "%1\$s".'**

- This message is displayed when the CUBRID system tries to access a backup file but cannot access it due to file-system permission problems, file corruption, or the file not existing; backup or restore operations can fail because this file-access failure blocks access to the backup file.

**ERROR CODE: -111, 'Transaction was aborted.'**

- This message is displayed when the CUBRID system unilaterally aborts an active transaction due to a server failure or a mode change; it means the system forcibly terminated the transaction without the client's request or consent, and it mainly occurs when the server process is terminated unexpectedly or during failover/failback or other mode transitions, which can lead to client errors and rollback of in-flight work.

**ERROR CODE: -113, 'Cannot restart server.'**

- This message is displayed when the CUBRID system fails while trying to restart or initialize the database server; during server restart/initialization, this can occur due to insufficient system

resources, permission problems, port conflicts, or other system-level errors, and it can prevent normal database service from starting.

**ERROR CODE: -114, 'Unknown database "%1\$s"'**

- This message is displayed when the CUBRID system cannot recognize the specified path or name as a database; it means that database volumes or files have been renamed or copied outside of the database domain, so CUBRID cannot find the correct database structure.

**ERROR CODE: -118, 'Unable to determine the current working directory.'**

- This message is displayed when the CUBRID system fails while checking the current working directory; such failures mainly occur due to file-system permission problems, the directory having been deleted, or process permission issues.

**ERROR CODE: -123, 'Unable to create database volumes.'**

- This message is displayed when the CUBRID system tries to create volumes or files required for the database but fails due to file-system permissions, insufficient disk space, path problems, and similar issues; database volume creation can fail because the needed files cannot be created, which can block database creation, volume expansion, or certain maintenance operations.

**ERROR CODE: -130, 'Unable to allocate %1\$zu bytes.'**

- This message is displayed when the CUBRID database system cannot allocate the required memory; it is printed when the system's virtual memory is insufficient or when a memory allocation request fails, which indicates that the system's memory resources have been exhausted.

**ERROR CODE: -313, 'Memory allocation failure.'**

- This message occurs during the process of reading database object data, and it is an important memory-related error that mainly occurs during object loading or unloading.

**ERROR CODE: -320, 'Encountered corrupted disk representation of object.'**

- This message is an error that appears when the representation of an object stored on disk is corrupted in a CUBRID database; it occurs when reading object data during the B-tree loading process, and it can be caused by disk I/O errors, memory corruption, or database file corruption.

**ERROR CODE: -542, 'Corrupted disk volume. The number of remaining free sectors in volume header does not match the bitmap's.'**

- This message occurs on a particular volume (disk file) in the CUBRID database when the number of remaining free sectors recorded in the volume header (metadata) differs from the number of remaining free sectors calculated from the actual bitmap (the internal table that

represents sector allocation status); such a mismatch means a consistency error in disk-space management, and it can appear when there were problems in the process of allocating/freeing storage space, or when the metadata and actual state became inconsistent due to physical damage, abnormal shutdown, bugs, and similar causes.

**ERROR CODE: -543, 'Corrupted disk volume. Disk volume header is broken.'**

- This message occurs on a particular volume (disk file) in the CUBRID database when the disk header (metadata that represents the volume's structure and state) is damaged or when the internally expected values differ from the actual values; because the disk header contains important metadata such as volume size, allocation information, version, and checksums, any mismatch can affect the entire storage structure of the database; it can mainly occur due to abnormal shutdown, disk errors, file-system corruption, bugs, and similar causes.

**ERROR CODE: -599, 'I/O error while synchronizing the volume status.'**

- This message appears when an I/O error occurs while the CUBRID database synchronizes a volume's status with disk; a volume is the physical storage unit of a CUBRID database and refers to a data file, and synchronization is the process of forcibly writing in-memory data to disk in order to guarantee data consistency and durability.

**ERROR CODE: -705, 'Permanent volume number mismatch. Permanent volumes in boot page (%1\$d). Permanent volumes in volume information file (%2\$d).'**

- This message is an error that appears when, during CUBRID database boot or recovery, the number of permanent volumes recorded in the boot page (boot page) does not match the number of permanent volumes actually found by the system; this means there is a problem with the database's volume configuration and it can affect database consistency and integrity; this message occurs when the CUBRID database server starts up or recovers after a crash.

**ERROR CODE: -708, 'Not enough space in temporary volume.'**

- This message is an error that appears when the CUBRID database attempts to extend a temporary disk volume but fails because there is not enough disk space; it can occur when CUBRID extends temporary volumes for large query processing or temporary table creation.

**ERROR CODE: -780, 'Cannot get system time.'**

- This message indicates that, when CUBRID tries to obtain the system time, it is in a situation where the system time cannot be obtained; this occurs in CUBRID's system-time mechanism and can mainly be caused by failures in OS-level time-related function calls.

**ERROR CODE: -792, 'Internal error: connection entry allocation error.'**

- This message is an internal error that occurs when the CUBRID system fails to allocate memory related to a connection entry; a memory allocation failure prevents the module from functioning normally and has a critical impact on client connection management and server

communication; this mainly occurs due to insufficient system memory, memory fragmentation, or operating-system memory-allocation limits.

**ERROR CODE: -864, 'Cannot open backupdb/restoredb verbose file '%1\$s''**

This error occurs when, during a database backup or restore operation, the detailed (verbose) log file cannot be created or opened; it is an I/O-related error that can be caused by file-system permissions, insufficient disk space, path problems, and similar issues.

**ERROR CODE: -879, 'Failed to get permission for "%1\$s''**

- This message occurs when CUBRID tries to query file-system permission information for a particular file or directory; this typically occurs when access permissions for database files or log files need to be checked, and it mainly appears when the user account running the CUBRID process does not have permission to query information about that file.

**ERROR CODE: -880, 'Failed to set permission for "%1\$s''**

- This message occurs when CUBRID tries to change file-system permissions for a particular file or directory; this typically occurs when access permissions for database files or log files need to be adjusted, and it mainly appears when the user account running the CUBRID process does not have permission to modify that file.

**ERROR CODE: -881, 'Failed to acquire lock for "%1\$s''**

- This message occurs when CUBRID tries to acquire a lock for a particular file; this typically occurs when opening or mounting database volumes and is related to the file system's lock-management mechanism; it can be caused by file-system access problems, permission problems, a lock being held by another process, insufficient system resources, and similar issues.

**ERROR CODE: -882, 'Failed to release lock for "%1\$s''**

- This message occurs when CUBRID tries to release a lock set on a particular file; this typically occurs when closing or unmounting database volumes and is related to the file system's lock-management mechanism; it can be caused by file-system access problems, permission problems, insufficient system resources, and similar issues.

**ERROR CODE: -980, 'Thread %1\$u waited %2\$lld milliseconds during %3\$s'**

- This message is a warning that occurs when a thread in the CUBRID database waits longer than the configured threshold while performing a particular task (entering a critical section, acquiring a lock, file I/O, and so on); it is part of a performance monitoring feature that detects situations where a thread is waiting longer than expected and notifies the system administrator; this is not an error but an informational message that helps discover performance issues early and respond to them, and it mainly occurs in critical sections, lock

management, and file I/O operations and is useful for identifying bottlenecks or resource contention.

**ERROR CODE: -1015, 'Specified directory '%1\$s' does not exist.'**

- This message occurs when the path of volume files used by the database server is incorrect, or when the directory cannot be created/used and therefore the required directory does not exist.

**ERROR CODE: -1113, 'Element index out of range.'**

- This message occurs when, in a CUBRID database, an attempt is made to add an element to a Binary Heap data structure and the heap's maximum capacity has been exceeded; that is, it means an insertion was attempted while the binary heap was already full; this is a protective error intended to ensure memory management and system stability, because the binary heap is an important data structure used for sorting, priority queues, heap sort, and so on, and exceeding its capacity could lead to memory overflow or unexpected behavior.

**ERROR CODE: -1185, 'Unexpected page refix on page %1\$d,%2\$d, while trying to fix page %3\$d, %4\$d.'**

- This message occurs in the page buffer management system of the CUBRID database. When trying to fix a particular page in memory for access, it indicates that another page was unexpectedly refixed; this means that there is a problem with the internal consistency or state management of the page buffer, and in general it is an abnormal situation that should not occur. Because the page buffer is a core component of the database, this kind of error can lead to data integrity issues or system instability.

## Query (SQL) Related Errors

**ERROR CODE: -64, 'Unknown class "%1\$s"'**

- This message is displayed when the specified table name cannot be found in the CUBRID system.

**ERROR CODE: -65, 'Class "%1\$s" already exists.'**

- This message is displayed when you attempt to create a new table with a table name that already exists in the CUBRID system.

**ERROR CODE: -176, 'Conversion error in date format.'**

- This message is an error that appears when an error occurs during the format conversion process for date/time-related data types in CUBRID; it occurs in the process of converting a string to a date/time type, or validating the validity of a date/time value; it can be caused by an invalid date format, an out-of-range value, or data in a format that cannot be converted.

**ERROR CODE: -181, 'Cannot coerce value of domain "%1\$s" to domain "%2\$s"'**

- This message is displayed when converting a value of one data type to another data type in CUBRID when the conversion is not possible or is incompatible; it occurs due to compatibility issues between data types or values that do not match the conversion rules; for example, it can occur when converting a string to a number, or performing an operation between different data types.

**ERROR CODE: -182, 'Cannot coerce value of domain "%1\$s" to domain "%2\$s" without overflow.'**

- This message is an error that appears when converting a value of one data type to another data type in CUBRID when overflow occurs and the conversion cannot be performed; it means that in the data type conversion process the value range exceeds the allowed range of the target data type and therefore cannot be converted; for example, it can occur when attempting to convert a very large integer value to a small integer type.

**ERROR CODE: -202, 'Attribute "%1\$s" was not found.'**

- This message is displayed when a column with the specified name cannot be found in the CUBRID database; it can mainly appear due to an incorrect column name reference, access to a non-existent column, or a schema definition error.

**ERROR CODE: -203, 'Value for attribute "%1\$s" must be of type "%2\$s", not type "%3\$s"'**

- This message is displayed when the data type of a column and the type of the value you are trying to assign do not match in the CUBRID database; it can mainly appear when trying to assign a value of an incorrect type, due to a data type definition issue or a data type conversion failure.

**ERROR CODE: -205, 'Attribute "%1\$s" cannot be made NULL.'**

- This message is displayed when you attempt to assign a NULL value to a column on which a NOT NULL constraint is set in the CUBRID database; it can mainly appear due to incorrect data insertion, assigning a NULL value during an update, or a mismatch between the schema definition and the data.

**ERROR CODE: -208, 'Method "%1\$s" not found.'**

- This message is displayed when a method with the specified name cannot be found in the CUBRID database; it can mainly appear due to an incorrect method name reference, access to a non-existent method, or a schema definition error.

**ERROR CODE: -218, 'Invalid object in db\_get path expression.'**

- This message is displayed when an invalid object is found while processing the path expression of the *db\_get* function in the CUBRID database.

**ERROR CODE: -219, 'Invalid db\_get path expression.'**

- This message is displayed when the path expression of the *db\_get* function is invalid in the CUBRID database.

**ERROR CODE: -220, 'Invalid set in db\_get path expression.'**

- This message is displayed when, while processing the path expression of the *db\_get* function in the CUBRID database, a set-related operation is attempted on an object that is not of a set type.

**ERROR CODE: -221, 'Invalid set index in db\_get path expression.'**

- This message is displayed when, while processing the path expression of the *db\_get* function in the CUBRID database, an invalid index is used for a collection object of type set, multiset, or sequence.

**ERROR CODE: -222, 'Attempt to assign string value greater than %2\$d characters to attribute "%1\$s"'**

- This message is displayed when, in the CUBRID database, you attempt to assign a string value to a specific column of an object and the length of the string to be assigned exceeds the maximum string length allowed by that column; it mainly occurs when inserting or updating data that exceeds the maximum length defined for a column of type *VARCHAR* or *CHAR*.

**ERROR CODE: -225, 'Missing value for attribute "%1\$s" with the NOT NULL constraint.'**

- This message is displayed when, in the CUBRID database, a value is not provided for a column with a *NOT NULL* constraint or when a *NULL* value is attempted to be assigned.

**ERROR CODE: -226, 'Empty component list in class.'**

- This message is displayed when, while performing an operation on a table or object in the CUBRID database, the list of components (columns, attributes, etc.) that the table or object must have is empty or invalid; it can mainly occur in operations such as schema unload, query result processing, or retrieving specific object information.

**ERROR CODE: -227, 'Attempt to assign value to attribute "%1\$s" more than once.'**

- This message is displayed when, in the CUBRID database, you create an object using an object template and attempt to assign a value to the same column more than once.

**ERROR CODE: -228, 'Method "%1\$s" called with %2\$d arguments. The system allows a maximum of %3\$d arguments.'**

- This message is displayed when, in the CUBRID database, you call a method and pass more arguments than the maximum number of arguments allowed.

**ERROR CODE: -229, 'Method "%1\$s" requires argument %2\$d to be within the domain "%3\$s". An invalid value of domain "%4\$s" was given.'**

- This message is displayed when, in the CUBRID database, the value of a specific argument falls outside the expected domain when calling a method; it can mainly appear when a value of an incorrect type is passed as a method argument, or when data type conversion (coercion) is not possible.

**ERROR CODE: -233, 'Cannot create class with basic type name "%1\$s"'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to use a basic type name as a table name when creating a table; CUBRID prohibits using primitive type names and reserved words as table names. This is to maintain consistency of the type system and prevent name collisions; it can appear when an invalid table name is used or when attempting to use a basic type or reserved word as a table name.

**ERROR CODE: -234, 'Method file "%1\$s" not found.'**

- This message is a schema definition error that occurs when, in the CUBRID database, a method file with a specific name cannot be found in the schema template; it can appear when an incorrect method file name is used, when the method file has already been deleted, or when the schema template has not been initialized correctly.

**ERROR CODE: -235, '%1\$d unresolved method functions after linking.'**

- This message is a schema definition error indicating that, even after the dynamic linking process is completed in the CUBRID database, there are still unresolved method functions (implementations cannot be found); it can appear when there is a problem with the method file, the function name is wrong, the required library has not been loaded, or a function referenced within the method file is missing.

**ERROR CODE: -236, 'Unresolved method "%1\$s"'**

- This message is a schema definition error that occurs when, in the CUBRID database, the implementation of a specific method (mainly a Java stored function/procedure) cannot be found during the dynamic linking process; it can appear when the method file is corrupted, the function name is wrong, or there is a problem with the linker settings.

**ERROR CODE: -239, 'Attribute "%1\$s" was not found.'**

- This message is a schema definition error that occurs when, in the CUBRID database, a column with a specific name cannot be found.

**ERROR CODE: -240, 'Method "%1\$s" was not found.'**

- This message is a schema definition error that occurs when, in the CUBRID database, a method with a specific name cannot be found.

**ERROR CODE: -241, 'There is no attribute or method with name "%1\$s"'**

- This message is a schema definition error that occurs when, in the CUBRID database, a column or method with a specific name cannot be found.

**ERROR CODE: -242, 'Signature for %2\$s not found for method "%1\$s"'**

- This message is a schema definition error that occurs when, in the CUBRID database, the specified signature cannot be found for a specific method.

**ERROR CODE: -243, 'Argument %2\$d of method "%1\$s" is undefined.'**

- This message is a schema definition error that occurs when, in the CUBRID database, the argument corresponding to the specified index of a specific method is not defined.

**ERROR CODE: -244, 'Domain name "%1\$s" is not the name of a class or basic type.'**

- This message is a schema definition error that occurs when, in the CUBRID database, the name specified as the data type of a column or method is not a valid table name or a basic data type.

**ERROR CODE: -245, 'The name "%1\$s" has already been used as an attribute name.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to define the name of a new method, table method, or other schema component, but that name is already used as the name of an existing column.

**ERROR CODE: -246, 'The name "%1\$s" has already been used as a method name.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to define the name of a new column, table column, or other schema component, but that name is already used as the name of an existing method.

**ERROR CODE: -248, 'The attribute domain "%1\$s" is not suitable for use with the %2\$s constraint.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to apply a UNIQUE constraint to a specific column but the data type is not suitable for a UNIQUE constraint; CUBRID restricts UNIQUE constraints to certain data types. Only indexable data types can have a UNIQUE constraint.

**ERROR CODE: -250, 'Cannot create index on attribute "%1\$s", defined with a shared value.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to create an index on a column defined with a shared value (shared value).

**ERROR CODE: -251, 'Signature %2\$s already exists for method "%1\$s"'**

- This message is a schema definition error that occurs when, in the CUBRID database, a definition with the same signature already exists for a specific method.

**ERROR CODE: -252, 'Attribute "%1\$s" must have a set domain for that operation.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to perform an operation that requires a SET type (collection types such as SET, MULTISSET) on a specific column, but the data type of that column is not a SET type; it can occur mainly when defining or modifying a column using *CREATE TABLE* or *ALTER TABLE*, or when a specific method or function requires a SET-type column as an argument.

**ERROR CODE: -253, 'Attribute "%1\$s" cannot be defined with a nested set domain.'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to define a column as a nested SET data type; CUBRID does not allow nesting another SET type inside a SET-type collection (e.g., SET, MULTISSET); it mainly occurs when defining or modifying a column using *CREATE TABLE* or *ALTER TABLE*.

**ERROR CODE: -254, 'Unable to remove domain "%2\$s" from attribute "%1\$s".'**

- This message is displayed when, in the CUBRID database, you attempt to remove a specific data type; it mainly occurs when trying to remove a column's data type using a *DROP TABLE* statement, in a situation where the data type cannot be removed from the column (e.g., the data type does not exist, is referenced by another constraint, or is the column's basic data type).

**ERROR CODE: -260, 'Argument %2\$d of method "%1\$s" is not of a set domain.'**

- This message is a schema definition error that occurs when, in the CUBRID database, the domain of a specific argument is not a set type when defining a method; in CUBRID, set types mean collection types such as set and multiset; it can occur mainly when defining or modifying a method using *CREATE TABLE* or *ALTER TABLE*.

**ERROR CODE: -269, 'Cannot define index on domain "%1\$s".'**

- This message is a schema definition error that occurs when, in the CUBRID database, you attempt to create an index on a specific data type; CUBRID does not allow index creation for all data types, and the data types on which index creation is not allowed (such as "SET", "MULTISSET", "BLOB", "CLOB", etc.) are restricted.

**ERROR CODE: -272, 'Index "%2\$s" already defined for class "%1\$s".'**

- This message indicates a schema management error that occurs when, in the CUBRID database, you attempt to create an index with the same name redundantly; it occurs when you try to create a new index with the same name as an index that already exists on a specific table.

**ERROR CODE: -273, 'Index "%1\$s" does not exist.'**

- This message indicates a schema management error that occurs when, in the CUBRID database, a specific index cannot be found; it can mainly occur during index DDL operations such as *DROP INDEX*, *ALTER INDEX*, or query execution that uses an index.

**ERROR CODE: -274, 'Illegal characters in name: "%1\$s"'**

- This message occurs when, in the CUBRID database, when defining or changing the name of a schema object (table, column, method, index, etc.), the name is NULL or an empty string; it can mainly occur when executing DDL (Data Definition Language) statements such as *CREATE TABLE*, *ALTER TABLE*, and *CREATE VIEW*.

**ERROR CODE: -293, 'Operation not allowed for this class type.'**

- This message is displayed when, in the CUBRID database, you attempt an operation that is not allowed for a specific table type; it can occur mainly in the process of schema definition, table alteration, or performing certain object-related operations, and indicates that you must understand the characteristics of the table and perform allowed operations.

**ERROR CODE: -294, 'Undefined environment variable "%1\$s" referenced in method file.'**

- This message is displayed when, in the CUBRID database, an environment variable included in the path of a method file is not defined; a method file is an external library file that implements user-defined methods (functions) in CUBRID, and this message mainly indicates a problem that occurs because the method file cannot be found during the dynamic linking process.

**ERROR CODE: -305, 'Sequence index %1\$d is out of bounds.'**

- This message is an error that appears when, in the CUBRID database, the index of a sequence collection is outside the valid range; it occurs during the index range validation process in the sequence object management system, mainly when accessing a sequence element with an index less than 0 or greater than the sequence size.

**ERROR CODE: -308, 'Element value is not within the domain of the set.'**

- This message is an error that appears when, in the CUBRID database, when adding an element to a set-type collection, the value of that element is not compatible with the domain of the set; it mainly occurs when the element value violates the domain rules of the set.

**ERROR CODE: -309, 'Illegal set element index given: %1\$d.'**

- This message is an error that appears when, in the CUBRID database, an invalid index is passed to a set-type collection; it mainly occurs when a negative index or an index exceeding the collection size is passed.

**ERROR CODE: -311, 'Element not found in sequence.'**

- This message is an error that appears when, in the CUBRID database, a specific element cannot be found in a sequence (an ordered collection); a sequence is an ordered data structure, and this message mainly occurs when the value does not exist in the sequence during an element search.

**ERROR CODE: -312, “”%1\$s” is not a valid set domain.’**

- This message is an error that appears when, in the CUBRID database, a set type is invalid; it can mainly occur when an incorrect set type is passed or when it is NULL.

**ERROR CODE: -424, ‘No statement to execute.’**

- This message is an error that appears when there is no SQL statement to execute in the CUBRID database; it occurs when there is no statement in the session or the statement array is empty during the statement validation process.

**ERROR CODE: -427, ‘Data overflow on data type “%1\$s”’**

- This message is an error that appears when overflow occurs for a specific data type in the CUBRID database; it occurs when, during the data type conversion process, the data value exceeds the allowed range of that data type.

**ERROR CODE: -428, ‘Statement is not updatable.’**

- This message is an error that appears when, in the CUBRID database, you attempt to modify a statement that cannot be updated; it occurs when trying to modify a non-updatable statement on a view table during the statement updatability check process.

**ERROR CODE: -435, ‘Multiple statements not allowed.’**

- This message is an error that appears when, in the CUBRID database, multiple SQL statements are provided in a context where multiple statements cannot be executed or processed at the same time; it occurs when multiple statements separated by a semicolon, etc., are entered in an API call or execution environment where only a single statement is allowed during SQL statement processing.

**ERROR CODE: -454, ‘Invalid data type referenced.’**

- This message is an error that appears when, in the CUBRID database, a non-existent or invalid data type is referenced; it occurs during the data type validation process in a query, that is, when an undefined data type or an invalid data type identifier is used.

**ERROR CODE: -457, ‘Invalid query result type.’**

- This message is an error that appears when, in the CUBRID database, the type of the query result structure is invalid; it occurs during the query result type validation process, that is, when an unsupported query result type is used.

**ERROR CODE: -458, ‘Overflow occurred in addition context.’**

- This message is an error that appears when overflow occurs while performing addition among arithmetic operations in the CUBRID database; it occurs during arithmetic operation processing

in a query, that is, when an addition operation is performed that exceeds the maximum value of the data type.

**ERROR CODE: -459, 'Query result contains more than a single tuple.'**

- This message is an error that appears when a query that must return a single tuple (row) returns multiple tuples in the CUBRID database; it occurs during the single-tuple validation process in a query, that is, when exactly one result must be returned in a subquery or certain operation but multiple results are returned.

**ERROR CODE: -482, "'%1\$s' is not a virtual class.'**

- This message is an error that appears when, in the CUBRID database, you attempt to use an object that is not a 'virtual class' (virtual table, view table) as a virtual table; a 'virtual class' is a table that does not store actual data but shows query results, such as a virtual table or view table; this message occurs when performing a virtual-table-related operation and the object is not a virtual table.

**ERROR CODE: -486, 'Object is not an updatable virtual class instance.'**

- This message is an error that appears when, in the CUBRID database, an instance of a virtual class (virtual table) is not updatable; it occurs when attempting to perform a modification operation on a non-updatable virtual class instance (record).

**ERROR CODE: -492, '%1\$s'**

- This message is an error that appears when a general error occurs in the parser in the CUBRID database; it is an error used to display the line and column when an error occurs during query parsing.

**ERROR CODE: -493, 'Syntax: %1\$s %2\$s'**

- This message is an error that appears when a syntax error occurs in the parser in the CUBRID database; it is an error that occurs at the parser's syntactic analysis stage, and it occurs when a problem arises during the grammatical analysis of an SQL query.

**ERROR CODE: -494, 'Semantic: %1\$s %2\$s'**

- This message is an error that appears when a semantic error occurs in the parser in the CUBRID database; it is an error that occurs at the parser's semantic analysis stage and is used when a problem arises during the meaning analysis of a query; it mainly occurs in situations such as semantic errors in a query or type mismatches.

**ERROR CODE: -495, 'Execute: %1\$s %2\$s'**

- This message is an error that appears when an execution error occurs in the parser in the CUBRID database; it is an error that occurs at the parser's execution stage, and it occurs when

processing cannot be performed as XASL; it mainly occurs in situations such as query execution failure or an internal parser error.

**ERROR CODE: -501, 'Invalid trigger priority.'**

- This message is an error that appears when the trigger priority is invalid in the CUBRID database; it occurs during the process of validating a trigger definition.

**ERROR CODE: -502, 'Missing target class in trigger.'**

- This message is an error that appears when, when defining a trigger in the CUBRID database, the target table is not specified; since a trigger is defined to respond to events (INSERT, UPDATE, DELETE) on a specific table, the target table must be specified; it occurs during the process of validating a trigger definition.

**ERROR CODE: -503, 'Trigger "%1\$s" was not found.'**

- This message is an error that appears when a trigger with the specified name cannot be found in the CUBRID database; it occurs when the trigger does not exist, or when the user does not have permission to access the trigger; it occurs during the trigger lookup and access process.

**ERROR CODE: -505, 'A trigger with the name "%1\$s" already exists.'**

- This message is an error that appears when a trigger with the same name already exists in the CUBRID database; because trigger names must be globally unique, you cannot create a trigger with a duplicate name or change it to a name that already exists; it occurs during the process of validating a trigger definition.

**ERROR CODE: -506, 'A trigger cannot be defined on "%1\$s" because it is a virtual class.'**

- This message is an error that appears when attempting to define a trigger on a virtual class (virtual table) in the CUBRID database; because a virtual table is a virtual table like a view and does not store actual data, you cannot define a trigger on it; it occurs during the process of validating a trigger definition.

**ERROR CODE: -507, 'Inappropriate trigger target class "%1\$s".'**

- This message is an error that appears when the target table of a trigger is inappropriate in the CUBRID database; it occurs when a trigger targets a specific table but that table does not exist or is not appropriate; it occurs during the process of validating a trigger definition.

**ERROR CODE: -508, 'Inappropriate trigger target attribute "%1\$s".'**

- This message is an error that appears when the target column of a trigger is inappropriate in the CUBRID database; it occurs when a trigger targets a specific column but that column does not exist or is not appropriate; it occurs during the process of validating a trigger definition.

**ERROR CODE: -511, 'Not authorized to access trigger "%1\$s"'**

- This message is an error that appears when the current user does not have permission to access (read/view) a specific trigger in the CUBRID database; it occurs when attempting to view or reference trigger information and there is insufficient privilege.

**ERROR CODE: -512, 'Not authorized to delete trigger "%1\$s"'**

- This message is an error that appears when the current user does not have permission to delete a specific trigger in the CUBRID database; it occurs when attempting to remove a trigger completely and there is insufficient privilege.

**ERROR CODE: -514, 'Not authorized to alter trigger "%1\$s"'**

- This message is an error that appears when the current user does not have permission to alter a specific trigger in the CUBRID database; it occurs when attempting operations such as renaming the trigger, changing its status, changing its priority, or changing its comment and there is insufficient privilege.

**ERROR CODE: -515, 'Trigger action execution time of %2\$s cannot be earlier than condition execution time of %1\$s.'**

- This message is an error that appears when you violate the rule that a trigger action execution time cannot be earlier than the condition execution time in the CUBRID database; it occurs when the trigger condition must be executed before the action, but the action is configured to execute before the condition; this is a safety device to guarantee the logical execution order of triggers.

**ERROR CODE: -516, 'Maximum trigger depth %1\$d exceeded at trigger "%2\$s"'**

- This message is an error that appears when the recursive call depth of a trigger exceeds the maximum allowed depth in the CUBRID database; it occurs when recursion repeats infinitely or exceeds the maximum depth in the process where a trigger calls another trigger and that trigger calls yet another trigger; this is a safety device to prevent an infinite loop or stack overflow due to recursive trigger calls.

**ERROR CODE: -517, 'The operation has been rejected by trigger "%1\$s"'**

- This message is an error that appears when a specific operation (e.g., INSERT, UPDATE, DELETE) is rejected by the *REJECT* action of a trigger in the CUBRID database; the *REJECT* action rolls back the current transaction and raises an error to stop the operation when the trigger is executed; it means that the trigger explicitly blocked the data modification operation according to the defined condition.

**ERROR CODE: -518, 'Internal error: processing trigger "%1\$s"'**

- This message is an error that appears when an internal error occurs while processing a trigger in the CUBRID database; it occurs when a parser error occurred during trigger compilation but detailed error information cannot be obtained; it indicates an unexpected internal state error in CUBRID's trigger system.

**ERROR CODE: -519, 'Illegal trigger condition type.'**

- This message is an error that appears when the trigger condition type is invalid in the CUBRID database; it indicates the constraint that a CUBRID trigger condition must be an appropriate expression.

**ERROR CODE: -520, 'The REJECT action cannot be used with an action time of AFTER or DEFERRED.'**

- This message is an error that appears when, when creating a trigger in the CUBRID database, you attempt to use the REJECT action together with an action time of AFTER or DEFERRED; the REJECT action is an action that rejects the transaction when the trigger is executed, and it is not compatible with AFTER or DEFERRED action times; it indicates the constraint that certain combinations of actions and action times are not allowed in CUBRID's trigger system.

**ERROR CODE: -521, 'The REJECT action cannot be used with the ABORT or TIMEOUT events.'**

- This message is an error that appears when, when creating a trigger in the CUBRID database, you attempt to use the REJECT action together with the ABORT or TIMEOUT events; the REJECT action is an action that rejects the transaction when the trigger is executed, and it is not compatible with ABORT or TIMEOUT events; it indicates the constraint that certain combinations of actions and events are not allowed in CUBRID's trigger system.

**ERROR CODE: -523, 'Trigger action expression was not given.'**

- This message is an error that appears when, when creating a trigger in the CUBRID database, the action type is set to *EXPRESSION* but the action source string (*action\_source*) is not provided; a trigger action is the part that defines the work to be performed when the trigger is executed, and when the action type is an expression (*EXPRESSION*), an action source string must be provided; this message occurs when a required parameter is missing during trigger creation.

**ERROR CODE: -524, 'The specified activity cannot be removed because it is owned by another user.'**

- This message is an error indicating that, when attempting to remove a trigger's deferred activity in the CUBRID database, the activity cannot be removed because it is owned by another user rather than the current user; trigger activity represents work performed when a trigger is executed, and deferred activity is an activity managed in a deferred trigger execution state; it occurs due to a privilege issue, and for security reasons removal of an activity owned by another user is restricted.

**ERROR CODE: -525, 'Error compiling condition for "%1\$s": %2\$s'**

- This message is an error that appears when an error occurs while compiling a trigger's condition in the CUBRID database; it mainly appears when a syntax error or compilation error occurs while parsing and compiling the SQL statement or script defined in the condition part of the trigger.

**ERROR CODE: -526, 'Error compiling action for "%1\$s", %2\$s'**

- This message is an error that appears when an error occurs while compiling a trigger's action in the CUBRID database; it mainly appears when a syntax error or compilation error occurs while parsing and compiling the SQL statement or script defined in the action part of the trigger.

**ERROR CODE: -527, 'Error evaluating condition for "%1\$s": %2\$s'**

- This message is an error that appears when an error occurs while evaluating (executing) a trigger's condition in the CUBRID database; it mainly appears when a syntax error or execution error occurs while executing the SQL statement or script in the condition part of the trigger.

**ERROR CODE: -528, 'Error evaluating action for "%1\$s", %2\$s'**

- This message is an error that appears when an error occurs while evaluating (executing) a trigger action in the CUBRID database, it usually appears when a syntax error or an execution error occurs while executing an SQL statement or a script in the action part of the trigger.

**ERROR CODE: -529, 'Transaction cannot be committed, it was invalidated by trigger "%1\$s"'**

- This message is an error that appears when you try to commit a transaction in the CUBRID database, but the transaction has been invalidated by a trigger and therefore cannot be committed, it usually occurs when the trigger's action is set to *INVALIDATE*.

**ERROR CODE: -539, 'Attempt to divide by zero.'**

- This message is an error that appears when attempting a division operation by zero in the CUBRID database, it usually occurs when the divisor in a division operation is 0 during query processing, since it is a mathematically undefined operation, CUBRID treats it as an error.

**ERROR CODE: -552, 'Date arithmetic underflow.'**

- This message is an error that appears when an underflow occurs while performing date arithmetic or functions in the CUBRID database, this usually occurs when subtracting or otherwise operating on a date value causes the result to go out of the date range, it is an error that occurs when the date arithmetic result becomes smaller than the minimum date value.

**ERROR CODE: -553, 'Time arithmetic underflow.'**

- This message is an error that appears when an underflow occurs while performing time arithmetic or functions in the CUBRID database, this usually occurs when subtracting or

otherwise operating on a time value causes the result to go out of the time range, it is an error that occurs when the time arithmetic result becomes smaller than the minimum time value.

**ERROR CODE: -618, 'Attribute is not updatable.'**

- This message appears when you try to update a specific column in the CUBRID database but the column is of a type that is not updatable, it can occur when you directly update certain columns of a view table or columns managed by the system.

**ERROR CODE: -621, 'Invalid data type. The arguments contain an invalid data type.'**

- This message appears when the data type of an argument passed to a function or an operation in the CUBRID database is invalid, for example, it can occur when you pass a numeric type to a string function, or when you pass a string type to a numeric operation.

**ERROR CODE: -622, 'Incompatible code sets. The code sets of the arguments are incompatible.'**

- This message appears when the character sets (character set) of the strings passed as arguments are incompatible with each other during string comparison or operations in the CUBRID database, for example, it can occur when you try to directly compare or operate on a UTF-8 string and an EUC-KR string.

**ERROR CODE: -623, 'Invalid escape sequence. An invalid escape sequence has caused an error in the regular expression compiler.'**

- This message appears when you use an invalid escape sequence in the ESCAPE clause of the LIKE operator in the CUBRID database, it occurs when the sequence used to escape special characters in the LIKE operator of an SQL statement is not valid.

**ERROR CODE: -624, 'Invalid escape character. The escape character is non-NULL with a length greater than 1.'**

- This message appears when you use an invalid escape character in the ESCAPE clause of the LIKE operator in the CUBRID database.

**ERROR CODE: -628, 'Invalid currency type: %1\$d.'**

- This message is displayed when processing the monetary data type in the CUBRID database, it occurs when an unsupported currency type is specified.

**ERROR CODE: -631, 'SQL statement violated NOT NULL constraint.'**

- This message is displayed when an SQL statement violates a NOT NULL constraint in the CUBRID database, it appears when a NOT NULL constraint is set on a table column but an INSERT or UPDATE statement attempts to input a NULL value into that column.

**ERROR CODE: -649, 'Given precision of %1\$d is invalid; it should be greater than %2\$d and no greater than %3\$d.'**

- This message is displayed when the precision value of a data type is invalid in the CUBRID database, it occurs when the specified precision value is outside the range allowed by the data type, it means a validation failure that occurs when defining a data type with a precision value that is too small or too large.

**ERROR CODE: -670, 'Operation would have caused one or more unique constraint violations. INDEX %1\$s%2\$s ON CLASS %3\$s%4\$s. key: %5\$s%6\$s.'**

- This message occurs when an operation that violates a UNIQUE constraint is attempted in the CUBRID database, it indicates a situation where a duplicated key value is found in a B+tree index and thus violates the UNIQUE constraint, it means that a UNIQUE constraint that does not allow duplicate values in order to guarantee data integrity has been violated.

**ERROR CODE: -683, 'Attempted to create string with illegal length %1\$d'**

- This message is displayed when you try to create a string in the CUBRID database but the specified length is not valid, the string length cannot exceed the maximum length defined in CUBRID and cannot be negative, it mainly occurs in the process of converting LOB (Large Object) data to a string in the clob\_to\_char() function.

**ERROR CODE: -685, 'Class "%1\$s" is invalid.'**

- This message is displayed when the specified table is invalid while changing the owner in the CUBRID database.

**ERROR CODE: -704, 'Evaluation of generic server function failed.'**

- This message occurs when evaluating (evaluation) a Java procedure fails in the CUBRID database,

**ERROR CODE: -709, 'Constraint "%1\$s" not found.'**

- This message is an error that appears when a constraint with a specific name cannot be found in the CUBRID database, CUBRID checks whether the constraint exists when dropping or modifying a constraint, this message occurs in the process of dropping or modifying a constraint in the CUBRID database

**ERROR CODE: -710, 'Invalid constraint.'**

- This message is an error that appears when a constraint is invalid in the CUBRID database, CUBRID validates whether a constraint is valid when creating or managing constraints, this message can occur in the process of creating or managing constraints in the CUBRID database.

**ERROR CODE: -711, 'An object with the supplied attribute value doesn't exist.'**

- This message is an error that appears when an object with a specific column value cannot be found in the CUBRID database, CUBRID raises this error when no object exists that satisfies the condition during object search or query execution.

**ERROR CODE: -712, 'Constraint' %1\$s' already exists.'**

- This message is an error that appears when a constraint with the same name already exists in the CUBRID database, CUBRID does not allow duplicate names when adding a constraint to a table or a table.

**ERROR CODE: -713, 'An index does not exist on this attribute.'**

- This message is an error that appears when an index does not exist for a specific column in the CUBRID database, it can occur during object search or index-related operations in the CUBRID database.

**ERROR CODE: -716, 'NOT NULL constraints are not allowed in virtual or proxy classes.'**

- This message is an error that appears when you try to add a NOT NULL constraint to a virtual class (virtual class) or a view table in the CUBRID database.

**ERROR CODE: -717, 'UNIQUE constraints are not allowed in virtual or proxy classes.'**

- This message is an error that appears when you try to add a UNIQUE constraint to a virtual class (virtual class) or a view table in the CUBRID database.

**ERROR CODE: -721, 'Insert query yields more than one row.'**

- This message is an error that appears when executing an INSERT statement in the CUBRID database and the result returns multiple rows rather than a single row, an INSERT statement generally must insert only one row, but this error occurs if a subquery or the VALUES clause returns multiple rows, this message mainly occurs when the VALUES clause of the INSERT statement has multiple rows, or when a subquery returns multiple rows.

**ERROR CODE: -722, 'Wrong number of attributes for NOT NULL constraint.'**

- This message is an error that appears when the number of columns is incorrect when creating or dropping a NOT NULL constraint in the CUBRID database, a NOT NULL constraint is a constraint that can be applied to only one column, this message occurs when you try to apply a NOT NULL constraint to multiple columns at the same time, or when no column is specified.

**ERROR CODE: -723, 'Cannot modify the domain of an existing attribute.'**

- This message is an error that appears when you attempt to change the data type of an existing column in the CUBRID database.

**ERROR CODE: -724, 'Invalid parameter(s) for default constraint name generation.'**

- This message can occur when dropping an index in the CUBRID database and the index name is NULL.

**ERROR CODE: -727, 'Invalid trigger event.'**

- This message is an error that appears when an invalid trigger event is used in the process of creating or managing a trigger in the CUBRID database, a trigger event is a condition that determines when a trigger is executed and is associated with database operations such as INSERT, UPDATE, and DELETE, this message occurs when an invalid event type is specified for a trigger.

**ERROR CODE: -729, 'Overflow occurred in subtraction context.'**

- This message is an error that appears when an overflow occurs while performing subtraction in the CUBRID database, an overflow occurs when the operation result exceeds the maximum range that the data type can represent, this mainly occurs when the difference between two numbers exceeds the maximum value of integer (INT, BIGINT, SHORT) or floating-point (FLOAT, DOUBLE) types, it can also occur when the subtraction part in a compound expression causes an overflow.

**ERROR CODE: -730, 'Overflow occurred in multiplication context.'**

- This message is an error that appears when an overflow occurs while performing multiplication in the CUBRID database, an overflow occurs when the operation result exceeds the maximum range that the data type can represent, this mainly occurs when the product of two numbers exceeds the maximum value of integer (INT, BIGINT, SHORT) or floating-point (FLOAT, DOUBLE) types, it can also occur when the result in multiplication of the NUMERIC type exceeds the representable range.

**ERROR CODE: -731, 'Overflow occurred in division context.'**

- This message is an error that appears when an overflow occurs while performing division in the CUBRID database, an overflow occurs when the operation result exceeds the maximum range that the data type can represent, this can occur when a very large value is produced in floating-point division, or when the result exceeds the range under certain conditions in integer division (e.g., INT\_MIN / -1), it can also occur when the result in division of the NUMERIC type exceeds the representable range.

**ERROR CODE: -732, 'Overflow occurred in unary minus context.'**

- This message is an error that appears when an overflow occurs while performing a unary minus operation in the CUBRID database, unary minus is an operation that changes the sign of a numeric value, converting a positive number to a negative number and a negative number to a positive number, this message occurs when applying unary minus to the minimum value of a

certain data type, for example, applying unary minus to the minimum value of the INT type (-2,147,483,648) yields a positive value (2,147,483,648) that exceeds the INT type range.

**ERROR CODE: -751, 'The OID of a new object isn't available in a BEFORE INSERT trigger.'**

- This message occurs when you define a BEFORE INSERT trigger in the CUBRID database and try to directly reference the new object inside the trigger, since a BEFORE INSERT trigger runs before the data is actually inserted into the table, the OID of the new object has not yet been assigned, referencing the "new" object itself inside the trigger is not allowed, and you can reference only individual attributes in the form "new.attribute\_name".

**ERROR CODE: -772, 'db\_serial class not found.'**

- This message indicates a situation where the db\_serial catalog table does not exist when the CUBRID database tries to find the db\_serial catalog table, this occurs in CUBRID's serial object management mechanism, and it can occur mainly when the db\_serial table is not registered in the system.

**ERROR CODE: -773, 'Serial "%1\$s" not found.'**

- This message indicates a situation where the serial object with the specified name does not exist when you try to query a serial object in the CUBRID database.

**ERROR CODE: -774, 'Serial "%1\$s" already exist.'**

- This message indicates a situation where a serial object with the same name already exists when you try to create a serial object in the CUBRID database.

**ERROR CODE: -775, 'Next value exceeds MAX(MIN) value.'**

- This message indicates a situation where the calculated next value (nextval) of a serial object exceeds the maximum value or the minimum value when calculating it in the CUBRID database.

**ERROR CODE: -776, 'Cannot fetch serial object.'**

- This message indicates a situation where a serial object cannot be read when you try to fetch a serial object in the CUBRID database.

**ERROR CODE: -777, 'Cannot update serial object.'**

- This message indicates a situation where a serial object cannot be modified when you try to update a serial object in the CUBRID database.

**ERROR CODE: -779, 'Result exceeds limit: year of Date MUST be in 1 and 9999.'**

- This message occurs when using date-related functions in the CUBRID database and the year of the resulting date goes out of the range from year 1 to year 9999, this occurs in CUBRID's date

processing mechanism, and it can occur mainly when a date arithmetic result exceeds the valid date range.

**ERROR CODE: -781, 'Format string is too long. It must be less than 16K.'**

- This message occurs when using a string format conversion function in the CUBRID database and the length of the format string exceeds 16K (16,000 bytes), this occurs in CUBRID's string format conversion mechanism, and it can occur mainly when the format string length limit is exceeded.

**ERROR CODE: -782, 'Empty string not allowed here.'**

- This message occurs when an empty string (") is used in a string operation or function where an empty string is not allowed, it is a data validation error that occurs when meaningful input is required in certain string functions or operations.

**ERROR CODE: -783, 'Invalid format.'**

- This message occurs when the string format or data format does not match the expected format. It is a format validation error that occurs when an invalid format is input in date/time formats, numeric formats, or string functions that require a specific pattern.

**ERROR CODE: -784, 'Two arguments are mismatched.'**

- This message occurs when two arguments do not match in the string processing module of the CUBRID database, that is, it is an error message that occurs when the source string and the format string do not match while performing date conversion, this message mainly occurs when numeric parsing fails, which means that the format of the source string does not match the expected format.

**ERROR CODE: -785, 'First argument string is too long. It must be less than 16K.'**

- This message occurs when calling a date/time conversion function in the string processing module of the CUBRID database and the length of the string passed as the first argument exceeds 16KB (16000 bytes), that is, if it exceeds this limit in the logic that checks the length of the original string, the error is set, this limit is set to prevent memory overflow or performance degradation that may occur when the database system processes strings.

**ERROR CODE: -786, 'Format is duplicated.'**

- This message occurs when calling a date/time conversion function in the string processing module of the CUBRID database and the same format specifier is used redundantly in the format string, that is, during parsing of the date/time format string, if a format specifier (e.g., YYYY, MM, DD, etc.) that has already been used once appears again, the error is set, this is CUBRID's internal validation mechanism to prevent syntactic errors in date/time format strings.

**ERROR CODE: -787, 'Conversion error in time format.'**

- This message is displayed in the time processing module of the CUBRID database during time format conversion, that is, the error is set when a problem occurs during converting time data to another format, converting time zones, or validating time values, this message can occur in multiple modules, and it mainly occurs during the validation process to ensure the integrity and consistency of time data.

**ERROR CODE: -788, 'Conversion error in timestamp format.'**

- This message is displayed in the timestamp processing module of the CUBRID database during timestamp format conversion, that is, the error is set when a problem occurs during converting timestamp data to another format, parsing a date/time string into a timestamp, or validating timestamp values, this message can occur in multiple modules, and it mainly occurs during the validation process to ensure the integrity and consistency of timestamp data.

**ERROR CODE: -791, 'Invalid serial value.'**

- This message is displayed when validation of a serial value fails in the serial object processing module of the CUBRID database, that is, the error is set when required attribute values are NULL or are not of the correct data type during validation of serial object property values, it occurs during the validation process to ensure the integrity of serial objects, and it mainly appears during schema export or SERIAL object management.

**ERROR CODE: -833, 'The index name "%1\$s" is ambiguous. Specify the class name of the index.'**

- This message occurs when the schema management module of the CUBRID database tries to find a table by index name, that is, when trying to find the table that owns an index by a specific index name and type, if indexes with the same name and type exist on multiple tables, it occurs when CUBRID cannot determine which table to return, it occurs when multiple tables use the same index name in database design or when the table name is not specified when referencing an index. Because CUBRID cannot distinguish which table's index it is by index name alone, it requires specifying the table name.

**ERROR CODE: -834, 'There are some mismatches between source string "%1\$s" and format string "%2\$s" given in to\_number().'**

- This message occurs in the query processing module of the CUBRID database during conversion of a string to a number using the `to_number()` function, that is, when attempting the conversion by comparing the source string and the format string, it occurs when the structures or contents of the two strings are not compatible and therefore conversion rules cannot be followed, it mainly occurs when the `to_number()` function is used incorrectly in an SQL query or when the input data format differs from what is expected. For example, it occurs when the string that must be converted to a numeric format contains non-numeric characters, or when the specified format string does not match the actual data format.

**ERROR CODE: -865, 'Cannot execute statement due to unknown type input markers.'**

- This message occurs during execution of an SQL statement in the CUBRID database, it usually appears when the type of a host variable cannot be determined or when type conversion is not possible.

**ERROR CODE: -874, 'Argument of power() is out of range.'**

- This message occurs during exponentiation (power) operations in the CUBRID database, specifically it occurs when using a non-integer exponent with a negative base. Since it is a mathematically undefined operation, CUBRID treats it as an error.

**ERROR CODE: -875, 'Overflow happened in power context.'**

- This message occurs during exponentiation (power) operations in the CUBRID database, this situation generally occurs when performing exponentiation on very large numbers, and it appears when the operation is mathematically valid but exceeds the floating-point representation range of the computer.

**ERROR CODE: -886, "'%1\$s' caused unique constraint violation.'**

- This message occurs when you try to insert (INSERT) or update (UPDATE) data that violates a unique (Unique) constraint defined on a table in the CUBRID database, it occurs when you insert the same value as an already existing value, or when you update an existing value to create a duplicate value with another record.

**ERROR CODE: -887, 'Stored procedure '%1\$s' is already exist.'**

- This message occurs when you try to create a stored procedure in the CUBRID database and a stored procedure with the same name already exists, that is, when executing a *CREATE PROCEDURE* statement, the error is set if the stored procedure name is duplicated, this occurs in CUBRID's stored procedure management mechanism, and it can occur mainly due to a duplicate stored procedure name.

**ERROR CODE: -888, 'Parameter count is invalid. expected: %1\$d, actual: %2\$d'**

- This message occurs when calling a stored procedure in the CUBRID database and the number of parameters passed does not match the number of parameters expected by the stored procedure definition, that is, the error is set when the parameter count does not match during a stored procedure call, this occurs in CUBRID's stored procedure call mechanism, and it can occur mainly due to a parameter count mismatch.

**ERROR CODE: -889, 'Stored procedure execute error: %1\$s'**

- This message is a general execution error that occurs during execution of a stored procedure (Stored Procedure) in the CUBRID database, that is, it indicates that an error occurred for various reasons during execution of the stored procedure, this situation generally occurs due

to failure of SQL statement execution inside the stored procedure, data type mismatch, insufficient privileges, insufficient memory, or other runtime errors.

**ERROR CODE: -890, 'Partition failed.'**

- This message occurs when a partitioning-related operation such as creating, altering, or dropping a table partition in the CUBRID database fails due to internal errors, parameter errors, data inconsistencies, lack of resources, constraint violations, and so on, it can appear due to various causes such as an incorrect partition definition, data not matching partition conditions, lack of system resources, internal bugs, or schema constraint violations.

**ERROR CODE: -891, 'Appropriate partition does not exist.'**

- This message occurs when performing a table partition operation (e.g., data insertion, query, move, exploration during partition changes, etc.) in the CUBRID database and a partition corresponding to the specified condition or value is not defined, has already been dropped, or cannot be accessed due to an incorrect partition definition, it can appear due to causes such as a partition key value not being included in the partition range, an incorrect partition name/ID, a partition being dropped/changed, or internal metadata inconsistencies.

**ERROR CODE: -892, 'Primary key "%2\$s" already defined for class "%1\$s".'**

- This message occurs when you try to add or define a primary key on a table in the CUBRID database and a primary key already exists on that table, that is, when you execute a DDL (Data Definition Language) statement such as *CREATE TABLE* or *ALTER TABLE ADD PRIMARY KEY* to define a primary key, the error is set if it already exists in the primary key duplication check, this occurs in CUBRID's schema management mechanism, and it can occur mainly due to duplicate primary key definitions.

**ERROR CODE: -893, 'Attribute '%1\$s', a member of the primary key, could not be dropped.'**

- This message occurs when you try to drop an attribute that is part of a primary key in the CUBRID database, that is, when executing a DDL (Data Definition Language) statement to drop an attribute, the error is set if that attribute is a member of the primary key. It occurs in CUBRID's schema management mechanism, and it can occur mainly due to primary key integrity protection.

**ERROR CODE: -894, 'Stored procedure/function '%1\$s' does not exist.'**

- This message occurs when you try to call a stored procedure or function that does not exist in the CUBRID database, that is, when you try to execute a stored procedure or function through a *CALL* statement or a function call and a stored procedure or function with the specified name does not exist in the database, the error is set, this occurs in CUBRID's stored procedure management mechanism, and it can occur mainly due to calling a non-existent stored procedure/function.

**ERROR CODE: -895, 'Invalid stored procedure type: '%1\$s' is the '%2\$s''**

- This message occurs when the type of a stored procedure or function does not match in the CUBRID database, that is, when executing a DDL statement (for example, declaring it as a function and then doing drop procedure), the error is set if the actual stored procedure type differs from the requested type.

**ERROR CODE: -899, 'Invalid partition requests.'**

- This message appears when an invalid request occurs while performing partition-related operations in the CUBRID database, that is, the error is set when attempting an inappropriate operation request on a partition table or an operation that violates partition-related constraints, it occurs in CUBRID's partition management mechanism, and it can occur mainly due to violations of partition-related constraints.

**ERROR CODE: -900, 'Java VM library is not found: %1\$s.'**

- This message occurs when the CUBRID database system fails to find or load the JVM (Java Virtual Machine) library required to start the JVM, that is, the CUBRID server process attempted to create a JVM process to execute Java-based stored procedures (Stored Procedure) or user-defined functions (User Defined Function), but could not load it because system environment variables (e.g., JAVA\_HOME, JVM\_PATH) are not correctly set for the JVM library path, the library file itself does not exist, or due to access permission issues. (From version 11.4, it occurs when the JVM library used by pl\_server cannot be found)

**ERROR CODE: -901, 'Java VM can not be started: %1\$s.'**

- This message occurs when the CUBRID database system tried to start a JVM (Java Virtual Machine) process but failed, that is, the CUBRID server process attempted to create and initialize a JVM process to execute Java-based stored procedures (Stored Procedure) or user-defined functions (User Defined Function), but the JVM process could not be started normally due to various problems such as JVM library loading failure, JVM creation failure, failure to find required Java tables, memory allocation failure, or issues during JVM initialization. (From version 11.4, it occurs when pl\_server for SP processing cannot be started)

**ERROR CODE: -902, 'Java VM is not running.'**

- This message occurs when the CUBRID database system tries to use Java-based features while the JVM (Java Virtual Machine) process is not running, that is, the CUBRID server process attempted to connect to the JVM to execute Java-based stored procedures (Stored Procedure) or user-defined functions (User Defined Function), but it means that the JVM process itself has not started, has already terminated, or CUBRID's PL server manager is not initialized. (From version 11.4, it occurs when pl\_server for SP processing is not running)

**ERROR CODE: -903, 'Can't connect Java VM: %1\$s'**

- This message occurs when the CUBRID database system tried to connect to the JVM (Java Virtual Machine) but failed, that is, the CUBRID server process attempted IPC (Inter-Process Communication) or socket communication with the JVM process to execute Java-based stored procedures (Stored Procedure) or user-defined functions (User Defined Function), but it means that the connection failed at the initial connection stage because the JVM process was not started, terminated abnormally, the CUBRID server could not find the JVM process, or there is a problem with communication settings. (From version 11.4, it occurs when it cannot connect to pl\_server for SP processing)

**ERROR CODE: -904, 'Invalid stored procedure name.'**

- This message occurs when the CUBRID database system determines that the name of a stored procedure (Stored Procedure) or a function (Function) is invalid, that is, when the CUBRID server tries to create (CREATE), alter (ALTER), drop (DROP), or call (CALL) a stored procedure, it means that the specified name does not satisfy CUBRID's naming rules or there was a problem during name processing, this is a protective error that occurs during validation of name validity in CUBRID's stored procedure management system.

**ERROR CODE: -905, 'Networking with JVM failed: %1\$d'**

- This message occurs when the CUBRID database system fails due to network-related problems while attempting to communicate with the JVM (Java Virtual Machine), that is, the CUBRID server process attempted socket communication with the JVM process to execute Java-based stored procedures (Stored Procedure) or user-defined functions (User Defined Function), but it means that communication was interrupted due to network-level issues such as connection failure, data transmission errors, or timeouts, this situation generally occurs due to network configuration issues between the CUBRID server and the JVM process, firewalls, abnormal termination of the JVM process, lack of system resources, or errors in CUBRID's internal JVM integration module. (From version 11.4, it occurs when an error occurs in pl\_server for SP processing and it does not return results, etc.)

**ERROR CODE: -907, 'The owner or a member of DBA group can drop stored procedure.'**

- This message occurs when the currently logged-in user tried to alter (ALTER) or drop (DROP) a specific stored procedure (Stored Procedure) but does not have sufficient privileges to drop that stored procedure, in CUBRID, only the owner of the stored procedure or a member of the DBA (Database Administrator) group can drop the stored procedure under a strict privilege policy.

**ERROR CODE: -908, 'Too many arguments of stored procedure '%1\$s''**

- This message occurs when defining or calling a stored procedure (Stored Procedure) or a function (Function) in the CUBRID database system and the number of arguments specified for the procedure exceeds the maximum number allowed by CUBRID, it means that, while

processing a *CREATE PROCEDURE* or *CREATE FUNCTION* statement, the CUBRID server has exceeded the number of arguments of the user-defined stored procedure, this is a protective error that occurs during validation of argument count validity in CUBRID's stored procedure management system.

**ERROR CODE: -911, 'Invalid call: it can not return ResultSet.'**

- This message occurs when calling a stored procedure (Stored Procedure) in the CUBRID database and the stored procedure is defined in a way that cannot return a ResultSet (query result set), or it is called in a context where returning a ResultSet is not allowed, that is, this error occurs when a specific stored procedure in CUBRID is not designed to return a ResultSet directly, or when the current execution environment (e.g., calling from inside another stored procedure, etc.) does not support returning a ResultSet, this situation generally occurs when calling a stored procedure using a *CALL* statement and the procedure definition or invocation method violates ResultSet return rules, this is a protective error to protect execution rules of stored procedures and the consistency of the database system.

**ERROR CODE: -912, 'ResultSet can not be used input parameter.'**

- This message occurs when trying to use the 'RESULTSET' type as an input parameter while defining a stored procedure (Stored Procedure) or a function (Function) in the CUBRID database system, because in CUBRID's stored procedure system, the *RESULTSET* type is restricted to be used only as an output parameter. This is a constraint to protect system stability in terms of data flow and memory management.

**ERROR CODE: -913, 'Too many nested stored procedure call.'**

- This message occurs when the nesting depth of calls where a stored procedure (Stored Procedure) calls another stored procedure exceeds the maximum allowed by the system in the CUBRID database system, this is a protective error to prevent system resource exhaustion or stack overflow caused by infinite recursive calls or excessive nested calls.

**ERROR CODE: -914, 'A serial object already exists as an auto increment constraint.'**

- This message occurs when you try to create an auto increment (Auto Increment) constraint in the CUBRID database and a serial object with the same name already exists in the system.

**ERROR CODE: -915, 'Increase value of an auto increment constraint should be greater than 0.'**

- This message occurs when creating or altering an auto increment (Auto Increment) constraint in the CUBRID database and the increment value is set to 0 or less, that is, the increment value of an auto increment sequence must be positive and 0 or negative values are not allowed. This is a constraint to ensure the logical meaning and mathematical consistency of auto increment, this situation generally occurs when defining an auto increment column using a *CREATE TABLE* or *ALTER TABLE* statement and specifying a value of 0 or less in the *INCREMENT BY* clause.

**ERROR CODE: -918, 'The class '%1\$s' referred by the foreign key does not exist.'**

- This message occurs when defining or altering a foreign key (Foreign Key) constraint in the CUBRID database and the parent table that the foreign key tries to reference does not exist in the database, this situation generally occurs when defining a foreign key using a *CREATE TABLE* or *ALTER TABLE* statement and the name of the parent table to be referenced is specified incorrectly or the table has already been dropped, this is a constraint validation error to protect the logical consistency of database design and referential integrity.

**ERROR CODE: -919, 'The class '%1\$s' referred by the foreign key does not have the primary key.'**

- This message occurs when defining or altering a foreign key (Foreign Key) constraint in the CUBRID database and the parent table that the foreign key tries to reference does not have a primary key (Primary Key) constraint defined, this situation generally occurs when defining a foreign key using a *CREATE TABLE* or *ALTER TABLE* statement and a primary key is not defined on the parent table or after the primary key has been dropped, this is a constraint validation error to protect data integrity and referential integrity.

**ERROR CODE: -920, 'The foreign key '%1\$s' does not include the primary key member '%2\$s'.'**

- This message occurs when defining or altering a foreign key (Foreign Key) constraint in the CUBRID database and the list of columns that make up the foreign key does not include all columns of the referenced primary key (Primary Key), this situation generally occurs when defining a foreign key using a *CREATE TABLE* or *ALTER TABLE* statement and the referenced key's column list is specified incorrectly or some columns are omitted due to typos, this is a constraint validation error to protect data integrity and referential integrity.

**ERROR CODE: -921, 'The domain of the foreign key member '%1\$s' is different from that of the primary key member '%2\$s'. (%3\$s: %4\$s vs. %5\$s)'**

- This message occurs when defining or altering a foreign key (Foreign Key) constraint in the CUBRID database and the domain (data type and related properties) of a foreign key member column does not match the domain of the referenced primary key (Primary Key) member column, this situation generally occurs when defining a foreign key using a *CREATE TABLE* or *ALTER TABLE* statement and a non-compatible domain is specified due to misunderstanding or typos in the referenced key's column domain, this is a constraint validation error to ensure data integrity and referential integrity.

**ERROR CODE: -922, 'The constraint of the foreign key '%1\$s' is invalid, due to value '%2\$s'.'**

- This message occurs when a foreign key (Foreign Key) constraint in the CUBRID database references an invalid value or violates data integrity due to a logical error in the constraint itself, that is, it means that a value inserted or updated in the foreign key column does not exist in the referenced parent table's primary key (Primary Key) or unique key (Unique Key), or that the foreign key constraint definition itself is incorrect and failed to pass validation, this situation generally occurs when adding or changing data in a child table using an *INSERT* or

*UPDATE* statement and attempting to specify a value in the foreign key column that does not exist in the parent table. Also, it may occur due to data type mismatches in the referenced columns or other schema mismatches during the process of defining a foreign key, this is a protective error to protect data integrity and referential integrity.

**ERROR CODE: -923, 'The primary key '%1\$s' referred by a foreign key '%2\$s' is not supposed to be dropped.'**

- This message occurs when you try to drop a primary key (Primary Key) in the CUBRID database and the primary key is referenced by a foreign key (Foreign Key) of another table, so the drop operation is not allowed, that is, to maintain referential integrity (Referential Integrity), the system restricts directly dropping a primary key of a parent table that is referenced by a child table. To drop the primary key, you must first remove all foreign key constraints that reference the primary key, this situation generally occurs when dropping a primary key using *ALTER TABLE ... DROP PRIMARY KEY* or when dropping a table with a primary key using *DROP TABLE* while foreign keys referencing it remain, this is a protective error to protect data integrity and maintain logical consistency of the database.

**ERROR CODE: -924, 'Update/Delete operations are restricted by the foreign key '%1\$s''**

- This message occurs when you try to update or delete a parent record in a table with a foreign key (Foreign Key) constraint set in the CUBRID database. In this case, since the foreign key's *ON UPDATE* or *ON DELETE* action is set to *RESTRICT*, the operation is not allowed if there are records in the child table that reference the parent record, that is, to maintain referential integrity (Referential Integrity), the system restricts modifying or deleting a parent record for which child records exist, this situation generally occurs when changing a parent table record using an *UPDATE* or *DELETE* statement while child table records that reference it remain, this is a protective error to protect data integrity and maintain logical consistency of the database.

**ERROR CODE: -926, 'The instance having the foreign key '%1\$s' cannot be dropped.'**

- This message occurs when you try to delete an instance (record) in the CUBRID database that is referenced by another table through a foreign key (Foreign Key) constraint, that is, it means that you are trying to delete an instance in the parent table but the delete operation is not allowed because a foreign key that references the parent instance exists in the child table and referential integrity could be broken, this situation generally occurs when deleting a parent table record using a *DELETE* statement while child table records that reference it remain, this is a protective error to protect data integrity and maintain logical consistency of the database.

**ERROR CODE: -927, 'The number of keys of the foreign key '%1\$s' is different from that of the primary key '%2\$s''**

- This message occurs when defining or altering a foreign key (Foreign Key) constraint in the CUBRID database and the number of columns that make up the foreign key differs from the number of columns that make up the referenced primary key (Primary Key), that is, a foreign key must be composed of the same number of columns as the referenced parent table's

primary key or unique key and the data types of each column must also be compatible. This message mainly occurs due to a mismatch in the number of columns, this situation generally occurs when defining a foreign key using a *CREATE TABLE* or *ALTER TABLE* statement and specifying a different number of columns due to misunderstanding the structure of the referenced key or due to typos, this is a constraint validation error to ensure data integrity and logical consistency of a relational database.

**ERROR CODE: -931, 'Start value of an auto increment constraint should be less then max value.'**

- This message occurs when creating or altering an auto increment (Auto Increment) constraint in the CUBRID database and the start value is greater than or equal to the maximum value, that is, it is a constraint violation error that occurs when the start value of an auto increment sequence exceeds the maximum allowable range of the data type, or when the start value and the maximum value are the same, this situation generally occurs due to incorrect auto increment settings in table schema definitions, mismatches between the data type and the start value, or when a user explicitly sets a start value that exceeds the limits of the data type.

**ERROR CODE: -935, 'Argument of %1\$s function is out of range.'**

- This message occurs when the argument of a math function or a system function in the CUBRID database is outside the valid range that the function can handle, that is, it is an error that occurs when the function receives an input value that is outside the function's domain (domain) or is not mathematically valid, this situation generally occurs when attempting a mathematically undefined operation or attempting an out-of-range access of a system function.

**ERROR CODE: -936, 'Overflow occurred in exp context.'**

- This message occurs when the CUBRID database query processor computes an exponential function for values of various data types and computes the exponential function for very large positive or negative values.

**ERROR CODE: -965, 'Cannot use duplicate attribute names in index key list. Attribute name '%1\$s' listed more than once.'**

- This message occurs when creating or altering an index in the CUBRID database and the same attribute (column) name is specified two or more times in the index key list, CUBRID does not allow including the same column redundantly in an index key for efficiency and consistency of the index. This is a protective error to prevent unnecessary duplication, optimize index performance, and maintain the integrity of the database schema, for example, this error occurs if you specify the same column twice like *CREATE INDEX idx\_name ON table\_name (col1, col2, col1)*.

**ERROR CODE: -979, 'CONNECT BY loop in user data.'**

- This message occurs when an infinite loop happens due to a circular reference in a *CONNECT BY* clause.

**ERROR CODE: -996, 'Incorrect number of values given. %1\$d values were given but %2\$d values are required.'**

- This message occurs in the CUBRID database when the number of host variables used in the PREPARE FROM statement and the number of values in the EXECUTE USING clause do not match.

**ERROR CODE: -997, 'Cannot add the foreign key constraint %1\$s to the partitioned %2\$s. Referential actions that update attributes are not yet supported on partitioned classes.'**

- This message occurs when you try to add a foreign key constraint to a partitioned table in the CUBRID database. CUBRID currently does not support foreign key constraints on partitioned tables where the referential action updates attributes. Referential actions are features that automatically update the child table's foreign key values when the parent table's key value changes, such as *ON UPDATE CASCADE*, *ON UPDATE SET NULL*, and *ON UPDATE SET DEFAULT*. Because partitioned tables store data distributed across multiple partitions, performing such complex referential actions can cause performance issues or data consistency issues, so CUBRID restricts them.

**ERROR CODE: -998, 'Cannot add the foreign key constraint %1\$s on the attribute %2\$s. The attribute cannot have a NOT NULL constraint because it has to match the SET NULL referential action.'**

- This message occurs when defining a foreign key that uses SET NULL as the referential action while the target column has a NOT NULL constraint. The SET NULL referential action must allow NULL values to maintain referential integrity, so it logically conflicts with a NOT NULL constraint.

**ERROR CODE: -999, 'Cannot create table '%1\$s' like table '%2\$s' because the existing table has features that will not be duplicated (%3\$s).'**

This error code occurs when using the CREATE TABLE LIKE statement and the source table has certain features or attributes that cannot be duplicated to the new table.

**ERROR CODE: -1000, '%1\$s' is a CLASS or SHARED attribute but only normal attributes are allowed in this context.'**

- This message is an error that occurs with the CREATE TABLE AS SELECT statement, indicating that SHARED or CLASS attributes cannot be used in the column properties. For example, it can occur if you use a DDL (shared replication) statement format like: *CREATE TABLE x (name varchar); CREATE TABLE y (name varchar shared '1111') as SELECT name FROM x;*

**ERROR CODE: -1003, 'The constraint '%1\$s' exists but has a different type.'**

- This message is a constraint type mismatch error that occurs during database schema management, and it occurs when trying to drop a primary key using *alter table .. drop index*.

**ERROR CODE: -1004, 'Please note that when using ALTER TABLE DROP FOREIGN KEY, CUBRID drops both the constraint and its associated index.'**

- This message is a notification provided to the user when executing the *ALTER TABLE DROP FOREIGN KEY* statement in the CUBRID database system. It is an informational message (not an error) that explains a characteristic of CUBRID's foreign key management system and warns the user that both the constraint and its associated index are dropped.

**ERROR CODE: -1011, 'Cannot add the foreign key constraint %1\$s on the shared attribute %2\$s.'**

This error code indicates that a foreign key constraint cannot be added to an attribute with the SHARED property.

**ERROR CODE: -1012, 'Cannot create table with NULL column type.'**

This error code occurs when executing the *CREATE TABLE AS SELECT* statement and the result includes a column with a NULL type. For example, it can occur with a DDL copy statement format like *CREATE TABLE tbl AS SELECT NULL AS a*.

**ERROR CODE: -1013, 'Set DEFAULT or SHARED on %1\$s typed column is not allowed.'**

This error code indicates that you cannot set a DEFAULT value or the SHARED attribute on a column of the BLOB or CLOB data type.

**ERROR CODE: -1014, 'Set NOT NULL on %1\$s typed column is not allowed.'**

This error code indicates that you cannot set a NOT NULL constraint on a column of the BLOB or CLOB data type.

**ERROR CODE: -1041, 'A string was truncated in context of "%1\$s".'**

- This message indicates that during query processing or data storage/retrieval in CUBRID, a string value was larger than the buffer or target column size, so the trailing part was truncated. It is a warning-type error message that may occur when reducing a column's string length in *ALTER TABLE*, or during string concatenation such as the *group\_concat* function.

**ERROR CODE: -1042, 'Trying to create a string requiring %1\$d bytes of memory, while the maximum allowed is %2\$d bytes.'**

- This message occurs when, during CUBRID query processing, the size of a string created as the result of a certain string operation (mainly string functions) exceeds the maximum size limit for a single string object allowed by the system. It is highly related to the *string\_max\_size\_bytes* parameter setting in *\$CUBRID/conf/cubrid.conf*.

**ERROR CODE: -1044, 'Cannot change attribute "%1\$s". CUBRID cannot change attributes that are partitioning keys.'**

- This message means that the user attempted to change an attribute definition using the *ALTER TABLE ... CHANGE* statement, but the change was rejected because the attribute is used as a partitioning key. To maintain data distribution rules and integrity for a partitioned table, CUBRID does not allow changing the definition (e.g., data type, constraints, etc.) of a column used as a partitioning key. Since the partitioning key determines which partition data is stored in, changing the key column's definition can invalidate the entire existing partition structure and break data consistency.

**ERROR CODE: -1045, 'Cannot change attribute "%1\$s". CUBRID cannot change attributes used in foreign keys (either referenced or referencing).'**

- This message occurs when you try to change a specific column using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY* in the CUBRID database. If the column is used in a foreign key relationship, CUBRID does not allow the change to guarantee data integrity and referential consistency. A foreign key is an important constraint that maintains referential integrity, defining the relationship between a referenced column (the parent table's primary key or unique key) and a referencing column (the child table's foreign key). Since changing such columns can break referential integrity, CUBRID restricts it.

**ERROR CODE: -1046, 'Cannot change attribute "%1\$s". CUBRID cannot change the attribute's domain. This change of domain is not supported.'**

- This message occurs when you try to change the data type of a specific column using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY* in the CUBRID database, and CUBRID currently does not support conversion between the involved data types. Not all data type conversions are always possible; in particular, changes between complex or incompatible data types may cause problems with data integrity or system stability, so CUBRID may explicitly not support them. This is a design limitation to keep database stability and consistency.

**ERROR CODE: -1047, 'Cannot change attribute "%1\$s". CUBRID cannot change the attribute's domain. The new domain may not correctly represent all the existing attribute values.'**

- This message occurs when you try to change the data type of a specific column using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY* in the CUBRID database. After analyzing the data stored in the existing column, CUBRID raises this error when it determines that there are values that cannot be converted to the requested new data type, or that there is a high likelihood of data loss. This is CUBRID's protection mechanism to ensure data integrity and prevent potential data loss. For example, it can occur when a *VARCHAR* column contains non-numeric strings and you attempt to change it to *INT*, or when an *INT* column contains values outside the *INT* range and you attempt to change it to *INT* from *BIGINT*.

**ERROR CODE: -1048, 'Cannot change attribute "%1\$s". CUBRID cannot currently change an attribute's AUTO\_INCREMENT if the attribute's domain also changes.'**

- This message occurs when you try to change both a column's *AUTO\_INCREMENT* attribute and its data type at the same time using *ALTER TABLE* in the CUBRID database. To maintain data integrity and reduce the complexity of schema changes, CUBRID does not allow such a simultaneous change. The *AUTO\_INCREMENT* attribute relates to value generation logic, while a data type change relates to conversion and storage of existing data; changing both at once can cause potential data loss, consistency issues, or unpredictable behavior. Therefore, CUBRID requires these changes to be performed in separate steps.

**ERROR CODE: -1049, 'Cannot change attribute "%1\$s". CUBRID cannot currently change the attribute's domain. The domain conversion is possible but this feature is not allowed by configuration.'**

- This message occurs when you try to change the data type of a specific column using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY* in the CUBRID database. Although CUBRID determines that the domain conversion is technically possible, it is restricted because the current system configuration does not allow this feature. It is highly likely that an administrator intentionally restricted the feature due to conversion complexity, potential data loss risk, or possible impact on system performance. This can occur when *alter\_table\_change\_type\_strict* is set to true in *\$CUBRID/conf/cubrid.conf*.

**ERROR CODE: -1050, 'Cannot change attribute "%1\$s". CUBRID cannot currently change the attribute's domain. The attribute has an index on it.'**

- This message occurs when you try to change the data type of a specific column using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY* in the CUBRID database. In particular, if an index already exists on the column you are trying to change, CUBRID does not allow the domain change due to data integrity and the complexity of index structures. Since an index is a structure that helps search quickly based on column values, changing a column's data type can invalidate the index structure or require rebuilding. To prevent such complexity and potential data damage, CUBRID restricts domain changes on indexed columns.

**ERROR CODE: -1052, 'Attribute "%1\$s" was not changed. CUBRID did not detect any effective changes in the attribute representation.'**

- This message is an informational warning that occurs when you try to change a column's properties using *ALTER TABLE ... CHANGE* or *ALTER TABLE ... MODIFY*, but CUBRID determines that the requested changes are effectively the same as the current column definition. In other words, the data type, length, constraints (NOT NULL, DEFAULT, etc.) you attempted to change are the same as the existing definition, so no actual change occurred. This is not an error; it informs you that the system did not perform unnecessary work.

**ERROR CODE: -1054, 'The new value of an auto increment constraint should be greater than or equal to the current value.'**

This message occurs when you try to change the value of an auto increment (AUTO\_INCREMENT) constraint using the *ALTER TABLE* statement in the CUBRID database system, and the new value is smaller than the current value. That is, during processing of *ALTER TABLE ... AUTO\_INCREMENT = x*, the CUBRID server raises this message when the new value specified by the user is smaller than the current auto-increment value of the column. This is a constraint to protect data integrity, because decreasing the auto-increment value can cause consistency issues with existing data. This is a protective error to maintain data consistency in CUBRID's auto-increment system.

**ERROR CODE: -1055, 'The new value of an auto increment constraint should be lower than the maximum value.'**

- This message occurs when you try to set an *AUTO\_INCREMENT* value larger than the maximum value using the *ALTER TABLE* statement in the CUBRID database. In particular, it occurs when the new *AUTO\_INCREMENT* start value (the N value in *ALTER TABLE table\_name AUTO\_INCREMENT = N*;) is larger than the maximum value allowed by the column's data type. Since *AUTO\_INCREMENT* must always increase and cannot exceed the data type's range or conflict with the existing maximum value, CUBRID rejects such a setting to ensure data integrity.

**ERROR CODE: -1056, 'To avoid ambiguity, the AUTO\_INCREMENT table option requires the table to have exactly one AUTO\_INCREMENT column and no seed/increment specification.'**

- This message is displayed in the CUBRID database when, during table creation or alteration, there are two or more auto\_increment columns and you try to specify an auto\_increment=seed value, because it is difficult to determine which auto\_increment column to apply it to. For reference, you can set multiple auto\_increment columns within a single table.

**ERROR CODE: -1057, 'Cannot add a NOT NULL '%1\$s' typed attribute without a DEFAULT value.'**

- This message occurs when, in the CUBRID database, you try to add an attribute with a *NOT NULL* constraint using a *CREATE TABLE* or *ALTER TABLE* statement, or when the column's type does not allow specifying a default value.

**ERROR CODE: -1058, 'ALTER TABLE .. CHANGE : changing to new domain : cast failed, current configuration doesn't allow truncation or overflow.'**

- This message occurs when you change a column's data type using the *ALTER TABLE ... CHANGE* statement in the CUBRID database. During conversion (casting) of existing column data to the new data type, a situation was detected where some data could exceed the new domain's range or be truncated. Under the current CUBRID configuration, such conversions are not allowed to prevent data loss. This is CUBRID's protection mechanism to ensure data integrity and prevent unintended data loss.

**ERROR CODE: -1059, 'ALTER TABLE .. CHANGE : changing to new domain : cast failed, default value of new domain was set.'**

- This message is an informational notification that occurs when changing a column's data type (when it is not numeric or string) using the *ALTER TABLE ... CHANGE* statement in the CUBRID database. During conversion (casting) of existing column data to the new data type, if some data does not fit the new domain's range or cannot be converted, CUBRID automatically sets that data to the new domain's default value. This is CUBRID's automatic data conversion mechanism to complete schema changes while minimizing data loss. For example, when changing a *VARCHAR* column to *INT*, strings that cannot be converted to numbers may be set to 0, the default value of *INT*. This message reports the automatic conversion work successfully performed by the system for data consistency.

**ERROR CODE: -1060, 'ALTER TABLE .. CHANGE : changing to new domain : cast failed, minimum value of new domain was set.'**

- This message is an informational notification that occurs when changing a column's data type using the *ALTER TABLE ... CHANGE* statement in the CUBRID database (when the domain value is negative). During conversion (casting) of existing column data to the new data type, if some data exceeds the new domain's range or cannot be converted, CUBRID automatically sets that data to the new domain's minimum value. This is CUBRID's automatic data conversion mechanism to complete schema changes while minimizing data loss.

**ERROR CODE: -1061, 'ALTER TABLE .. CHANGE : changing to new domain : cast failed, maximum value of new domain was set.'**

- This message is an informational notification that occurs when changing a column's data type using the *ALTER TABLE ... CHANGE* statement in the CUBRID database (when the domain value is positive). During conversion (casting) of existing column data to the new data type, if some data exceeds the new domain's range or cannot be converted, CUBRID automatically sets that data to the new domain's maximum value. This is CUBRID's automatic data conversion mechanism to complete schema changes while minimizing data loss.

**ERROR CODE: -1062, 'Cannot change attribute "%1\$s". The change would result in multiple primary keys being defined.'**

- This message occurs when you try to change a specific column using the *ALTER TABLE* statement in the CUBRID database. If the requested change would result in multiple primary keys being defined on the table, CUBRID rejects the change to guarantee data integrity and table structure consistency. In a relational database, only one primary key is allowed per table; having multiple primary keys can cause issues with uniqueness and referential integrity. This violates a fundamental database design principle.

**ERROR CODE: -1063, 'Cannot add NOT NULL constraint for attribute "%1\$s": there are existing NULL values for this attribute.'**

- This message occurs when you try to add a *NOT NULL* constraint to a specific column using the *ALTER TABLE* statement in the CUBRID database. If one or more *NULL* values already exist in the column, CUBRID refuses to add the *NOT NULL* constraint to ensure data integrity. Because a *NOT NULL* constraint completely disallows storing *NULL* values in the column, you must handle or remove the existing *NULL* values first. This is CUBRID's safety mechanism to protect database consistency and integrity.

**ERROR CODE: -1064, 'ALTER TABLE .. CHANGE : adding NOT NULL : all existing NULL values were changed to domain's hard default.'**

- This message is an informational notification that occurs when adding a *NOT NULL* constraint to a specific column using the *ALTER TABLE ... CHANGE* statement in the CUBRID database. If *NULL* values already exist in the column and the user did not specify an explicit *DEFAULT* value, CUBRID automatically converts all existing *NULL* values to the column data type's hard default value to maintain data integrity. For example, numeric types are changed to 0, and string types are changed to an empty string (""). This is not an error; it reports the automatic conversion work successfully performed by the system for data consistency.

**ERROR CODE: -1067, 'Column '%1\$s' cannot have a NOT NULL constraint and a NULL default value.'**

- This message occurs when creating or altering a table in the CUBRID database while attempting to apply a *NOT NULL* constraint to a specific column and simultaneously set *NULL* as the default value. Because a *NOT NULL* constraint does not allow storing *NULL* values in the column, a *NULL* default value logically conflicts with the constraint and is not allowed. This is the system's protection mechanism to ensure data integrity and keep data definitions consistent.

**ERROR CODE: -1068, 'Maximum trigger depth cannot exceed %1\$d.'**

- This message occurs when the maximum trigger depth limit allowed by CUBRID is exceeded. To prevent infinite trigger loops or excessive resource consumption, CUBRID limits the maximum depth of trigger invocations, and this message means that the setting itself has exceeded the system's internal limit. This is an important protective error to safeguard database stability and performance.

**ERROR CODE: -1080, 'The maximum length of filter predicate string must be %1\$d.'**

- This message is displayed when creating a function index in the CUBRID database, if the length of the argument (expression) used in the function is larger than the internally defined limit.

**ERROR CODE: -1085, 'Cannot compile regular expression: '%1\$s''**

- This message appears when the CUBRID database cannot process a regular expression normally because a problem occurred while compiling it. This can mainly occur due to a syntax

error in the regular expression itself, an invalid pattern, or an internal issue in the regular expression engine. If this error occurs when the database compiles the pattern before processing a regular expression function in a query, the query execution fails.

**ERROR CODE: -1086, 'Cannot execute regular expression: '%1\$s''**

- This message appears when the CUBRID database cannot process a regular expression normally because a problem occurred while executing it. This can mainly occur due to a syntax error in the regular expression itself, an invalid pattern, or an internal issue in the regular expression engine. If this error occurs while the database processes a regular expression function in a query, the query execution fails.

**ERROR CODE: -1092, 'Cannot prepare statement of type '%1\$s' with host variables.'**

- This message occurs when, in the CUBRID database, you try to prepare a certain type of SQL statement with host variables using a PREPARE statement. A PREPARE statement pre-compiles an SQL statement and builds an execution plan, allowing dynamic SQL construction using host variables. However, some statement types (e.g., DDL statements, certain system commands, etc.) are restricted and cannot be used with host variables. This is a constraint to protect database security and stability.

**ERROR CODE: -1096, 'Altering partitioning schema is not allowed when the partitioned class is referenced by a foreign key.'**

- This message occurs when you try to change the partitioning schema of a partitioned table in the CUBRID database while that table is referenced by a foreign key constraint from another table. It is a protection mechanism that restricts structural changes to a partition table when foreign key relationships exist, in order to protect data integrity.

**ERROR CODE: -1097, 'Column '%1\$s' cannot have a PRIMARY KEY constraint and a NULL default value.'**

- This message occurs when creating or altering a table in the CUBRID database while attempting to apply a PRIMARY KEY constraint to a specific column and simultaneously set NULL as the default value. Because a PRIMARY KEY requires uniqueness and the NOT NULL property, a NULL default value conflicts with the constraint and is not allowed. This is the system's protection mechanism to ensure data integrity.

**ERROR CODE: -1098, 'Locales for language '%1\$s' are not available with charset '%2\$s''**

- This message is displayed when using date/time formatting functions (e.g., DATE\_FORMAT, TIME\_FORMAT) in the CUBRID database. That is, it occurs when locale data for a specific language/charset combination is not installed on the system or is not supported. This is a multilingual support-related error that appears when trying to output a date or time in a specific language format but the locale information for that language is not compatible with the current charset.

**ERROR CODE: -1106, 'Multiple rows in source table match the same row in destination table.'**

- This message is displayed in the CUBRID database when, during GROUP BY processing, there are two or more identical records in the result, and it also occurs in the process of merging results after sorting.

**ERROR CODE: -1107, 'Invalid bucket number for NTILE. Should be greater than zero and no more than 2,147,483,647.'**

- This message occurs when using the SQL window function NTILE() in the CUBRID database and the number of buckets (groups) specified as the argument is outside the valid range. That is, in NTILE(n), this error occurs if n is less than or equal to 0, or if it exceeds the maximum value representable by CUBRID's integer type (2,147,483,647). The NTILE function requires a positive integer bucket count to evenly divide rows, and values beyond the system's integer limit cannot be processed. This is a protective error to prevent inputs that exceed the correct usage of the NTILE function and the limits of the data type.

**ERROR CODE: -1108, 'Invalid bucket number for WIDTH\_BUCKET. Should be greater than zero and less than 2,147,483,647.'**

- This message occurs when the fourth argument (bucket count) of the WIDTH\_BUCKET function in the CUBRID database is outside the valid range. That is, WIDTH\_BUCKET divides data into a specified number of equal-width buckets, and this error occurs when the bucket count is less than 1 or is greater than or equal to the maximum 32-bit integer value (2,147,483,647). This is a protective error to guarantee normal function operation. WIDTH\_BUCKET is mainly used in data analysis or statistical tasks, and if the bucket count is too large or too small, memory usage or performance problems can occur.

**ERROR CODE: -1109, 'Invalid value for partition definition.'**

- This message occurs when, in the CUBRID database, a partition table's partition key value does not match the partition definition. That is, when trying to insert or update data into a specific partition, if the partition key value of the data does not belong to any partition range or does not match the partition definition, this error occurs. This is a protective error to ensure data integrity for partition tables. It mainly occurs when the partition key value is outside the ranges defined by the partition definition during INSERT or UPDATE operations, or when the partition definition is incorrect and the data cannot be placed into an appropriate partition.

**ERROR CODE: -1118, 'The argument of "%1\$s" can not be coerced to desired domain "%2\$s"'**

- This message occurs when, in the CUBRID database, the argument of a function or operation cannot be converted to the desired domain type. That is, it means that an incompatible data type conversion (type casting) was attempted. This mainly occurs when performing operations between different data types in aggregate functions (MEDIAN, AVG, SUM, etc.) or arithmetic operations. The system attempts automatic conversion to compatible types such as DOUBLE, DATETIME, TIME, etc., but if conversion is not possible, it raises this error.

**ERROR CODE: -1121, 'NOT NULL constraints do not allow NULL value.'**

- This message occurs when, in the CUBRID database, after inserting data and then creating an index, NULL data exists in a column with a NOT NULL constraint. This is a protective error due to a constraint violation. This message mainly occurs during operations such as index creation, data insertion, and updates, especially when trying to process data that includes NULL values in a column with a NOT NULL constraint during the B-tree index loading process.

**ERROR CODE: -1124, 'Query execution error. ERROR\_CODE = %1\$d, /\* SQL\_ID: %2\$s \*/ %3\$s'**

- This message indicates a general execution error that occurred during SQL query execution in the CUBRID database. That is, parsing or compilation succeeded, but a problem occurred during the actual execution phase. This message can occur in various situations such as internal errors in the query execution engine, data type conversion errors, insufficient memory, system resource issues, and more.

**ERROR CODE: -1137, 'The query has been rejected due to attempt to exceed the maximum allowed nesting level(%1\$d).'**

- This message occurs when the nesting level (subqueries, recursive queries, etc.) of an SQL query exceeds the maximum depth allowed by the system (default: 400). It is a safety mechanism to protect system resources and prevent infinite recursion.

**ERROR CODE: -1150, 'Context requires compatible collations.'**

- This message occurs when, in the CUBRID database, incompatible collations are used or required while processing string data (e.g., comparison, sorting, joins, etc.). That is, it occurs when the database system detects that the collation of string data required for a certain operation does not match the expected collation in the current context. This situation can generally occur due to operations between tables or columns with different collation settings, or due to incorrect collation specification. This is a protective error to ensure consistency of data and accurate string processing.

**ERROR CODE: -1153, 'Attempt to use 'zero date''**

- This message occurs when, in the CUBRID database, you try to perform arithmetic operations or functions on a date/time type value that is a 'zero date' (a date value stored as 0). That is, it is a validation error that occurs when attempting operations on values stored internally as 0 (invalid dates) for date/time types such as TIMESTAMP, DATE, and DATETIME. This situation generally occurs when date/time data is not initialized, an incorrect value is stored, or 0 is stored instead of NULL.

**ERROR CODE: -1169, 'Partition key attributes must be present in the index key.'**

- This message occurs when creating or modifying a unique index on a partitioned table in the CUBRID database. CUBRID has special constraints for unique indexes on partitioned tables. That is, the columns (index keys) that make up the unique index must include all columns used

as the table's partition keys. This constraint exists to guarantee uniqueness across the entire table beyond partition boundaries. If you define a unique index without including the partition key columns in the index key, the database raises this error and rejects index creation.

**ERROR CODE: -1193, 'The length of the processed partition expression exceeds the maximum allowed(%1\$d).'**

- This message occurs when, in the CUBRID database, the length of the partition expression used when partitioning a table (e.g., a column or function used as the partition key for *RANGE*, *LIST*, or *HASH*) exceeds the maximum length allowed by the system. Since partition expressions must be processed and stored internally, overly long expressions can cause system resource usage issues or violate internal constraints. This mainly occurs when executing *CREATE TABLE ... PARTITION...*, and it can appear when the partition key expression is complex or the string is long.

**ERROR CODE: -1195, 'The recursive part of a CTE should not contain aggregate functions without GROUP BY clause.'**

- This message occurs when, in the CUBRID database, you define a recursive CTE (Common Table Expression) and use aggregate functions (e.g., *SUM*, *COUNT*, *AVG*, *MAX*, *MIN*) without a *GROUP BY* clause in the recursive member part. A recursive CTE repeatedly references itself to generate results, and using aggregate functions without *GROUP BY* in the recursive part can lead to unexpected results or infinite loops, so CUBRID restricts it syntactically. This is a limitation based on SQL standards or specific database system rules for recursive query processing.

**ERROR CODE: -1196, 'Maximum recursions %1\$d reached executing CTE.'**

- This message occurs when, in the CUBRID database, a recursive CTE (Common Table Expression) exceeds the maximum allowed recursion count during execution. Recursive CTEs are used to process hierarchical data or perform iterative computations, and to prevent infinite loops and protect system resources, the database system limits the maximum recursion count by default. When this limit is reached, query execution is stopped and this error message is returned.

**ERROR CODE: -1197, 'Invalid json: %1\$s (%2\$d)'**

- This message occurs when, in the CUBRID database, an input JSON string does not follow valid JSON syntax while parsing or processing JSON-formatted data. When the JSON parser detects a syntax error while analyzing the string, it returns this error along with detailed information including the error type and position. This can occur when calling functions that take JSON data as arguments, loading JSON-format configuration files, or inserting values into columns that contain JSON data.

**ERROR CODE: -1199, 'The provided JSON has been invalidated by the JSON schema (Invalid schema path: %1\$s, Keyword: %2\$s, Invalid provided JSON path: %3\$s)'**

- This message occurs when, in the CUBRID database, the JSON format is not correct while handling JSON data.

**ERROR CODE: -1200, 'Invalid JSON path'**

- This message occurs when, in the CUBRID database, the syntax of a JSON Path Expression is invalid while handling JSON data. When trying to select or access specific elements within a JSON document using a JSON path, if the provided path string does not follow the JSON Path standard or the syntax rules supported by CUBRID, this error is returned. This can occur when using functions that take a JSON path as an argument, such as JSON\_EXTRACT, JSON\_SET, JSON\_INSERT, and JSON\_REPLACE.

**ERROR CODE: -1201, 'Json object name cannot be NULL.'**

- This message occurs when, in the CUBRID database, the member (property) name of a JSON object is specified as NULL while creating or manipulating JSON objects. According to the JSON standard, a member name must be a string and cannot be NULL. This message can appear when using the JSON\_OBJECT function or the JSON\_OBJECTAGG aggregate function if a NULL value is passed as the key argument or if the expression used as the key evaluates to NULL.

**ERROR CODE: -1202, 'Json PATH "%1\$s" does not exist in %2\$s'**

- This message occurs when, in the CUBRID database, you provide a JSON path that does not exist while using JSON functions.

**ERROR CODE: -1203, 'Invalid JSON type at path %1\$s. Expected %2\$s, but found %3\$s.'**

- This message occurs when, in the CUBRID database, you provide a non-JSON-object value while using the JSON\_INSERT or JSON\_SET functions.

**ERROR CODE: -1204, 'Json KEY "%1\$s" is duplicate'**

- This message occurs when, in the CUBRID database, the same key name is used two or more times while creating or manipulating a JSON object. According to the JSON standard, all keys in a JSON object must be unique. Therefore, when building JSON data using functions such as JSON\_OBJECT or JSON\_OBJECTAGG, if you attempt to include duplicate keys, the system detects this and returns this error to ensure the validity of the data.

**ERROR CODE: -1205, 'Invalid type %1\$s. Expecting JSON document compatible data type (STRING or JSON).'**

- This message occurs when, in the CUBRID database, a data type that cannot be converted to a JSON document is provided while using JSON functions.

**ERROR CODE: -1206, 'Json PATH "%1\$s" does not address a cell in an Json ARRAY.'**

- This message is an error that can occur when using the `JSON_ARRAY_INSERT` function in the CUBRID database while handling JSON data.

**ERROR CODE: -1207, 'Invalid JSON path. Index is larger than allowed by system parameter json\_max\_array\_idx.'**

- This message occurs when, in the CUBRID database, while using the `JSON_ARRAY_INSERT` function, the index in the JSON path provided as the second argument is not a number or exceeds the value set in `json_max_array_idx`.

**ERROR CODE: -1208, 'Invalid one/all argument. The one/all argument may only take one of these two values: "one", "all".'**

- This message occurs when, in the CUBRID database, while using the `JSON_CONTAINS_PATH` function, the value passed as the second argument ("one" or "all") is invalid.

**ERROR CODE: -1284, 'Cannot truncate the table due to the primary key referred to on %1\$s. Try again with CASCADE option.'**

- This message occurs when, in the CUBRID database, you execute `TRUNCATE TABLE` without the `CASCADE` option on a table whose primary key is referenced by a foreign key.

**ERROR CODE: -1285, 'Cannot cascade truncate because the ON DELETE action of the foreign key (%1\$s) is not set to CASCADE.'**

- This message occurs when, in the CUBRID database, you execute `TRUNCATE TABLE CASCADE` on a table referenced by a foreign key, but the foreign key's `ON DELETE` action is not set to `CASCADE`.

**ERROR CODE: -1339, 'Unsupported argument type of stored procedure: %1\$s'**

- This message occurs when using an argument data type that is not supported by Java stored procedures in CUBRID.

**ERROR CODE: -1340, 'Unsupported return type of stored procedure: %1\$s'**

- This message occurs when using a return data type that is not supported by Java stored procedures in CUBRID.

**ERROR CODE: -1343, 'RENAME does not allow change of owner.'**

- This message occurs when, in CUBRID, you use the `RENAME` command and attempt to change the owner along with the object name. Under CUBRID's security and integrity policy, the `RENAME` command supports changing only the object name and does not support changing the owner. Owner changes are possible only through separate privilege management or DDL commands.

**ERROR CODE: -1344, 'DBA, members of DBA group, and owner can perform CREATE SERIAL.'**

- This message occurs when, in CUBRID, you try to create a serial (Serial, auto-increment sequence) object but the user executing the command is not a DBA, a member of the DBA group, or the owner of the target object for which the serial is being created. In other words, it is a privilege-related error that occurs when a user without permission attempts CREATE SERIAL.

**ERROR CODE: -1348, 'Synonym "%1\$s" already exists.'**

- This message occurs when, in CUBRID, you execute a CREATE SYNONYM statement and the specified synonym name already exists in the database. That is, it is a constraint violation error that occurs when a synonym with the same name is already registered and duplicate creation is not possible.

**ERROR CODE: -1349, 'Synonym "%1\$s" does not exist.'**

- This message occurs when, in CUBRID, the specified synonym name does not exist in the database in contexts such as DROP SYNONYM, ALTER SYNONYM, or queries that reference a synonym. That is, the synonym entered by the user is not currently registered in the database or has already been dropped.

**ERROR CODE: -1351, 'The maximum length of the function expression string must be %1\$d.'**

- This message occurs when creating a function-based index in CUBRID and the expression string used as a function argument exceeds the maximum allowed length. That is, it is a constraint violation error that occurs when attempting to define an overly long function expression.

**ERROR CODE: -1360, 'In line %1\$d, column %2\$dStored procedure compile error: %3\$s'**

- This message is a compilation error that occurs when creating CUBRID PL/SQL.

**ERROR CODE: -1363, 'Dropping system generated stored procedure is not allowed.'**

- This message occurs when a user tries to drop a Java stored procedure/function generated by CUBRID.

**ERROR CODE: -1365, 'Only DBA and the owner can grant the %1\$s privilege.'**

- This message occurs when setting (granting) privileges for a Java stored procedure/function in CUBRID, if the user is neither the owner nor a DBA (DBA group).

**ERROR CODE: -1366, 'String representation of a default value of a Stored procedure/function parameter may not exceed 255 characters.'**

- This message occurs when creating a Java stored procedure/function in CUBRID and setting a default value for a parameter, if the string length for a char type is 255 characters or more.

## Database Management Errors

### **ERROR CODE: -1, 'Missing message for error code %1\$d.'**

- This message is an error used when the CUBRID system encounters an error that it cannot define, it is printed together with an error message about the cause that occurred, and it is an error that is used in various ways when it cannot be specifically defined.

### **ERROR CODE: -2, 'Internal system failure: no more specific information is available.'**

- This message is a general (Generic) system error that occurs when an unexpected error has occurred inside the CUBRID system, or when it is not possible to set a more specific error code for a particular error situation, CUBRID is composed of various internal components and modules, and each component is designed to return a unique error code for a specific failure situation. However, sometimes this error is used when it is difficult to clearly identify a specific error due to exceptional situations or complex internal states, this message may be a sign of a serious internal problem, and the possibility of affecting the stability and consistency of the database is very high.

### **ERROR CODE: -4, 'Has been interrupted.'**

- This message is an error indicating that a task being executed by the CUBRID system was interrupted by an external signal or a system event, CUBRID can receive an interrupt signal while performing various tasks (query execution, data loading, backup, recovery, etc.), and in this case it safely interrupts the current task and returns this error.

### **ERROR CODE: -83, 'Length of path "%1\$s" plus length of prefix logname "%2\$s" is too long; the combined length must be less than %3\$d.'**

- This message is displayed when the total length combining the path of the log file and the log name exceeds the maximum length allowed, CUBRID enforces a limit on the total path length of log files, and this message mainly occurs when the database path or log file name is too long and the overall path exceeds the system limit.

### **ERROR CODE: -84, 'Length of prefix logname "%1\$s" is too long; the length must be less than %2\$d.'**

- This message is displayed when the length of a log file name exceeds the maximum length allowed, CUBRID enforces a length limit on log file names, and this message mainly occurs when the database name is too long, or when the log file path exceeds the system limit.

### **ERROR CODE: -85, 'The prefix name "%1\$s" is not the same as "%2\$s" on the log disk. The log may have been renamed outside the database domain.'**

- This message is displayed when the name of the log file found on the log disk does not match the name expected by the database, this may occur when the database transaction log file has

been manually renamed outside the database system, or when the log file is connected to the wrong database.

**ERROR CODE: -86, 'Database is incompatible with current "%1\$s" release "%2\$s"'**

- This message indicates that the currently used CUBRID release (engine) version is not compatible with the database, it occurs when the database was created with a different version of CUBRID, or when the current CUBRID version is not compatible with the database format, this is mainly a compatibility issue that occurs during the CUBRID version upgrade/downgrade process.

**ERROR CODE: -87, 'There are recovery actions that must recovered using "%1\$s" release "%2\$s" instead of release "%3\$s". After the recovery, the database can be run on release "%4\$s"'**

- This message indicates that the database recovery operation contains log records that are not compatible with the currently used CUBRID release, it is mainly caused by CUBRID version compatibility issues, and occurs when trying to recover log files created with a different version of CUBRID, or during the database upgrade/downgrade process.

**ERROR CODE: -88, 'Internal error: Release string "%1\$s" cannot exceed %2\$d. Must change header log.'**

- This message is an internal error that occurs when the CUBRID system detects that the length of the "release string" stored in the log header exceeds the maximum length allowed, that is, it occurs when the release string length exceeds the allowed length when saving the log header.

**ERROR CODE: -89, 'Log "%1\$s" does not belong to the given database.'**

- This message is displayed when the CUBRID system determines that a specific log file does not belong to the database currently being worked on, it is an error that occurs during the consistency verification process between the log file and the database, and this can occur when the log file is connected to the wrong database, when the log file is corrupted, or when the database configuration is incorrect.

**ERROR CODE: -99, 'Unable to create backup directory information file "%1\$s"'**

- This message is displayed when the CUBRID system fails while trying to create the backup information file (DBname\_bkvinf) that stores backup directory information when performing a database backup operation.

**ERROR CODE: -100, 'Unable to backup database "%1\$s"'**

- This message is displayed when the CUBRID system tries to perform a database backup operation, but the backup fails due to an error during the backup process, backup failures can occur due to various causes such as file system permission issues, insufficient disk space, file access errors, or insufficient system resources.

**ERROR CODE: -115, 'Database "%1\$s" already exists.'**

- This message is displayed when the CUBRID system tries to create a new database, but a database with the same name already exists, CUBRID database names are case-sensitive, and this message means that you cannot create a new database with the same name as an existing database.

**ERROR CODE: -116, 'Database "%1\$s" is unknown, or the file "databases.txt" cannot be accessed.'**

- This message is displayed when the CUBRID system cannot find the specified database, or cannot access the databases.txt file that manages the database list, it mainly occurs when the database name is incorrect, when the databases.txt file is corrupted, or when access is not possible due to file system permission issues.

**ERROR CODE: -117, 'Absolute pathname for the database is too long. The combined length of the path "%1\$s" plus the name "%2\$s" is %3\$d; the combined length must be less than %4\$d.'**

- This message is displayed when the CUBRID system tries to handle the full pathname of the database (absolute path + database name), but the length exceeds the maximum length allowed by the system, it means that an overly long pathname cannot be handled due to file system or internal CUBRID limitations.

**ERROR CODE: -119, 'Cannot find hostname ("%1\$s") in "%2\$s". Please check permissions of the file or if there is the hostname.'**

- This message is displayed when the CUBRID system tried to find a specific host name but failed, it mainly occurs in the process of configuring network communication or querying host information, and appears when the specified host name is invalid, or when it cannot access the file that contains host information (e.g., /etc/hosts).

**ERROR CODE: -120, 'The maximum number of volumes (%1\$d) has been exceeded.'**

- This message is displayed when the CUBRID system tries to add a new volume, but exceeds the maximum number of volumes allowed by the system., CUBRID limits the maximum number of volumes per database for system stability and performance. If this limit is exceeded, the volume addition fails.

**ERROR CODE: -121, 'Trying to remove "%1\$s" a permanent volume from the database.'**

- This message is displayed when the CUBRID system tries to remove a temporary volume (temp temp volume) from the database, a temporary volume is a space in the database for sorting queries, and deletion is not allowed while the database is running (operating). This error is an event message that informs the user that an attempt to remove a permanent volume has been detected.

**ERROR CODE: -122, 'Unable to access system message catalog.'**

- This message is displayed when the CUBRID system tries to initialize message catalog files, but cannot access the message catalog files, the message catalog consists of files that include all of CUBRID's error messages and locale-specific messages, and they must be loaded during system initialization.

**ERROR CODE: -124, 'Volume "%1\$s" already exists.'**

- This message is displayed when the CUBRID system tries to create a new volume, but a volume with the same name already exists, it means that creation failed due to a duplicate volume name during volume expansion or new volume creation.

**ERROR CODE: -126, 'Unknown purpose "%1\$s" given on line %2\$d.'**

- This message is displayed when the CUBRID system parses a database volume-addition configuration file and the 'volume purpose (PURPOSE)' value specified on a particular line is invalid or unrecognizable, it mainly occurs when using the `-more-volume-file` option in the `createdb` command, and it means that a string that is not allowed was entered into the PURPOSE parameter that specifies the purpose of a volume in the volume expansion configuration file.

**ERROR CODE: -127, 'Incorrect value %1\$d for number of pages given on line %2\$d.'**

- This message is displayed when the CUBRID system parses a database volume-addition configuration file and the 'number of pages' value specified on a particular line is invalid, it mainly occurs when using the `-more-volume-file` option in the `createdb` command, and it means that the number of pages that specifies the size of a volume in the volume expansion configuration file was specified with a value that is not allowed.

**ERROR CODE: -128, 'Number of pages was not given on line %1\$d.'**

- This message is displayed when the CUBRID system parses a database volume-addition configuration file and the required 'number of pages' information is missing or invalid on a particular line, it mainly occurs when using the `-more-volume-file` option in the `createdb` command, and it means that the number of pages that defines the size of a volume in the volume expansion configuration file was not defined, or was specified in an incorrect format.

**ERROR CODE: -129, 'Unknown token "%1\$s" was found on line %2\$d.'**

- This message is displayed when the CUBRID system parses a database volume-addition configuration file and finds an unexpected, undefined token (keyword), it means that an unsupported keyword or an incorrect syntax was used in the volume expansion configuration file.

**ERROR CODE: -131, 'Database system error.'**

- This message indicates that an unexpected error occurred inside the CUBRID database system, it is generally printed when a problem occurs in the core components of the database engine, and mainly occurs when there is no related query or result information in a related query execution request.

**ERROR CODE: -137, 'Corrupted authorization objects.'**

- This message occurs when permission information is inconsistent in the CUBRID database, or when a column is missing.

**ERROR CODE: -138, 'Authorization class "%1\$s" not found.'**

- This message occurs when a table cannot be found due to a permission problem in the CUBRID database.

**ERROR CODE: -139, 'Access error on authorization attribute "%2\$s" of class "%1\$s".'**

- This message occurs when a related column cannot be accessed due to a permission problem in the CUBRID database.

**ERROR CODE: -140, 'Operation "%1\$s" can only be performed by the DBA or a DBA group member.'**

- This message is displayed when, in the CUBRID system, a user tries to perform a specific operation and that operation requires privileges that only the DBA or a member of the DBA group can have, it occurs when a general user attempts an operation that requires system administrator privileges, and it means that access has been denied for security reasons.

**ERROR CODE: -141, 'Cannot add "%1\$s" as a member of "%2\$s".'**

- This message is a warning-type message that occurs during user creation in the CUBRID database, in the process of registering as a member of public.

**ERROR CODE: -142, 'Adding member causes the user hierarchy to become a cyclic graph.'**

- This message is displayed when adding a member to a user or group causes a cyclic reference (cyclic dependency) in the user hierarchy structure in the CUBRID system, for example, it can occur when trying to add group B as a member of group A, and at the same time trying to add group A as a member of group B. Since this can cause an infinite loop or a logical contradiction, it is not allowed by the system.

**ERROR CODE: -143, 'Encountered a class with no owner.'**

- This message is displayed when the object whose privileges are being modified has no owner in the CUBRID database.

**ERROR CODE: -146, 'Cannot issue GRANT/REVOKE to owner of a %1\$s.'**

- This message is displayed when attempting to perform GRANT on the owner's object in the CUBRID database.

**ERROR CODE: -147, 'No GRANT option.'**

- This message is displayed when performing GRANT in the CUBRID database without giving the GRANT OPTION.

**ERROR CODE: -148, 'Cannot obtain write lock on authorization object.'**

- This message is displayed when the CUBRID database cannot obtain a write lock during GRANT or REVOKE processing and therefore cannot update.

**ERROR CODE: -150, 'Cannot revoke privileges from self.'**

- This message is displayed when attempting to perform REVOKE on one's own object in the CUBRID database.

**ERROR CODE: -151, 'Cannot revoke privileges from owner of a %1\$s.'**

- This message is displayed when attempting to perform REVOKE on the owner's object in the CUBRID database.

**ERROR CODE: -152, 'GRANT not found.'**

- This message is displayed when, during REVOKE execution in the CUBRID database, it cannot find the related GRANT information.

**ERROR CODE: -153, 'No authorization privileges in effect for the database.'**

- This message is displayed when, in the CUBRID database, there is no permission-related catalog class in the relevant DB.

**ERROR CODE: -154, 'Incomplete authorization installation no authorization privileges in effect for the database.'**

- This message is displayed when, in the CUBRID database, the DBA and public users do not exist in the relevant DB.

**ERROR CODE: -156, 'Authorization failure.'**

- This message is displayed when an unknown authorization is requested in the CUBRID database.

**ERROR CODE: -157, 'SELECT authorization failure.'**

- This message occurs when the SELECT privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -158, 'ALTER authorization failure.'**

- This message occurs when the ALTER privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -159, 'UPDATE authorization failure.'**

- This message occurs when the UPDATE privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -160, 'INSERT authorization failure.'**

- This message occurs when the INSERT privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -161, 'DELETE authorization failure.'**

- This message occurs when the DELETE privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -162, 'INDEX authorization failure.'**

- This message occurs when the INDEX processing privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -163, 'EXECUTE authorization failure.'**

- This message occurs when the EXECUTE privilege does not exist on the relevant table in the CUBRID database.

**ERROR CODE: -164, 'User "%1\$s" already exists.'**

- This message is displayed when the CUBRID system tries to create a new user, but a user with the same name already exists in the system, it means that user creation failed due to a duplicate user name when executing the CREATE USER statement.

**ERROR CODE: -165, 'User "%1\$s" is invalid.'**

- This message is an authentication-related error that occurs when, in the CUBRID system, the specified user name is invalid or a user that does not exist in the system, it means that an incorrect user name was used in operations such as connecting to the database, changing user privileges, or specifying an owner of a specific object.

**ERROR CODE: -166, 'Invalid user specified.'**

- This message is displayed when performing a user privilege (GRANT) operation in the CUBRID system, if the specified user is invalid or does not exist, it mainly occurs due to a user name error or when referencing a non-existent user.

**ERROR CODE: -167, 'DBA, members of DBA group and %1\$s owner can perform the operation.'**

- This message is an authentication-related error that occurs when, in the CUBRID system, a user who does not have the privilege to perform a particular operation tries to do so, it informs that only the DBA, members of the DBA group, or the owner of a particular object can perform the operation.

**ERROR CODE: -168, '168 Member not found.'**

- This message is displayed in the CUBRID database when requesting deletion of a user that is not a member during drop member.

**ERROR CODE: -169, '169 Cannot remove user %1\$s from the database.'**

- This message is displayed when requesting deletion of a currently logged-in user during drop user in the CUBRID database.

**ERROR CODE: -171, 'Incorrect or missing password.'**

- This message is displayed when, during user authentication in the CUBRID system, the provided password is incorrect, or when no password is provided at all, it means that a password mismatch or omission was detected in the authentication process required to connect to the database or to perform CUBRID command operations.

**ERROR CODE: -172, '172 Password string cannot have more than 31 bytes.'**

- This message is displayed when the password length of a CUBRID database DB user exceeds 31 characters.

**ERROR CODE: -173, 'Could not locate database file "%1\$s"'**

- This message is displayed when the CUBRID system cannot find a specific databases.txt file.

**ERROR CODE: -174, 'Could not obtain write access to database file "%1\$s"'**

- This message is displayed when the CUBRID system fails to obtain write permission for a specific databases.txt file.

**ERROR CODE: -183, 'Unexpected amount of received data; %1\$d expected, %2\$d received.'**

- This message is displayed when the CUBRID client receives data from the server and the expected data size does not match the actual received data size, it can occur due to data integrity issues during network communication, protocol mismatch, or data transfer errors, and

it can indicate incorrect communication where the amount of data received from the server differs from what was expected.

**ERROR CODE: -184, 'Cannot allocate communications buffer.'**

- This message is displayed when the CUBRID system cannot allocate a buffer for network communication, it occurs due to insufficient memory, system resource limits, or buffer allocation failure, and occurs when it cannot create a communications buffer for data transmission between the client and server.

**ERROR CODE: -185, 'Error receiving data from client.'**

- This message is an error that appears when the CUBRID server encounters an error while receiving data from the client, it occurs due to failures in receiving client data during network communication, protocol mismatch, client response errors, and so on, and occurs when the server did not receive the expected data from the client, or when the received data is not valid.

**ERROR CODE: -186, 'Error receiving data from server.'**

- This message is an error that appears when the CUBRID client encounters an error while receiving data from the server, it occurs due to data receiving failures during network communication, protocol mismatch, server response errors, and so on, and occurs when the client did not receive the expected data from the server, or when the received data is not valid.

**ERROR CODE: -187, 'Communications buffer not used.'**

- This message is displayed when the CUBRID client receives data from the server and the expected buffer differs from the buffer actually received, it occurs when there is a problem with buffer management during network communication or when unexpected data is received.

**ERROR CODE: -188, 'Unknown database "%1\$s"'**

- This message occurs when the CUBRID system detects that the specified database name is NULL or exceeds the maximum length.

**ERROR CODE: -189, 'Invalid host name "%1\$s"'**

- This message is displayed when the host name provided by the CUBRID client when connecting to the server is invalid or in an incorrect format, it occurs when the host name is NULL, exceeds the maximum allowed length, or is not in a valid format, and occurs when validating the server host information during the client initialization process.

**ERROR CODE: -190, 'Server host not identified.'**

- This message is displayed when the CUBRID client cannot find server host information, it occurs when the server host name or server name is not set or is empty during the client initialization process, and indicates a state where the client does not know which server to connect to.

**ERROR CODE: -191, 'Cannot connect to server "%1\$s" on "%2\$s"'**

- This message is displayed when the CUBRID client cannot connect to the database server process (cub\_server) on the specified host, it can occur due to network connection failure, the server not running, firewall blocking, port issues, and so on, and indicates a state where the client cannot establish communication with the server.

**ERROR CODE: -193, 'Server received shutdown command from client.'**

- This message occurs when the CUBRID database receives a shutdown command from a client. It informs that the database server has started the normal shutdown process according to the client's request, this is not an error but an event message that indicates the server's normal shutdown.

**ERROR CODE: -194, 'Unknown server request id %1\$d.'**

- This message is displayed when the request ID (service ID) received by the CUBRID server from the client is invalid or an undefined request, it occurs when the server receives a request ID it cannot process, and is mainly due to a protocol version mismatch between the client and server or an incorrect request format.

**ERROR CODE: -195, 'Server communications error: %1\$s.'**

- This message indicates an error that occurs during communication between internal/external clients and the server in the CUBRID database, it occurs when communication with the server fails or the connection is dropped, or when there is a problem with the server communication protocol, and is mainly related to network connection issues, server status issues, or communication protocol errors.

**ERROR CODE: -196, 'Server name not identified.'**

- This message is displayed when attempting to connect to the CUBRID database server, if the server name is not set or is not valid, it mainly indicates a state where the name of the server or host information that the client is trying to connect to is not correctly configured.

**ERROR CODE: -197, 'Could not make contact with master server.'**

- This message indicates that the CUBRID database attempted to connect to the master (cub\_master) process but failed, the master (cub\_master) is a core process in the CUBRID system that manages multiple databases, and a connection to the master server is required to perform database operations, it mainly occurs when the master process is in an abnormal operating state or in an environment (such as a firewall) that prevents connection.

**ERROR CODE: -199, 'Server no longer responding.'**

- This message is displayed when the CUBRID database server does not respond to the client's request, or when the server process unexpectedly terminates, it indicates a state where the

server can no longer communicate with the client, and can occur due to DB connection problems, disconnections, or server process interruption, and so on.

**ERROR CODE: -204, 'Function called with missing or invalid arguments.'**

- This message is displayed when, inside the CUBRID database, a function is called with required arguments missing or with invalid argument values, in general it is less likely to be a direct user SQL error and more likely to be an internal CUBRID engine issue or a case where a developer used the CUBRID API incorrectly.

**ERROR CODE: -210, 'Internal error: processing object template.'**

- This message is an error that appears when an internal error occurs during object template processing in the CUBRID database, it can mainly occur due to table cache inconsistency, lock upgrade failure, or template state validation errors.

**ERROR CODE: -217, 'Operation can only be performed on class objects.'**

- This message indicates that, when a specific operation in the CUBRID database is valid only for table objects, that operation was attempted on an object type other than a table object, it can occur mainly in operations related to table definitions such as schema management, metadata querying, or object template processing.

**ERROR CODE: -224, 'A database has not been restarted.'**

- This message is displayed when database work is attempted in the CUBRID database while the database connection is not established or the database has not been restarted, it mainly occurs when the connection to the database server has been lost, or when the database is not started normally and an SQL statement is executed or database work is attempted.

**ERROR CODE: -231, 'Invalid API operation attempted on a temporary object.'**

- This message is displayed when attempting an API operation that is not allowed on a temporary object in the CUBRID database, in CUBRID, temporary objects are temporary objects mainly related to schema templates or triggers, and they have a different lifecycle and constraints than general database objects, it mainly occurs when attempting operations (e.g., data access, modification, deletion, etc.) that are allowed only for general objects on a temporary object.

**ERROR CODE: -232, 'Not allowed to use object templates over multiple transactions.'**

- This message is displayed when an object template is attempted to be used across multiple transactions in the CUBRID database, an object template is a temporary schema-definition object that must generally be created and used within a single transaction. If it is used across multiple transactions, it can cause data consistency issues or unexpected behavior, so the system prohibits this, it occurs in logic related to lifecycle management of object templates, and appears when a template is used outside the transaction scope in which it was created.

**ERROR CODE: -247, 'Invalid arguments to schema manager internal function.'**

- This message is an internal error that occurs when invalid arguments (NULL, an empty string, or an invalid value) are passed to an internal function of the schema manager in the CUBRID database, it mainly occurs during operations such as schema creation, modification, and querying, and indicates a developer- or system-level issue.

**ERROR CODE: -263, 'Schema manager internal corruption detected.'**

- This message is a system error indicating that data corruption has been detected inside the schema manager in the CUBRID database, it mainly occurs when an internal consistency check fails during object representation, table definition, or metadata processing, and can occur due to database file corruption, memory errors, or abnormal system shutdown, and so on.

**ERROR CODE: -314, 'Object buffer overflow while writing.'**

- This message occurs when, in the CUBRID database, while storing (writing) data of an object (such as a table record), data is attempted to be written that exceeds the size of an internally allocated buffer, it can appear due to large data processing, abnormally large objects, buffer size configuration errors, internal bugs, and so on, and can lead to data loss, transaction failure, or system errors.

**ERROR CODE: -321, 'Possible corruption in the workspace detected.'**

- This message is displayed when unwanted information exists during processing in the workspace in the CUBRID database, it occurs during the data integrity verification process in the workspace management system, generally the workspace is a memory-resident object management structure and it must keep consistency, and this error is reported when that consistency is broken.

**ERROR CODE: -322, 'MOP not found in the workspace.'**

- This message is an error that appears when a specific MOP cannot be found in the hash table in the workspace in the CUBRID database, it can appear when there is a problem in the internal MOP management logic of CUBRID, or when unexpected problems occur in the concurrency control mechanism

**ERROR CODE: -324, 'Object found in workspace without class.'**

- This message is an error that appears when an object (MOP) exists in the workspace without table information in the CUBRID database, it can appear when there is a problem in the internal object-table management logic of CUBRID, or when unexpected problems occur in the concurrency control mechanism.

**ERROR CODE: -325, 'Attempt to garbage collect a MOP in the dirty list.'**

- This message is an error that appears when, during the garbage collection process of the workspace in the CUBRID database, it attempts to clean up a MOP that is in the 'dirty list', it occurs during the state consistency verification process of MOPs in the workspace management system, generally, if a MOP is in the 'dirty list' it should not be a garbage collection target, and this error is reported when such an inconsistency occurs.

**ERROR CODE: -326, 'Changing class pointer for object in workspace.'**

- This message is an error that occurs due to class MOP during instance caching in the workspace in the CUBRID database, it occurs during the table assignment process of objects in the workspace management system, and it mainly occurs when attempting to reassign an object that already belongs to another table to a different table.

**ERROR CODE: -327, 'Cannot create MOP with NULL OID.'**

- This message is an error that appears when, in the CUBRID database, a Managed Object Pointer (MOP) is created with a NULL Object ID (OID), it occurs during the OID validity verification process when creating a MOP in the workspace management system, and it can occur when OID assignment fails, or when the memory structure that includes the OID is corrupted.

**ERROR CODE: -328, 'Instance encountered in workspace without class.'**

- This message is an error that appears when, in the CUBRID database, a record without a table definition is found in the workspace, it occurs during the verification process of the relationship between records and tables in the schema management system, and it mainly occurs when the table cannot be loaded or the table cannot be found.

**ERROR CODE: -335, 'Ignoring attempt to free object not allocated within the workspace.'**

- This message is an error that appears when, in the CUBRID database, it attempts to free a memory object that was not allocated within the workspace (work area), it occurs during the pointer validity verification process in the memory management system, and it mainly occurs when the memory pointer is not within a valid area block.

**ERROR CODE: -344, '%1\$s.'**

- This message is a warning-type message indicating that the CUBRID database process (cub\_server) is in the middle of shutdown.

**ERROR CODE: -345, 'Error occurred during reading a shutdown message from master.'**

- This message occurs when the CUBRID database process (cub\_server) checks a shutdown request message from the master process (cub\_master).

**ERROR CODE: -347, 'Could not establish a pipe to the master server.'**

- This message is displayed when, in the CUBRID database server process (cub\_server), it tries to perform communication with the master process (cub\_master) and the socket is invalid.

**ERROR CODE: -350, 'Cannot find hostname ("%1\$s") in "%2\$s". Please check permissions of the file or if there is the hostname.'**

- This message is displayed when the CUBRID system tries to obtain an IP address from a hostname, it occurs in cases such as a permission error on /etc/hosts, when there is no hostname information, when use\_user\_host = yes, and when there is no hostname information in \$CUBRID/conf/cubrid\_hosts.conf.

**ERROR CODE: -363, 'Recvmsg from master socket failed.'**

- This message is displayed when a message is received after connecting between the CUBRID database process (cub\_server) and the master process (cub\_master).

**ERROR CODE: -364, 'Sending a new request to server.'**

- This message occurs when the connection between the CUBRID database process (cub\_server) and the master process (cub\_master) has been terminated.

**ERROR CODE: -366, '366 Error from server: %1\$s'**

- This message is displayed when changing mode in a CUBRID HA environment, or when the CAS process is connected to a standby server and the database server process (cub\_server) terminates the connection.

**ERROR CODE: -367, 'Server %1\$s already exists.'**

- This message occurs when, in the CUBRID system, a database with the same name already exists when creating a database.

**ERROR CODE: -368, 'Communication error during connect for %1\$s.'**

- This message occurs while connecting to the master process (cub\_master) when starting the database process (cub\_server) in the CUBRID system.

**ERROR CODE: -423, 'Invalid session.'**

- This message is an error that appears when an invalid session is used in the CUBRID database, it is when the session is NULL or the parser (parser) is not initialized in the session validation process.

**ERROR CODE: -430, 'Unknown variable "%1\$s"'**

- This message is an error that appears when an undefined variable is referenced in the CUBRID database, it is when the variable cannot be found during the variable validation process, in the host variable (host variable) handling process.

**ERROR CODE: -456, 'Data type references are incompatible.'**

- This message is an error that appears when a reference or operation between different data types is incompatible in the CUBRID database, it occurs during the data type compatibility verification process in a query, that is, it occurs when comparison, operation, assignment, and so on between different data types are not possible.

**ERROR CODE: -469, 'Invalid data type used.'**

- This message is an error that appears when an unsupported or incorrect data type is used in the CUBRID database.

**ERROR CODE: -547, 'Server release %1\$s is different from client release %2\$s.'**

- This message is an error that appears when the server and client release versions are different in the CUBRID database, it mainly occurs during the version compatibility check between the server and client in the network connection process, and the connection is rejected when the server and client release versions are not compatible.

**ERROR CODE: -554, 'The loader has entered an invalid state. No further operations are possible.'**

- This message is displayed when the CUBRID database loaddb command enters an invalid state, this mainly occurs when the loaddb command session is invalid, or when the loader is in an unexpected state, and if the loader (loaddb) is in this state, no further data load operations can be performed.

**ERROR CODE: -555, 'Memory allocation error during database loading.'**

- This message occurs when the CUBRID database loaddb command fails to allocate the required memory, the allocation request may fail due to processing a large amount of data during the loading work, insufficient available memory on the system, or due to memory fragmentation, operating system limits, and so on.

**ERROR CODE: -556, 'Too many values supplied. Expecting %1\$d.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, the number of supplied values is greater than the expected number, it mainly occurs when processing attribute values during the data loading process, and it occurs when more values are provided than the number of attributes defined in the table.

**ERROR CODE: -559, 'For attribute %1\$s of %2\$s, expected type %3\$s, got %4\$s.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, the domain type of an attribute does not match the expected type, it mainly occurs when validating the domain type during the data loading process, and it occurs when the expected type and the actually received type are different for a specific attribute.

**ERROR CODE: -560, 'For attribute %1\$s of %2\$s, domain is not specific enough to supportn unqualified object references.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, the domain of an object reference is ambiguous, it mainly occurs when validating an object domain during the data loading process, and it occurs when the domain of a specific attribute is not specific enough to support unqualified object references.

**ERROR CODE: -561, 'Nested sets are not allowed.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, it tries to handle nested sets (collections), it mainly occurs when processing collection elements during the data loading process, and because CUBRID does not allow nested sets, this error occurs when a set is attempted to contain another set.

**ERROR CODE: -562, 'System class %1\$s cannot be populated using the database loader.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, it tries to load a system table, it mainly occurs when initializing the table context during the data loading process, system tables are special tables used internally by CUBRID and cannot be loaded through a general loaddb.

**ERROR CODE: -563, 'Reference to internal class %1\$s converted to NULL.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, it processes a reference to an internal table, it mainly occurs when creating a table record during the data loading process, and when a reference to an internal table is found, it is converted to NULL and processed.

**ERROR CODE: -565, 'Constructor method %1\$s is not defined on class %2\$s.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, the specified constructor method is not defined on the table, it mainly occurs when creating a table record during the data loading process, and it occurs when the constructor method does not exist on the table or is not defined.

**ERROR CODE: -566, 'No class specified or no attribute in class.'**

- This message is displayed when, while loading data with the CUBRID database loaddb command, no table is specified or there is no attribute in the table, it mainly occurs when

creating a table record during the data loading process, and it occurs when the table does not exist, or when the table exists but no attributes are defined.

**ERROR CODE: -567, 'Too many constructor method arguments supplied. Expected %1\$d.'**

- This message is displayed when more arguments are supplied than the number of arguments expected by the CUBRID database loaddb command, it mainly occurs when creating a table record during the data loading process, and it occurs when more arguments are provided than the number of arguments required for the constructor method.

**ERROR CODE: -568, 'Missing constructor method parameters. Expected %1\$d, found %2\$d.'**

- This message is displayed when the expected number of arguments and the actually supplied number of arguments do not match in the CUBRID database loaddb command, it mainly occurs when creating a table record during the data loading process, and it occurs when fewer arguments are provided than the number of arguments required for the constructor method.

**ERROR CODE: -569, 'Missing attribute values. Expected %1\$d, found %2\$d.'**

- This message is displayed when, during the process of loading data with the CUBRID database loaddb command, the expected number of attribute values and the actually found number of attribute values do not match, it mainly occurs when creating a table record during the data loading process, and it occurs when fewer attribute values are provided than the number of attributes defined in the table.

**ERROR CODE: -570, 'Could not access Glo data file "%1\$s".'**

- This message is displayed when, in the CUBRID database loaddb command, it cannot access a GLO (Generalized Large Object) data file, it mainly occurs when processing BLOB (Binary Large Object) or CLOB (Character Large Object) data during the data loading process, and it occurs when the path to the LOB data file is wrong, the file does not exist, or there are no permissions.

**ERROR CODE: -571, 'Instance was previously created through a forward reference. This is not allowed for instances created using constructor methods.'**

- This message is displayed when, in the CUBRID database loaddb command, it tries to create again, using a constructor method, a record that has already been created through a forward reference, it mainly occurs when creating a table record during the data loading process.

**ERROR CODE: -576, 'Reference to class %3\$s is not compatible with the domain of %1\$s of %2\$s.'**

- This message is displayed when, in the CUBRID database loaddb command, when referencing a table object, the reference is not compatible with the domain of a specific attribute, it mainly occurs when creating or updating a table record during the data loading process, and it occurs when the table reference does not match the attribute's domain.

**ERROR CODE: -579, 'Target domain must include type "object" to allow references to classes.'**

- This message is displayed when, in the CUBRID database loaddb command, the domain type is not correct when referencing a table object, to reference a table object, the target domain must include the "object" type, this is a special requirement for table references in CUBRID's type system.

**ERROR CODE: -581, 'Attempted to update the database when updates are disabled.'**

- This message is displayed when trying to modify the database while database updates are disabled because the CUBRID database server is in standby or to\_be\_active status, the state where database updates are disabled can occur in read-only mode or in special situations.

**ERROR CODE: -582, 'Unknown storage purpose %1\$d. Valid range is from %2\$d to %3\$d.'**

- This message is a disk management error that occurs when the purpose (purpose) of a volume is invalid in the CUBRID database, the volume purpose is a value indicating whether the data is permanent (permanent) or temporary (temporary), and because a value outside the valid range is passed, the volume cannot be created or managed.

**ERROR CODE: -588, 'INTERNAL ERROR: Assertion '%1\$s' failed.'**

- This message is an internal error that occurs when, due to an internal error in the CUBRID database, a specific condition has failed, when this error occurs it means there is a problem in CUBRID's internal logic.

**ERROR CODE: -589, 'Invalid user name "%1\$s"'**

- This message indicates that the user name is invalid or does not exist in the CUBRID database, it occurs when validating a user name in user authentication, privilege management, stored procedure creation, and so on, and it can occur when referencing a user that does not exist.

**ERROR CODE: -595, 'The database name "%1\$s" is too long. Database name should be less than %2\$d characters.'**

- This message is displayed in CUBRID when the database name exceeds the maximum length and it tries to create a volume file name that is the same as the database name.

**ERROR CODE: -611, '%1\$s cannot be executed in client/server mode.'**

- This message appears when a specific feature cannot be executed in client/server mode in the CUBRID database, it means that the feature can be executed only in standalone mode.

**ERROR CODE: -612, 'Logging cannot be disabled at this moment since there are pending actions to recover.'**

- This message occurs when attempting to disable logging in CUBRID database loaddb -S when using -no-logging, it means that logging cannot be disabled when there are pending actions to recover.

**ERROR CODE: -619, 'Bad source codeset.'**

- This message appears when the source (source) codeset is invalid or unsupported during codeset conversion of a string in the CUBRID database, it can occur when the source codeset is specified incorrectly when converting a string from one codeset to another codeset.

**ERROR CODE: -629, 'Pagesize %1\$d is not a power of 2 or pagesize is too small. Pagesize of %2\$d is used instead.'**

- This message is a warning that occurs when setting the page size in the CUBRID database, it appears when the page size specified by the user is not a power of 2 or is smaller than the minimum size, and it notifies that the CUBRID system has automatically adjusted it to a valid page size.

**ERROR CODE: -630, 'Conversion not supported by %1\$s.'**

- This message is displayed when the CUBRID database attempts conversion between certain data types but the conversion is not supported by the system, it occurs when an internal function attempts conversion between types, for example, when attempting an unsupported data type combination or conversion between composite types, this error may occur.

**ERROR CODE: -632, '%1\$s is not a backup volume.'**

- This message is displayed when, in the CUBRID database, the specified file or directory is not a valid backup volume, it appears when the header of the backup file cannot be read or when the magic number of the backup file is not correct, and it occurs when trying to recognize a file in a format other than a CUBRID backup file as a backup file.

**ERROR CODE: -633, '1\$s is a backup of database %2\$s created on %3\$s instead of given database %4\$s created on %5\$s'**

- This message is displayed when restoring a backup file in the CUBRID database, it appears when the backup file is a backup of another database or a backup of a database created at another point in time, and it occurs when the database specified by the user and the database information contained in the backup file do not match.

**ERROR CODE: -634, 'A database volume/file was expected in backup.'**

- This message is displayed when restoring a backup file or checking the list in the CUBRID database, it appears when database volume or file information cannot be found in the backup

file, and it occurs when the structure of the backup file is damaged or differs from the expected format.

**ERROR CODE: -648, 'Backup is incompatible with current "%1\$s" release "%2\$s"'**

- This message is displayed when a backup file is not compatible with the current CUBRID version in the CUBRID database, it indicates a compatibility problem between the CUBRID version that created the backup file and the CUBRID version attempting recovery, and it occurs when the backup file is not supported in the current version.

**ERROR CODE: -669, 'Server refused client connection: max clients, (%1\$d), exceeded.'**

- This message occurs when the CUBRID database server refuses a new client connection because the configured maximum number of client (max\_clients) connections has been exceeded, it is a mechanism that limits the number of concurrent connections to protect server resources and maintain performance, and it means that the number of currently active client connections has exceeded the maximum value allowed by the server.

**ERROR CODE: -675, 'Cannot read the database location file, '%1\$s''**

- This message is displayed when the CUBRID database system attempted to read the database location file (e.g., *databases.txt*) but failed, this file is used by CUBRID to identify the location and information of databases registered in the system, and this error occurs when the file cannot be accessed or its contents are damaged.

**ERROR CODE: -676, 'Database '%1\$s', cannot be found in the database location file, '%2\$s''**

- This message is displayed when the CUBRID database system tries to start or connect to a specific database, but information for that database is not found in the database location file (e.g., *databases.txt*), CUBRID manages the location and information of databases registered in the system through a configuration file such as *databases.txt*, and if there is no database information in this file, the system cannot recognize that database.

**ERROR CODE: -677, 'Failed to connect to database server, '%1\$s', on the following host(s): %2\$s'**

- This message is displayed when a client in the CUBRID database attempted to connect to the database server on the specified host(s) but failed, it indicates a situation where the database server cannot be connected to due to various causes such as network connection, server status, authentication, and so on, and for detailed causes it is necessary to check csq, err files, or \$CUBRID/log/\*.err files, and so on.

**ERROR CODE: -695, 'Wrong interface has been used to kill a client.'**

- This message occurs when, in the CUBRID database, when trying to forcibly terminate a client session with the killtran command, the wrong interface or inappropriate parameters are used, to perform a client termination operation, information such as transaction index, user name,

host name, and so on is required, but this error occurs when such information is insufficient or incorrect.

**ERROR CODE: -696, 'Unknown transaction (index %1\$d, %2\$s@%3\$s|%4\$d).'**

- This message occurs when, in the CUBRID database, when trying to forcibly terminate a specific transaction with the killtran command, the transaction corresponding to the requested transaction index does not exist in the system, it can mainly occur when the client uses an incorrect transaction index, or when the transaction has already ended and has been removed from the system.

**ERROR CODE: -697, 'Given transaction index (index %1\$d, %2\$s@%3\$s|%4\$d) does not match with current transaction index (index %5\$d, %6\$s@%7\$s|%8\$d). Likely, the given transaction has finished and its transaction index was re-assigned to another transaction.'**

- This message occurs when, in the CUBRID database, when trying to forcibly terminate a specific transaction with the killtran command, the requested transaction index does not match the transaction information recognized by the current system, it can mainly occur when the client has an old (stale) transaction index, or when the transaction has already ended on the server and the index was reassigned to another transaction.

**ERROR CODE: -743, 'Failed on handshake between client and server. (peer host %1\$s)'**

- This message is an error that appears when an error occurs during the initial connection setup process (handshake) between the client and the server in the CUBRID database, handshake is the process of checking each other's version, features, and compatibility before the client and server start communication, and it occurs when the client version information cannot be received or when the feature compatibility check between the server and client fails, it can occur due to network connection problems or server status problems.

**ERROR CODE: -752, 'Error restoring backup unit\_num %1\$d.'**

- This message is a general I/O error that occurs while restoring CUBRID database backup, while reading data from the backup file, it can occur due to various causes such as physical damage to the backup file, disk I/O errors, file access permission issues, or backup file format mismatch.

**ERROR CODE: -753, 'Error restoring backup unit\_num %1\$d, pageid %2\$d exceeds total number of pages %3\$d for valid %4\$d.'**

- This message occurs when, during the process of restoring a CUBRID database backup, the page ID in the backup file is outside the valid page range of the target volume to be restored, it can occur when the metadata of the CUBRID backup file is damaged, or when attempting to restore to a different environment than when the backup was created (e.g., a smaller volume size).

**ERROR CODE: -755, '%1\$s cannot be executed in stand-alone mode.'**

- This message occurs when, while running in stand-alone mode in the CUBRID database, an operation that requires client-server communication is attempted, it indicates this error that occurs when a specific operation or command such as checkpoint cannot be executed in stand-alone mode in the CUBRID database.

**ERROR CODE: -757, 'Internal Error: cannot assign permanent OID during object encode.'**

- This message occurs when, in the CUBRID database, during the process of encoding an object, it fails to assign a permanent OID. OID is an important value that uniquely identifies each object in the database. Failure to assign a permanent OID means that there is a problem in the object creation or persistence process, it can occur mainly due to internal data consistency problems, insufficient storage space, transaction problems, or internal logic errors, and so on.

**ERROR CODE: -767, 'Cannot create a level %1\$d backup without first creating a level %2\$d backup.'**

- This message occurs when, in the CUBRID database, when performing incremental backup, continuity of backup levels is not guaranteed, in this case, when specifying the backup level, 2 causes an error when there is no level 1 backup, and 1 causes an error when there is no level 0 backup, and CUBRID supports the following backup levels:

Level 0 (Full Backup): Full database backup  
Level 1 (Big Incremental): Incremental backup based on level 0 backup  
Level 2 (Small Incremental): Incremental backup based on level 1 backup

**ERROR CODE: -769, 'Attribute "%1\$s", of class "%2\$s" is not a valid class or shared attribute.'**

- This message indicates, when processing table attributes while executing the loaddb command in the CUBRID database, that the specified attribute is not a valid table attribute or shared attribute, it occurs in CUBRID's data loader mechanism, and can mainly occur due to failure of the attribute namespace validation.

**ERROR CODE: -771, 'Invalid parameter for function.'**

- This message occurs when, in the CUBRID database, the parameter passed during a function call is invalid or does not follow the expected format, an error occurs when CUBRID's internal specific function fails in the process of validating the parameter validity required to perform its work.

**ERROR CODE: -778, 'Cannot create a symbolic link "%1\$s" to the file "%2\$s".'**

- This message indicates a situation where creation of a symbolic link fails in the CUBRID database, it occurs in CUBRID's file system management mechanism, and can mainly occur when executing createdb, copydb, renamedb commands.

**ERROR CODE: -820, 'Cannot initialize a connection.'**

- This message is an internal error that occurs when the CUBRID system fails to initialize a connection between the client and server, connection initialization is the process of creating a connection object when the client connects to the server, allocating necessary resources, and setting the connection state, failure in this process means that memory allocation failure, client ID allocation failure, mutex initialization failure, and so on have occurred, connection initialization failure prevents the client from connecting to the server, making use of the database service impossible.

**ERROR CODE: -821, 'Shutdown a connection.'**

- This message is an internal error that occurs when the CUBRID system forcibly terminates a connection between the client and server, rather than an error, it is an informational message that the system is terminating a specific connection, it mainly occurs during the slam transaction process, and it is the process of cleaning up all resources related to that connection.

**ERROR CODE: -827, 'Connection list traverse function returned invalid value.'**

- This message is an internal error that occurs when, in the process of traversing the connection list by the CUBRID system, a callback function returns an invalid return value, an invalid return value means that there is a bug in the callback function or an unexpected situation has occurred.

**ERROR CODE: -829, 'This mutex lock has been unlocked already.'**

- This message occurs when releasing a critical section in the thread management module of the CUBRID database, that is, it is an error message that occurs when trying to unlock a critical section that has already been unlocked, it indicates a programming error or a problem in the concurrency control logic, and it is a safeguard to prevent double unlocking of a mutex lock.

**ERROR CODE: -831, 'All transaction descriptors(%1\$d) are in use. Raise up max\_clients parameter.'**

- This message occurs when the CUBRID database receives connection requests exceeding the max\_clients setting value in its configuration, it can occur when too many clients connect to the database simultaneously beyond the max\_clients parameter setting value, or when existing clients continue to remain without ending their transactions.

**ERROR CODE: -832, 'Backup is already running. Backup cannot be run by two processes.'**

- This message occurs in the log page buffer management module of the CUBRID database to prevent duplicate execution of backup (backupdb) tasks, it occurs when the database administrator tries another backup before the backup job is completed, or when multiple clients request backup at the same time.

**ERROR CODE: -835, 'Undefined statistics item.'**

- This message occurs when trying to reference an undefined statistics item in the statistics management module of the CUBRID database, CUBRID supports only a limited number of statistics items, and it returns this error for requests outside that range.

**ERROR CODE: -837, 'Cannot drop the user who owns database objects.'**

- This message occurs when trying to delete a user in the user management module of the CUBRID database, as a constraint to ensure database integrity and security, it prevents objects owned by the user from being deleted indiscriminately. Before deleting a user, you must first delete all database objects owned by that user or transfer ownership to another user.

**ERROR CODE: -841, 'Requested operation can be executed by only sole client(transaction).'**

- This message occurs when trying to perform a specific operation in the system parameter management module of the CUBRID database in a situation where multiple clients (transactions) are connected at the same time, it indicates a constraint for operations that must be performed only in a single-client environment to ensure data consistency and stability when changing certain system parameters or performing certain administrative operations.

**ERROR CODE: -877, 'No data to be unloaded.'**

- This message occurs during the process of unloading (unload) schema or data in the CUBRID database, such a situation generally appears when there is no schema information in the database, or when the table or object to be unloaded does not exist.

**ERROR CODE: -878, 'Invalid database location file, '%1\$s''**

- This message occurs during the process of reading and parsing the *databases.txt* file in the CUBRID database.

Such a situation generally appears when, at database startup, the format of the *databases.txt* file is not correct, or when required information (database name, path, host, log path, etc.) is missing.

**ERROR CODE: -883, 'Failed to get '%1\$s' file status.'**

- This message occurs when, in the CUBRID database, when executing the *renamedb* command, it tries to obtain status information of a specific file or directory, it can occur due to file system access issues, the file not existing, and so on.

**ERROR CODE: -884, 'Volext-pathname '%1\$s' is not permitted to write.'**

- This message occurs when, in the CUBRID database, when executing the *renamedb* command, there is no write permission for a specific path, it means that a file operation essential to database operation has failed due to file system access permission issues.

**ERROR CODE: -885, 'Failure to move from '%1\$s' to '%2\$s'. Use the same device(disk).'**

- This message occurs when, in the CUBRID database, when executing the command with renamedb -E option, it tries to move extension volume files to a different location, it is a protective error to protect database integrity and performance.

**ERROR CODE: -896, 'Compression failed. Zip Method: %1\$d (%2\$s), Zip Level: %3\$d (%4\$s)'**

- This message occurs because compression failed when compressing varchar data or log data using the LZ4 compression algorithm in the CUBRID database.

**ERROR CODE: -897, 'Decompression failed.'**

- This message occurs in the process where CUBRID decompresses data compressed with the LZ4 algorithm. It can occur when decompressing object (varchar) data or log data, and it indicates a failure due to data corruption or memory problems.

**ERROR CODE: -910, 'Not allowed access to partition.'**

- This message occurs when, in the CUBRID database, an attempt to access a specific partition is denied due to insufficient privileges, a partition state problem, or an incorrect access method, that is, the database system needs to access a specific partition to perform the operation requested by the user (e.g., data insert, query, update, delete, or schema change), but it occurs when there is no access privilege to that partition or the partition itself is in an inaccessible state (e.g., offline, corrupted).

Such a situation generally appears when performing DML/DDI operations on a partitioned table, when the user account does not have the required privileges, when the partition is damaged and cannot be accessed, or when there is a problem in the partition management logic internally in the system, and it is a protective error to protect database security, data integrity, and system stability.

**ERROR CODE: -941, 'The operation is not supported.'**

- This message is a generic error code that can occur in various situations in the client interface of the CUBRID database, that is, it is used when the requested operation is not supported in the current CUBRID version or implementation.

**ERROR CODE: -962, 'Out of memory'**

- This message occurs when the DBlink gateway of the CUBRID database fails to allocate memory.

**ERROR CODE: -969, 'Server bit platform (%1\$d) is different from client bit platform (%2\$d).'**

- This message occurs when, when a CUBRID database client attempts to connect to the server, it detects that the client and server are running on different bit platforms (e.g., a 32-bit client and a 64-bit server, or vice versa), CUBRID recommends running in the same bit platform environment for stable communication and data consistency between client and server, and

when the bit platforms differ like this, it refuses the connection and raises this error, it is a protective error to prevent data corruption or unexpected behavior.

**ERROR CODE: -971, 'Program '%1\$s' (pid %2\$d) connected to database server '%3\$s' on the host '%4\$s' (port %5\$d).'**

- This message is a notification that occurs when a client successfully connects to a CUBRID database server, it is an informational message indicating a normal connection state rather than an actual error, and it shows in detail the client's connection information and the server access state.

**ERROR CODE: -972, 'Program '%1\$s' (pid %2\$d) was connected from the host '%3\$s'. (transaction index %4\$d).'**

- This message is an informational log message notifying that a client program has successfully connected to the CUBRID database, it is not an actual error, but records that the database server has accepted the client's connection request and established a session. This message provides important information for system administrators to trace and monitor which client connected to the database when, from where, and with which program, in particular, it can be used usefully during abnormal connection attempts or security audits.

**ERROR CODE: -973, 'Server status is %1\$s.'**

- This message is an informational message that tells the current state of the server in the CUBRID database, it is not actually an error, but a notification message that records the current state of the server in the log during the boot process or HA (High Availability) state changes, the server starts in DOWN state during the boot process and transitions to UP state, or outputs this message when switching to MAINTENANCE mode in an HA environment, it helps system administrators monitor the current state of the server and debug when problems occur.

**ERROR CODE: -974, 'Archive log "%1\$s" is created to archive pages from %2\$lld to %3\$lld.'**

- This message is an informational message rather than an actual error, indicating that the database system has successfully created an archive log file for a specific range of pages. This is part of the normal log archiving process for database backup and recovery.

**ERROR CODE: -977, 'Checkpoint started (previous checkpoint page id: %1\$lld, previous redo page id: %2\$lld).'**

- This message is a system notification that informs that a checkpoint operation has started in the CUBRID database. It indicates the start of an important operation to ensure the database's consistency and recoverability.

**ERROR CODE: -978, 'Checkpoint finished (checkpoint page id: %1\$lld, checkpoint redo page id: %2\$lld, flushed page count: %3\$d).'**

- This message is a system notification that informs that a checkpoint operation has been completed in the CUBRID database. It indicates the successful end of the operation together with information about the pages processed during the checkpoint process.

**ERROR CODE: -982, 'Set interrupt to the transaction %1\$d.'**

- This message indicates that an interrupt (stop signal) has been successfully set for a specific transaction in the CUBRID database, this generally means that there was an attempt to stop execution of the transaction due to external factors (e.g., user request, forced termination command by an administrator, timeout, etc.), and that attempt was processed internally by the system, it is closer to an informational message that the transaction interruption request has been processed rather than an error. When an interrupt is set, the transaction can stop its current work and may be rolled back.

**ERROR CODE: -984, 'Cannot set %3\$s to "%6\$s" in the "[%5\$s]" section when it is set to "%4\$s" in the "[%2\$s]" section of the configuration file "%1\$s".'**

- This message occurs when the `ha_mode` parameter setting value in the CUBRID configuration file (`$CUBRID/conf/cubrid.conf`) is set to a different value, it is a protective error to ensure consistency of the configuration file and prevent conflicts of parameter values, and it can occur especially for important parameters such as HA (High Availability) mode.

**ERROR CODE: -985, 'The hostname on the database connection string should be specified when multihost is set in "databases.txt". ex) csql demodb@localhost'**

- This message occurs when a CUBRID database client attempts to connect to a database for which the *multihost* option is enabled in the *databases.txt* file. The *multihost* option indicates that the database can be serviced across multiple hosts, and in this case the client must explicitly specify the host name of the specific server it wants to connect to, if the client attempts to connect with only the database name, such as *csql demodb*, CUBRID cannot know which host to connect to and therefore raises this error, it is a protective error to guide the client to connect to the correct server record and prevent ambiguous connection attempts.

**ERROR CODE: -991, 'Flush victim candidates of page buffer started.'**

- This message is a system message that informs that the flush operation for victim candidate pages has started in the page buffer of the CUBRID database. It indicates the start of an important operation that writes dirty pages to disk for memory management.

**ERROR CODE: -992, 'Flush victim candidates of page buffer finished (count: %1\$d).'**

- This message is a system message that informs that the flush operation for victim candidate pages has completed in the page buffer of the CUBRID database. It indicates the successful end of the operation together with the number of flushed pages.

**ERROR CODE: -994, 'This statement cannot be a prepared statement.'**

- This message occurs when, in the CUBRID database, attempting to use prepared statement syntax (prepare, execute, deallocated/drop) in the prepare from statement.

**ERROR CODE: -995, 'A prepared statement with the name %1\$s does not exist.'**

- This message occurs when, in the CUBRID database, attempting to execute a prepared statement with a specific name using the *EXECUTE* statement, a prepared statement is an SQL statement prepared in advance through the *PREPARE* statement and executed through *EXECUTE*, but this error occurs when the prepared statement with the requested name does not exist in the current session.

This can occur in the following situations, when the prepared statement has not been created yet, when the session has ended and the prepared statement has been deleted, when the prepared statement name was entered incorrectly, or when trying to execute a prepared statement created in another session in the current session, because prepared statements are managed per session, when the session changes you cannot access statements prepared previously.

**ERROR CODE: -1001, 'An unexpected condition or state has been reached. %1\$s'**

- This message occurs when the CUBRID database system internally encounters an unexpected state or condition, it is a comprehensive error code used for general internal error situations that the developer did not anticipate or that are difficult to assign a specific error code to, it usually provides a description of the specific error situation to help trace the cause of the problem. This message can occur due to logical defects in the database, data corruption, abnormal system state, or environmental issues.

**ERROR CODE: -1009, 'COMPACTDB already started.'**

This error code occurs when there is already a COMPACTDB process running and you attempt a new COMPACTDB operation.

**ERROR CODE: -1066, 'Session expired.'**

- This message occurs when a client session in the CUBRID database has expired by exceeding its validity period. A session is a logical unit that maintains the connection state between the client and server and stores user-specific information. When a session expires, all work in progress through that session is interrupted, and the client loses access rights to the database. This can mainly occur due to session timeout settings, prolonged client inactivity, or unstable network connections, and it is a protective error for database security and resource management.

**ERROR CODE: -1069, 'Too many prepared statements.'**

- This message occurs when, in the CUBRID database, a single session attempts to prepare or use statements by exceeding the maximum allowed number of prepared statements, this is in the

PREPARE STMT syntax, the database system limits the number of prepared statements per session to prevent excessive memory use or resource exhaustion. This message mainly appears when the application or queries use more prepared statements than expected, or when related parameters such as `MAX_PREPARED_STMT_COUNT` are set too low compared to the current workload, and it is a protective error for database stability and resource management.

**ERROR CODE: -1070, 'Session variable '@%1\$s' not defined.'**

- This message occurs when, in the CUBRID database, trying to use a session variable that does not exist or is not defined in the current session. A session variable is a temporary variable valid only within a specific user session, and the database system returns this error when it cannot find the requested variable. This can occur due to a typo in the variable name, the variable not being defined, or an access attempt outside the valid scope (scope), and it is a protective error to prevent operations on non-existent data and ensure data integrity.

**ERROR CODE: -1071, 'Too many session variables.'**

- This message occurs when, in the CUBRID database, a single session attempts to create or use session variables by exceeding the maximum allowed number of session variables. A session variable is a temporary variable valid only within a specific user session, and the database system limits the number of session variables to prevent excessive memory usage or resource exhaustion.

**ERROR CODE: -1072, 'IP address(%1\$s) is not authorized.'**

- This message occurs when the CUBRID database server determines that the client's IP address is not authorized in the Access Control List (Access Control List, ACL). That is, it means that the IP address attempting to connect to the database has been blocked by the server's security policy. This is a protective error to prevent unauthorized access to the database and strengthen security.

**ERROR CODE: -1073, 'Invalid format in file(%1\$s).'**

- This message occurs when the CUBRID database system, in the process of reading and parsing a specific file (especially an IP access control file), the contents of that file do not follow the expected format or grammar. This can mainly occur due to typos in the file contents, incorrect syntax, or abnormal modification. If this error occurs, CUBRID cannot apply the settings in the file correctly, so service startup may fail or unexpected access control issues may occur. This is an integrity issue with a configuration file that is essential to system security and stable operation, and immediate checking and correction are required.

**ERROR CODE: -1074, 'Cannot read access list file(%1\$s).'**

- This message occurs when the CUBRID database system fails to open or read a specific access list file (Access List File). The access list file is an important configuration file used to define CUBRID's security and access control policy. This message mainly appears when the file does

not exist, the file path is incorrect, the user running the CUBRID process does not have read permission for the file, or the file itself is damaged. If this error occurs, CUBRID cannot apply the correct access control policy, so service startup may fail or unexpected access problems may occur.

**ERROR CODE: -1076, 'Could not load system parameter.'**

- This message occurs when the CUBRID database system fails to load essential system parameters (e.g., settings defined in the *cubrid.conf* file) during startup or initialization. System parameters are very important for configuring how the database works, resource allocation, and operational policy. If it cannot load these parameters, the system cannot configure itself properly, leading to startup failure or abnormal behavior, and it is a critical error that prevents the database from functioning correctly.

**ERROR CODE: -1077, 'The '%1\$s' parameter at line %2\$d in file '%3\$s' : Unknown parameter'**

- This message occurs when the CUBRID database system, in the process of reading and parsing a configuration file such as *cubrid.conf*, finds a parameter name that the system does not recognize or support. This can generally occur due to a typo in the parameter name, use of a parameter that is no longer supported in the current CUBRID version, or abnormal modification of the configuration file. If this error occurs, CUBRID cannot process that parameter, so the server or related services may not start normally or may operate in an unexpected way. This is an integrity issue with a configuration file that is essential to stable operation of the system, and immediate checking and correction are required.

**ERROR CODE: -1078, 'Character at offset %1\$d is invalid with current codeset.'**

- This message occurs when, in the CUBRID database, when executing the *loaddb* command, it finds an invalid character that cannot be handled with the currently set character set (codeset). It occurs because the actual encoding of the data and the system's *codeset* setting do not match during the internal string processing process, and it is a protective error to ensure data integrity and correctness of string processing.

**ERROR CODE: -1087, 'Backup active log '%1\$s' started.'**

- This message is an informational notification message indicating that the backup operation of an active log file has started in the CUBRID database. It means that the system has started the log backup process and is performing work to secure data stability and recoverability. It is generally an informational message that records the start of an important operation in a database management system.

**ERROR CODE: -1088, 'Backup active log '%1\$s' finished.'**

- This message is a success notification message indicating that the backup operation of an active log file has successfully completed in the CUBRID database. It means that the system has performed the log backup normally to secure data stability and recoverability. It is generally an

informational message recorded when an important operation in a database management system has been successfully finished.

**ERROR CODE: -1090, 'Locale initialization: %1\$s.'**

- This message appears when a problem occurs during the process in which the CUBRID database initializes locale-related information. Locale is an important setting that defines language, country, and character encoding rules so that data sorting, string comparison, and character set conversion can be performed correctly. If an error occurs in this process, it means there is a problem with the system's locale settings, CUBRID's configuration, or the operating system's locale support capabilities. This can affect character set processing, internationalization features, and overall data integrity, and it is an important error.

**ERROR CODE: -1091, 'Locale generation: %1\$s.'**

- This message appears when a problem occurs during the process in which the CUBRID database generates or processes locale-related information. Locale is an important setting that defines language, country, and character encoding rules so that data sorting, string comparison, and character set conversion can be performed correctly. If an error occurs in this process, it means there is a problem with the system's locale settings, CUBRID's configuration, or the operating system's locale support capabilities. This can affect character set processing, internationalization features, and overall data integrity, and it is an important error.

**ERROR CODE: -1093, 'The arg '%1\$s' for inet\_aton is not a valid string formatted ipv4 address.'**

- This message occurs when, in the CUBRID database, when using the *inet\_aton* function to convert a string-formatted IP address into a numeric format, the input argument is not a valid IPv4 address string format. The *inet\_aton* function is a standard library function that converts a string IPv4 address in the "a.b.c.d" format to a 32-bit integer in network byte order. This message mainly occurs due to incorrect data input, data type mismatch, or abnormal values, and it means that operations requiring IP address conversion (e.g., network-related functions, log recording, specific data processing) have failed. This is a protective error due to data validity check failure.

**ERROR CODE: -1094, 'The arg '%1\$lld' for inet\_ntoa is not a valid number formatted ipv4 address.'**

- This message occurs when, in the CUBRID database, when using the *inet\_ntoa* function to convert a numeric-formatted IP address into a string format, the input argument is not a valid IPv4 address format. The *inet\_ntoa* function is a standard library function that converts a 32-bit integer IPv4 address in network byte order to a string in the "a.b.c.d" format. This message mainly occurs due to incorrect data input, data type mismatch, or abnormal values, and it means that operations requiring IP address conversion (e.g., network-related functions, log recording, specific data processing) have failed.

**ERROR CODE: -1095, 'User name is too long.'**

- This message occurs when, in the CUBRID database system, when creating or changing a user name (User Name), the length of the entered user name exceeds the maximum length allowed by the system, that is, during the process where the CUBRID server handles user management operations, if the user name provided through commands such as *CREATE USER* or *ALTER USER* exceeds the internally defined maximum string length, it returns this error. This is a protective constraint to maintain consistency of the database schema and system metadata and to prevent potential issues such as internal buffer overflow.

**ERROR CODE: -1099, 'DDL statement is not allowed by configuration (block\_ddl\_statement=yes).n SQL Text: %1\$s'**

- This message is displayed when trying to execute a DDL (Data Definition Language) statement in the CUBRID database, that is, when the system parameter *block\_ddl\_statement* is set to *yes*, it is a protection feature that blocks schema change operations such as creating, modifying, and dropping tables, it is a protective error to ensure stability and security of the database schema and prevents unintended schema changes, it checks whether it is a DDL statement with the *pt\_is\_ddl\_statement* function in a DDL statement and allows or blocks execution according to the system parameter setting.

**ERROR CODE: -1100, 'Statement without WHERE clause is not allowed by configuration (block\_nowhere\_statement=yes).'**

- This message is displayed when trying to execute a DELETE statement without a WHERE clause in the CUBRID database, that is, when the system parameter *block\_nowhere\_statement* is set to *yes*, it is a protection feature that blocks execution of dangerous SQL statements that delete all records without conditions, it is a protective error to ensure data integrity and system stability and prevents accidentally deleting data of an entire table, it mainly occurs by detecting the case where *search\_cond* (search condition) is NULL in a DELETE statement, and allows or blocks execution according to the system parameter setting.

**ERROR CODE: -1102, 'Unknown system parameter or bad value.'**

- This message is displayed when setting or changing a system parameter in the CUBRID database when there is no change value, that is, it occurs when referencing a system parameter that does not exist, or when the parameter value is outside the allowed range or format, it is a protective error to ensure system stability and data integrity.

**ERROR CODE: -1103, 'Cannot change system parameter.'**

- This message is displayed when trying to change a system parameter in the CUBRID database when there is no change value, that is, it occurs when attempting to change a parameter that cannot be changed dynamically while the database is running, or when trying to modify a parameter for which there is no change permission, it is a protective error to ensure system stability and data integrity.

**ERROR CODE: -1104, 'Slow query (%1\$d msec)n%2\$s'**

- This message is not actually an error but an informational message for performance monitoring in the CUBRID database, that is, it detects that a query that took longer than the configured threshold has been executed and provides detailed information for performance analysis, it is an important monitoring feature for database performance optimization and problem diagnosis, and the system collects detailed information such as query execution time, SQL statement, execution plan, buffer statistics, wait time, and so on to help identify performance bottlenecks.

**ERROR CODE: -1115, 'Started to update statistics (class "%1\$s", oid : %2\$d|%3\$d|%4\$d).'**

- This message is not actually an error but an informational message that indicates that the statistics update *update statistics* operation in the CUBRID database has started, that is, it means that the operation to update statistics (index statistics, column distribution, cardinality, etc.) of a table has started, it is a positive message that indicates that the process of collecting and updating statistics information necessary for query optimization has started, updating statistics is an important operation to optimize query execution plans by analyzing table data distribution, index structure, column value distributions, and so on.

**ERROR CODE: -1116, 'Finished to update statistics (class "%1\$s", oid : %2\$d|%3\$d|%4\$d, error code : %5\$d).'**

- This message is not actually an error but an informational message that indicates that the statistics update *update statistics* operation in the CUBRID database has completed, that is, it means that the operation to update statistics (index statistics, column distribution, cardinality, etc.) of a table has ended normally, it is a positive message that indicates that the process of collecting and updating statistics information necessary for query optimization has completed.

**ERROR CODE: -1117, 'Cannot change attribute "%1\$s". CUBRID cannot change an attribute as a SHARED and vice versa.'**

- This message occurs when attempting to change the SHARED attribute property of an already defined attribute in CUBRID. The SHARED attribute is a property determined at table definition time, and it cannot be changed afterward.

**ERROR CODE: -1123, 'pthread\_cond\_timedwait() timed out.'**

- This message occurs when a thread used internally by the CUBRID database waits for a critical section (e.g., buffer latch, etc.) and exceeds the specified time.

**ERROR CODE: -1130, 'Transaction is aborted because transaction lock counts exceeds %1\$d'**

- This message occurs when the number of locks held by a transaction in the CUBRID database exceeds the threshold set in the system, that is, it occurs when, in the \$CUBRID/conf/cubrid.conf configuration parameters, *rollback\_on\_lock\_escalation* is true, and the configured

threshold of lock escalation is exceeded, such a situation can generally occur when many row locks are required in queries that process a large amount of data.

**ERROR CODE: -1132, 'Encryption library failure: %1\$s'**

- This message is an error that occurs during encryption/decryption related to encryption in the CUBRID dblink server.

**ERROR CODE: -1135, 'A previous link of B+tree(%1\$s) is corrupted.: vpid = (%2\$d, %3\$d)'**

- This message is a warning message indicating that b-tree corruption was detected when executing the CUBRID database `checkdb -repair-prev-link` command.

**ERROR CODE: -1136, 'A previous link of B+tree(%1\$s) is repaired.: vpid = (%2\$d, %3\$d)'**

- This message is a warning message indicating that the b-tree corruption detected when executing the CUBRID database `checkdb -repair-prev-link` command has been repaired.

**ERROR CODE: -1138, 'Handshake error (peer host %1\$s): incompatible interruptibility. (client: %2\$s, server: %3\$s)'**

- This message occurs during the handshake process that establishes a network connection between the CUBRID database client and the server when the two sides' 'interruptibility' settings are not compatible with each other; that is, it means that a communication connection cannot be established because the client and the server do not agree on how to handle interrupts (e.g., Ctrl+C or *KILL TRANSACTION*) during transaction or query execution; this is a protective error to ensure the consistency and stability of network communication.

**ERROR CODE: -1145, 'To change the owner of a system class is not allowed.'**

- This message occurs when you attempt to change the owner of a 'system table' that plays an important internal role in the CUBRID database; that is, in order to maintain the core structure and security of the database, it is a protective error that does not allow even a normal user or a user with specific privileges to arbitrarily change the ownership of a system table; this situation generally occurs when you try to change the owner for a system table using a DDL (Data Definition Language) statement such as `ALTER CLASS ... CHANGE OWNER TO ...`; this is an important security policy to protect the stability and integrity of the database.

**ERROR CODE: -1152, 'The owner or a member of DBA group is only allowed to kill the transaction (%1\$d).'**

- This message occurs when, in the CUBRID database, a user without the required privileges attempts to forcibly terminate (kill) a specific transaction; that is, transaction termination is designed so that only users with restricted privileges can perform it for database stability and security; this situation generally occurs when a normal user tries to terminate another user's transaction, or when trying to terminate a system transaction; this is a protective error to protect the database security policy and integrity.

**ERROR CODE: -1158, 'Serializable conflict due to concurrent updates'**

- This message occurs when, in the CUBRID database, a transaction running at the *SERIALIZABLE* isolation level conflicts with update work from another concurrent transaction and the serializability is broken. The *SERIALIZABLE* isolation level is the strictest level that guarantees that concurrently executed transactions produce the same result as if they had been executed sequentially. This message occurs when the data that the current transaction tries to access has been changed by another transaction, or when a non-serializable phenomenon such as a phantom read is detected, and, in order to maintain data consistency, it rolls back one of the conflicting transactions. This is normal behavior caused by the strict nature of the *SERIALIZABLE* isolation level.

**ERROR CODE: -1159, 'Timezone compile error: %s'**

- This message indicates that a problem occurred while the CUBRID database internally processes or “compiles” timezone data; it includes logic to parse timezone rules and data and convert them into a form that can be used internally. This message mainly occurs when the timezone data files installed on the system are corrupted, the format is incorrect, or CUBRID fails to interpret the data. This can prevent the database from performing timezone-related operations accurately and is an important issue that can affect the validity and consistency of date/time data.

**ERROR CODE: -1160, 'Timezone library loader error: %s'**

- This message indicates that the CUBRID database failed to load the timezone library or data required to perform timezone-related operations. CUBRID relies on the system's timezone information for accurate processing of date/time data, especially for timezone conversion of *DATETIME WITH TIME ZONE* types or *TIMESTAMP* values; this message mainly occurs when timezone data files are missing, corrupted, lack access permissions, or timezone-related environment settings are incorrect. Failure to load the timezone library prevents the database from performing timezone-related features normally, which can lead to database startup failure or errors in date/time-related queries and operations.

**ERROR CODE: -1161, 'Timezone conversion error.'**

- This message indicates that an unexpected internal problem occurred while converting a date/time value from one timezone to another in the CUBRID database. CUBRID internally manages time based on UTC (Coordinated Universal Time) and converts the displayed time according to the timezone setting of the user session. This message can mainly occur in the following situations:

**ERROR CODE: -1162, 'Invalid or missing timezone.'**

- This message occurs when timezone information is invalid in the CUBRID database, or when timezone information required to perform date/time-related operations is missing. CUBRID requires valid timezone information to accurately process and convert date/time data.

**ERROR CODE: -1163, 'Invalid or missing daylight saving time.'**

- This message occurs when, while processing date/time values in the CUBRID database, Daylight Saving Time (DST) information is invalid or required DST information is missing. CUBRID strictly applies DST rules to ensure the accuracy of timezone conversion and date/time calculations. This message can mainly occur in the following situations:

**ERROR CODE: -1165, 'Invalid combination of date, time, timezone and daylight specifier.'**

- This message occurs when, in the CUBRID database, the combination of date, time, timezone, and daylight saving time (DST) specifiers is logically invalid; CUBRID validates in timezone-related operations whether the input date/time and timezone information and DST rules are consistent with each other. For example, this error occurs when the date and time given conflict with DST rules in the specified timezone, or when a non-existent time combination is specified (e.g., a time that does not exist during the DST transition interval). This is a validation mechanism to ensure the accuracy and consistency of data and prevents incorrect timezone conversion or calculations.

**ERROR CODE: -1166, 'The specified combination of date and time do not exist (during daylight saving interval).'**

- This message occurs when, in the CUBRID database, the date and time combination specified by the user is a time that does not actually exist due to the Daylight Saving Time (DST) transition interval of a particular timezone. For example, when DST starts and the clock jumps forward by one hour from 2 AM to 3 AM, the times from 2:00 AM to 2:59 AM do not exist on that date. When the user attempts to input or calculate such a non-existent time, CUBRID raises this error to ensure the validity of the data. This can mainly occur during date/time data insert, update, or when using date/time functions.

**ERROR CODE: -1167, 'Comment string cannot have more than 1024 bytes.'**

- This message indicates an error that occurs when, in the CUBRID database, the length of a comment (annotation) string for a user or an object exceeds the allowed maximum size of 1024 bytes. Comments are used to store descriptions or memos for database user objects (tables, columns, users, etc.), and there is a length limit for system stability and performance; that is, this message occurs when setting a user comment in the user authentication system of the CUBRID database.

**ERROR CODE: -1168, 'Unable to update statistics on table (%1\$s) because a lock is not immediately granted.'**

- This message indicates that, in the CUBRID database, an attempt was made to update the statistics of a specific table, but the operation failed because the required lock could not be acquired immediately. Statistics updates provide essential information for the query optimizer to establish an optimal execution plan; this message mainly occurs when another transaction holds an exclusive lock on the target table for statistics update, or when lock contention is

severe and the statistics update cannot obtain the needed lock in time. This means that the statistics update is delayed or fails, which can negatively affect the performance of queries executed afterward.

**ERROR CODE: -1177, 'Incompatible timezone data: %1\$s has different checksum from %2\$s.'**

- This message is an error indicating that the timezone data between the client and the server in the CUBRID database is not compatible with each other. CUBRID requires the client and server to use the same timezone data to ensure the accuracy of timezone-related operations. This message occurs when the checksums of the client's and server's timezone data differ, which means that different versions of timezone data are being used or the timezone data is corrupted. Since a mismatch of timezone data can cause inaccurate results of date/time conversion functions, the database raises an error in this situation to protect data integrity.

**ERROR CODE: -1179, 'Found not vacuumed entries in heap.'**

- This message is an informational or warning message that can occur when running the CUBRID `checkdb` command, indicating that there are entries (records) in the heap file (the space where a table's actual data is stored) that have not been vacuumed. When records are deleted or updated in a database, the space is not immediately reused and is marked as "dead" space. The vacuum operation reclaims such dead space and organizes it so it can be reused; this message tells you that vacuum work is needed, or that space that has not yet been cleaned up was found during a particular check process. This is information related to space efficiency and performance maintenance rather than a database consistency issue.

**ERROR CODE: -1180, 'Found not vacuumed OIDs. INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d| %4\$d| %5\$d).'**

- This message is an informational or warning message that can occur when running the CUBRID `checkdb` command, indicating that there are object IDs (OIDs) remaining in an index that have not been vacuumed (i.e., deleted but the space has not yet been reclaimed). When a record is deleted in a database, the OID of that record is not immediately reused and is cleaned up into an inactive or reusable state through vacuum work; this message tells you that such "uncleaned" OIDs exist in a specific index, which can mean inefficient use of index space or potential performance degradation. In general, this is information related to maintenance rather than a database consistency issue.

**ERROR CODE: -1186, 'checksumdb: %1\$s (error code: %2\$d).'**

- This message indicates that an internal problem occurred while running the `checksumdb` utility of the CUBRID database. `checksumdb` is a tool that checks the checksums of database files to verify whether data corruption exists; this message means that the utility could not complete its work normally due to various causes such as file access problems, data mismatches, internal logic errors, and so on during the checksum checking process.

**ERROR CODE: -1187, 'Invalid access on page %1\$d,%2\$d which was part of a deleted heap.'**

- This message occurs when, in the CUBRID database, an attempt is made to access a page that belonged to a heap file (the actual data store of a table) that has already been deleted (released). That is, it is a protective error that detects and blocks attempts to refer to or read a data page of a table (or object) that has been logically or physically deleted; this situation generally occurs when a wrong reference remains to the page after a table DROP, TRUNCATE, or after the heap file has been deleted internally.

**ERROR CODE: -1188, 'Dropping an active user '%1\$s' is not allowed.'**

- This message occurs when, in the CUBRID database, when performing *DROP USER*, it is not possible to DROP a user who is in the middle of executing a transaction.

**ERROR CODE: -1189, 'The specified combination of date and time do not exist (during transition of timezone offset rules).'**

- This message occurs when, in the CUBRID database, while processing date and time values, a date and time combination that does not exist is entered during a transition period when the offset rules of a particular timezone change (e.g., at the start or end of Daylight Saving Time (DST)). For example, when DST starts and the clock skips from 2 AM to 3 AM, a time such as 2:30 AM does not physically exist on that date. This message occurs to protect the validity of the data by detecting such a non-existent time.

**ERROR CODE: -1190, 'Stand-alone vacuum execution is started.'**

- This message is an informational message indicating that a stand-alone vacuum operation has started in the CUBRID database. This is not an error, but a log message that informs the user that the vacuum operation, which reclaims database space and optimizes performance, has started normally.

**ERROR CODE: -1191, 'Stand-alone vacuum execution is ended.'**

- This message is an informational message indicating that a stand-alone vacuum operation has been successfully completed in the CUBRID database. This is not an error, but a log message that informs the user that the vacuum operation, which reclaims database space and optimizes performance, has ended normally.

**ERROR CODE: -1194, 'Unable to check file %1\$d|%2\$d because lock on class %3\$d|%4\$d|%5\$d is not immediately granted.'**

- This message indicates a problem that occurs when, in the CUBRID checkdb command, while checking an object (heap, btree, etc.), when trying to inspect or access a specific file (generally a data page file), the lock on the class (table) to which that file belongs cannot be acquired immediately due to a lock acquisition error. This mainly occurs in situations related to concurrency control, such as when another transaction holds an exclusive lock on the table, or when there are too many lock requests and they cannot be processed immediately. It means

that the system needs a lock to check the integrity of the file or to access it safely, but it cannot proceed because it could not obtain it.

**ERROR CODE: -1241, 'XASL tree needs recompile.'**

- This message is an internal request or error indicating that, during the query processing process in the CUBRID database system, the XASL (eXtensible Abstract Syntax Language) tree needs to be recompiled; XASL is CUBRID's internal query representation format and is an intermediate stage in which an SQL query is parsed and optimized and then converted into an execution plan. This execution plan can be cached to improve performance; this message means that the cached XASL tree is no longer valid, or that a situation has occurred where the optimized execution plan must be generated again. This mainly occurs due to reasons such as table schema changes, statistics information updates, or changes in the internal system state; in general, rather than being a serious error directly exposed to the user, it occurs as part of a mechanism to maintain consistency and optimization of query processing inside CUBRID.

**ERROR CODE: -1247, 'The time(%1\$s) specified must be after the time(%2\$s) of the specified backup.'**

- This message occurs when, while the CUBRID system performs a database recovery operation, the recovery time specified by the user is earlier than or equal to the creation time of the backup to be used; database recovery is the process of restoring a database to a specific point in time (Point-In-Time Recovery) or to the latest state by starting from a specific backup point and applying subsequent transaction logs. The recovery time must always be in the future relative to the backup time. Recovering to a time before the backup time is logically impossible, and recovering to the same time as the backup time is the same as using the backup itself, so this error can occur when attempting to recover to a particular point in time after the backup time.

**ERROR CODE: -1248, 'Invalid Key file : %1\$s'**

- This message occurs when the CUBRID system detects that the key file used for TDE (Transparent Data Encryption) is invalid or corrupted while reading or processing it.

**ERROR CODE: -1249, 'Cannot find the key (index: %1\$d).'**

- This message is an error indicating that the CUBRID system failed because it tried to find the master key corresponding to a specific index while using the TDE (Transparent Data Encryption) feature, but could not find that key.

**ERROR CODE: -1250, 'The master key set on the database and what is given don't match. The key index set on the database: %1\$d'**

- This message occurs when, while using the TDE (Transparent Data Encryption) feature, the CUBRID system detects that the master key information (especially the key index) set in the database does not match the master key information provided to the current system; TDE is a

feature that strengthens security by encrypting database data, and the master key is the top-level key used to encrypt the Data Encryption Key (DEK). If this master key does not match, encrypted data cannot be accessed; this message mainly occurs when the contents of the TDE key file have been changed, an incorrect key file is used, or the key index recorded in the database metadata differs from the index of the currently loaded key.

**ERROR CODE: -1251, 'Error while TDE-encrypting.'**

- This message is an error indicating that the CUBRID system failed the encryption operation because an unexpected error occurred during the process of encrypting data using the TDE (Transparent Data Encryption) feature; TDE is a feature that strengthens security by encrypting database data, and data is encrypted before being written to disk and decrypted when read. This message means that a problem occurred in this encryption process; encryption failure suggests that data may not be stored properly, data integrity may be damaged, or normal operation of the database may be hindered.

**ERROR CODE: -1252, 'Error while TDE-decrypting.'**

- This message is an error indicating that the CUBRID system failed the decryption operation because an unexpected error occurred during the process of decrypting encrypted data using the TDE (Transparent Data Encryption) feature; TDE is a feature that strengthens security by encrypting database data, and data is encrypted before being written to disk and decrypted when read. This message means that a problem occurred in this decryption process; decryption failure suggests that encrypted data cannot be accessed, data integrity may be damaged, or normal operation of the database may be hindered.

**ERROR CODE: -1253, 'TDE Module is not loaded.'**

- This message is an error indicating that, when the CUBRID system tries to use the TDE (Transparent Data Encryption) feature, the TDE module has not been properly loaded or initialized; that is, it occurs when you perform TDE-related operations in a state where the database was started without a TDE KEY file, or was started with an incorrect TDE KEY file so that the TDE module does not operate properly.

**ERROR CODE: -1254, 'Cannot create a key.'**

- This message is an error indicating that the CUBRID system failed the key creation operation because an unexpected error occurred during the process of generating an encryption key while using the TDE (Transparent Data Encryption) feature; TDE is a feature that strengthens security by encrypting database data, and it requires keys such as the master key or the Data Encryption Key (DEK). This message means that a problem occurred in this key generation process; key generation failure suggests that the TDE feature may not operate normally or that there may be a problem with data security.

**ERROR CODE: -1255, 'Cannot load TDE module. You can't use TDE feature.n'**

- This message is an informational message that occurs when the CUBRID system tries to use the TDE (Transparent Data Encryption) feature, informing that the TDE feature cannot be used because there is no TDE KEY file at database startup.

**ERROR CODE: -1256, 'Cannot copy key file (\_keys). You can't use TDE feature on the copied database.'**

- This message is an error indicating that, during the process of copying a CUBRID database with the copydb command, copying the key file (\_keys) used for TDE (Transparent Data Encryption) failed.

**ERROR CODE: -1258, 'Cannot find the key set on the database from %1\$s. The key file from backup volume is going to be used.'**

- This message indicates that, when the CUBRID system starts or accesses a database that uses the TDE (Transparent Data Encryption) feature, it cannot find the master key file (\_keys file) set on the database at the specified path; however, the system has fortunately found the key file within the backup volume and is a warning message indicating that it will continue operating the database using this backup key file.

**ERROR CODE: -1259, 'Rename the key file from "%1\$s" to "%2\$s".'**

- This message is a warning message indicating that, during the process of recovering or restoring the key file of a database that uses the TDE (Transparent Data Encryption) feature, it is changing back to the previous key file.

**ERROR CODE: -1260, 'Copy the key file "%1\$s" to "%2\$s".'**

- This message is a warning message indicating that, during the process of restoring a database that uses the TDE (Transparent Data Encryption) feature, it restored the key file from the backup.

**ERROR CODE: -1261, 'The first key (key index: %1\$d, created time: %2\$s) on the restored key file has been set.'**

- This message is an informational or warning message indicating that, during the CUBRID database restore process, the TDE (Transparent Data Encryption) key file has been successfully restored, and the first master key (with the specified index and creation time) in that key file has been set on the database; TDE is a feature that strengthens security by encrypting database data, and the master key is the top-level key used to encrypt the Data Encryption Key (DEK). This message means that the restored database is ready to access encrypted data using the TDE feature; generally this is a positive result, but it is important to check whether the key matches what the user intended.

**ERROR CODE: -1262, 'The key file is full.'**

- This message occurs when, while the CUBRID system uses the TDE (Transparent Data Encryption) feature, it exceeds the maximum number of keys that can be stored when adding a new TDE KEY.

**ERROR CODE: -1263, 'It fails to TDE-encrypt the log page (pageid: %1\$lld). It won't be tried to encrypt this page any longer.'**

- This message is an error indicating that the CUBRID system failed the encryption operation because an unexpected error occurred while encrypting a database log page using the TDE (Transparent Data Encryption) feature; log pages are a very important part that record all changes in the database, and in an environment where TDE is enabled, these log pages must also be encrypted for security.

**ERROR CODE: -1286, 'Cannot find the log lsa at the time to extract. (input time : %1\$S).'**

- This message is an error indicating that, when the CUBRID system tries to find the log LSA (Log Sequence Address) for a specific time while using the CDC (Change Data Capture) feature, it cannot find the log LSA corresponding to that time; CDC is a feature that captures and tracks database changes in real time, and LSA is used as a log sequence address to identify a specific point in time in the database.

**ERROR CODE: -1287, 'Timed out attempting to extract log info. (elapsed time : %1\$d sec, extraction timeout : %2\$d sec)'**

- This message is an error indicating that, when the CUBRID system uses the CDC (Change Data Capture) feature to extract log information, the work was stopped because it exceeded the configured timeout value.

**ERROR CODE: -1289, 'Skip producing log info for invalid transaction. (trid : %1\$d)'**

- This message means that, while the CUBRID system uses the CDC (Change Data Capture) feature to process log information, it found an invalid transaction and skipped generating log information for that transaction.

**ERROR CODE: -1290, 'Invalid log lsa (%1\$lld|%2\$d) to extract log info.'**

- This message is an error indicating that, when the CUBRID system tries to extract log information using the CDC (Change Data Capture) feature, it encountered an invalid log LSA (Log Sequence Address); CDC is a feature that captures and tracks database changes in real time, and LSA is used to identify a specific point in time in the database; this message mainly occurs when the specified LSA is outside the log range of the database, log files are corrupted, or the LSA format is incorrect.

**ERROR CODE: -1291, 'Cannot connect to server for extracting log info. Try again with setting 'supplemental\_log' parameter.'**

- This message is an error indicating that, when the CUBRID system tries to extract log information using the CDC (Change Data Capture) feature, it cannot connect to the server; CDC is a feature that captures and tracks database changes in real time, and using this feature requires a connection to the server.

**ERROR CODE: -1292, 'Cannot find the log lsa at the time (%1\$s). Log lsa is adjusted to the time (%2\$s).'**

- This message is a warning message indicating that, when the CUBRID system tries to find the log LSA (Log Sequence Address) for a specific time using the CDC (Change Data Capture) feature, it could not find an LSA that exactly matches that time, so it adjusted to the LSA of the closest valid time; CDC is a feature that captures and tracks database changes in real time, and LSA is used to identify a specific point in time in the database; this message means that the system could not find a log that exactly matches the requested time, but adjusted it so that the work can continue by finding the closest valid time log.

**ERROR CODE: -1293, 'Cannot get log page while producing log infos. Log lsa to generate log info indicates NULL.'**

- This message is an error indicating that, while the CUBRID system generates log information using the CDC (Change Data Capture) feature, it cannot perform the work because the log LSA (Log Sequence Address) has a NULL value when trying to retrieve a log page.

**ERROR CODE: -1294, 'Log info has been generated. (type : "%1\$s").'**

- This message is an informational message indicating that the CUBRID system successfully generated log information using the CDC (Change Data Capture) feature; CDC is a feature that captures and tracks database changes in real time, and log information is the data that records such changes; this message generally indicates successful work and informs what type of log information was generated by including the type of the generated log information.

**ERROR CODE: -1296, 'Log recovery: ANALYSIS Phase is started.'**

- This message is an informational message indicating that, when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts, the 'ANALYSIS phase', the first step of the transaction log recovery process, has started; log recovery is an essential process to ensure the consistency and integrity of the database, and it rolls back uncommitted transactions due to system crashes and re-applies committed changes that were not reflected on disk; in the 'ANALYSIS phase', it scans the log file to identify all transaction activities after the last checkpoint and collects information such as which transactions were committed and which transactions should be rolled back.

**ERROR CODE: -1297, 'Log recovery: REDO Phase is started. Log pages to redo: %1\$lld, Log records to redo: %2\$lld.'**

- This message is an informational message indicating that, when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts, the 'REDO phase', the second step of the transaction log recovery process, has started; log recovery is an essential process to ensure the consistency and integrity of the database, and it re-applies changes that were committed but not reflected on disk due to system crashes in the order recorded in the logs; in the 'REDO phase', based on the information identified in the previous 'ANALYSIS phase', it applies the changes of committed transactions to the data files; this message provides the number of log pages to redo and the number of log records to redo together to indicate the scale of the recovery work.

**ERROR CODE: -1298, 'Log recovery: UNDO Phase is started. Log pages to undo: %1\$lld, transactions to undo: %2\$d.'**

- This message is an informational message indicating that, when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts, the 'UNDO phase', the third step of the transaction log recovery process, has started; log recovery is an essential process to ensure the consistency and integrity of the database, and it rolls back uncommitted transactions due to system crashes; in the 'UNDO phase', based on the information identified in the previous 'ANALYSIS phase', it reverts the changes of uncommitted transactions; this message provides the number of log pages to undo and the number of transactions to undo together to indicate the scale of the recovery work.

**ERROR CODE: -1299, 'Log recovery: %1\$s Phase is being finished up.'**

- This message is an informational message indicating that, when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts, a specific phase (e.g., ANALYSIS, REDO, UNDO) of the transaction log recovery process is being successfully wrapped up; log recovery is an essential process to ensure the consistency and integrity of the database, and it rolls back uncommitted transactions due to system crashes and re-applies committed changes that were not reflected on disk; this message indicates that each recovery phase is proceeding successfully and suggests that the overall recovery process is progressing smoothly.

**ERROR CODE: -1300, 'Log recovery: %1\$s Phase is finished.'**

- This message is an informational message indicating that, when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts, a specific phase (e.g., ANALYSIS, REDO, UNDO) of the transaction log recovery process has been successfully completed; log recovery is an essential process to ensure the consistency and integrity of the database, and it rolls back uncommitted transactions due to system crashes and re-applies committed changes that were not reflected on disk; this message indicates that

each recovery phase has been successfully completed and suggests that the overall recovery process is progressing smoothly.

**ERROR CODE: -1301, 'Log recovery: %1\$s progress: (%2\$lld/%3\$lld), %4\$.2f percent, elapsed time: %5\$.2f (s), estimated remaining time: %6\$.2f (s).'**

- This message is an informational message that provides real-time progress of a specific phase (ANALYSIS, REDO, UNDO) of the transaction log recovery process when the CUBRID database system is restarted after an abnormal shutdown or when a specific recovery operation starts; log recovery is an essential process to ensure the consistency and integrity of the database, and it rolls back uncommitted transactions due to system crashes and re-applies committed changes that were not reflected on disk; this message provides detailed information about the current state of the recovery work, the amount completed, the total amount, the progress rate, the elapsed time, and the estimated remaining time, helping the administrator monitor the recovery progress.

**ERROR CODE: -1302, 'dblink %1\$s'**

- This message is a general (inclusive) error message that occurs in CUBRID's DBLink feature and is used in various subordinate error situations; it is an error code used by the parser, etc., when a dblink-related error occurs, and the actual cause of the error depends on the detailed message that is delivered by substituting multiple messages; it can occur at all layers related to DBLink, including network communication, authentication, parameters, query execution, and so on.

**ERROR CODE: -1303, 'dblink invalid number of columns specified.'**

- This message occurs when, in CUBRID, while executing a query on an external DB through DBLink, the specified number of columns does not match the number of columns in the actual query result, or does not satisfy the conditions required by the system; for example, it can occur when the number of columns returned by a SELECT query differs from the number of columns specified in the DBLink object, or when column mapping is incorrect.

**ERROR CODE: -1304, 'dblink catalog \_db\_server class not found.'**

- This message occurs when, in CUBRID, while performing DBLink-related operations (creating, querying, modifying server objects, etc.), the internally referenced system catalog table (\_db\_server table) does not exist in the database; that is, it is a case where the core information repository of the DBLink feature is damaged, or it is abnormal due to a product bug.

**ERROR CODE: -1305, 'dblink server "%1\$s" not found.'**

- This message occurs when, in CUBRID, when trying to reference (e.g., connect, modify, delete, etc.) a DBLink server object, a server object with the specified name does not exist in the database; that is, the server name was entered incorrectly, has already been deleted, or has not yet been created.

**ERROR CODE: -1306, 'dblink server "%1\$s" already exists.'**

- This message occurs when, in CUBRID, when trying to create (CREATE SERVER) a DBLink server object, a server object with the specified name already exists; that is, it is a situation where duplicate creation is not possible because the same server name is already registered.

**ERROR CODE: -1307, 'dblink Cannot update server object.'**

- This message occurs when, in CUBRID, when trying to modify (UPDATE) the information of a DBLink server object, the operation is not allowed due to system policy or privilege restrictions; for example, it can be denied due to lack of privileges if not the owner, DBA, or DBA member, or it can be denied for reasons such as ensuring consistency of the server object.

**ERROR CODE: -1308, 'dblink not supported type %1\$s.'**

- This message occurs when, in CUBRID, while executing a query on an external DB through DBLink, the data type used is a type that is not supported by the CUBRID DBLink feature; for example, it occurs when a particular data type of an external DB (e.g., large binary, special types, etc.) cannot be mapped/converted/processed in CUBRID DBLink.

**ERROR CODE: -1309, 'dblink invalid bind param.'**

- This message occurs when, in CUBRID, while executing a query on an external DB through DBLink, the bind parameter passed is not valid. For example, it can occur when the number of parameters does not match, the type is different, the value is NULL/abnormal, and so on, in cases that are not allowed.

**ERROR CODE: -1310, 'dblink password length exceeds max size.'**

- This message occurs when, in CUBRID, when creating or modifying a DBLink server object, the length of the password entered exceeds the maximum size allowed by the system; this can also occur when the actual byte count exceeds due to an encoding issue even if the password appears not too long.

**ERROR CODE: -1311, 'dblink encrypted password length is incorrect.'**

- This message occurs when, in CUBRID, while decrypting or validating an encrypted password of a DBLink server object, the length of the encrypted string differs from the length required by the system; this can occur when the encrypted password is corrupted, generated/stored in an incorrect way, or an incorrect ciphertext was entered when creating the DBLink object.

**ERROR CODE: -1312, 'dblink the checksum of the encrypted password does not match.'**

- This message occurs when, in CUBRID, while decrypting or validating an encrypted password of a DBLink server object, the checksum value of the encrypted string differs from the expected value; this can occur when the encrypted password is corrupted, the encryption/decryption environment (algorithm, key, etc.) does not match, or data was stored/transmitted incorrectly.

**ERROR CODE: -1313, 'dblink invalid cipher string format.'**

- This message occurs when, in CUBRID, while decrypting or validating an encrypted password of a DBLink server object, the format of the encrypted string (ciphertext) is not correct; it can occur when the encrypted string is corrupted, the format does not match, or it was stored in an unexpected way (e.g., insufficient length, missing delimiter, encoding error, etc.).

**ERROR CODE: -1314, 'dblink Failed to decryption password. error=%1\$d''**

- This message occurs when, in CUBRID, when trying to connect to an external DB through a DBLink server object, the stored password fails internally during the decryption process; it is returned when decryption cannot be performed normally due to various causes such as issues with the crypto library, mismatch of encryption/decryption keys, corruption of encrypted data, system environment issues, internal bugs, and so on.

**ERROR CODE: -1315, 'dblink Failed to encryption password. error=%1\$d''**

- This message occurs when, in CUBRID, when creating or modifying a DBLink server object, the encryption of the password for connecting to an external DB fails internally; it is returned when encryption cannot be performed normally due to various causes such as issues with the crypto library, input value errors, insufficient system resources, unsupported crypto algorithm, internal bugs, and so on.

**ERROR CODE: -1317, 'dblink Not allowed "%1\$s" Server.'**

- This message occurs when, in CUBRID, when attempting an operation (ALTER, etc.) that is not allowed on a DBLink server object; depending on certain system policies, privileges, or the attributes of the DBLink server, changes (ALTER, DROP, etc.) to that server may be prohibited. For example, it can occur when the server is protected by the system, or when the current session/user does not have the authority to change that server.

**ERROR CODE: -1318, '[%1\$5s][%2\$d] %3\$s'**

- This message is a message that, when an error occurs from an external database (such as an ODBC driver) in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), formats and delivers the detailed information of that error as-is. That is, it shows the SQLSTATE, error code, and detailed message of an error that occurred in an external DBMS or ODBC driver, not inside CUBRID.
- This message serves to pass through the error information of the external system without CUBRID directly interpreting the cause of the problem that occurred during DBLink external DB integration.

**ERROR CODE: -1319, 'Parameter binding error.'**

- This message is printed when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), a problem occurs during the parameter (input variable) binding process when

executing an SQL query. It mainly occurs when the number of parameters to bind does not match, the types do not match, or an internal binding handle (structure, etc.) is not created correctly. For example, it can occur when a query needs 3 parameters but only 2 are bound, or when the type of a bound value does not match the DB column type.

**ERROR CODE: -1320, 'Invalid ODBC handle.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), an ODBC handle (identifier, pointer, etc.) is invalid. That is, it can occur when referencing a handle that has already been closed (freed), using a handle that was not created correctly, or when the handle is corrupted internally. It mainly occurs in cases such as reuse after disconnect, missing handle, memory corruption, driver bugs, and so on.

**ERROR CODE: -1322, 'not supported type %1\$s(%2\$d).'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), a data type not supported by CUBRID is used during integration with an external database or during query execution. For example, it is a case where an external DB table contains a type that CUBRID cannot recognize (e.g., BLOB, CLOB, user-defined types, etc.), or where type mapping is not defined. This message mainly occurs due to data type compatibility issues, unimplemented type conversion logic, or limitations of the driver/integration module.

**ERROR CODE: -1323, 'Invalid Statement handle.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), the Statement handle (identifier, pointer, etc.) that manages an SQL statement is invalid. That is, it can occur when referencing a Statement that has already been closed, using a handle that was not created correctly, or when the handle is corrupted internally. It mainly occurs in cases such as reuse after Statement free, missing handle, memory corruption, driver bugs, and so on.

**ERROR CODE: -1324, 'Invalid db connection handle.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), a handle (identifier, pointer, etc.) that manages a database connection is invalid. That is, it can occur when referencing a connection that has already been closed, using a handle that was not created correctly, or when the handle is corrupted internally. It mainly occurs in cases such as reuse after disconnect, missing handle, memory corruption, driver bugs, and so on.

**ERROR CODE: -1325, 'Link server connection url do not exist.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), when attempting to connect to an external database, the URL (connection information) required for the connection is not defined or the system cannot find the information. That is, it is a case where the connection URL was omitted when creating the DBLink or Gateway server object, or where the information was not properly registered internally.

**ERROR CODE: -1326, 'Invalid numeric value.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), processing an invalid numeric type value in a query.

**ERROR CODE: -1327, 'Invalid precision value of "%1\$s" column.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), while processing an external DB table or query result, the precision value of a particular column is specified as an invalid value (out of range, negative, 0, too large, etc.). It can mainly occur when the external DB schema definition is wrong, or when the ODBC driver returns column precision information incorrectly.

**ERROR CODE: -1329, 'Not supported dbms.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), the external DBMS you attempted to connect to is not an officially supported DBMS in CUBRID. That is, it occurs when you attempt to connect to a DBMS type that the CUBRID Gateway cannot recognize, or a DBMS that is not included in the supported list. For example, if CUBRID Gateway supports only some DBMS such as Oracle, MySQL, MSSQL, and so on, and you attempt to connect to an unsupported DBMS (e.g., SQLite, MariaDB, special-purpose DB, etc.), this error is returned.

**ERROR CODE: -1330, 'Unable to allocate an environment handle.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), while starting a connection to an external database, it fails during the process of creating (allocating) an environment handle (such as an ODBC environment handle). Since the environment handle is the base resource for all work such as sessions, connections, and transactions with an external DB, if allocation fails, all subsequent DB integration work becomes impossible. It can mainly occur due to insufficient system memory, ODBC driver/library issues, internal resource exhaustion, and so on.

**ERROR CODE: -1331, 'A null column binder was referenced.'**

- This message occurs when, in CUBRID's Gateway feature (DBLink external DB integration, ODBC, etc.), while binding a query execution result to an application variable, a column binder (binding handle) is referenced in a NULL (not initialized) state. That is, it is a programming error that occurs when the column binder was not created/allocated properly or when you attempt to access it after it has already been freed. It can mainly occur due to issues in DBLink external DB integration, the ODBC driver, or internal binding logic.

**ERROR CODE: -1332, 'The active log volume (%1\$s) is too sane to recreate. If you remove the active log, it could cause an unexpected and irreversible problem.'**

- This message occurs when, in CUBRID, when using the *cubrid emergencylog -r* command, if the active log is normal, it indicates that it cannot be recreated; this occurs when you try to

recreate the active log volume and the system does not allow recreation because the log file is in a sane state and not corrupted.

**ERROR CODE: -1333, 'Invalid time (%1\$s) to start flashback. Time is required to be set between (%2\$s) and (%3\$s).'**

- This message occurs when, in CUBRID, when executing the Flashback feature, the recovery point in time (time) specified by the user is outside the range allowed by the system. Flashback is limited to a recoverable time range depending on log retention, database state, backup time, and so on, and if a request is made for a time outside this range, the operation is denied to ensure data consistency and integrity.

**ERROR CODE: -1334, 'Can not find the class to flashback (%1\$s).'**

- This message occurs when, in CUBRID, when executing the Flashback feature, the target table (table) to be recovered does not exist in the database, or the system cannot find the table; it can mainly occur when the table has been deleted, the name is specified incorrectly, or there is a problem in the system catalog.

**ERROR CODE: -1335, 'Too many transactions to flashback. Less than %1\$d transactions can be flashback.'**

- This message occurs when, in CUBRID, when executing the Flashback feature, the number of transactions to be recovered exceeds the maximum value allowed by the system. Flashback work has a limit on the number of transactions that can be processed at once for database consistency and performance. If this limit is exceeded, problems such as system overload, performance degradation, and recovery failure can occur, so the system imposes a policy limit.

**ERROR CODE: -1336, 'Cannot support flashback for this class (name : %1\$s , OID : %2\$d|%3\$d| %4\$d). Class schema has been changed.'**

- This message occurs when, in CUBRID, when executing the Flashback feature, the schema (structure) of the target table (table) has been changed after the flashback target time. For example, if the schema is changed such as adding/deleting columns, changing types, changing constraints, and so on, data recovery becomes impossible because the data at the flashback time and the current structure do not match. To ensure data integrity and consistency, flashback is not supported for tables whose schema has been changed.

**ERROR CODE: -1337, 'Log record does not exist (lsa : %1\$lld|%2\$d). The archive log volume has been deleted.'**

- This message occurs when, in the CUBRID database, a specific log record (needed for transaction recovery, flashback, etc.) does not exist, or the archive log volume storing that log has already been deleted so it can no longer be accessed; it can mainly occur when old logs have been deleted automatically/manually, when log files have been cleaned up according to backup/recovery/archive policies, or due to log file corruption, incorrect LSA access, and so on.

**ERROR CODE: -1338, 'Flashback is already running. Flashback cannot be run by more than one user at the same time.'**

- This message occurs when, in CUBRID, when trying to execute the Flashback feature, another session or user is already running a flashback operation. Flashback is restricted so that only a single user can execute it concurrently to ensure database consistency and integrity. Therefore, only one flashback operation is allowed at a time, and if a duplicate request comes in, this error is returned.

**ERROR CODE: -1341, 'Invalid arguments to authorization internal function.'**

- This message occurs in the CUBRID database when, while changing the owner of a class or method, the desired information is missing.

**ERROR CODE: -1342, 'AUTO\_INCREMENT does not allow change of owner.'**

- This message occurs in the CUBRID database when attempting to change the owner of a serial object of auto increment.

**ERROR CODE: -1345, 'DBA, members of DBA group, and owner can perform CREATE TRIGGER.'**

- This message occurs when, in CUBRID, when attempting to create a trigger (CREATE TRIGGER), the user executing the command is not the DBA, a member of the DBA group, or the owner of the target object for the trigger. That is, it is a privilege-related error that occurs when a user without trigger creation privileges tries to execute CREATE TRIGGER.

**ERROR CODE: -1350, 'Invalid synonym value.'**

- This message occurs from a synonym (SYNONYM) object that has incorrect information when running the umloaddb command in CUBRID.

**ERROR CODE: -1356, 'There is no hint in the DBLink query, or the statement type is incorrect. %1\$s'**

- This message occurs because, in CUBRID, a DBLink query internally adds the statement type as a hint and passes it to the dblink gateway to determine what kind of query it is, and an unknown statement type was delivered.

**ERROR CODE: -1357, 'Converting SQL string to wide string failed.'**

- This message occurs when, while CUBRID communicates with an external database through the DBLink Gateway, it cannot convert the SQL query string from UTF8 to Unicode; it mainly occurs when the character encoding does not match, or when the input string contains invalid (broken) characters.

**ERROR CODE: -1358, 'Number of rows affected is unknown.'**

- This message occurs when CUBRID cannot correctly determine the number of rows actually affected when executing DML (INSERT, UPDATE, DELETE). It can occur when, during inter-database integration work in a DBLink query, the external system does not return the number of affected rows, or when the returned value is not clear.

**ERROR CODE: -1362, 'Locale '%1\$s' is unavailable.'**

- This message occurs when CUBRID uses locale information that has not been loaded on the server when converting a string to date/time,

## Database File Errors

**ERROR CODE: -17, 'Internal error: fetching deallocated pageid %1\$d of volume "%2\$s"'**

- This message is an internal error that occurs when the CUBRID system attempts to fetch a page ID that has already been deallocated; it means that a problem has occurred in page allocation/deallocation management, memory management, or page access logic, and it can lead to corruption of database consistency and data loss.

**ERROR CODE: -19, 'Internal error: pageptr = %1\$p of page %2\$d of volume "%3\$s" is not fixed.'**

- This message is an internal error that occurs when the CUBRID system attempts to access a page pointer for a specific page in a specific volume while that page pointer is not "fixed" in memory; it means that a problem has occurred in page buffer management, memory protection, or page access logic, and it can lead to corruption of database consistency and data loss.

**ERROR CODE: -35, 'Internal error: Unknown volume identifier %1\$d.'**

- This message is an internal error that occurs when the CUBRID system tries to reference a volume with a specific volume ID (Volume Identifier), but it cannot find a volume corresponding to that volume ID or recognizes it as an invalid volume; it can mainly occur when deleting a temporary volume (temp temp volume).

**ERROR CODE: -38, 'Internal error: Unknown file VFID %1\$d|%2\$d.'**

- This message occurs when, in the CUBRID database, while executing the loaddb command, it cannot find the object file (object file) or cannot open the file due to issues such as file permission problems.

**ERROR CODE: -43, 'Internal error: The page %1\$d of volume "%2\$s" may be corrupted. %3\$d records was found when %4\$d was expected.'**

- This message is an internal error that occurs when the CUBRID system, while inspecting a slotted page of a specific volume, detects that the number of actual records found in the page does not match the expected number of records recorded in the page header; this mismatch strongly suggests that the internal structure of the slotted page has been damaged and indicates that database consistency has been broken; this message mainly occurs while performing a slot cleanup/compaction operation on the page.

**ERROR CODE: -44, 'No space available in slotted page %1\$d of volume "%2\$s"'**

- This message is an error indicating that the CUBRID system attempted to insert new data into a slotted page of a specific volume or to expand existing data, but there is no more available space on that page; it mainly occurs when the page is full, and operations such as inserting new records, updating existing records (size increase), or adding index entries may fail.

**ERROR CODE: -45, 'Slot %1\$d on page %2\$d of volume "%3\$s" is allocated to an anchored record. A new record cannot be inserted here.'**

- This message is an internal error indicating that the CUBRID system attempted to insert a new record into a slot on a specific page of a specific volume, but it cannot insert because that slot is already allocated to an "anchored record"; it indicates that there is a problem in the database's internal structure (especially the slotted-page structure) or that there is an error in the record insertion logic, and it can lead to insertion failure, query errors, or data loss.

**ERROR CODE: -46, 'Internal error: slot %1\$d on page %2\$d of volume "%3\$s" is not allocated.'**

- This message is an internal error that occurs when the CUBRID system attempts to access a slot on a specific page of a specific volume but detects that the slot is not allocated; it indicates that there is a problem in the database's internal structure (especially the slotted-page structure), and it can lead to data access failure, query errors, or data loss; this mainly occurs when accessing by slot ID on a database page and the corresponding slot does not exist.

**ERROR CODE: -47, 'Unable to create a heap file in volume "%1\$s"'**

- This message is an error indicating that the CUBRID system attempted to create a new heap file in the specified volume but failed; it may occur due to lack of disk space, file system permission issues, volume corruption, or problems in CUBRID's internal file system management; it directly affects operations such as creating new tables, creating indexes, or adding data to existing tables.

**ERROR CODE: -48, 'Accessing deleted object %1\$d|%2\$d|%3\$d.'**

- This message is an internal error that occurs when the CUBRID system attempts to access an object that has already been deleted or is invalid; it represents an internal inconsistency in which a reference to the object remains even after the object itself has been deleted, causing

the system to try to access an invalid object; as a result, it can lead to data access failure, query errors, or system instability.

**ERROR CODE: -49, 'Internal error: class of object %1\$d|%2\$d|%3\$d is unknown.'**

- This message is an internal error that occurs when the CUBRID system cannot find the table (class) information for a specific object (identified by an OID); it indicates that the link between the object and the table has been damaged, that the table metadata is invalid, or that the database's internal consistency has been broken; as a result, it can lead to data access failure, query errors, or data loss.

**ERROR CODE: -52, 'Internal error: object overflow address %1\$d|%2\$d|%3\$d may be corrupted.'**

- This message is an internal error that occurs when the CUBRID system detects the possibility that an object's overflow address may be corrupted; it indicates that there is a problem in internal structure management of the database, and it can lead to data access failure, query errors, or data loss.

**ERROR CODE: -53, 'Fetching object %1\$d|%2\$d|%3\$d when only its OID has been assigned.'**

- This message is an error indicating that the CUBRID system attempted to fetch the data of a specific object, but only an OID (Object Identifier) has been assigned to that object and the actual data has not been stored; it indicates a timing issue between object creation and data storage, or a consistency issue that occurs during transaction processing.

**ERROR CODE: -55, 'Internal error: A page cycle reference was detected on page %1\$d|%2\$d of heap file %3\$d|%4\$d|%5\$d.'**

- This message is an internal error that occurs when the CUBRID system detects a cyclic reference between pages in a heap file; it indicates that there is a problem in internal structure management of the database, and it can lead to data access failure, query errors, or data loss.

**ERROR CODE: -56, 'Internal error: unknown extendible hashing file (Valid: %1\$d Fileid: %2\$d) page (Valid: %3\$d Pageid: %4\$d) was specified.'**

- This message is an internal error that occurs when the CUBRID system tries to reference an unknown or invalid file and page in an extendible hashing structure; it indicates that there is a problem in internal structure management of the database, and it can lead to data access failure, query errors, or data loss.

**ERROR CODE: -57, 'Key does not exist in the extendible hashing structure.'**

- This message is an error indicating that the CUBRID system attempted to find a specific key in an extendible hashing structure, but the key does not exist in the structure; it can occur when querying data with a non-existent key, when the key is incorrect, or when the hashing structure itself has a problem.

**ERROR CODE: -59, 'Internal error: the specified key type %1\$d is not valid for the extendible hashing structure.'**

- This message is an internal error that occurs when the CUBRID system detects that the key type to be used in an extendible hashing structure is an invalid type that is not supported by that structure; it indicates that there is a problem in internal structure management of the database, and it can lead to query execution failure or data access errors.

**ERROR CODE: -60, 'Internal error: the extendible hashing structure has been corrupted.'**

- This message is an internal error that occurs when the CUBRID system detects that corruption has occurred in the database's extendible hashing structure; corruption of this structure has a fatal impact on the integrity of the database and may lead to data access failure, query errors, or data loss.

**ERROR CODE: -61, 'Internal error: the directory root page of the extendible hashing structure (Valid: %1\$d Fileid: %2\$d Pageid: %3\$d) has been corrupted.'**

- This message means that corruption was detected during an integrity check of the top-level directory page of Extendible Hashing in the CUBRID system; since the starting point of the index/hash directory is broken, access to the entire structure may be impossible or the results may not be trustworthy.

**ERROR CODE: -63, 'Internal error: a temporary page was corrupted during sorting.'**

- This message is an internal error that occurs when the CUBRID system detects that a temporary page used during a data sorting operation has been corrupted; when sorting large amounts of data, CUBRID creates and uses temporary files on disk if memory is insufficient, and a page of that temporary file was corrupted during read/write; this can affect database consistency and the correctness of the sort operation and may lead to query failure.

**ERROR CODE: -66, 'Internal error: unknown force operation %1\$d for object %2\$d|%3\$d|%4\$d.'**

- This message is an internal error that occurs when the CUBRID system attempts to perform an unknown or invalid "force operation" on a specific object; it can occur when there is a problem in the internal logic of the CUBRID engine or when the database's internal consistency has been severely damaged.

**ERROR CODE: -67, 'Internal error: a heap file has not been allocated to store object %1\$d|%2\$d|%3\$d.'**

- This message is an internal error that occurs when a heap file to store a specific object (OID) has not been allocated in the CUBRID system; it means that there is a problem in internal structure management of the database and it can have a fatal impact on object storage and access.

**ERROR CODE: -68, 'Internal error: different classnames for class with oid = %1\$d|%2\$d|%3\$d were found. Found classnames are "%4\$s", "%5\$s" using classname hash table and heap, respectively.'**

- This message is an internal error that occurs when the CUBRID system finds two different table names for a table with a specific object (OID); this discrepancy means that the database's internal metadata structure has been severely damaged and indicates that a fatal problem has occurred in the database's consistency and integrity.

**ERROR CODE: -69, 'Internal error: different class object identifiers were found for class with name "%1\$s". Found OIDs are %2\$d|%3\$d|%4\$d, %5\$d|%6\$d|%7\$d using classname hash table and heap, respectively.'**

- This message is an internal error that occurs when the CUBRID system finds two different object identifiers (OIDs) for a specific table; this discrepancy means that the database's internal metadata structure has been severely damaged and indicates that a fatal problem has occurred in the database's consistency and integrity.

**ERROR CODE: -70, 'Internal error: Class with name "%1\$s" and oid = %2\$d|%3\$d|%4\$d does not exist in classname hash table.'**

- This message is an internal error that occurs when the CUBRID system attempts to find a specific table (OID) in the classname hash table but fails; the classname hash table is an internal data structure that CUBRID uses to quickly look up table names; this message indicates that an inconsistency or corruption has occurred in the database's metadata management system, meaning that there is a problem in the database's internal structure.

**ERROR CODE: -71, 'Internal error: Class with name "%1\$s" and oid = %2\$d|%3\$d|%4\$d does not exist in its heap.'**

- This message is an internal error that occurs when the CUBRID system attempts to find a specific table (OID information) in the database heap area but fails; the heap refers to the space where actual data objects are stored; this message indicates that an inconsistency or corruption has occurred between the database metadata (table definition) and the actually stored data, meaning that there is a problem with the integrity of the database.

**ERROR CODE: -80, 'Insufficient space in operating system device when writing logical log page %1\$lld (physical page %2\$lld) of "%3\$s". Could not write more than %4\$d bytes.'**

- This message is an error indicating that when the CUBRID system tried to write a logical log page to a physical page, the write failed because there was not enough space on the operating system device; it mainly occurs due to insufficient disk space, file system limits, or I/O errors.

**ERROR CODE: -81, 'Internal error: logical log page %1\$lld may be corrupted.'**

- This message is an internal error that occurs when the CUBRID system detects the possibility that a specific logical log page in the transaction log file of the database may be corrupted; it is a very important warning indicating database stability and the risk of data loss.

**ERROR CODE: -96, 'Media recovery may be needed on volume "%1\$s".'**

- This message is an error indicating that the CUBRID system detected a consistency or integrity problem in a database volume and that media recovery (Media Recovery) may be needed; it occurs when there is a possibility that a specific volume of the database has been damaged due to abnormal termination, disk damage, log file inconsistency, and so on.

**ERROR CODE: -97, 'Internal error: unable to find log page %1\$lld in log archives.'**

- This message is an internal error that occurs when the CUBRID system tries to find a specific log page in the log archives but fails; it occurs when a log page required while processing the database transaction logs does not exist in the archive files, the archive files are corrupted, or the archive files cannot be accessed.

**ERROR CODE: -98, 'Unable to create archive log "%1\$s" to archive pages from %2\$lld to %3\$lld.'**

- This message is displayed when the CUBRID system fails to create an archive log file while performing log archiving; it is an important error that can affect database consistency and recoverability.

**ERROR CODE: -296, 'Invalid property list encountered.'**

- This message is an error that appears when, in the CUBRID database, an object's property list is invalid or corrupted; it occurs during validation of the property list in object representation or the schema management system, and it suggests that internal metadata or object definitions in the CUBRID database may be incorrect or damaged.

**ERROR CODE: -315, 'Illegal metaclass definition encountered.'**

- This message is an error that appears when a metaclass definition is incorrect in the CUBRID database; a metaclass refers to a structure that defines CUBRID's system catalog tables, and this message occurs when the metaclass attribute definition is not correct.

**ERROR CODE: -316, 'Transformer size calculation mismatch, expected %1\$d calculated %2\$d.'**

- This message is an error that appears when, during object transformation in the CUBRID database, the expected size and the actually calculated size do not match; the system calculates the size before storing the object on disk and verifies it after actual storage; a size mismatch can indicate an internal logic error or data corruption.

**ERROR CODE: -317, 'Invalid disk representation encountered for class "%1\$s"'**

- This message is an error that appears when the disk representation (representation) of a table is invalid in the CUBRID database; the disk representation is a structure that defines how an object is stored on disk, and it occurs when a representation corresponding to a specific representation ID cannot be found for the table.

**ERROR CODE: -318, 'Out of sync during object loading. Database is likely corrupted or out of date.'**

- This message is an error that appears when a synchronization (sync) problem occurs while loading objects in the CUBRID database; it occurs when the size of the data read from disk differs from the expected size; it can generally occur due to database file corruption, version compatibility issues, or memory corruption.

**ERROR CODE: -406, 'Invalid B+tree index identifier: (vfid = (%1\$d, %2\$d), rt\_pgid: %3\$d).'**

- This message is an error that appears when a B-tree index identifier (BTID) is invalid in the CUBRID database; it mainly occurs during validity checks of index identifiers in B-tree storage management when the vfid (volume file ID) or pageid of the B-tree index identifier is wrong.

**ERROR CODE: -407, 'Unknown key %1\$s referenced in B+tree index {vfid: (%2\$d, %3\$d), rt\_pgid: %4\$d, key\_type: %5\$s}.'**

- This message is a system error that occurs when trying to reference a non-existent or corrupted key in a B+tree index structure; it is an important error message indicating that there is a problem with the integrity of the database index structure, and it may mean that index consistency has been broken or data corruption has occurred.

**ERROR CODE: -412, 'Invalid range search specification.'**

- This message is an error that appears when, while performing a range search using a B-tree index in the CUBRID database, the range search specification is invalid; it occurs when an unsupported range search type or an incorrect range search condition is used in the range search validity check process in B-tree storage management.

**ERROR CODE: -415, 'Invalid class identifier: %1\$d|%2\$d|%3\$d.'**

- This message occurs when the internal table identifier (OID, Object Identifier) used in the CUBRID database is invalid or when it references a table that does not exist; it can occur when an incorrect OID is passed in system catalog access, query execution, object access, and so on, when a table has been deleted/changed and is no longer valid, or due to internal data corruption.

**ERROR CODE: -416, 'Unknown representation identifier: %1\$d.'**

- This message occurs when the ID (REPRID) that identifies the internal representation (Representation) of an object (table, record, etc.) in the CUBRID database is invalid or when it references a value that is not registered in the system; it can occur when an incorrect identifier is passed in system catalog access, object access, query execution, and so on, or when the identifier was lost/mismatched during table structure changes, data corruption, or recovery/migration processes.

**ERROR CODE: -417, 'Invalid representation identifier: %1\$d.'**

- This message occurs when the ID (REPRID) that identifies the internal representation (Representation) of an object (table, record, etc.) in the CUBRID database is invalid or when an unacceptable value is passed; it can occur when an incorrect identifier is used in system catalog access, object access, query execution, and so on, or when the identifier is mismatched or corrupted due to table structure changes, data corruption, or recovery/migration processes.

**ERROR CODE: -421, 'Representations Directory Missing in Catalog for Class: %1\$d|%2\$d|%3\$d.'**

- This message is an error that appears when the representation directory of a table is missing from the system catalog in the CUBRID database; there is a very high possibility that this error occurs when required information cannot be found due to system catalog corruption.

**ERROR CODE: -422, 'Representation Information Record Missing in Catalog for Class Repr\_Id: %1\$d|%2\$d|%3\$d %4\$d.'**

- This message is an error that appears when the representation information record of a specific table is missing from the system catalog in the CUBRID database; there is a very high possibility that this error occurs when required information cannot be found due to system catalog corruption.

**ERROR CODE: -475, 'No query specification with index %1\$s.'**

- This message is an error that appears when the CUBRID database cannot find a query specification (Query Specification) corresponding to a specific index number; a query specification refers to an SQL query definition used in a virtual table or a view, and each specification is identified by an index number; this message occurs when trying to query or delete a query specification with a non-existent index number.

**ERROR CODE: -540, '%1\$s.'**

- This message is a general error message that appears when a critical error occurs in the CUBRID database; it is a generic error message mainly used when an internal system error or an unexpected situation occurs; the specific contents of this error may be a trigger compilation error, a B+Tree structure error, or corruption or inconsistency of the index structure.

**ERROR CODE: -544, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). B+tree key %6\$s entry for object OID: %7\$d|%8\$d|%9\$d was not found on B+tree: %10\$d|%11\$d|%12\$d.'**

- This message is an internal error that appears when the CUBRID database cannot find a specific key entry in a B+tree index; it mainly occurs during an index consistency check when the key of an object that exists in the heap does not exist in the B+tree index; it is an internal error indicating data inconsistency between the index and the heap.

**ERROR CODE: -545, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). Key and OID: %6\$d|%7\$d|%8\$d entry on B+tree: %9\$d|%10\$d|%11\$d is incorrect. The object does not exist.'**

- This message is an internal error that appears when the key and OID entry of a B+tree index in the CUBRID database is not correct; it mainly occurs during an index scan when an OID that exists in the B+tree does not actually exist in the heap; it is an internal error indicating data inconsistency between the index and the heap.

**ERROR CODE: -546, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). Expecting %6\$d OID entry values, but %7\$d were found on B+tree: %8\$d|%9\$d|%10\$d.'**

- This message is an internal error that appears when the number of OID entries in a B+tree index in the CUBRID database differs from what is expected; it mainly occurs during an index consistency check when the number of OIDs in the heap does not match the number of OIDs in the B+tree; it is an internal error indicating data inconsistency between the index and the heap.

**ERROR CODE: -551, 'Unable to locate volume information path file "%1\$s"... Continue reading from internal tables'**

- This message is an error that appears when the CUBRID database cannot find the volume information file (DB\_vinf); it mainly occurs when the volume information file cannot be accessed during database boot or during a log page buffer scan process.

**ERROR CODE: -585, 'Unknown heap %1\$s|%2\$d|%3\$d'**

- This message is displayed when trying to access a heap file that does not exist or is unknown in the CUBRID database; a heap file is the basic unit for storing data in CUBRID, and each heap file has a unique identifier (HFID).

**ERROR CODE: -587, 'Entries of permanent volumes are unsorted in your "%1\$s" volinfo file. Entry %2\$d: %3\$d %4\$s is out of sequence.'**

- This message indicates that the permanent volume entries in the CUBRID database's DBname\_vinf file are not sorted in the correct order; the DBname\_vinf file stores volume information for the database and must be sorted in volume ID order, including file paths and file information.

**ERROR CODE: -596, 'The %1\$d pages of total temporary space allowed have been exceeded.'**

- This message indicates that the number of pages of total temporary space allowed for the backend (Backend) to use in the CUBRID database has been exceeded; CUBRID uses temporary space to store temporary data when processing complex queries, sorting, joining, and so on; this message occurs when the temporary space limited by a setting parameter such as *temp\_file\_max\_size\_in\_pages* in the cubrid.conf file has been exceeded.

**ERROR CODE: -597, 'Number of pages for heap file %1\$d|%2\$d|%3\$d is inconsistent. n%4\$d and %5\$d were found according to heap chain and file table, respectively.'**

- This message is an internal error indicating that, when executing the checkdb command in the CUBRID database, an inconsistency in the number of pages in a heap file was found; a heap file is the space where actual data records are stored, the heap chain is the logical linkage of pages within the heap file, and the file table refers to page information managed at the file-system level.

**ERROR CODE: -603, 'Internal Error: Sector/page table of file VFID %1\$d|%2\$d seems corrupted.'**

- This message occurs when corruption is detected in the internal structure (sector/page table) of the file system in the CUBRID database; it is a fatal internal error indicating that the integrity of the database file has been broken and that normal data access and management may be impossible.

**ERROR CODE: -610, 'Your database is likely to be corrupted since logging was turned off when your database crashed.'**

- This message occurs during the log recovery process in the CUBRID database; it means that there is a high possibility that the database has been corrupted because logging was disabled at the time the database crashed.

**ERROR CODE: -614, 'Number of active log archives has been exceeded the max desired number of %1\$d.'**

- This message appears when the number of active log archives in the CUBRID database has exceeded the configured maximum allowed number; it is a notification that occurs during the process in which the log archive management system automatically deletes old log archives.

**ERROR CODE: -625, 'Internal Error. Trying to update the wrong instance object %1\$d|%2\$d|%3\$d attribute information template with instance object %4\$d|%5\$d|%6\$d.'**

- This message is displayed internally in the CUBRID database; it is an internal error caused by an OID mismatch in attribute information for the wrong record object; an OID (Object Identifier) is an 8-byte identifier that uniquely identifies each object in a CUBRID database.

**ERROR CODE: -626, 'Internal Error. %1\$d requested attributes were not found.'**

- This message is displayed internally in the CUBRID database; it appears when some of the requested attributes cannot be found, and it occurs while caching or retrieving attribute information for a table.

**ERROR CODE: -638, 'Warning: Flushing a non-updatable log archive pageid = %1\$d'**

- This message is a warning that occurs when trying to flush a log archive page that cannot be updated in the CUBRID database; it occurs when a flush operation is attempted while the log page is outside the archive range or is in a state where it can no longer be updated.

**ERROR CODE: -644, 'LOG FATAL ERROR: %1\$s'**

- This message indicates a fatal error that occurs in the log system of the CUBRID database; it is used when an unrecoverable error occurs during log processing, and it is an error that can affect the integrity and stability of the database.

**ERROR CODE: -694, 'SYSTEM ERROR: Unable to load B+tree.'**

- This message is a system-level error that occurs when trying to load (create) a B+tree index in the CUBRID database; it can occur due to insufficient memory, disk I/O errors, parameter validation failures, or internal algorithm errors during index creation.

**ERROR CODE: -698, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). the number of OIDs in the unique hierarchy: %6\$d does not equal the number of OIDs: %7\$d found in the unique B+tree plus the number of NULLs: %8\$d found in the unique hierarchy for B+tree: %9\$d|%10\$d|%11\$d.'**

- This message indicates an internal consistency error in the CUBRID database; it occurs when the total number of OIDs in the hierarchy to which a UNIQUE constraint for an index of a specific table applies does not match the sum of the number of OIDs found in the B+tree and the number of NULLs found in the unique hierarchy; this means a mismatch between database metadata (schema information) and the actual B+tree index structure and suggests that data integrity may have been damaged or that there may be a problem in the index structure.

**ERROR CODE: -699, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). the number of OIDs in the unique hierarchy: %6\$d does not equal the number of OIDs: %7\$d found in the unique B+tree root statistics for B+tree: %8\$d|%9\$d|%10\$d.'**

- This message indicates an internal consistency error in the CUBRID database; it occurs when the number of OIDs (Object Identifiers) in the hierarchy to which a UNIQUE constraint for an index of a specific table applies does not match the number of OIDs recorded in the B+tree root statistics for that index; this means a mismatch between database metadata (schema information) and the actual B+tree index structure and suggests that data integrity may have been damaged or that there may be a problem in the index structure.

**ERROR CODE: -700, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). the number of OIDs: %6\$d does not equal the number of NULLs: %7\$d plus the number of keys: %8\$d in the unique B+tree: %9\$d|%10\$d|%11\$d.'**

- This message indicates an internal consistency error in the CUBRID database; it occurs when, in a unique B+tree for an index of a specific table, the total number of OIDs does not match the sum of the number of NULL values and the number of keys; this means that the internal statistics of the B+tree index are inconsistent and suggests that data integrity may have been damaged or that there may be a problem in the index structure.

**ERROR CODE: -702, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). the number of NULLs in the unique hierarchy: %6\$d does not equal the number of NULLs: %7\$d found in the unique B+tree root statistics for B+tree: %8\$d|%9\$d|%10\$d.'**

- This message indicates an internal consistency error in the CUBRID database; it occurs when the number of NULL values in the hierarchy to which a UNIQUE constraint for an index of a specific table applies does not match the number of NULL values recorded in the B+tree root statistics for that index; this means a mismatch between database metadata (schema information) and the actual B+tree index structure and suggests that data integrity may have been damaged or that index statistics may be incorrect.

**ERROR CODE: -703, 'Internal error: INDEX %1\$s ON CLASS %2\$s (CLASS\_OID: %3\$d|%4\$d|%5\$d). OID: %6\$d|%7\$d|%8\$d found in unique B+tree: %9\$d|%10\$d|%11\$d does not belong to one of the classes for the unique constraint.'**

- This message indicates an internal consistency error in the CUBRID database; it occurs when an object OID found in the unique B+tree for an index of a specific table does not belong to one of the classes in the table hierarchy to which the unique constraint applies (UNIQUE hierarchy); this means a mismatch between the database metadata (schema) and the actual data storage structure (B+tree) and suggests that data integrity may have been damaged.

**ERROR CODE: -714, 'Query failed due to insufficient temporary file space.'**

- This message is an error that appears when query processing fails because there is insufficient temporary file space during query execution in the CUBRID database; CUBRID uses temporary files to store intermediate results when processing complex queries (e.g., sorting, joins, grouping, etc.).

**ERROR CODE: -725, 'Internal error: expected temporary oid and encountered permanent oid.'**

- This message is an internal error that appears when, while processing a collection data type in the CUBRID database, a temporary OID was expected but a permanent OID was encountered; an OID is an identifier that uniquely identifies database objects in CUBRID, and this message occurs when the object's state and the expected OID type do not match.

**ERROR CODE: -728, 'Query failed because temporary file vfid is invalid for transaction %1\$d.'**

- This message is an error that appears when, during query execution in the CUBRID database, the VFID (Volume File ID) of a temporary file is invalid for a specific transaction; CUBRID uses temporary files to store intermediate results when processing complex queries or large amounts of data, and a VFID is an identifier that uniquely identifies a file in CUBRID and is composed of a volume ID and a file ID; this message occurs when the VFID of the temporary file is corrupted or when the temporary file associated with the transaction is in an unexpected state.

**ERROR CODE: -858, 'Volume "%1\$s" is unknown at server restart.'**

- This is a warning message indicating that, when the database server starts up or shuts down, it deletes unnecessary temp temp volumes, and it is deleting because there is a temp temp volume that is not registered in the system information.

**ERROR CODE: -909, 'Missing or invalid catalog class/vclass is found.'**

- This message occurs when the CUBRID database system cannot find a catalog table or a virtual table (view) that it uses internally, or when the definition of that catalog is not valid; in other words, it means a situation in which the system cannot operate normally because a problem has occurred in internal objects that manage the core metadata of the database (tables, columns, indexes, user information, and other information essential for system operation); such situations generally occur due to database corruption, abnormal system shutdown, database upgrade failure, or errors in CUBRID's internal metadata management logic, and it is a fatal protective error to protect the integrity and stability of the database system.

**ERROR CODE: -934, 'Null domain referenced.'**

- This message occurs in the CUBRID database due to the domain information for a data type being NULL or invalid, and it is generally caused by an incorrect data type definition.

**ERROR CODE: -983, 'Instances of a reusable OID class are non-referable. This operation is not permitted on non-referable instances.'**

- This message occurs when, in the CUBRID database, you try to reference a record of a table with the *REUSE\_OID* option set; *REUSE\_OID* is a special CUBRID feature that reuses the OIDs of deleted records to improve the space efficiency of the database; however, records in a table with this feature enabled are restricted so that they cannot be referenced from outside, and this is a protective error to protect data integrity and to prevent reference errors caused by OID reuse; it can especially occur when a foreign key constraint, object reference, or a reference from another table is attempted.

**ERROR CODE: -1016, '%1\$s external storage error: %2\$s'**

- This message is a general error that occurs when the CUBRID database system processes LOB (Large Object) data or external files using External Storage; that is, it means that when the

CUBRID server attempts to access an external storage system, operations such as file creation, reading, writing, and deletion have failed; it can occur due to failure to initialize external storage, file system permission issues, insufficient disk space, network connectivity issues, or errors in the external storage system itself, and it is a protective error that occurs during the integration process with external storage in CUBRID's LOB data management system.

**ERROR CODE: -1017, 'Path for external storage '%1\$s' is invalid.'**

- This message occurs when the CUBRID database system, while validating the path of External Storage, determines that the path is invalid; that is, when the CUBRID server attempts to initialize or use an external storage path for storing LOB data, it means that the path format is incorrect, an unsupported external storage type was specified, or a path component is missing, and it is a protective error that occurs during the process of validating the path in CUBRID's external storage system.

**ERROR CODE: -1019, 'External storage is not initialized because the path is not specified in "databases.txt"'**

- This message occurs when initialization fails because the external storage (LOB) path of the CUBRID database is not defined in the databases.txt file; it indicates that the external storage path setting for storing LOB (Large Object) data is missing.

**ERROR CODE: -1020, 'External file "%1\$s" was not found.'**

- This message occurs when CUBRID tries to find a specific file in external storage (a LOB repository or another external file system) but the file does not exist; it indicates a situation in which the file cannot be found due to an incorrect file path, the file having actually been deleted, access permission issues, and so on.

**ERROR CODE: -1075, 'Descending index scan aborted because of lower priority on B+tree with index identifier: (vfid = (%1\$d, %2\$d), rt\_pgid: %3\$d).'**

- This message occurs when, in the CUBRID database, a descending scan operation on a B+tree index is aborted because the system internally determined that the operation has a lower priority; it mainly occurs when, during a descending scan, the desired B-tree page cannot be obtained.

**ERROR CODE: -1084, 'Skip invalid page in checkpoint. (page id: %1\$d, "%2\$s", oldest\_unflush\_lsa: %3\$lld|%4\$d, previous checkpoint redo lsa: %5\$lld|%6\$d)'**

- This message is an error message that occurs because, during checkpoint in the CUBRID database, the internal time information does not match; it is an error that has no impact on system operation and data consistency.

**ERROR CODE: -1125, 'Create the overflow key file. INDEX %1\$s%2\$s ON CLASS %3\$s%4\$s. key: %5\$s%6\$s.'**

- This is an informational notice that occurs when, while creating or updating a B-tree index in the CUBRID database system, the index key size exceeds the maximum size that can be stored directly on a page; that is, when the CUBRID server encounters a key larger than a certain page size while processing B-tree index operations, it automatically creates an overflow key file and stores the key in a separate overflow page.

이는 B-tree의 깊이를 제한하고 인덱스 성능을 유지하기 위한 정상적인 동작으로, 오류가 아닌 시스템의 자동 최적화 기능입니다.

**ERROR CODE: -1126, 'Create a new overflow page. INDEX %1\$s%2\$s ON CLASS %3\$s%4\$s. key: %5\$s%6\$s.'**

- This is an informational notice that occurs when, while creating or updating a B-tree index in the CUBRID database system, the number of OIDs (Object Identifiers) that can be stored in an index leaf node exceeds the page limit and an overflow page is created.

즉, CUBRID 서버가 B-tree 인덱스 작업을 처리하는 과정에서, 페이지 특정 크기에 맞는 최대(OID 개수)보다 많은 OID를 하나의 키에 대해 저장해야 할 때 자동으로 오버플로우 페이지를 생성하여 추가 OID를 별도 페이지에 저장합니다. 이는 B-tree의 깊이를 제한하고 인덱스 성능을 유지하기 위한 정상적인 동작으로, 오류가 아닌 시스템의 자동 최적화 기능입니다.

**ERROR CODE: -1127, 'Delete an empty overflow page. INDEX %1\$s%2\$s ON CLASS %3\$s%4\$s. key: %5\$s%6\$s.'**

- This is an informational notice that occurs when, while cleaning up or optimizing a B-tree index in the CUBRID database system, an empty overflow page that is no longer used is deleted; that is, when the CUBRID server performs B-tree index maintenance, if OIDs (Object Identifiers) for a specific key are deleted or changed and the overflow page becomes empty, the system automatically cleans up and deletes the page; this is normal behavior to manage storage space efficiently and to optimize the index structure, and it is an automatic cleanup function of the system, not an error.

**ERROR CODE: -1128, 'Log recovery is started.'**

- This message is actually not an error but an informational message indicating that the log recovery process of the CUBRID database has started.

**ERROR CODE: -1129, 'Log recovery is finished.'**

- This message is actually not an error but an informational message indicating that the log recovery process of the CUBRID database has successfully completed.

**ERROR CODE: -1146, 'volume identifier %1\$d does not exist.'**

- This message occurs when, in the CUBRID database, while trying to access a volume using a specific volume ID, the system detects that the volume does not exist in the system; that is, it is a diagnostic error that can occur when executing the *show volume header* statement and occurs when the database cannot find the physical storage space (volume) it is trying to reference; this situation can generally occur when the volume file has been deleted, the path has been changed, or incorrect volume information has been set in the database configuration files.

**ERROR CODE: -1149, 'Cannot find the page %1\$d of volume %2\$d.'**

- This message occurs when, in the CUBRID database, while trying to access a specific page of a specific volume, the page does not exist or has already been deallocated; that is, it is a diagnostic error that can occur when executing the *show slotted page header/slots* statement and occurs when the system cannot find the requested page; this situation can generally occur when the page has been deleted, the volume has been corrupted, or there is an incorrect page reference.

**ERROR CODE: -1151, 'The page %1\$d of volume %2\$d is not a slotted page.'**

- This message occurs when, in the CUBRID database, while trying to access a specific page of a specific volume, the system detects that the page is not in the expected "slotted page" (Slotted Page) format; that is, it is a diagnostic error that can occur when executing the *show slotted page header/slots* statement and occurs when the database expected the page to be a slotted page but the page header information or internal structure failed the validity checks for a slotted page.

**ERROR CODE: -1181, 'Manual vacuum is disabled for client-server mode.'**

- This message occurs when the CUBRID database is running in client-server (Client-Server) mode and the user attempts to perform a manual vacuum operation; in the client-server environment, CUBRID restricts manual vacuum operations in order to maintain database consistency and stability, and internally manages space reclamation and optimization through an automatic vacuum (auto vacuum) mechanism; therefore, this message is a protective error indicating that the manual vacuum command is not permitted in the current operating mode.

## Transaction-Related Errors

**ERROR CODE: -72, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) has been unilaterally aborted by the system.'**

- This message is an error indicating that, in the CUBRID system, a specific transaction has been unilaterally aborted by the system; here, "unilaterally aborted" means that the system automatically rolled back the transaction regardless of the intent of the user or application

that was executing it; this mainly occurs due to deadlock resolution, insufficient system resources, server failures, or other system-level problems.

**ERROR CODE: -73, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on object %6\$d|%7\$d|%8\$d. You are waiting for user(s) %9\$s to finish.'**

- This message is a lock timeout (lock timeout) error indicating that, in the CUBRID system, a specific transaction timed out while waiting to acquire a lock on a specific object (record); the current transaction is waiting for another user to release the lock on that object (record), but the lock was not released within the configured time and a timeout occurred; this mainly occurs due to record-level concurrency-control problems, deadlock situations, or long-running transactions.

**ERROR CODE: -74, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on class %6\$s. You are waiting for user(s) %7\$s to finish.'**

- This message is a lock timeout (lock timeout) error indicating that, in the CUBRID system, a specific transaction timed out while waiting to acquire a lock on a table; the current transaction is waiting for another user to release the lock on that table, but the lock was not released within the configured time and a timeout occurred; this mainly occurs due to table-level concurrency-control problems, deadlock situations, or long-running transactions.

**ERROR CODE: -75, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on instance %6\$d|%7\$d|%8\$d of class %9\$s. You are waiting for user(s) %10\$s to finish.'**

- This message is a lock timeout (lock timeout) error indicating that, in the CUBRID system, a specific transaction timed out while waiting for a lock on an instance of a table; this mainly occurs due to record-level concurrency-control problems, deadlock situations, or long-running transactions.

**ERROR CODE: -76, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s on page %6\$d|%7\$d. You are waiting for user(s) %8\$s to release the page lock.'**

- This message is a latch timeout (latch timeout) error indicating that, in the CUBRID system, a specific transaction timed out while waiting for a page lock in order to perform work on a page; this mainly occurs due to concurrency-control problems, deadlock situations, or long-running transactions.

**ERROR CODE: -106, 'Cannot prepare to commit the current transaction with global transaction identifier %1\$d because that transaction identifier is in use by another transaction.'**

- This message is displayed when the CUBRID system tries to prepare-commit the current transaction in a 2PC (Two-Phase Commit) distributed transaction, but cannot proceed with the prepare operation because the specified global transaction identifier is already in use by another active transaction.

**ERROR CODE: -107, 'There is no global distributed transaction associated with transaction identifier %1\$d.'**

- This message is displayed when the CUBRID system cannot find a global distributed transaction associated with a specific transaction identifier; that is, in a 2PC (Two-Phase Commit) distributed-transaction environment, the client attempted an operation on a distributed transaction using a specific transaction ID, but the global distributed transaction for that ID does not exist or has already completed.

**ERROR CODE: -108, 'Current transaction %1\$d must be committed or aborted before attempting to join to the distributed transaction with global identifier %2\$d.'**

- This message is displayed when the CUBRID system tries to participate in a 2PC (Two-Phase Commit) distributed transaction but cannot participate because there is already an active transaction; it means that the current transaction must be completed (committed or aborted) before participating in the distributed transaction.

**ERROR CODE: -198, 'Receive buffer too small, data truncated.'**

- This message indicates that, while receiving data in the CUBRID database, the allocated buffer size was smaller than the size of the data to be received, so part of the data was truncated; it mainly occurs when processing large data in network communication or file I/O, and it is an error that can affect data integrity.

**ERROR CODE: -440, 'Invalid cursor position.'**

- This message is an error that appears when the cursor position is invalid while processing query results in the CUBRID database; it occurs during cursor-position validation in the query processor when the cursor is at an invalid position or the cursor state is not correct.

**ERROR CODE: -441, 'Invalid cursor operation.'**

- This message is displayed when trying to extract a record's OID from a result (cursor) that does not include OIDs in the CUBRID database; it can occur during cursor-operation validation in the query processor when an operation that the cursor does not support is attempted, or when the cursor state does not allow that operation.

**ERROR CODE: -442, 'Unknown cursor position.'**

- This message is an error that appears when the cursor position is in an unexpected or undefined state in the CUBRID database; it can occur during cursor-position validation in the query processor when the cursor position has an unexpected value.

**ERROR CODE: -443, 'Tuple value index %1\$d is out of range.'**

- This message is an error that appears when, in a tuple of query results in the CUBRID database, an attempt is made to fetch a value by a specific index, but that index is out of the valid range;

it occurs during tuple-value index validation in the query processor when an index larger than the number of tuple columns or a negative index is used.

**ERROR CODE: -444, 'Invalid attribute name: "%1\$s"'**

- This message is an error that appears when a column name or attribute name in query results is invalid in the CUBRID database; it occurs during column-name validation in the query processor when a non-existent column name or attribute name is referenced.

**ERROR CODE: -447, 'Attempted to operate a query result structure already closed.'**

- This message is an error that appears when trying to perform an operation on a query result structure that has already been closed in the CUBRID database; it occurs during validation of the query result structure's state in the query processor; it can happen when an application has explicitly closed the query result, or when it tries to access a query result that has been closed internally due to transaction end, and so on.

**ERROR CODE: -449, 'Unknown query identifier: %1\$d.'**

- This message is an error that appears when a non-existent query identifier is referenced in the CUBRID database; it occurs during query-identifier validation in the query layer; that is, when an undefined query ID or an invalid query identifier is used.

**ERROR CODE: -452, 'Invalid XASL tree node content.'**

- This message is an error that appears when the content of an XASL (eXtensible Abstract Syntax Language) tree node is invalid in the CUBRID database; it occurs during validation of XASL tree nodes in a query; that is, when the structure or contents of an XASL tree node are not correct.

**ERROR CODE: -460, 'Too few input host variables provided.'**

- This message is an error that appears when fewer host variables are provided than the number of host variables required to execute a query in the CUBRID database.

**ERROR CODE: -550, 'Unknown savepoint name %1\$s'**

- This message is an error that appears when referencing a savepoint name that does not exist in the CUBRID database; it mainly occurs when performing a partial rollback of a transaction and the specified savepoint does not exist.

**ERROR CODE: -609, 'Your transaction cannot be rolled back since logging was ignored. Your database may be corrupted.'**

- This message occurs when attempting a transaction rollback in the CUBRID database; when logging is ignored, it is not possible to attempt a rollback or perform transaction recovery, and there is a possibility that the database may be damaged.

**ERROR CODE: -640, 'System Error: a savepoint cannot be added when the transaction is not active (e.g., during commit or rollback).'**

- This message is a system error that occurs when trying to add a savepoint when no transaction is active in the CUBRID database; a savepoint cannot be created when a transaction is committing or rolling back, has not yet started, or has already ended; it indicates an internal system error related to transaction lifecycle management.

**ERROR CODE: -641, 'A name must be given for a savepoint.'**

- This message is displayed when creating a savepoint in the CUBRID database but no name is provided; a savepoint is a feature that marks a specific point within a transaction, and it must require a unique name; this is a validation error that occurs when the required parameter (the name) is missing when creating a savepoint.

**ERROR CODE: -642, ' System Error: there is not an active top system operation for current transaction.'**

- This message is a system error that occurs when there is no active top-level system operation for the current transaction in the CUBRID database; it occurs when trying to end a system operation but that operation is not active; it indicates an internal system error related to system-operation state management.

**ERROR CODE: -643, 'May be a system error: Committing/Aborting transaction = %1\$d (index = %2\$d) which has permanent operationsn attached to it. Will attach those system operations to the transaction'**

- This message is a warning that occurs when there is a permanent system operation linked while trying to commit or abort a transaction in the CUBRID database; it occurs when attempting to commit or abort while system operations are linked to the transaction; it may indicate a system error, but CUBRID automatically attaches and processes those system operations with the transaction.

**ERROR CODE: -674, 'There is not enough active threads to continue current server execution. Current number of active threads is %1\$d. You may need up to %2\$d threads for clean server execution in your environment. Transaction index %3\$d has been timed out to continue server execution.'**

- This message is a warning from the CUBRID database server meaning that all worker threads are tied up in a "waiting (suspend)" state and, as a result, there appear to be not enough active threads available to process work immediately.

**ERROR CODE: -735, 'Unknown transaction index %1\$d.'**

- This message is an error that appears when an invalid transaction index is used in the CUBRID database; the transaction index is an internal identifier used by CUBRID to uniquely identify each transaction; this message occurs when the system attempts to reference a non-existent or

incorrect transaction index; that is, it can occur due to an internal state inconsistency in the transaction-management system or due to memory corruption.

**ERROR CODE: -830, 'Cannot allocate query entry any more. Maximum allocatable entries are %1\$d.'**

- This message occurs when, in the query management module of the CUBRID database, allocating a query entry to execute a new query fails; that is, it is an error message that occurs when a new query entry cannot be allocated because the maximum number of query entries per transaction has been exceeded.

**ERROR CODE: -836, 'LATCH ON PAGE(%1\$d|%2\$d) TIMEDOUT'**

- This message appears when an attempt to acquire a latch (synchronization lock) on a specific page in the CUBRID database does not complete within the specified time and times out; a latch (LATCH) is a lightweight lock mechanism used internally to control concurrent access to pages, and it can occur when contention is heavy because many transactions access the same page at the same time, or when acquisition is delayed due to long holding; it mainly appears when latch contention becomes severe due to a large number of concurrent transactions, inefficient queries, system load, internal deadlocks, bugs, and so on; the impact includes cases where an I/O bottleneck prevents the desired page from being fetched from the file, or where a dead-latch occurs while performing a B-tree split or merge.

**ERROR CODE: -842, 'Cannot cache lock of object %1\$d|%2\$d|%3\$d.'**

- This message is an error message that occurs when, while checking locks (LOCK) cached in the client module, the lock is NULL LOCK or there is a lock change error and, during the process of acquiring locks for multiple objects (records), acquiring the lock for a specific object (record) fails or a lock-cache operation fails.

**ERROR CODE: -843, 'Wrong arguments in %1\$s, a %2\$s was passed.'**

- This message occurs when an invalid argument is passed to lock manager functions in the CUBRID database; it mainly occurs when, while calling lock manager functions internally from application code, a parameter is NULL.

**ERROR CODE: -844, 'Unknown isolation(%1\$d) is found. The transaction index is %2\$d.'**

- This message occurs when, in the lock manager of the CUBRID database, the system finds an invalid isolation level value that it cannot recognize while checking a transaction's isolation level; CUBRID supports defined isolation levels such as *TRAN\_READ\_COMMITTED*, *TRAN\_REPEATABLE\_READ*, and *TRAN\_SERIALIZABLE*; if a value outside this range is found, this error occurs; it is an error that generally occurs due to memory corruption, concurrency-control problems, or an internal state inconsistency in the transaction manager.

**ERROR CODE: -845, 'Invalid object type(%1\$d) is found. The lockable object is %2\$d|%3\$d|%4\$d.'**

- This message occurs when, in the lock manager of the CUBRID database, deleting a lock entry from a transaction hold list; if a value outside the range supported by CUBRID is found, this error occurs; it is an error that generally occurs due to memory corruption, concurrency-control problems, or an internal state inconsistency in the lock manager.

**ERROR CODE: -846, '%1\$s of tran(%2\$d) is not found in the holder list of an object(%3\$d|%4\$d|%5\$d).'**

- This message occurs during table-lock demotion in the lock manager of the CUBRID database; that is, when trying to find a transaction's lock entry in the holder list for a specific object (record), it occurs when an abnormal state is found where the entry does not exist in the holder list; this typically appears when there is a problem in CUBRID's internal lock-management logic, or when memory corruption or concurrency-control problems make the state information of lock entries inconsistent; if this error repeatedly occurs at the same time, it can affect database service stability.

**ERROR CODE: -847, '%1\$s on a %2\$s(%3\$d|%4\$d|%5\$d) is not found in the transaction(%6\$d) hold list(cnt=%7\$d).'**

- This message occurs during hold-list management in the lock manager of the CUBRID database; that is, when trying to delete a lock entry from a specific transaction's hold list, it occurs when an abnormal state is found where the entry does not exist in the list; this typically appears when there is a problem in CUBRID's internal lock-management logic, or when memory corruption or concurrency-control problems make the state information of lock entries inconsistent; if this error repeatedly occurs at the same time, it can affect database service stability.

**ERROR CODE: -849, 'Trying to abort a transaction(%1\$d) twice.'**

- This message occurs during deadlock resolution in the lock manager of the CUBRID database; that is, when trying to abort a transaction because of a deadlock, it occurs when an abnormal situation is found where an abort is attempted again while the transaction is already in the process of aborting; this generally occurs due to concurrency-control problems in the deadlock detection/resolution process or inconsistencies in transaction state management.

**ERROR CODE: -850, 'Tran(%1\$d) is neither lock holder nor lock waiter of an object(%2\$d|%3\$d|%4\$d).'**

- This message occurs when releasing a lock in the lock manager of the CUBRID database; that is, when trying to release a lock on a specific object (record), it occurs when an abnormal state is found where the transaction is neither a holder (owner) of that object's lock nor a waiter waiting for it; this typically appears when there is a problem in CUBRID's internal lock-management logic, or when memory corruption or concurrency-control problems make the state information of lock resources inconsistent.

**ERROR CODE: -851, 'Failed to allocate lock resource (%1\$s).'**

- This message occurs when allocating a lock entry in the lock manager of the CUBRID database; that is, it is an error message that occurs when allocation of the memory resources needed to acquire a new lock or manage lock state fails; this generally occurs due to insufficient system memory, exhaustion of the lock manager's internal resources, or problems with the memory allocator; it is an error that prevents the database's lock-management function from operating normally.

**ERROR CODE: -852, 'Total holders mode(%1\$d) of an empty lock holder list is not NULL\_LOCK.'**

- This message occurs during deadlock detection in the lock manager of the CUBRID database; that is, while traversing lock resources to detect a deadlock, it occurs when an abnormal state is found where there is no holder but the lock is not NULL\_LOCK.

**ERROR CODE: -854, 'WARNING: No lock holder, but lock waiters exist. refer to %1\$s.'**

- This message is a warning that occurs during deadlock detection in the lock manager of the CUBRID database; that is, while traversing lock resources to detect a deadlock, it occurs when an abnormal state is found where there is no holder but there are waiters waiting for the lock; this typically appears when there is a problem in CUBRID's internal lock-management logic, or when memory corruption or concurrency-control problems make the state information of lock resources inconsistent.

**ERROR CODE: -855, 'WARNING: Two or more threads are lock-waiting for one transaction(%1\$d).'**

- This message occurs during the process of requesting a lock in the lock manager of the CUBRID database; this situation typically appears when a single transaction is executed concurrently across multiple threads, or when nested lock requests occur within a transaction.

**ERROR CODE: -856, 'WARNING: Strange lockwait state(%1\$d|%2\$d), thread(%3\$d|%4\$lld) and transaction(%5\$d).'**

- This message is a warning that occurs when, while checking the lock-wait (lockwait) state in the lock manager of the CUBRID database, an unexpected abnormal state is detected; this typically appears when there is a problem in CUBRID's internal lock-management logic, or when memory corruption or concurrency-control problems make lock-wait state information inconsistent.

**ERROR CODE: -859, 'LATCH ON PAGE(%1\$d|%2\$d) ABORTED'**

- This message occurs when, in the CUBRID database, an attempt to acquire a latch (synchronization lock) for a specific page is aborted due to internal policies or exceptional situations (e.g., deadlock, forced abort, transaction rollback, and so on); it mainly appears when, during concurrency control, a deadlock is detected, a forced abort occurs due to long holding, an internal system error occurs, or a transaction is forcibly terminated and latch acquisition cannot be completed normally; the impact includes cases where an I/O bottleneck prevents

the desired page from being fetched from the file, or where a dead-latch occurs while performing a B-tree split or merge.

**ERROR CODE: -860, ‘Cannot make current transaction as a part of a global transaction because its state is ‘%1\$s’**

- This message occurs when trying to start a global transaction using the 2PC (Two-Phase Commit) protocol in the CUBRID database; that is, it is an error that occurs when the current transaction is not active or not in an appropriate state, but an attempt is made to make it part of a global transaction; it is a protective error to ensure correct use of the 2PC protocol and to guarantee the integrity of transaction state management.

**ERROR CODE: -861, ‘Cannot prepare to commit the current transaction with transaction identifier %1\$d because that transaction is not made as a part of a global transaction.’**

- This message occurs when trying to prepare a transaction using the 2PC (Two-Phase Commit) protocol in the CUBRID database; that is, it is an error that occurs when the current transaction was not started as part of a global transaction, but a 2PC prepare is attempted; it is a protective error to ensure the correct sequence of using the 2PC protocol and to protect the integrity of the global transaction.

**ERROR CODE: -862, ‘Cannot set the user information of the global transaction with the identifier %1\$d because its state is ‘%2\$s’**

- This message occurs when trying to set user information for a global transaction that uses the 2PC (Two-Phase Commit) protocol in the CUBRID database; that is, it is an error that occurs when the global transaction is already in an intermediate phase of the 2PC protocol and user information cannot be changed; this situation generally occurs when using the 2PC protocol to ensure transaction consistency among multiple databases in a distributed-transaction environment; it is a protective error to protect transaction state management and data consistency.

**ERROR CODE: -966, ‘Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on object %6\$d|%7\$d|%8\$d because of deadlock. You are waiting for user(s) %9\$s to finish.’**

- This message indicates that, in the CUBRID database, while a transaction is waiting to acquire a lock on a specific object (record), a deadlock situation occurred and a timeout happened; a deadlock means a situation where two or more transactions fall into an infinite wait state while each waits for locks on resources held by the others, and CUBRID detects and resolves this by aborting some of the transactions.

**ERROR CODE: -967, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on class %6\$s because of deadlock. You are waiting for user(s) %7\$s to finish.'**

- This message indicates that, in the CUBRID database, while a transaction is waiting to acquire a lock on a specific table, a deadlock situation occurred and a timeout happened; a deadlock means a situation where two or more transactions fall into an infinite wait state while each waits for locks on resources held by the others; CUBRID detects the deadlock and resolves it by aborting some transactions, and in this case it informs that the transaction timed out due to a deadlock.

**ERROR CODE: -968, 'Your transaction (index %1\$d, %2\$s@%3\$s|%4\$d) timed out waiting on %5\$s lock on instance %6\$d|%7\$d|%8\$d of class %9\$s because of deadlock. You are waiting for user(s) %10\$s to finish.'**

- This message appears when, in a deadlock situation, a lock on a specific object (record) cannot be acquired and a timeout occurs.

**ERROR CODE: -1002, 'The current transaction could not acquire a database lock it requires to continue processing.'**

- This message occurs when a transaction could not acquire a lock on a required resource.

**ERROR CODE: -1021, 'A deadlock cycle is detected. %1\$s.'**

- This message indicates that a deadlock (Deadlock) occurred in the database system: two or more transactions are in a circular wait state where each cannot proceed because it is waiting for locks held by others to be released; CUBRID's lock manager (Lock Manager) detects such a deadlock and, to prevent the entire system from stopping, forcibly terminates (rolls back) one of the involved transactions and reports this error.

**ERROR CODE: -1154, 'MVCC row %1\$d|%2\$d|%3\$d does not satisfies reevaluation.'**

- This message occurs when, in the CUBRID database under an MVCC (Multi-Version Concurrency Control) environment, reevaluation of conditions for a specific record fails; that is, when a transaction attempts to access a specific record, the system detects that the record does not satisfy the MVCC conditions for the current transaction and raises this error; this situation generally occurs when the record's version has changed during concurrency control, or when the visibility conditions required by the transaction isolation level are not satisfied; it is a protective error for database consistency and concurrency control. (However, "reevaluation" varies depending on the isolation level.)

**ERROR CODE: -1156, 'MVCC can't get snapshot'**

- This message indicates an error that occurs when, in the MVCC (Multi-Version Concurrency Control) system of the CUBRID database, a snapshot for a transaction cannot be created; an MVCC snapshot is an important mechanism that captures a consistent state of the database when a transaction starts, and through it the transaction can maintain a consistent data view.

**ERROR CODE: -1157, 'Isolation level value in MVCC must be 'read committed', 'repeatable read' or 'serializable''**

- This message occurs when, in the CUBRID database under an MVCC environment, an unsupported value is specified when setting the transaction isolation level (Isolation Level); that is, in CUBRID's MVCC mode, only three isolation levels are supported: 'read committed', 'repeatable read', and 'serializable', and this validation error occurs when a value outside that range is about to be set; this situation generally occurs when an incorrect value is passed in a SET TRANSACTION ISOLATION LEVEL statement or an internal API call that changes the transaction isolation level; it is a validation error to protect the database's concurrency-control mechanism.

**ERROR CODE: -1176, 'Latch promotion for page %1\$d of volume %2\$d failed.'**

- This message indicates that, in the CUBRID database system, a latch (latch) promotion (promote) operation failed for a specific page (B-tree); a latch is a lightweight lock mechanism used internally to control concurrency for in-memory data structures (e.g., pages in the page buffer); "latch promotion" generally means upgrading a shared latch to an exclusive latch, or attempting to acquire a higher-level latch in order to perform a write on the page; this failure can occur during page buffer management, file management, or B-tree operations, and it suggests that there was a problem acquiring the latch necessary to maintain page consistency; it can occur due to concurrency issues, page-state inconsistencies, or internal errors, and it can lead to transaction failures or database instability.

## CUBRID HA Errors

**ERROR CODE: -898, 'Replication error: "%1\$s"'**

- This message appears when various problems occur during replication operations in a CUBRID database HA (High Availability) replication environment. That is, it occurs during database replication processes such as memory allocation, class information processing, or replication log generation.

**ERROR CODE: -970, 'Server HA mode is changed from '%1\$s' to '%2\$s''**

- This message is a system notification that occurs when the mode is changed in a CUBRID HA (High Availability) replication environment. It occurs when the server state transitions between states such as active, standby, and maintenance, and this is part of the normal HA operation process.

**ERROR CODE: -975, 'Current version of replication does not allow changing multiple rows with a single UPDATE statement which can violate the UNIQUE constraint.'**

- This message is related to a special restriction that occurs in a CUBRID HA (High Availability) replication environment. Although changing multiple rows with a single UPDATE statement is

normally allowed, in an environment where HA replication is enabled, multi-row UPDATE operations that may violate UNIQUE constraints are restricted. This is a protective error to ensure data consistency in the replication environment and to prevent synchronization problems between the master and the slave. When HA mode is enabled (when *ha\_mode* is not *off*), the system rejects multi-row UPDATE operations that may violate UNIQUE constraints.

**ERROR CODE: -986, 'CUBRID heartbeat feature started.'**

- This message is an informational notification indicating that the heartbeat subsystem has successfully started in a CUBRID HA (High Availability) replication environment. The heartbeat feature periodically checks the status of each node in a CUBRID cluster environment and plays an essential role in detecting failures and performing automatic failover. This message usually occurs when the CUBRID master process starts, when the *cubrid heartbeat start* command is executed, or when HA mode is enabled, and it means that the system has started to operate normally in high-availability mode.

**ERROR CODE: -987, 'CUBRID heartbeat feature stopped.'**

- This message is an event notification indicating that the HA heartbeat subsystem has been deactivated in a CUBRID HA (High Availability) replication environment. It occurs during administrator stop commands, master shutdown or restart, HA mode OFF transitions, or deactivation request processing flows, and after this, failure detection and automatic failover functions are stopped.

**ERROR CODE: -988, 'Node event: %1\$s.'**

- This message is an informational message that notifies node state changes or event occurrences in the CUBRID HA (High Availability) system. It records various events related to node state monitoring, such as connections, disconnections, and state changes.

**ERROR CODE: -989, 'Process event: %1\$s. %2\$s'**

- This message is a system message that notifies process events in the CUBRID HA (High Availability) system. It is used as a core monitoring message to track and record server state changes or important events.

**ERROR CODE: -990, 'Command execution: %1\$s. %2\$s'**

- This message indicates that a problem occurred during the execution of a specific command inside the CUBRID HA (High Availability) system. In particular, this error suggests that a command execution failure occurred during heartbeat management or request processing, which are core functions of the CUBRID master process. When an actual error occurs, additional information about the specific command content or failure cause is provided, which means that important internal processes did not operate normally and may directly affect database stability and availability.

**ERROR CODE: -1023, 'log applier filter: %1\$s.'**

- This message occurs when the log applier encounters a generic error while processing user-defined replication filter rules in a CUBRID HA (High Availability) replication environment. Replication filters define rules to exclude or include specific tables or data change operations (INSERT, UPDATE, DELETE) from replication, and this means that a problem occurred during the processing of those rules.

**ERROR CODE: -1024, 'log writer: failed to get log page(s) starting from page id %1\$lld.'**

- This message occurs when the copylogdb process requests replication logs from the replication target server in a CUBRID HA (High Availability) environment.

**ERROR CODE: -1025, 'HA delay info: The replication delay (%1\$d secs) has exceeded the limit (%2\$d secs).'**

- This message indicates that the replication delay time between the master server and the standby server in a CUBRID HA (High Availability) environment has exceeded the threshold configured by the user (*ha\_delay\_limit*, *ha\_delay\_limit\_delta*). That is, it means that the standby server is taking longer than the configured time to catch up with the latest changes of the master server. This may be a warning or informational message indicating that the data synchronization status between the master and standby is not good, and depending on the configuration, it may trigger specific actions such as additional transaction delays on the master.

**ERROR CODE: -1026, 'HA delay info: The replication delay (%1\$d secs) is decreased below the acceptable level (%2\$d secs).'**

- This message is an informational log indicating that a previously occurring replication delay condition in a CUBRID HA (High Availability) environment has been resolved. That is, it means that the replication delay time between the active (master) server and the standby server has been reduced below the user-configured threshold (*ha\_delay\_limit*, *ha\_delay\_limit\_delta*), and the data synchronization status has returned to a normal range.

**ERROR CODE: -1027, 'log applier: failed to change apply state from '%1\$s' to '%2\$s'.'**

- This message is displayed when the applylogdb process cannot change its operation state as requested by the internal system in a CUBRID HA (High Availability) environment.

**ERROR CODE: -1028, 'log applier: unexpected EOF record in archive log. LSA: %1\$lld|%2\$d.'**

- This message is an error message that occurs when the applylogdb process encounters an unexpected end-of-log record in a replicated archive log in a CUBRID HA (High Availability) environment, and the applylogdb process proceeds without applying the corresponding log record.

**ERROR CODE: -1029, 'log applier: invalid replication log page/offset. page HDR: %1\$lld|%2\$d, final: %3\$lld|%4\$d, append LSA: %5\$lld|%6\$d, EOF LSA: %7\$lld|%8\$d, ha file status: %9\$d, is end-of-log: %10\$d.'**

- This message occurs when the applylogdb process finds an invalid page ID or offset while processing replication logs in a CUBRID HA (High Availability) environment. It indicates a state where replication cannot proceed because the log record location information is not valid.

**ERROR CODE: -1030, 'log applier: invalid replication record. LSA: %1\$lld|%2\$d, forw LSA: %3\$lld|%4\$d, backw LSA: %5\$lld|%6\$d, Trid: %7\$d, prev tran LSA: %8\$lld|%9\$d, type: %10\$d.'**

- This message occurs during the process in which the applylogdb process verifies replication log records in a CUBRID HA (High Availability) environment. If the LSA chain (forward/backward linkage) or transaction information of the log record is determined to be invalid during verification, this error occurs.

**ERROR CODE: -1031, 'log applier: failed to apply the following statement. class: "%1\$s", statement: "%2\$s", server error: %3\$d, %4\$s.'**

- This message occurs when the applylogdb process on the standby server in a CUBRID HA (High Availability) environment fails to actually apply (execute) a change log (in the form of an SQL statement) received from the master server to the standby database. That is, it means that although the log itself was received and parsed normally, the corresponding SQL (mainly DDL statements) could not be executed in the current database state of the standby server. The causes of failure vary, including schema mismatch, data conflicts (such as unique key violations), constraint violations, and resource shortages, and the detailed 'server error' information included in the message indicates the specific reason for the failure.

**ERROR CODE: -1032, 'log applier: failed to apply insert replication log. class: "%1\$s", key: "%2\$s", server error: %3\$d, %4\$s'**

- This message occurs when the applylogdb process on the standby server in a CUBRID HA (High Availability) environment fails while trying to apply (execute) a replicated *INSERT* log received from the master server to the standby database. The most common cause is that a record with the same key already exists on the standby server, resulting in a primary key or unique key constraint violation (duplicate key). In addition, there may be other causes that prevent execution of the INSERT statement, such as schema mismatches or other constraint violations, and the included 'server error' information shows the direct reason for the failure.

**ERROR CODE: -1033, 'log applier: failed to apply update replication log. class: "%1\$s", key: "%2\$s", server error: %3\$d, %4\$s'**

- This message occurs when the applylogdb process on the standby server in a CUBRID HA (High Availability) environment fails while trying to apply (execute) a replicated *UPDATE* log received from the master server to the standby database. This means that the UPDATE operation was rejected on the standby server. Major causes include cases where the target record to be

updated does not exist on the standby server, the update result violates a unique key or primary key constraint or other constraints (NOT NULL, FK, etc.), or schema mismatches, and the 'server error' information included in the message provides the specific reason for the failure.

**ERROR CODE: -1034, 'log applier: failed to apply delete replication log. class: "%1\$s", key: "%2\$s", server error: %3\$d, %4\$s'**

- This message occurs when the applylogdb process on the standby server in a CUBRID HA (High Availability) environment fails while trying to apply (execute) a replicated *DELETE* log received from the master server to the standby database. This means that the *DELETE* operation was rejected on the standby server. Major causes include cases where the target record does not exist on the standby server, constraint violations (unique key, primary key, NOT NULL, FK, etc.), or schema mismatches, and the 'server error' information included in the message provides the specific reason for the failure.

**ERROR CODE: -1035, 'log applier: mem size(%1\$d MB) of log applier is greater than max mem size (%2\$d MB) or has been grow more than 2 times (%3\$d MB). required LSA: %4\$lld|%5\$d. last committed LSA: %6\$lld|%7\$d.'**

- This message occurs when the amount of memory used by the applylogdb process on the standby server in a CUBRID HA (High Availability) environment exceeds the configured maximum allowed value (*ha\_log\_applier\_max\_mem\_size*) or increases abnormally fast (more than two times in a short period). This is a protection mechanism to prevent resource exhaustion on the standby server and to maintain system stability. It can occur when a very large transaction (generating many logs) occurs on the master server, or when log application is delayed due to insufficient processing performance or network delays on the standby server. If the difference between the 'required LSA' and the 'last committed LSA' is large, it indicates that log application is significantly delayed.

**ERROR CODE: -1036, 'log applier: log applier shut itself down by signal.'**

- This message indicates a normal termination of the applylogdb process that occurs in the CUBRID HA (High Availability) system. It means that the log replication process performed a normal shutdown procedure after receiving a system signal. This usually occurs due to a planned system shutdown or an intentional shutdown request by an administrator.

**ERROR CODE: -1037, 'log writer: log writer shut itself down by signal.'**

- This message indicates a normal termination of the copylogdb log replication process that occurs in the CUBRID HA (High Availability) system. It means that the log replication process performed a normal shutdown procedure after receiving a system signal. This usually occurs due to a planned system shutdown or an intentional shutdown request by an administrator.

**ERROR CODE: -1038, 'log applier: log applier started. required LSA: %1\$lld|%2\$d. last committed LSA: %3\$lld|%4\$d. last committed repl LSA: %5\$lld|%6\$d.'**

- This message is an informational message printed when the applylogdb process starts in a CUBRID HA (High Availability) environment. It includes LSA information at the start time and shows the starting position of log replication and the last committed state. LSA is an address value that identifies the position of logs and serves as a reference point for data synchronization.

**ERROR CODE: -1039, 'log writer: log writer started. mode: %1\$d.'**

- This message is an informational message printed when the copylogdb process starts in a CUBRID HA (High Availability) environment. It includes LSA information at the start time and shows the starting position of log replication and the last committed state. LSA is an address value that identifies the position of logs and serves as a reference point for data synchronization. This message indicates the normal startup of the copylogdb process.

**ERROR CODE: -1040, 'HA generic: %1\$s.'**

- This message represents an exceptional or general error situation that occurred within the CUBRID HA (High Availability) system and was not classified under a specific error code. That is, it is a comprehensive error code used when it is no longer possible to proceed due to unexpected internal states or external factors while performing HA-related functions (heartbeat, copylogdb, applylogdb, etc.). Therefore, the detailed error messages included in the error message provide critical clues for diagnosing the actual cause of the error.

**ERROR CODE: -1105, 'Internal error: partially failed to flush dirty object.'**

- This message occurs when only part of the operation succeeds and part fails during the process of writing modified data (dirty objects) in memory to disk in the CUBRID database. That is, it means that some changes of a transaction were successfully written to disk, but some of the remaining changes failed to be written. This is an internal error to ensure data integrity and system stability, and it can mainly occur when data is applied by applylogdb and may occur during the replication process.

**ERROR CODE: -1122, 'Time out in receiving data.'**

- This message is an execution error that occurs in the copylogdb process among the problems that occur within the CUBRID HA (High Availability) system. It occurs when the requested log page is not received within the timeout period after requesting a log page from the cub\_server process.

**ERROR CODE: -1133, 'Copylogdb for %1\$s already exists.'**

- This message occurs when copylogdb is already running while copylogdb requests a connection to cub\_master in a CUBRID HA (High Availability) environment.

**ERROR CODE: -1134, 'Applylogdb for %1\$s already exists.'**

- This message occurs when applylogdb is already running while applylogdb requests a connection to cub\_master in a CUBRID HA (High Availability) environment.

**ERROR CODE: -1139, 'Handshake error (peer host %1\$s): incompatible read/write mode. (client: %2\$s, server: %3\$s)'**

- This message appears when a compatibility problem occurs with the read/write mode during the handshake process between the database client and the server in a CUBRID HA (High Availability) environment. That is, it occurs when the client and server modes (RW/RO) are different during the handshake process between the database client and the database server.

**ERROR CODE: -1140, 'Handshake error (peer host %1\$s): HA replication delayed.'**

- This message appears when a delay occurs during the replication process between database servers in a CUBRID HA (High Availability) environment. It is an error that indicates a situation in which data synchronization between the master and slave is delayed beyond the configured threshold.

**ERROR CODE: -1141, 'Handshake error (peer host %1\$s): replica-only client to non-replica server.'**

- This message occurs when a client attempts to directly access a server that is configured as replica-only in a CUBRID HA (High Availability) environment. That is, it occurs when a replica-only client (replica broker) requests a connection to a master or slave server that is not a replica server during the handshake process between the database client and the database server.

**ERROR CODE: -1142, 'Handshake error (peer host %1\$s): unidentified server version.'**

- This message occurs when the client cannot identify the server version when attempting to connect to the database server in a CUBRID HA (High Availability) environment. It represents a situation where server version information is not properly delivered or is incompatible during the client-server handshake process.

**ERROR CODE: -1143, 'Handshake error (peer host %1\$s): remote access to server not allowed.'**

- This message occurs when the database client (csql, cas, copylogdb, applylogdb, etc.) cannot identify version information between servers in a CUBRID HA (High Availability) environment.

**ERROR CODE: -1144, 'Timed out attempting to connect to %1\$s. (timeout: %2\$d sec(s))'**

- This message is displayed when a CUBRID client or component (for example, CSQL, JDBC driver, etc.) attempts to connect to a specified server but fails to receive a response within the configured timeout period. It can generally occur due to network failures, abnormal server states, firewall blocking, or port opening failures.

- Reference: This message is summarized as “equipment down” in the CUBRID HA replication inconsistency detection section of the CUBRID manual.

**ERROR CODE: -1170, 'Failed to flush replication items (error code : %1\$d)'**

- This message indicates that a failure occurred while flushing replication items, that is, changes generated in the master database, to the slave (replica) database during the replication process in a CUBRID HA (High Availability) environment. This can occur due to various causes such as network problems, disk I/O problems, internal state issues of the slave database, or problems with the replication items themselves.

## CUBRID HA

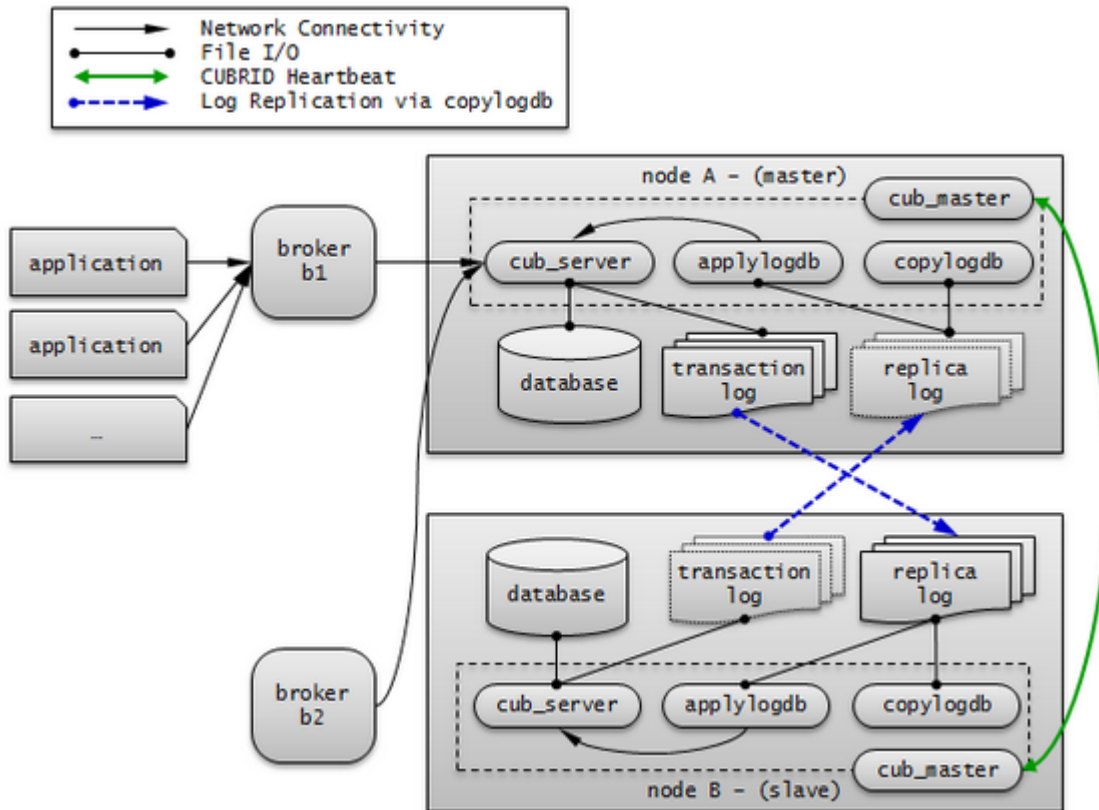

High Availability (HA) refers to a feature to provide uninterrupted service in the event of hardware, software, or network failure. This ability is a critical element in the network computing area where services should be provided 24/7. An HA system consists of more than two server systems, each of which provides uninterrupted services, even when a failure occurs in one of them.

CUBRID HA is an implementation of High Availability. CUBRID HA ensures database synchronization among multiple servers when providing service. When an unexpected failure occurs in the system which is operating services, this feature minimizes the service down time by allowing the other system to carry out the service automatically.

CUBRID HA is in a shared-nothing structure. To synchronize data from an active server to a standby server, CUBRID HA executes the following two steps.

1. Transaction log multiplexing: Replicates the transaction logs created by an active server to another node in real time.
2. Transaction log reflection: Analyzes replicated transaction logs in real time and reflects the data to a standby server.

CUBRID HA executes the steps described above in order to always maintain data synchronization between an active server and a standby server. For this reason, if an active server is not working properly because of a failure occurring in the master node that had been providing service, the standby server of the slave node provides service instead of the failed server. CUBRID HA monitors the status of the system and CUBRID in real time. It uses heartbeat messages to execute an automatic failover when a failure occurs.

## CUBRID HA Concept

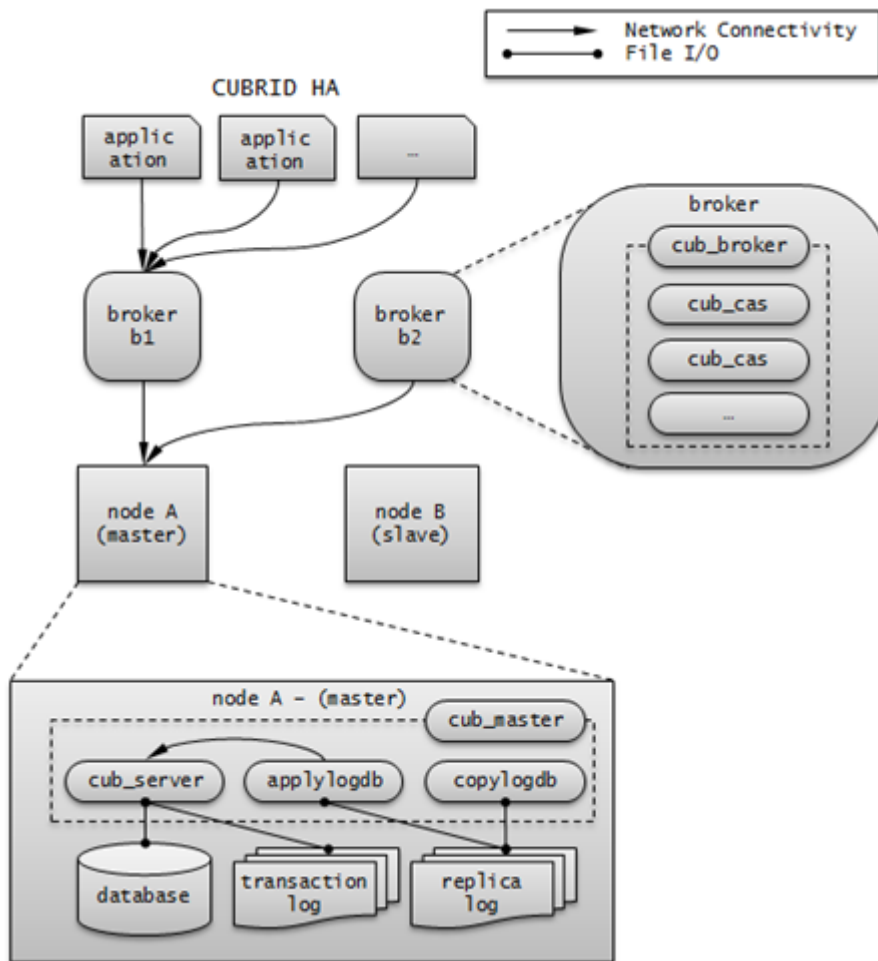

### Nodes and Groups

A node is a logical unit that makes up CUBRID HA. It can become one of the following nodes according to its status: master node, slave node, or replica node.

- **Master node** : A node to be replicated. It provides all services which are read, write, etc. using an active server.
- **Slave node** : A node that has the same information as a master node. Changes made in the master node are automatically reflected to the slave node. It provides the read service using a standby server, and a failover will occur when the master node fails.
- **Replica node** : A node that has the same information as a master node. Changes made in the master node are automatically reflected to the replica node. It provides the read service using a standby server, and no failover will occur when the master node fails.

The CUBRID HA group consists of the nodes described above. You can configure the members of this group by using the **ha\_node\_list** and **ha\_replica\_list** in the **cubrid\_ha.conf** file. Nodes in a group have the same information. They exchange status checking messages periodically and a failover will occurs when the master node fails.

A node includes the master process (cub\_master), the database server process (cub\_server), the replication log copy process (copylogdb), the replication log reflection process (applylogdb), etc.

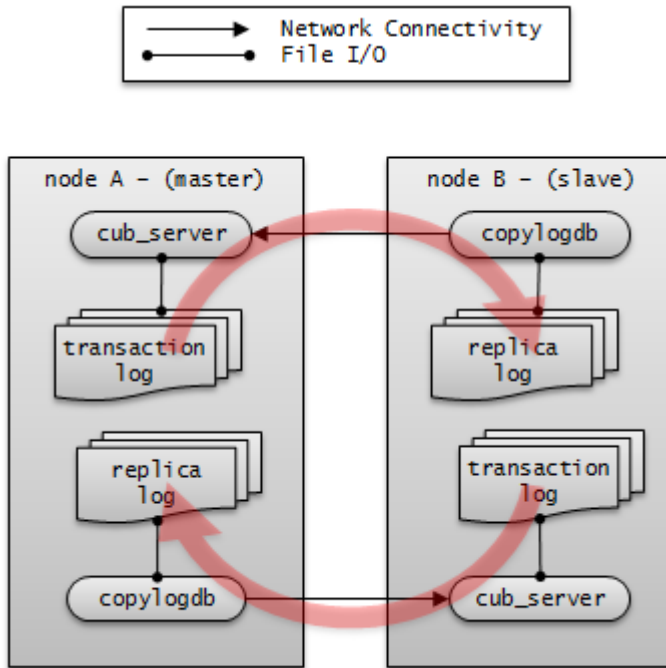

## Processes

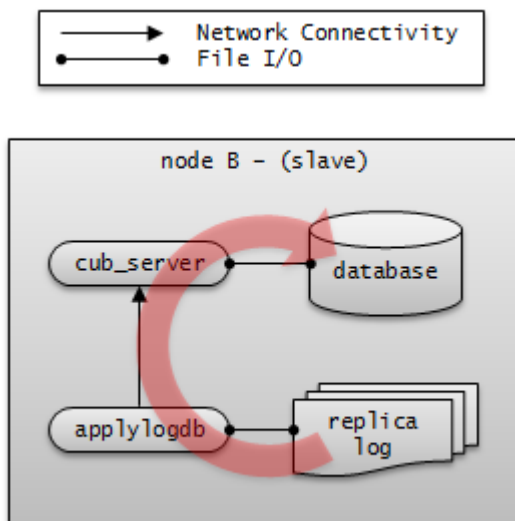

A CUBRID HA node consists of one master process (cub\_master), one or more database server processes (cub\_server), one or more replication log copy processes (copylogdb), and one or more replication log reflection processes (applylogdb). When a database is configured, database server processes, replication log copy processes, and replication log reflection processes will start. Because copy and reflection of a replication log are executed by different processes, the delay in replicating reflections does not affect the transaction that is being executed.

- **Master process (cub\_master)** : Exchanges heartbeat messages to control the internal management processes of CUBRID HA.
- **Database server process (cub\_server)** : Provides services such as read or write to the user. For details, see [Servers](#).
- **Replication log copy process (copylogdb)** : Copies all transaction logs in a group. When the replication log copy process requests a transaction log from the database server process of the target node, the database server process returns the corresponding log. The location of copied

transaction logs can be configured in the **ha\_copy\_log\_base** of **cubrid\_ha.conf**. Use **applyinfo** utility to verify the information of copied replication logs. The replication log copy process has following two modes: SYNC and ASYNC. You can configure it with the **ha\_copy\_sync\_mode** of **cubrid\_ha.conf**. For details on these modes, see [Log Multiplexing](#).

- **Replication log reflection process (applylogdb)** : Reflects the log that has been copied by the replication log copy process to a node. The information of reflected replications is stored in the internal catalog (**\_db\_ha\_apply\_info**). You can use the **applyinfo** utility to verify this information.

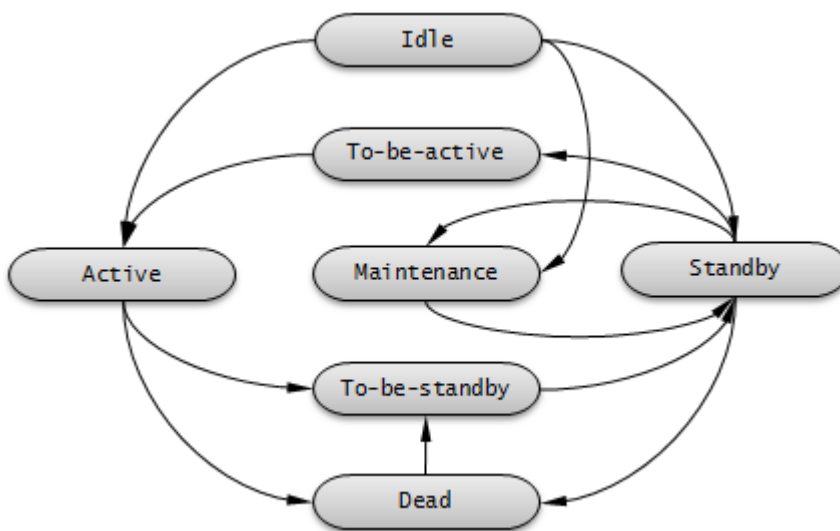

## Servers

Here, the word “server” is a logical representation of database server processes. Depending on its status, a server can be either an active server or a standby server.

- **Active server** : A server that belongs to a master node; the status is active. An active server provides all services, including read, write, etc. to the user.
- **Standby server** : A standby server that belongs to a non-master node; the status is standby. A standby server provides only the read service to the user.

The server status changes based on the status of the node. You can use the **cubrid changemode** utility to verify server status. The maintenance mode exists for operational convenience and you can change it by using the **cubrid changemode** utility.

- **active** : The status of servers that run on a master node is usually active. In this status, all services including read, write, etc. are provided.
- **standby** : The status of servers that run on a slave node or a replica node is standby. In this status, only the read service is provided.
- **maintenance** : The status of servers can be manually changed for operational convenience is maintenance. In this status, only a csql can access and no service is provided to the user.
- **to-be-active** : The status in which a standby server will become active for reasons such as failover, etc. is to-be-active. In this status, servers prepare to become active by reflecting transaction logs from the existing master node to its own server. The node in this status can accept only SELECT query.
- **Other** : This status is internally used.

When the node status is changed, on `cub_master` process log and `cub_server` process log, following error messages are saved. But, they are saved only when the value of **error\_log\_level** in **cubrid.conf** is **error** or less.

- The following log information of `cub_master` process is saved on **\$CUBRID/log/<hostname>\_master.err** file.

```
HA generic: Send changemode request to the server. (state:
1[active], args:[cub_server demodb ], pid:25728).
HA generic: Receive changemode response from the server. (state:
1[active], args:[cub_server demodb ], pid:25728).
```

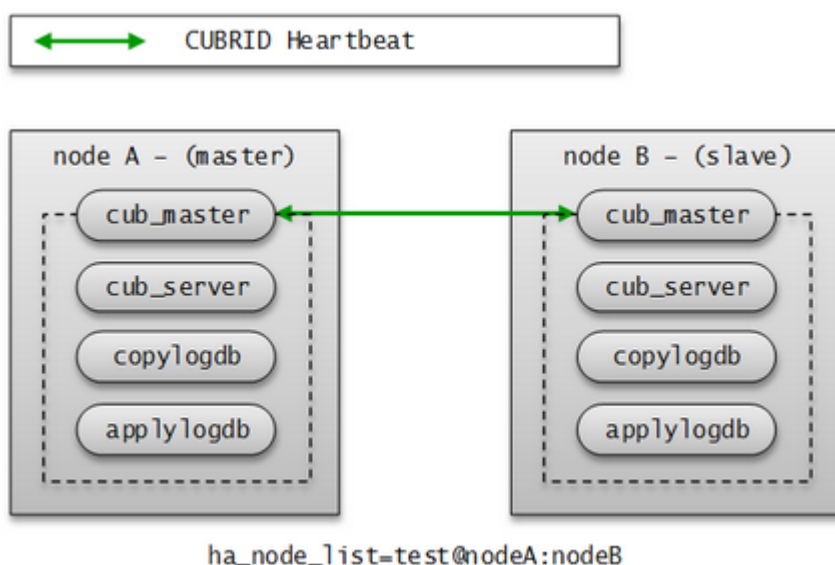

- The following log information of `cub_server` is saved on **\$CUBRID/log/server/<db\_name>\_<date>\_<time>.err** file.

```
Server HA mode is changed from 'to-be-active' to 'active'.
```

## heartbeat Message

As a core element to provide HA, it is a message exchanged among master, slave, and replica nodes to monitor the status of other nodes. A master process periodically exchanges heartbeat messages with all other master processes in the group. A heartbeat message is exchanged through the UDP port configured in the **ha\_port\_id** parameter of **cubrid\_ha.conf**. The exchange interval of heartbeat messages is determined by an internally configured value.

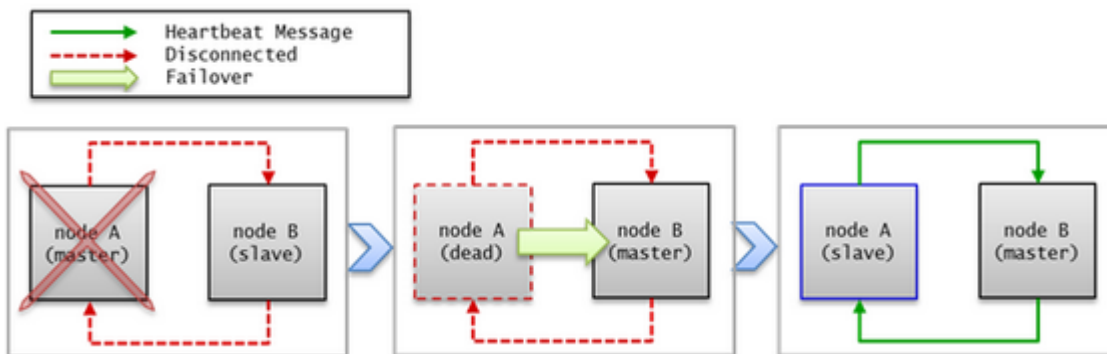

When the master node fails, a failover occurs to a slave node.

## failover and failback

A failover means that the highest priority slave node automatically becomes a new master node when the original master node fails to provide services due to a failure. A master process calculates scores for all nodes in the CUBRID HA group based on the collected information, promotes slave nodes to master modes when it is necessary, and then notifies the management process of the changes it has made.

A failback means that the previously failed master node automatically becomes a master node back after the failure node is restored. The CUBRID HA does not currently support this functionality.

If a heartbeat message fails to deliver, a failover will occur. For this reason, servers with unstable connection may experience failover even though no actual failures occur. To prevent a failover from occurring in the situation described above, configure **ha\_ping\_hosts**. Configuring **ha\_ping\_hosts** will send a ping message to the hosts specified in **ha\_ping\_hosts** in order to verify whether the network is stable or not when a heartbeat message fails to deliver. For details on configuring **ha\_ping\_hosts**, see [cubrid\\_ha.conf](#).

## Broker Mode

A broker can access a server with one of the following modes: **Read Write**, **Read Only** or **Standby Only**. This configuration value is determined by a user.

A broker finds and connects to a suitable DB server by trying to establish a connection in the order of DB server connections; this is, if it fails to establish a connection, it tries another connection to the next DB server defined until it reaches the last DB server. If no connection is made even after trying all servers, the broker fails to connect to a DB server.

For details on how to configure broker mode, see [cubrid\\_broker.conf](#).

DB connection is affected by **PREFERRED\_HOSTS**, **CONNECT\_ORDER** and **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP** parameters in [cubrid\\_broker.conf](#). See [Connecting a Broker to DB](#) for further information.

The below is the description if the above parameters are not specified.

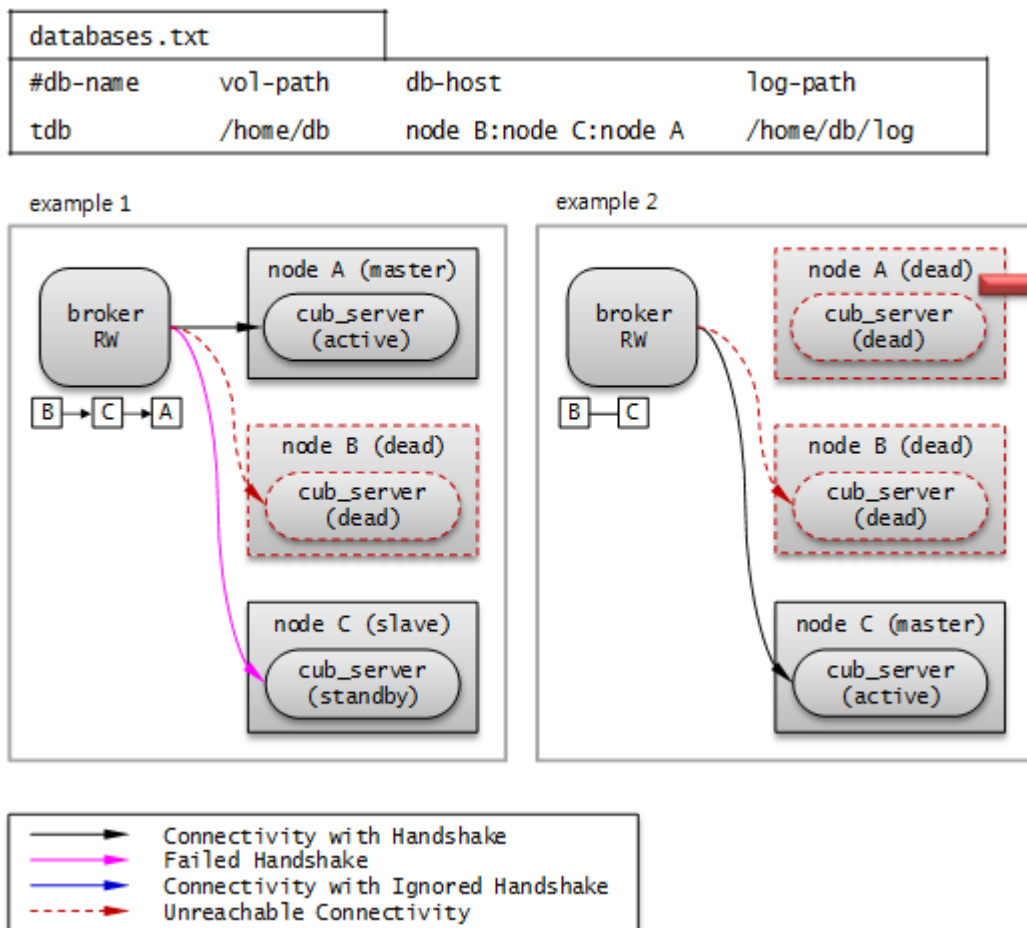

## Read Write

“ACCESS\_MODE=RW”

A broker that provides read and write services. This broker is usually connected to an active server. If there is no active server, this broker will be connected to a standby server temporarily. Therefore, a Read Write broker can be temporarily connected to a standby server.

When the broker temporarily establishes a connection to a standby server, it will disconnect itself from the standby server at the end of every transaction so that it can attempt to find an active server at the beginning of the next transaction. When it is connected to the standby server, only read service is available. Any write requests will result in a server error.

The following picture shows how a broker connects to the host through the **db-host** configuration.

The broker tries to connect as the order of B, C, A because db-host in databases.txt is “node B:node C:node A”. At this time, “node B:node C:node A” specified in db-host is the real host names defined in the /etc/hosts file.

- Example 1. *node B* is crashed, *node C* is in standby status, and *node A* is in active status. Therefore, at last, the broker connects to *node A*.
- Example 2. *node B* is crashed, and *node C* is in active status. Therefore, at last, the broker connects to *node C*.

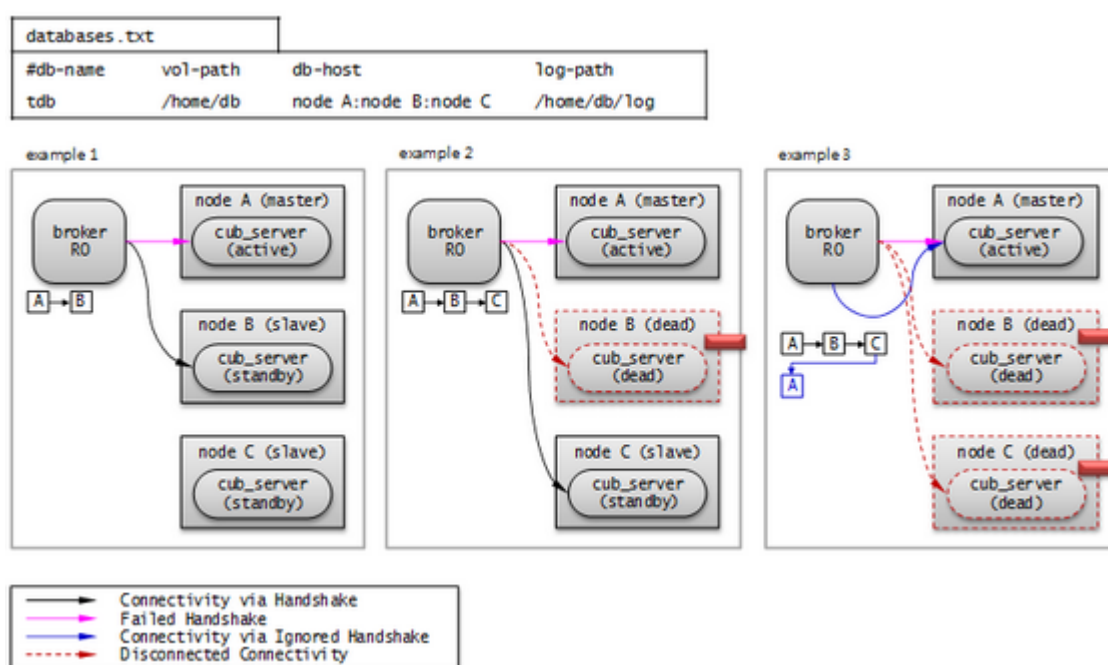

## Read Only

“ACCESS\_MODE=RO”

A broker that provides the read service. This broker is connected to a standby server if possible. Therefore, the Read Only broker can be connected to an active server temporarily.

Once it establishes a connection with an active server, it will maintain that connection until the time specified by **RECONNECT\_TIME**. After **RECONNECT\_TIME**, the broker tries to reconnect as disconnecting the old connection. Or you can reconnect to the standby server by running **cubrid broker reset**. If a write request is delivered to the Read Only broker, an error occurs in the broker; therefore, only the read service will be available even if it is connected to an active server.

The following picture shows how a broker connects to the host through the **db-host** configuration.

The broker tries to connect as the order of A, B, C because db-host in databases.txt is “node A:node B:node C”. At this time, “node A:node B:node C” specified in db-host is the real host names defined in the /etc/hosts file.

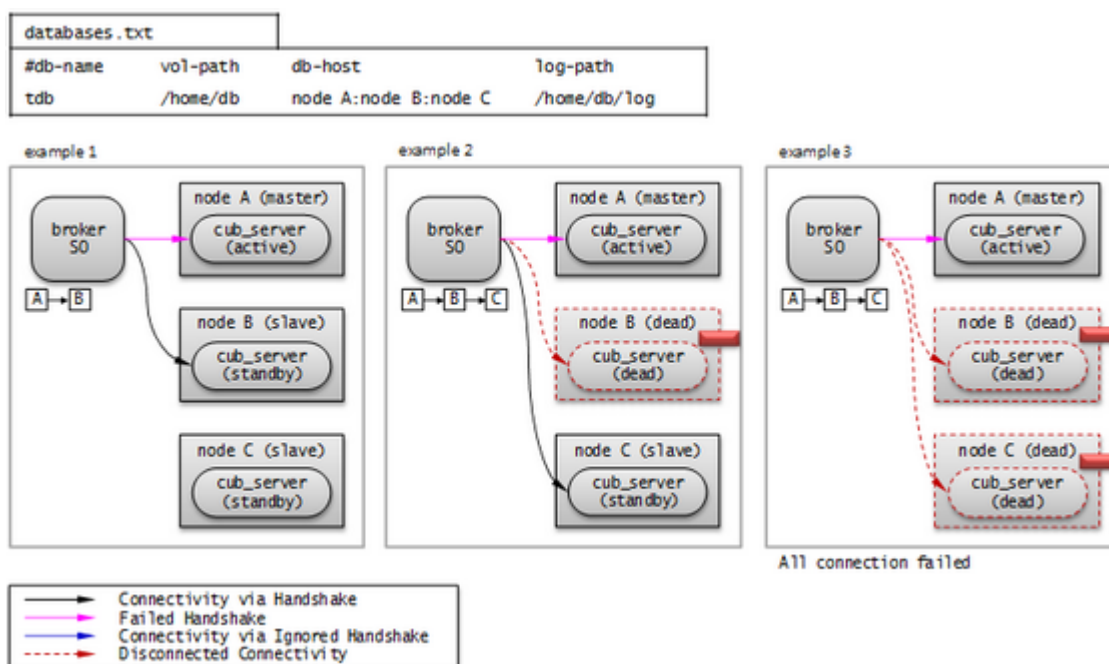

- Example 1. *node A* is in active status, *node B* is in standby status. Therefore, at last, the broker connects to *node B*.
- Example 2. *node A* is in active status, *node B* is crashed, and *node C* is in standby status. Therefore, at last, the broker connects to *node C*.
- Example 3. *node A* is in active status, *node B* and *node C* are crashed. Therefore, at last, the broker connects to *node A*.

## Standby Only

“ACCESS\_MODE=SO”

A broker that provides the read service. This broker can only be connected to a standby server. If no standby server exists, no service will be provided.

The following picture shows how a broker connects to the host through the **db-host** configuration.

The broker tries to connect as the order of A, B, C because `db-host` in `databases.txt` is "node A:node B:node C". At this time, "node A:node B:node C" specified in `db-host` is the real host names defined in the `/etc/hosts` file.

- Example 1. *node A* is in active status, *node B* is in standby status. Therefore, at last, the broker connects to *node B*.
- Example 2. *node A* is in active status, *node B* is crashed, and *node C* is in standby status. Therefore, at last, the broker connects to *node C*.
- Example 3. *node A* is in active status, *node B* and *node C* are crashed. Therefore, at last, the broker does not connect to any node. This is the difference with Read Only broker.

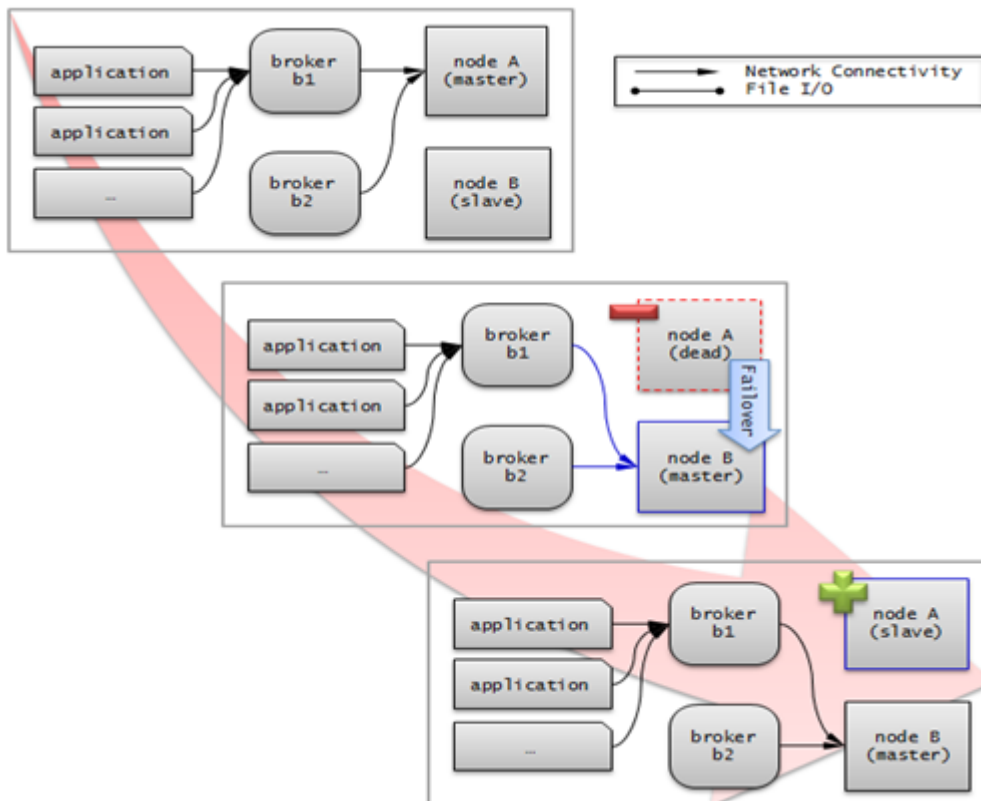

## CUBRID HA Features

### Duplexing Servers

Duplexing servers is building a system by configuring duplicate hardware equipment to provide CUBRID HA. This method will prevent any interruptions in a server in case of occurring a hardware failure.

#### Server failover

A broker defines server connection order and connects to a server according to the defined order. If the connected server fails, the broker connects to the server with the next highest priority. This requires no processing in the application side. The actions taken when the broker connects to another server may differ according to the current mode of the broker. For details on the server connection order and configuring broker mode, see [cubrid\\_broker.conf](#).

## Server failback

CUBRID HA does not automatically support server failback. Therefore, to manually apply failback, restore the master node that has been abnormally terminated and run it as a slave node, terminate the node that has become the master from the slave due to failover, and finally, change the role of each node again.

For example, when *nodeA* is the master and *nodeB* is the slave, *nodeB* becomes the master and *nodeA* becomes the slave after a failover. After terminating *nodeB* (**cubrid heartbeat stop**) check (**cubrid heartbeat status**) whether the status of *nodeA* has become active. Start (**cubrid heartbeat start**) *nodeB* and it will become the slave.

## Duplexing Brokers

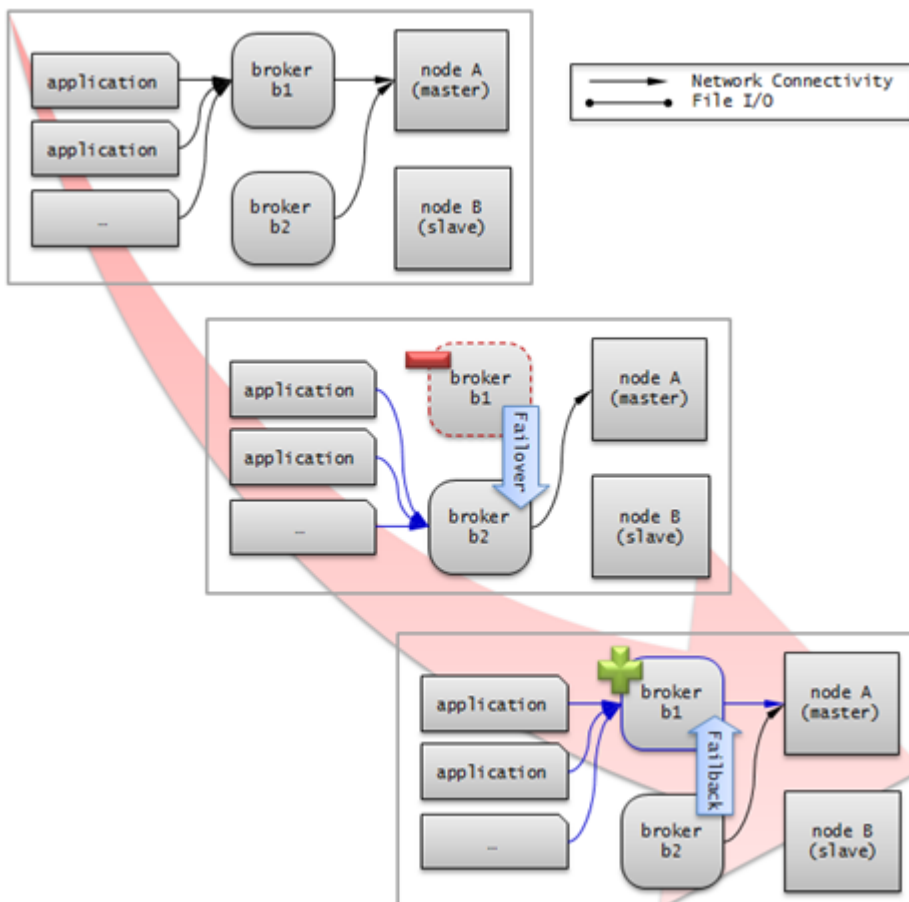

As a 3-tier DBMS, CUBRID has middleware called the broker which relays applications and database servers. To provide HA, the broker also requires duplicate hardware equipment. This method will prevent any interruptions in a broker in case of occurring a hardware failure.

The configuration of broker redundancy is not determined by the configuration of server redundancy; it can be user-defined. In addition, it can be separated by piece of individual equipment.

To use the failover and failback functionalities of a broker, the **altHosts** attribute must be added to the connection URL of the JDBC, CCI, or PHP. For a description of this, see [JDBC Configuration](#), [CCI Configuration](#) and [PHP Configuration](#).

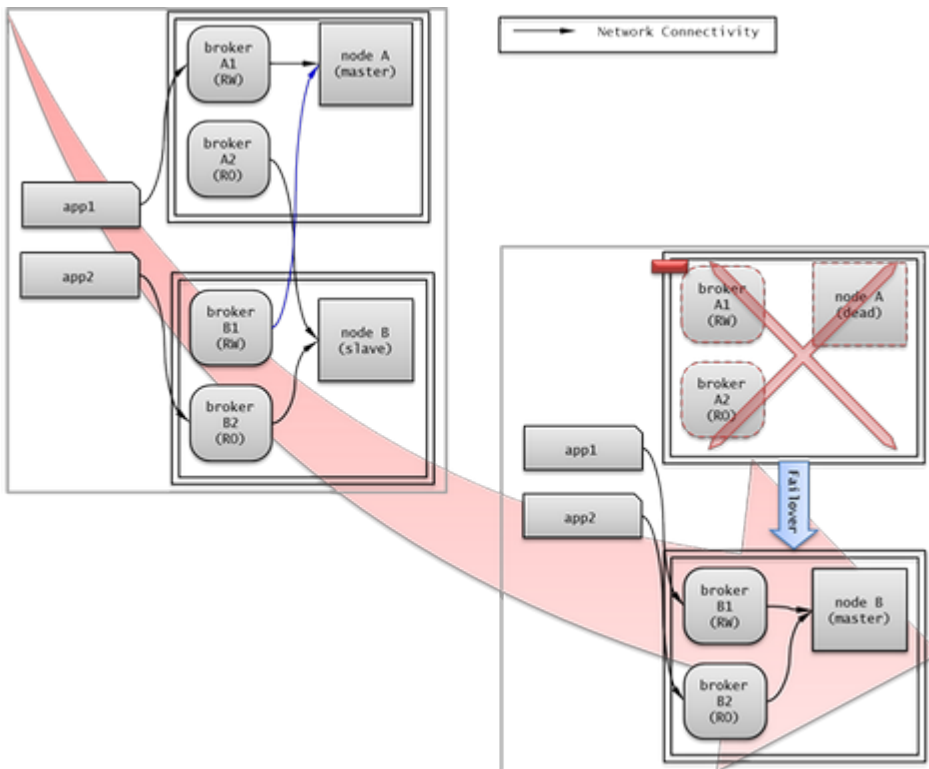

To set a broker, configure the **cubrid\_broker.conf** file. To set the order of failovers of a database server, configure the **databases.txt** file. For more information, see [Configuring and Starting Broker, and Verifying the Broker Status](#).

The following is an example in which two Read Write (RW) brokers are configured. When the first connection broker of the application URL is set to *broker B1* and the second connection broker to *broker B2*, the application connects to *broker B2* when it cannot connect to *broker B1*. When *broker B1* becomes available again, the application reconnects to *broker B1*.

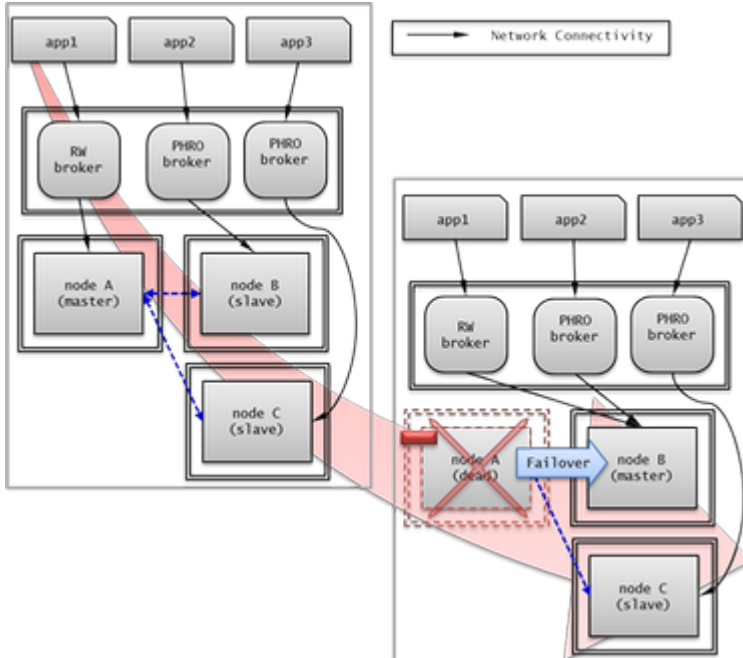

The following is an example in which the Read Write (RW) broker and the Read Only (RO) broker are configured on each piece of equipment for the master node and the slave node. First, the *app1* and *app2* URLs connect to *broker A1* (RW) and *broker B2* (RO), respectively. The second connection (*altHosts*) is made to *broker A2* (RO) and *broker B1* (RW). When the equipment that includes *nodeA* fails, *app1* and *app2* connect to the broker that includes *nodeB*.

The following is an example of a configuration in which broker equipment includes one Read Write broker (master node) and two Preferred Host Read Only brokers (slave nodes). The Preferred Host Read Only brokers are connected to nodeB and nodeC to distribute the reading load.

### Broker failover

The broker failover is not automatically failed over by the settings of system parameters. It is available in the JDBC, CCI, and PHP applications only when broker hosts are configured in the **altHosts** of the connection URL. Applications connect to the broker with the highest priority. When the connected broker fails, the application connects to the broker with the next highest

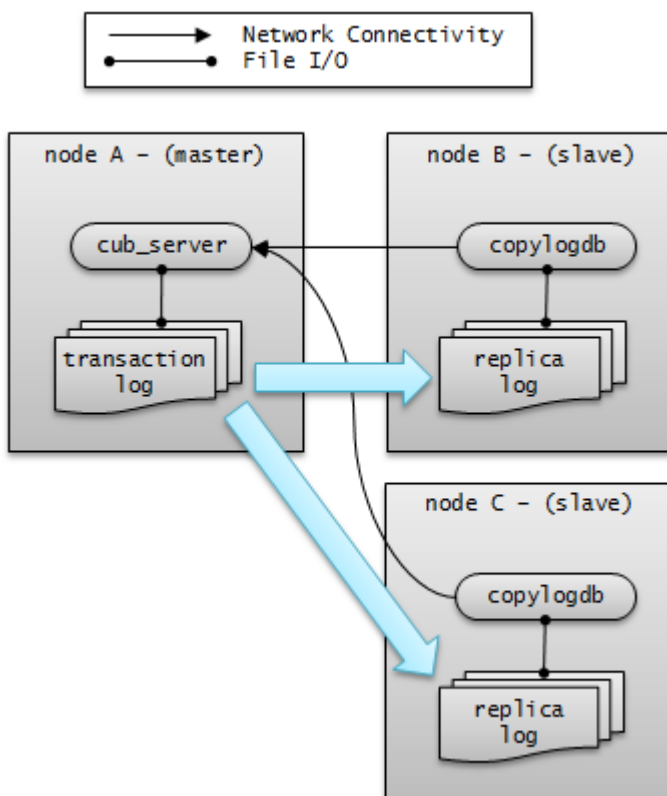

priority. Configuring the **altHosts** of the connection URL is the only necessary action, and it is processed in the JDBC, CCI, and PHP drivers.

### Broker failback

If the failed broker is recovered after a failover, the connection to the existing broker is terminated and a new connection is established with the recovered broker which has the highest priority. This requires no processing in the application side as it is processed within the JDBC, CCI, and PHP drivers. Execution time of failback depends on the value configured in JDBC connection URL. For details, see [JDBC Configuration](#).

## Log Multiplexing

CUBRID HA keeps every node in the CUBRID HA group with the identical structure by copying and reflecting transaction logs to all nodes included in the CUBRID HA group. As the log copy structure of CUBRID HA is a mutual copy between the master and the slave nodes, it has a disadvantage of increasing the size of a log volume. However, it has an advantage of flexibility in terms of configuration and failure handling, comparing to the chain-type copy structure.

The transaction log copy modes include **SYNC** and **ASYNC**. This value can be configured by the user in [cubrid\\_ha.conf](#) file.

### SYNC Mode

When transactions are committed, the created transaction logs are copied to the slave node and stored as a file. The transaction commit is complete after receiving a notice on its success. Although the time to execute commit in this mode may take longer than that in **ASYNC** mode, this is the safest method because the copied transaction logs are always guaranteed to be reflected to the standby server even if a failover occurs.

### ASYNC Mode

When transactions are committed, commit is complete without verifying the transfer of transaction logs to a slave node. Therefore, it is not guaranteed that committed transactions are reflected to a slave node in a master node side.

Although **ASYNC** mode provides a better performance as it has almost no delay when executing commit, there may be data inconsistency in its nodes.

#### Note

**SEMISYNC** mode is deprecated, and this operates in the same way as **SYNC** mode.

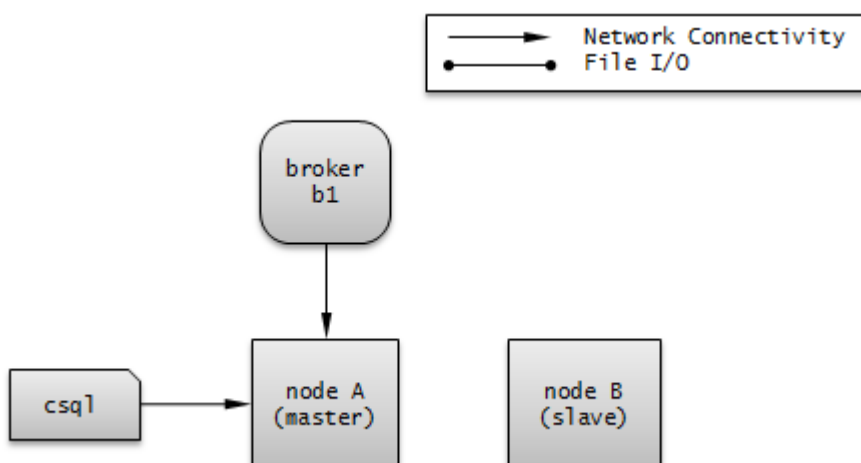

## Quick Start

This chapter simply explains how to build a master node and a slave node as 1:1 from DB creation. For details of various replication building methods, see [Building Replication](#).

## Preparation

### Structure Diagram

The diagram below aims to help users who are new to CUBRID HA, by explaining a simple procedure of the CUBRID HA configuration.

## Specifications

Linux and CUBRID version 2008 R2.2 or later must be installed on the equipment to be used as the master and the slave nodes. CUBRID HA does not support Windows operating system.

### Specifications of Configuring the CUBRID HA Equipment

|                  | CUBRID Version            | OS    |
|------------------|---------------------------|-------|
| For master nodes | CUBRID 2008 R2.2 or later | Linux |
| For slave nodes  | CUBRID 2008 R2.2 or later | Linux |

#### Note

This document describes the HA configuration in CUBRID 9.2 or later versions. Note that the previous versions have different settings. For example, **cubrid\_ha.conf** is only available in CUBRID 2008 R4.0 or later. **ha\_make\_slavedb.sh** is introduced from CUBRID 2008 R4.1 Patch 2 or later.

## Creating Databases and Configuring Servers

### Creating Databases

Create databases to be included in CUBRID HA at each node of the CUBRID HA in the same manner. Modify the options for database creation as needed.

```
[nodeA]$ cd $CUBRID_DATABASES
[nodeA]$ mkdir testdb
[nodeA]$ cd testdb
[nodeA]$ mkdir log
[nodeA]$ cubrid createdb -L ./log testdb en_US
Creating database with 512.0M size. The total amount of disk space
needed is 1.5G.

CUBRID 10.0

[nodeA]$
```

### cubrid.conf

Ensure **ha\_mode** of **\$CUBRID/conf/cubrid.conf** in every CUBRID HA node has the same value. Especially, take caution when configuring the **log\_max\_archives** and **force\_remove\_log\_archives** parameters (logging parameters) and the **ha\_mode** parameter (HA parameter).

```
# Service parameters
[service]
service=server,broker,manager

# Common section
[common]
service=server,broker,manager

# Server parameters
server=testdb
data_buffer_size=512M
log_buffer_size=4M
sort_buffer_size=2M
max_clients=100
cubrid_port_id=1523
db_volume_size=512M
log_volume_size=512M

# Adds when configuring HA (Logging parameters)
log_max_archives=100
force_remove_log_archives=no

# Adds when configuring HA (HA mode)
ha_mode=on
```

### **cubrid\_ha.conf**

Ensure **ha\_port\_id**, **ha\_node\_list**, **ha\_db\_list** of **\$CUBRID/conf/cubrid\_ha.conf** in every CUBRID HA node has the same value. In the example below, we assume that the host name of a master node is *nodeA* and that of a slave node is *nodeB*.

```
[common]
ha_port_id=59901
ha_node_list=cubrid@nodeA:nodeB
ha_db_list=testdb
ha_copy_sync_mode=sync:sync
ha_apply_max_mem_size=500
```

### **databases.txt**

Ensure that you must configure the host names (*nodeA:nodeB*) of master and slave nodes in db-host of **\$CUBRID\_DATABASES/databases.txt**; if **\$CUBRID\_DATABASES** is not configured, do it in **\$CUBRID/databases/databases.txt**.

```
#db-name vol-path db-host log-path lob-base-path
testdb /home/cubrid/DB/testdb nodeA:nodeB /home/cubrid/DB/testdb/log
file:/home/cubrid/DB/testdb/lob
```

## Starting and Verifying CUBRID HA

### Starting CUBRID HA

Execute the **cubrid heartbeat start** at each node in the CUBRID HA group. Note that the node executing **cubrid heartbeat start** first will become a master node. In the example below, we assume that the host name of a master node is *nodeA* and that of a slave node is *nodeB*.

- Master node

```
[nodeA]$ cubrid heartbeat start
```

- Slave node

```
[nodeB]$ cubrid heartbeat start
```

### Verifying CUBRID HA Status

Execute **cubrid heartbeat status** at each node in the CUBRID HA group to verify its configuration status.

```
[cubrid@nodeA]$ cubrid heartbeat status
@cubrid heartbeat list
HA-Node Info (current nodeA, state master)
  Node nodeB-node-name (priority 2, state slave)
  Node nodeA-node-name (priority 1, state master)
HA-Process Info (nodeA 9289, state nodeA)
  Applylogdb testdb@localhost:/home1/cubrid1/DB/testdb_nodeB (pid
9423, state registered)
  Copylogdb testdb@nodeB-node-name:/home1/cubrid1/DB/testdb_nodeB
(pid 9418, state registered)
  Server testdb (pid 9306, state registered_and_active)

[nodeA]$
```

Use the **cubrid changemode** utility at each node in the CUBRID HA group to verify the status of the server.

- Master node

```
[nodeA]$ cubrid changemode testdb@localhost
The server 'testdb@localhost''s current HA running mode is active.
```

- Slave node

```
[nodeB]$ cubrid changemode testdb@localhost
The server 'testdb@localhost''s current HA running mode is standby.
```

## Verifying the CUBRID HA Operation

Verify that action is properly applied to standby server of the slave node after performing write in an active server of the master node. To make a success connection via the CSQL Interpreter in HA environment, you must specify the host name to be connected after the database name like “@<host\_name>”). If you specify a host name as localhost, it is connected to local node.

### Warning

Ensure that primary key must exist when creating a table to have replication successfully processed.

- Master node

```
[nodeA]$ csql -u dba testdb@localhost -c "create table abc(a int, b
int, c int, primary key(a));"
[nodeA]$ csql -u dba testdb@localhost -c "insert into abc values
(1,1,1);"
[nodeA]$
```

- Slave node

```
[nodeB]$ csql -u dba testdb@localhost -l -c "select * from abc;"
=== <Result of SELECT Command in Line 1> ===
<00001> a: 1
        b: 1
        c: 1
[nodeB]$
```

## Configuring and Starting Broker, and Verifying the Broker Status

### Configuring the Broker

To provide normal service during a database failover, it is necessary to configure an available database node in the **db-host** of **databases.txt**. And **ACCESS\_MODE** in the **cubrid\_broker.conf** file must be specified; if it is omitted, the default value is configured to Read Write mode. If you want to divide into a separate device, you must configure **cubrid\_broker.conf** and **databases.txt** in the broker device.

- databases.txt

```
#db-name          vol-path          db-host          log-
path          lob-base-path
testdb          /home1/cubrid1/CUBRID/testdb  nodeA:nodeB      /
home1/cubrid1/CUBRID/testdb/log file:/home1/cubrid1/CUBRID/testdb/
lob
```

- cubrid\_broker.conf

```
[%testdb_RWbroker]
SERVICE                =ON
BROKER_PORT              =33000
MIN_NUM_APPL_SERVER     =5
MAX_NUM_APPL_SERVER     =40
APPL_SERVER_SHM_ID      =33000
LOG_DIR                  =log/broker/sql_log
ERROR_LOG_DIR            =log/broker/error_log
SQL_LOG                  =ON
TIME_TO_KILL             =120
SESSION_TIMEOUT          =300
KEEP_CONNECTION          =AUTO
CCI_DEFAULT_AUTOCOMMIT   =ON

# broker mode parameter
ACCESS_MODE              =RW
```

## Starting Broker and Verifying its Status

A broker is used to access applications such as JDBC, CCI or PHP. Therefore, to simply test server redundancy, execute the CSQL interpreter that is directly connected to the server processes, without having to start a broker. To start a broker, execute **cubrid broker start**. To stop it, execute **cubrid broker stop**.

The following example shows how to execute a broker from the master node.

```
[nodeA]$ cubrid broker start
@ cubrid broker start
++ cubrid broker start: success
[nodeA]$ cubrid broker status
@ cubrid broker status
```

```
% testdb_RWbroker
```

```
-----
ID    PID    QPS    LQS  PSIZE  STATUS
-----
1    9532     0      0   48120   IDLE
```

## Configuring Applications

Specifies the host name (*nodeA\_broker*, *nodeB\_broker*) and port for an application to connect in the connection URL. The **altHosts** attribute defines the broker where the next connection will be made when the connection to a broker fails. The following is an example of a JDBC program. For more information on CCI and PHP, see [CCI Configuration](#) and [PHP Configuration](#).

```
Connection connection =
DriverManager.getConnection("jdbc:CUBRID:nodeA_broker:
33000:testdb:::charset=utf-8&altHosts=nodeB_broker:33000", "dba",
"");
```

## Environment Configuration

The below is the description for setting the HA environment. See [Connecting a Broker to DB](#) for further information regarding the process connecting between a broker and a DB server.

### cubrid.conf

The **cubrid.conf** file that has general information on configuring CUBRID is located in the **\$CUBRID/conf** directory. This page provides information about **cubrid.conf** parameters used by CUBRID HA.

HA or Not

#### ha\_mode

**ha\_mode** is a parameter used to configure whether to use CUBRID HA. The default value is **off**. CUBRID HA does not support Windows; it supports Linux only.

- **off** : CUBRID HA is not used.
- **on** : CUBRID HA is used. Failover is supported for its node.
- **replica** : CUBRID HA is used. Failover is not supported for its node.

If **ha\_mode** is **on**, the CUBRID HA values are configured by reading **cubrid\_ha.conf**.

This parameter cannot be modified dynamically. To modify the value of this parameter, you must restart it.

## Logging

### **log\_max\_archives**

**log\_max\_archives** is a parameter used to configure the minimum number of archive log files to be archived. The minimum value is 0 and the default is **INT\_MAX** (2147483647). When CUBRID has installed for the first time, this value is set to 0 in the **cubrid.conf** file. The behavior of the parameter is affected by **force\_remove\_log\_archives**.

If the value of **force\_remove\_log\_archives** is set to **no**, the existing archive log files to which the activated transaction refers or the archive log files of the master node not reflected to the slave node in HA environment will not be deleted. For details, see the following **force\_remove\_log\_archives**.

For details about **log\_max\_archives**, see [Logging-Related Parameters](#).

### **force\_remove\_log\_archives**

It is recommended to configure **force\_remove\_log\_archives** to **no** so that archive logs to be used by HA-related processes always can be maintained to set up HA environment by configuring **ha\_mode** to **on**.

If you configure the value for **force\_remove\_log\_archives** to yes, the archive log files which will be used in the HA-related process can be deleted, and this may lead to an inconsistency between replicated databases. If you want to maintain free disk space even though doing this could lead to risk, you can configure the value to yes.

For details about **force\_remove\_log\_archives**, see [Logging-Related Parameters](#).

#### Note

From 2008 R4.3 in replica mode, it will be always deleted except for archive logs as many as specified in the **log\_max\_archives** parameter, regardless the **force\_remove\_log\_archives** value specified.

## Access

### **max\_clients**

**max\_clients** is a parameter used to configure the maximum number of clients to be connected to a database server simultaneously. The default is **100**.

Because the replication log copy and the replication log reflection processes start by default if CUBRID HA is used, you must configure the value to twice the number of all nodes in the CUBRID HA group, except the corresponding node. Furthermore, you must consider the case in which a client that is connected to another node at the time of failover attempts to connect to that node.

For details about **max\_clients**, see [Connection-Related Parameters](#).

### The Parameters That Must Have the Same Value for All Nodes

- **log\_buffer\_size** : The size of a log buffer. This must be same for all nodes, as it affects the protocol between **copylogdb** that duplicate the server and logs.
- **log\_volume\_size** : The size of a log volume. In CUBRID HA, the format and contents of a transaction log are the same as that of the replica log. Therefore, the parameter must be same for all nodes. If each node creates its own DB, the **cubrid createdb** options (**--db-volume-size**, **--db-page-size**, **--log-volume-size**, **--log-page-size**, etc.) must be the same.
- **cubrid\_port\_id** : The TCP port number for creating a server connection. It must be same for all nodes in order to connect **copylogdb** that duplicate the server and logs.
- **HA-related parameters** : HA parameters included in **cubrid\_ha.conf** must be identical by default. However, the following parameters can be set differently according to the node.

### The Parameters That Can be Different Among Nodes

- The **ha\_mode** parameter in replica node
- The **ha\_copy\_sync\_mode** parameter
- The **ha\_ping\_hosts** parameter
- The **ha\_tcp\_ping\_hosts** parameter

### Example

The following example shows how to configure **cubrid.conf**. Please take caution when configuring **log\_max\_archives** and **force\_remove\_log\_archives** (logging-related parameters), and **ha\_mode** (an HA-related parameter).

```
# Service Parameters
[service]
service=server,broker,manager

# Server Parameters
server=testdb
data_buffer_size=512M
log_buffer_size=4M
sort_buffer_size=2M
max_clients=200
```

```
cubrid_port_id=1523
db_volume_size=512M
log_volume_size=512M

# Adds when configuring HA (Logging parameters)
log_max_archives=100
force_remove_log_archives=no

# Adds when configuring HA (HA mode)
ha_mode=on
log_max_archives=100
```

## cubrid\_ha.conf

The **cubrid\_ha.conf** file that has generation information on CUBRID HA is located in the **\$CUBRID/conf** directory. CUBRID HA does not support Windows; it supports Linux only.

See [Connecting a Broker to DB](#) for further information regarding the process connecting between a broker and a DB server.

## Node

### ha\_node\_list

**ha\_node\_list** is a parameter used to configure the group name to be used in the CUBRID HA group and the host name of member nodes in which failover is supported. The group name is separated by @. The name before @ is for the group, and the names after @ are for host names of member nodes. A comma(,) or colon(:) is used to separate individual host names. The default is **localhost@localhost**.

#### Note

The host name of the member nodes specified in this parameter cannot be replaced with the IP. You should use the host names which are registered in **/etc/hosts**.

If the host name is not specified properly, the below message is written into the server.err error log file.

```
Time: 04/10/12 17:49:45.030 - ERROR *** file ../../src/connection/
tcp.c, line 121 ERROR CODE = -353 Tran = 0, CLIENT = (unknown):
(unknown)(-1), EID = 1 Cannot make connection to master server on
host "Wrong_HOST_NAME".... Connection timed out
```

A node in which the **ha\_mode** value is set to **on** must be specified in **ha\_node\_list**. The value of the **ha\_node\_list** of all nodes in the CUBRID HA group must be identical. When a failover occurs, a node becomes a master node in the order specified in the parameter.

This parameter can be modified dynamically. If you modify the value of this parameter, you must execute **cubrid heartbeat reload** to apply the changes.

### **ha\_replica\_list**

**ha\_replica\_list** is a parameter used to configure the group name, which is used in the CUBRID HA group, and the replica nodes, which are host names of member nodes in which failover is not supported. There is no need to specify this if you do not construct replica nodes. The group name is separated by @. The name before @ is for the group, and the names after @ are for host names of member nodes. A comma(,) or colon(:) is used to separate individual host names. The default is **NULL**.

The group name must be identical to the name specified in **ha\_replica\_list**. The host names of member nodes and the host names of nodes specified in this parameter must be registered in **/etc/hosts**. A node in which the **ha\_mode** value is set to **replica** must be specified in **ha\_replica\_list**. The **ha\_replica\_list** values of all nodes in the CUBRID HA group must be identical.

This parameter can be modified dynamically. If you modify the value of this parameter, you must execute **cubrid heartbeat reload** to apply the changes.

#### **Note**

The host name of the member nodes specified in this parameter cannot be replaced with the IP. You should use the host names which are registered in **/etc/hosts**.

### **ha\_db\_list**

**ha\_db\_list** is a parameter used to configure the name of the database that will run in CUBRID HA mode. The default is **NULL**. You can specify multiple databases by using a comma (,).

#### Access

### **ha\_port\_id**

**ha\_port\_id** is a parameter used to configure the UDP port number; the UDP port is used to detect failure when exchanging heartbeat messages. The default is **59,901**.

If a firewall exists in the service environment, the firewall must be configured to allow the configured port to pass through it.

## ha\_ping\_hosts

**ha\_ping\_hosts** is a parameter used to configure the host which verifies whether or not a failover occurs due to unstable network when a failover has started in a slave node. The default is **NULL**. A comma(,) or colon(:) is used to separate individual host names.

The host name of the member nodes specified in this parameter can be replaced with the IP. When a host name is used, the name must be registered in **/etc/hosts**.

CUBRID checks hosts specified in **ha\_ping\_hosts** every hour; if there is a problem on a host, “ping check” is paused temporarily and checks every 5 minutes if the host is normalized or not.

Configuring this parameter can prevent split-brain, a phenomenon in which two master nodes simultaneously exist as a result of the slave node erroneously detecting an abnormal termination of the master node due to unstable network status and then promoting itself as the new master.

However, the “ping check” does not work if the ICMP protocol is disabled. CUBRID provides **ha\_tcp\_ping\_hosts** as an alternative to address this.

This parameter can be modified dynamically. If you modify the value of this parameter, you must execute **cubrid heartbeat reload** to apply the changes.

## ha\_tcp\_ping\_hosts

**ha\_tcp\_ping\_hosts** is a parameter that can be used as an alternative to **ha\_ping\_hosts** when the ICMP protocol is disabled. **ha\_tcp\_ping\_hosts** works like **ha\_ping\_hosts** except that the TCP layer is used instead of the IP layer for the “ping check”. The default is **NULL**. A comma(,) is used to separate individual host names, and a colon(:) is used to separate a host name and a port number. So, the format of this parameter is like “ha\_tcp\_ping\_hosts=host1:port1,host2:port2”. In order to use the TCP ping properly, a TCP socket that can receive the requests must be opened in advance with the port number on the host specified in **ha\_tcp\_ping\_hosts** and the firewall must not block the requests. **ha\_tcp\_ping\_hosts** is ignored if the **ha\_ping\_hosts** is also set.

This parameter can be modified dynamically. If you modify the value of this parameter, you must execute **cubrid heartbeat reload** to apply the changes.

## Replication

### ha\_copy\_sync\_mode

**ha\_copy\_sync\_mode** is a parameter used to configure the mode of storing the replication log, which is a copy of transaction log. The default is **SYNC**.

The value can be one of the following: **SYNC** and **ASNYC**. The number of values must be the same as the number of nodes specified in **ha\_node\_list**. They must be ordered by the specified value. You can specify multiple modes by using a comma(,) or colon(:). The replica node is always working in **ASNYC** mode regardless of this value.

For details, see [Log Multiplexing](#).

### **ha\_copy\_log\_base**

Specifies the parent path for saving replication logs. The default value is the directory path set in the `$CUBRID_DATABASES` environment variable. Replication logs are stored in a subdirectory of `<db_name>_<host_name>`, depending on the server and database name.

The replication log path can be set to either a relative or absolute path. The following are examples of each setting.

ex1) `ha_copy_log_base=copylog`: Considered a relative path and stores replication logs in `$CUBRID_DATABASES/copylog`. ex2) `ha_copy_log_base=/log/copy_log`: Saves replication logs in `/log/copy_log` as an absolute path.

### **ha\_copy\_log\_max\_archives**

**ha\_copy\_log\_max\_archives** is a parameter used to configure the maximum number of keeping replication log files. The default is 1. However, even if the number of replication log files exceeds the specified number of replication log files, they are not deleted if they are not applied to the database.

To prevent wasting needless disk space, it is recommended to keep this value as 1, the default.

### **ha\_apply\_max\_mem\_size**

**ha\_apply\_max\_mem\_size** is a parameter used to configure the value of maximum memory that the replication log reflection process of CUBRID HA can use. The default value is **500** (unit: MB) and the maximum value is **INT\_MAX** (2147483647). When the value is larger than the size allowed by the system, memory allocation fails and the HA replication reflection process may malfunction. For this reason, you must check whether or not the memory resource can handle the specified value before setting it.

### **ha\_applylogdb\_ignore\_error\_list**

**ha\_applylogdb\_ignore\_error\_list** is a parameter used to configure for proceeding replication in CUBRID HA process by ignoring an error occurrence. The error codes to be ignored are separated by a comma (,). This value has a high priority. Therefore, when this value is the same as the value of the **ha\_applylogdb\_retry\_error\_list** parameter or the error code of “List of Retry Errors,” the values of the **ha\_applylogdb\_retry\_error\_list** parameter or the error code of “List of Retry Errors” are ignored and the tasks that cause the error are not retried. For “List of Retry Errors,” see the description of **ha\_applylogdb\_retry\_error\_list** below.

### **ha\_applylogdb\_retry\_error\_list**

**ha\_applylogdb\_retry\_error\_list** is a parameter used to configure for retrying tasks that caused an error in the replication log reflection process of CUBRID HA until the task succeeds. When

specifying errors to be retried, separate each error with a comma (,). The following table shows the default “List of Retry Errors.” If these values exist in **ha\_applylogdb\_ignore\_error\_list**, the error will be overridden.

### List of Retry Errors

| Error Code Name                         | Error Code |
|-----------------------------------------|------------|
| ER_LK_UNILATERALLY_ABORTED              | -72        |
| ER_LK_OBJECT_TIMEOUT_SIMPLE_MSG         | -73        |
| ER_LK_OBJECT_TIMEOUT_CLASS_MSG          | -74        |
| ER_LK_OBJECT_TIMEOUT_CLASSOF_MSG        | -75        |
| ER_LK_PAGE_TIMEOUT                      | -76        |
| ER_PAGE_LATCH_TIMEDOUT                  | -836       |
| ER_PAGE_LATCH_ABORTED                   | -859       |
| ER_LK_OBJECT_DL_TIMEOUT_SIMPLE_MS<br>G  | -966       |
| ER_LK_OBJECT_DL_TIMEOUT_CLASS_MSG       | -967       |
| ER_LK_OBJECT_DL_TIMEOUT_CLASSOF_M<br>SG | -968       |
| ER_LK_DEADLOCK_CYCLE_DETECTED           | -1021      |

### ha\_replica\_delay

This parameter specifies the term of applying the replicated data between a master node and a replica node. CUBRID intentionally delays replicating by the specified time. You can set a unit as ms, s, min or h, which stands for milliseconds, seconds, minutes or hours respectively. If you omit the unit, milliseconds(ms) will be applied. The default value is 0.

### **ha\_replica\_time\_bound**

In a master node, only the transactions which have been run on the specified time with this parameter are applied to the replica node. The format of this value is “YYYY-MM-DD hh:mi:ss”. There is no default value.

#### **Note**

The following example shows how to configure **cubrid\_ha.conf**.

```
[common]
ha_node_list=cubrid@nodeA:nodeB
ha_db_list=testdb
ha_copy_sync_mode=sync:sync
ha_apply_max_mem_size=500
```

#### **Note**

The following example shows how to configure the value of /etc/hosts (a host name of a member node: nodeA, IP: 192.168.0.1).

```
127.0.0.1 localhost.localdomain localhost
192.168.0.1 nodeA
```

### **ha\_delay\_limit**

**ha\_delay\_limit** is a standard time for CUBRID itself to measure replication delay status, and **ha\_delay\_limit\_delta** is a value to subtract a time which replication delay is released from a replication delay time. Once a server is measured as a replication delay, it keeps this status until the replication delay time is equal or lower than (**ha\_delay\_limit** - **ha\_delay\_limit\_delta**). A slave node or a replica node corresponds to a standby DB server, that is a target server to judge whether replication is delayed or not.

For example, if you want set replication delay time as 10 minutes and replication-delay-releasing time as 8 minutes, the value of **ha\_delay\_limit** will be 600s(or 10min) and the value of **ha\_delay\_limit\_delta** will be 120s(or 2min).

If it is measured as replication delay, CAS judges that there is a problem for standby DB to process jobs, and attempts to reconnect the other standby DBs.

CAS, which is connected to the DB which has the lower priority because of the replication delay, expects that the replication delay is released when the time by **RECONNECT\_TIME** in **cubrid\_broker.conf** is elapsed, then attempts to reconnect to the standby DB which has higher priority.

### **ha\_delay\_limit\_delta**

See the above description of **ha\_delay\_limit**.

### **ha\_copy\_log\_timeout**

This is the maximum value of the time in which a node's database server process (cub\_server) waits a response from another node's replication-log-copy process (copylogdb). The default is 5(seconds). If this value is -1, this means to be infinite wait. It only works with **SYNC** log copy mode(**ha\_copy\_sync\_mode**) parameter.

### **ha\_check\_disk\_failure\_interval**

CUBRID judges the disk failure for each time which is set to the value of this parameter. The default is 15, and the unit is second.

- If the value of **ha\_copy\_log\_timeout** parameter is -1, the value of **ha\_check\_disk\_failure\_interval** parameter is ignored and the disk failure is not judged.
- If the value of **ha\_check\_disk\_failure\_interval** parameter is smaller than the value of **ha\_copy\_log\_timeout** parameter, the disk failure is judged for each **ha\_copy\_log\_timeout** + 20 seconds.

### **ha\_unacceptable\_proc\_restart\_timediff**

When the abnormal status of a server process is kept, the server can be restarted infinitely; it is better to remove this kind of node from the HA components. Because the server is restarted within a short time when the abnormal status is continued, specify this term with this parameter to detect this situation. If the server is restarted within the specified term, CUBRID assumes that this server is abnormal and remove(demote) this node from the HA components. The default is 2min. If the unit is omitted, it is specified as milliseconds(msec).

## SQL Logging

### **ha\_enable\_sql\_logging**

If the value of this parameter is **yes**, CUBRID generates the log file of SQL which **applylogdb** process applies to the DB volume. The log file is located under the sql\_log of the replication log directory(**ha\_copy\_log\_base**). The default is **no**.

The format of this log file name is *<db name>\_<master hostname>.sql.log.<id>*, and *<id>* starts from 0. If this size is over **ha\_sql\_log\_max\_size\_in\_mbytes**, a new file with "*<id>* + 1" is created. For example, if "ha\_sql\_log\_max\_size\_in\_mbytes=100", demodb\_nodeA.sql.log.1 is newly created as the size of demodb\_nodeA.sql.log.0 file becomes 100MB. *<id>* will wrap around to 0 once it exceeds the maximum value (4,294,967,295).

By default, only two latest SQL log files are maintained, and the maximum number of them can be adjusted through **ha\_sql\_log\_max\_count**.

The SQL log format is as follows.

- INSERT/DELETE/UPDATE

```
-- date | SQL id | SELECT query's length for sampling | the length
of a transformed query
-- SELECT query for sampling
transformed query
```

```
-- 2013-01-25 15:16:41 | 40083 | 33 | 114
-- SELECT * FROM [t1] WHERE "c1"=79186;
INSERT INTO [t1]("c1", "c2", "c3") VALUES
(79186,'b3beb3decd2a6be974',0);
```

- DDL

```
-- date | SQL id | 0 | the length of a transformed query
DDL query
(GRANT query will follow when CREATE TABLE, to grant the authority
to the table created with DBA authority.)
```

```
-- 2013-01-25 14:22:59 | 1 | 0 | 50
create class t1 ( id integer, primary key (id) );
-- 2013-01-25 14:22:59 | 2 | 0 | 38
GRANT ALL PRIVILEGES ON [t1] TO public;
```

### Warning

When you apply this SQL log from a specific point as creating other DB, triggers should be turned off because the jobs performed by triggers from master node are written to the SQL log file.

- See [TRIGGER\\_ACTION](#) for turning off the triggers with a broker configuration.
- See `csql --no-trigger-action` for turning off the triggers when you run CSQL.

### **ha\_sql\_log\_max\_size\_in\_mbytes**

The value of this parameter is the maximum size of the file which is created when SQL applied to DB by **applylogdb** process is logged. The new file is created when the size of a log file is over this value.

### **ha\_sql\_log\_max\_count**

The value of this parameter indicates the maximum number of SQL log files to be maintained. The oldest ones are removed when the number of SQL log files exceeds this. This parameter can be set within the range of 2 to 5, and the default is 2. **ha\_sql\_log\_max\_count** and **ha\_sql\_log\_max\_size\_in\_mbytes** need to be set properly in order to adjust the amount of SQL log to maintain.

### **ha\_sql\_log\_path**

The value of this parameter indicates the path where the SQL log files will be created. The default value is **NULL**. This parameter can be set to an absolute or relative path. If a relative path is set, it is determined based on the replication log directory described in **ha\_enable\_sql\_logging**. The database server process (cub\_server) should have appropriate permissions on the path to create SQL log files. If this parameter is not set, the SQL log files will be created on the path described in **ha\_enable\_sql\_logging**.

## cubrid\_broker.conf

The **cubrid\_broker.conf** file that has general information on configuring CUBRID broker is located in the **\$CUBRID/conf** directory. This section explains the parameters of **cubrid\_broker.conf** that are used by CUBRID HA.

See [Connecting a Broker to DB](#) for further information regarding the process connecting between a broker and a DB server.

Access Target

**ACCESS\_MODE**

**ACCESS\_MODE** is a parameter used to configure the mode of a broker. The default is **RW**.

Its value can be one of the following: **RW** (Read Write), **RO** (Read Only), **SO** (Standby Only), or **PHRO** (Preferred Host Read Only). For details, see [Broker Mode](#).

## REPLICA\_ONLY

CAS is only accessed to the replica DB if the value of **REPLICA\_ONLY** is **ON**. The default is **OFF**. If the value of **REPLICA\_ONLY** is **ON** and the value of **ACCESS\_MODE** is **RW**, writing job is possible to even replica DB.

## Access Order

### CONNECT\_ORDER

This parameter specifies whether the host-connecting order from a CAS is sequential or random. The host is configured from **db-host** of **\$CUBRID\_DATABASES/databases.txt**.

The default is **SEQ**; CAS tries to connect in the order. When it is **RANDOM**, CAS tries to randomly connect. If **PREFERRED\_HOSTS** parameter is given, CAS tries to connect to the hosts configured in **PREFERRED\_HOSTS** with the order, then uses the value of **db-host** only when the connection by **PREFERRED\_HOSTS** fails; and **CONNECT\_ORDER** does not affects on the order of **PREFERRED\_HOSTS**.

If you concern that the connections are centralized into one DB, set this value as **RANDOM**.

### PREFERRED\_HOSTS

Specify the order to connect by listing host names. The default value is **NULL**.

You can specify multiple nodes by using a colon (:). First, it tries to connect to host in the following order: host specified in the **PREFERRED\_HOSTS** parameter first and then host specified in **\$CUBRID\_DATABASES/databases.txt**.

The following example shows how to configure **cubrid\_broker.conf**. To access localhost in a first priority, set **PREFERRED\_HOSTS** as *localhost*.

```
[%PHRO_broker]
SERVICE                =ON
BROKER_PORT              =33000
MIN_NUM_APPL_SERVER     =5
MAX_NUM_APPL_SERVER     =40
APPL_SERVER_SHM_ID      =33000
LOG_DIR                  =log/broker/sql_log
ERROR_LOG_DIR            =log/broker/error_log
SQL_LOG                  =ON
TIME_TO_KILL             =120
SESSION_TIMEOUT          =300
```

```
KEEP_CONNECTION      =AUTO
CCI_DEFAULT_AUTOCOMMIT =ON

# Broker mode setting parameter
ACCESS_MODE          =RO
PREFERRED_HOSTS      =localhost
```

## Access Limitation

### MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP

When replication is delayed on all DB servers in the HA environment which specified multiple DB servers to **db-host** of **databases.txt**, CUBRID checks the replication-delayed servers until only the specified numbers in the **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP** parameter and decides the connection (checking the delay of replication is judged for the standby hosts; the delayed time is decided by the **ha\_delay\_limit** parameter). Also, **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP** is not applied to **PREFERRED\_HOSTS**.

For example, when **db-host** is specified as “host1:host2:host3:host4:host5” and “MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP=2”, if the status of them as follows:

- *host1*: active status
- *host2*: standby status, replication is delayed
- *host3*: unable to access
- *host4*: standby status, replication is delayed
- *host5*: standby status, replication is not delayed

then the broker tries to access the two hosts, *host2* and *host4* which their replications are delayed, then decides to access *host4*.

The reason to behave like the above is that CUBRID assumes that the replication will be delayed to the other hosts if the replication of the number (specified by **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP**) of hosts are delayed; therefore, CUBRID decides to connect to the last hosts which CUBRID have tried to access, as CUBRID does not try to access for the left hosts. However, if **PREFERRED\_HOSTS** is specified together, CUBRID tries to access to them first and then tries to access to the hosts of **db-host** list from the first.

The step which the broker accesses CUBRID is divided into the primary connection and the secondary connection.

- The primary connection: the step which the broker tries to access DB at first.

It checks the DB status(active/standby) and whether the replication is delayed or not. At this time, the broker checks DB's status if it's active or standby based on the **ACCESS\_MODE** then decides the connection.

- The secondary connection: After the failure of the primary connection, the broker tries to connect from the failed position. At this time, the broker ignores the DB status(active/standby) and the delay of replication. However, **SO** broker always accepts a connection only to a standby DB.

At this time, the connection is decided if the DB is accessible, by ignoring the delay of replication and DB status(active/standby). However, the error can occur during the query execution. For example, If **ACCESS\_MODE** of the broker is **RW** but the broker accesses standby DB, it occurs an error during INSERT operation. Regardless of the error, after it is connected to a standby DB and the transaction is executed, the broker retries the primary connection. However, **SO** broker can never connect to the active DB.

Depending on the value of **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP**, how the number of hosts, attempting to connect is limited as follows:

- **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP=-1**

The same as you do not specify this parameter, which is the default value. In this case, at the primary step, the delay of replication and the DB status are checked to the end, then the connection is decided. At the second step, even if there is a replication, or even if that is not the expected DB status(active/standby), the broker connects to the last host which was accessible.

- **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP=0**

The secondary connection is processed after the connection is tried only to **PREFERRED\_HOSTS** at the primary step; and at the secondary step, the broker tries to connect to a host even it is delayed in replication or it is not an expected DB status(active/standby). That is, because it is the secondary connection, **RW** broker can connect to a standby host and **RO** broker can connect to an active host. However, **SO** broker can never connect to the active DB.

- **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP=n(>0)**

The broker tries to connect until the specified number of replication-delayed hosts. At the primary connection, the broker inspects until the specified number of replication-delayed hosts; at the secondary connection, the broker connects to a host that there is a delay of replication.

## Reconnection

### **RECONNECT\_TIME**

When a broker tries to connect a DB server which are not in **PREFERRED\_HOSTS**, **RO** broker tries to connect to active DB server, or a broker tries to connect to the replication-delayed DB server, if connecting time is over **RECONNECT\_TIME**(default: 10min), the broker tries to reconnect.

See **RECONNECT\_TIME** for further information.

## databases.txt

The **databases.txt** file has information on the order of servers for the CAS of a broker to connect. It is located in the **\$CUBRID\_DATABASES** (if not specified, \$CUBRID/databases) directory; the information can be configured by using **db\_hosts**. You can specify multiple nodes by using a colon (:). If "**CONNECT\_ORDER=RANDOM**", the connection order is decided as randomly. But if **PREFERRED\_HOSTS** is specified, the specified hosts have the first priority of the connection order.

The following example shows how to configure **databases.txt**.

```
#db-name      vol-path      db-host      log-path      lob-base-path
testdb        /home/cubrid/DB/testdb nodeA:nodeB   /home/cubrid/DB/
testdb/log    file:/home/cubrid/DB/testdb/lob
```

## JDBC Configuration

To use CUBRID HA in JDBC, you must specify the connection information of another broker (*nodeB\_broker*) to be connected when a failure occurs in broker (*nodeA\_broker*). The attribute configured for CUBRID HA is **altHosts** which represents information of one or more broker nodes to be connected. For details, see [Configuration Connection](#).

The following example shows how to configure JDBC:

```
Connection connection =
DriverManager.getConnection("jdbc:CUBRID:nodeA_broker:
33000:testdb:::?charSet=utf-8&altHosts=nodeB_broker:33000", "dba",
"");
```

## CCI Configuration

To use CUBRID HA in CCI, you must use the `cci_connect_with_url()` function which additionally allows specifying connection information in connection URL; the connection information is used when a failure occurs in broker. The attribute configured for CUBRID HA is **altHosts** which represents information of one or more broker nodes to be connected.

The following example shows how to configure CCI.

```
con = cci_connect_with_url ("cci:CUBRID:nodeA_broker:33000:testdb::?  
altHosts=nodeB_broker:33000", "dba", NULL);  
if (con < 0)  
{  
    printf ("cannot connect to database\n");  
    return 1;  
}
```

## PHP Configuration

To use the functions of CUBRID HA in PHP, connect to the broker by using `cubrid_connect_with_url`, which is used to specify the connection information of the failover broker in the connection URL. The attribute specified for CUBRID HA is **altHosts**, the information on one or more broker nodes to be connected when a failover occurs.

The following example shows how to configure PHP.

```
<?php  
$con = cubrid_connect_with_url ("cci:CUBRID:nodeA_broker:  
33000:testdb::?altHosts=nodeB_broker:33000", "dba", NULL);  
if ($con < 0)  
{  
    printf ("cannot connect to database\n");  
    return 1;  
}  
?>
```

### Note

If you want to run smoothly the broker's failover in the environment which the broker's failover is enabled by setting **altHosts**, you should set the value of **disconnectOnQueryTimeout** in URL as **true**.

If this value is **true**, an application program releases the existing connection from a broker and reconnects to the other broker which is specified on **altHosts**.

## Connecting a Broker to DB

A broker in HA environment should decide the one DB server to connect among multiple DB servers. At this time, it is different depending on the setting of the DB server and broker; how to

connect to the DB server and what DB server should be chosen. In this chapter, we will look over how a broker choose DB server by the setting of HA environment. See [Environment Configuration](#) for the description about each parameters used in the environment setting.

Here are the main parameters used in the DB connection with the broker.

| Location  | Configuration file | Parameter name       | Description                                                                                                        |
|-----------|--------------------|----------------------|--------------------------------------------------------------------------------------------------------------------|
| DB server | cubrid.conf        | ha_mode              | HA mode(on/off/replica) of DB server. Default: off                                                                 |
|           | cubrid_ha.conf     | ha_delay_limit       | A period to determine whether the replication-delay                                                                |
|           |                    | ha_delay_limit_delta | Time subtracting the resolution time of replication-delay from the time of replication-delay                       |
| Broker    | cubrid_broker.conf | ACCESS_MODE          | Broker mode(RW/RO/SO). Default: RW                                                                                 |
|           |                    | REPLICA_ONLY         | Connectible to REPLICA server or not(ON/OFF). Default: OFF                                                         |
|           |                    | PREFERRED_HOSTS      | Connecting to the host that is specified here in priority to the host that you set in the db-host of databases.txt |

| Location | Configuration file | Parameter name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|--------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          |                    | MAX_NUM_DELAYED_H<br>OSTS_LOOKUP | <p>The number of hosts to determine the delay of replication in databases.txt. If up to the specified number of hosts was determined as the delay of replication, the broker is connected to the host checked at last.</p> <ul style="list-style-type: none"> <li>• -1: check all hosts specified in databases.txt whether replication is delayed or not</li> <li>• 0: do not check whether replication-delay or not, and process the secondary connection immediately</li> <li>• n(&gt;0): check up to n hosts whether replication is delayed or not</li> </ul> |
|          |                    | RECONNECT_TIME                   | Time to try reconnecting after the broker is connected to the improper DB server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Location | Configuration file | Parameter name | Description                                                                                                     |
|----------|--------------------|----------------|-----------------------------------------------------------------------------------------------------------------|
|          |                    |                | Default: 600s. If this value is 0, no try for reconnection.                                                     |
|          |                    | CONNECT_ORDER  | A parameter specifying the connecting order whether to connect as or the random order(SEQ/RANDOM). Default: SEQ |

## Connection Process

When a broker accesses DB server, it tries the primary connection; if it fails, it tries the secondary connection.

- The primary connection: Check the DB status(active/standby) and the delay of replication.
  1. A broker tries to connect as the order specified by **PREFERRED\_HOSTS**. The broker rejects connecting to the improper DB of which the status does not match with **ACCESS\_MODE** or in which the replication is delayed.
  2. By the **CONNECT\_ORDER**, a broker tries to connect to the host in the order specified in **databases.txt** or the random order. The broker checks the DB status followed by the **ACCESS\_MODE** and checks the replication-delayed host up to the number specified in **MAX\_NUM\_DELAYED\_HOSTS\_LOOKUP**.
- The secondary connection: Ignore the DB status(active/standby) and the delay of replication. However, **SO** broker always accepts to connect only to standby DB.
  1. A broker tries to connect as the order specified by **PREFERRED\_HOSTS**. The broker accepts connecting to the improper DB of which status does not match with **ACCESS\_MODE** or in which the replication is delayed. However, **SO** broker can never connect to active DB.
  2. By the **CONNECT\_ORDER**, a broker tries to connect to the host in the order specified in **databases.txt** or the random order. The broker ignores the DB status(active/standby) and the delay of replication; it is connected if possible.

## Examples on Behaviours by Configuration

The following shows the example of configuration.

### Host DB status

- *host1*: active
- *host2*: standby, replication is delayed.
- *host3*: standby, replica, unable to access.
- *host4*: standby, replica, replication is delayed.
- *host5*: standby, replica, replication is delayed.

When the status of host DBs are as the above, the below shows samples of behaviours by the configuration.

### Behaviours by configuration

- 2-1, 2-2, 2-3: From 2, (+) is addition and (#) is modification.
- 3-1, 3-2, 3-3: From 3, (+) is addition and (#) is modification.

| No. | Configuration                                                                                                                                                                                                                              | Behavior                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Running and Monitoring

### cubrid heartbeat Utility

**cubrid heartbeat** command can be run as **cubrid hb**, the abbreviated command.

#### start

This utility is used to activate CUBRID HA feature and start all processes of CUBRID HA in the node(database server process, replication log copy process, and replication log reflection process). Note that a master node or a slave node is determined based on the execution order of **cubrid heartbeat start**.

How to execute the command is as shown below.

```
$ cubrid heartbeat start
```

The database server process configured in HA mode cannot be started with the **cubrid server start** command.

Specify the database name at the end of the command to run only the HA configuration processes (database server process, replication log copy process, and replication log reflection process) of a specific database in the node. For example, use the following command to run the database *testdb* only:

```
$ cubrid heartbeat start testdb
```

#### stop

This utility is used to disable and stop all components of CUBRID. The node that executes this command stops and a failover occurs to the next slave node according to the CUBRID HA configuration.

How to use this utility is as shown below.

```
$ cubrid heartbeat stop
```

The database server process cannot be stopped with the **cubrid server stop** command.

Specify the database name at the end of the command to stop only the HA configuration processes (database server process, replication log copy process, and replication log reflection

process) of a specific database in the node. For example, use the following command to run the database *testdb* only:

```
$ cubrid heartbeat stop testdb
```

If you want to deactivate CUBRID HA feature immediately, add *-i* option into the “cubrid heartbeat stop” command. This option is used when the speedy quitting is required because the DB server process is working improperly.

```
$ cubrid heartbeat stop -i  
or  
$cubrid heartbeat stop --immediately
```

## copylogdb

This utility is used to start or stop the **copylogdb** process that copies the transaction logs for the *db\_name* of a specific *peer\_node* in the CUBRID HA configuration. You can pause log copy for rebuilding replications in the middle of operation and then rerun it whenever you want.

Even though only the **cubrid heartbeat copylogdb start** command has succeeded, the functions of detecting and recovering the failure between the nodes are executed. Since the node is the target of failover, the slave node can be changed to the master node.

How to use this utility is as shown below.

```
$ cubrid heartbeat copylogdb <start|stop> [ -h <host-name> ] db_name  
peer_node
```

**<host-name>**: the name of the remote host where copylogdb command will be executed

When *nodeB* is a node to run a command and *nodeA* is *peer\_node*, you can run the command as follows.

```
[nodeB]$ cubrid heartbeat copylogdb stop testdb nodeA  
[nodeB]$ cubrid heartbeat copylogdb start testdb nodeA
```

When the **copylogdb** process is started/stopped, the configuration information of the **cubrid\_ha.conf** is used. We recommend that you do not change the configuration as possible after you have set the configuration once. If you need to change it, it is recommended to restart the whole nodes.

## applylogdb

This utility is used to start or stop the **copylogdb** process that reflects the transaction logs for the *db\_name* of a specific *peer\_node* in the CUBRID HA configuration. You can pause log copy for rebuilding replications in the middle of operation and then rerun it whenever you want.

Even though only the **cubrid heartbeat copylogdb start** command has succeeded, the functions of detecting and recovering the failure between the nodes are executed. Since the node is the target of failover, the slave node can be changed to the master node.

How to use this utility is as shown below.

```
$ cubrid heartbeat applylogdb <start|stop> [ -h <host-name> ]  
db_name peer_node
```

```
<host-name>: the name of the remote host where applylogdb command  
will be executed
```

When *nodeB* is a node to run a command and *nodeA* is *peer\_node*, you can run the command as follows.

```
[nodeB]$ cubrid heartbeat applylogdb stop testdb nodeA  
[nodeB]$ cubrid heartbeat applylogdb start testdb nodeA
```

When the **applylogdb** process is started/stopped, the configuration information of the **cubrid\_ha.conf** is used. We recommend that you do not change the configuration as possible after you have set the configuration once. If you need to change it, it is recommended to restart the whole nodes.

## reload

This utility is used to retrieve the CUBRID HA information again. To start/stop HA replication processes of the added/removed nodes at once, you can use “**cubrid heartbeat replication start/stop**” command.

How to use this utility is as shown below.

```
$ cubrid heartbeat reload
```

Reconfigurable parameters are **ha\_node\_list** and **ha\_replica\_list**. Even if an error occurs on a special node during running this command, the left jobs are continued. After **reload** command is finished, check if the reconfiguration of nodes is applied well or not. If it fails, find the reason and resolve it.

## replication(or repl) start

This utility is used to run in batch HA processes(copylogdb/applylogdb) related to a specific node; in general, it is used to run in batch HA replication processes of added nodes after running **cubrid heartbeat reload**.

**replication** command can be abbreviated by **repl**.

```
cubrid heartbeat repl start <node_name>
```

- *node\_name*: one of nodes specified in **ha\_node\_list** of cubrid\_ha.conf.

## replication(or repl) stop

This utility is used to stop in batch HA processes(copylogdb/applylogdb) related to a specific node; in general, it is used to stop in batch HA replication processes of removed nodes after running **cubrid heartbeat reload**.

**replication** command can be abbreviated by **repl**.

```
cubrid heartbeat repl stop <node_name>
```

- *node\_name*: one of nodes specified in **ha\_node\_list** of cubrid\_ha.conf.

## status

```
$ cubrid heartbeat status [-v] [ -h <host-name> ]
```

**<host-name>**: the name of the remote host where status command will be executed

This utility is used to output the information of CUBRID HA group and CUBRID HA components. How to use this utility is as shown below.

```
$ cubrid heartbeat status
@ cubrid heartbeat status

HA-Node Info (current nodeB, state slave)
  Node nodeB (priority 2, state slave)
  Node nodeA (priority 1, state master)
```

```
HA-Process Info (master 2143, state slave)
  Applylogdb testdb@localhost:/home/cubrid/DB/testdb_nodeA (pid
2510, state registered)
  Copylogdb testdb@nodeA:/home/cubrid/DB/testdb_nodeA (pid 2505,
state registered)
  Server testdb (pid 2393, state registered_and_standby)
```

The -v option displays detailed information about the node.

- score : Indicates the priority of the node, with a lower score indicating a higher priority.
- missed heartbeat : Indicates the loss rate of heartbeat signals sent between nodes configured in an HA environment. If this value is unusually high, the configuration, network, or firewall settings should be inspected.

The event occurrence times for the Applylogdb, Copylogdb, and Server processes are also displayed. If no event has occurred, it is displayed as "00:00:00.000."

- registered-time : The time when a process startup request was made via a user command.
- deregistered-time : The time when a remote process stop request was made via a user command (applicable only to copylogdb and applylogdb).
- shutdown-time : The time that HA-manager(cub\_master) stopped the process
- start-time : The time that HA-manager(cub\_master) restarted the process

## Example

```
$ cubrid heartbeat status -v
@ cubrid heartbeat status

HA-Node Info (current cubrid1, state master)
  Node cubrid2 (priority 2, state slave)
    - score 2
    - missed heartbeat 0
  Node cubrid1 (priority 1, state master)
    - score -32767
    - missed heartbeat 0

HA-Process Info (master 7392, state master)
Copylogdb testdb@cubrid2:/home/cubha/CUBRID-11.4-latest-Linux.x86_64/
databases/testdb_cubrid2 (pid 7841, state registered)
  - exec-path [/home/cubha/CUBRID-11.4-latest-Linux.x86_64/bin/
cub_admin]
  - argv      [cub_admin copylogdb -L /home/cubha/CUBRID-11.4-latest-
Linux.x86_64/databases/testdb_cubrid2 -m sync testdb@bagus2 ]
  - registered-time    08/26/24 14:28:37.019
  - deregistered-time 00/00/00 00:00:00.000
  - shutdown-time     08/26/24 14:28:35.010
```

```

- deregistered-time   00/00/00 00:00:00.000
- shutdown-time       08/26/24 14:29:27.593
- start-time          08/26/24 14:29:28.594

```

### Note

**act**, **deact**, and **deregister** commands which were used in versions lower than CUBRID 9.0 are no longer used.

## Registering HA to cubrid service

If you register heartbeat to CUBRID service, you can use the utilities of **cubrid service** to start, stop or check all the related processes at once. The processes specified by **service** parameter in **[service]** section in **cubrid.conf** file are registered to CUBRID service. If this parameter includes **heartbeat**, you can start/stop all the service processes and the HA-related processes by using **cubrid service start / stop** command.

How to configure **cubrid.conf** file is shown below.

```

# cubrid.conf

...

[service]

...

service=broker,heartbeat

```

```
...
[common]
...
ha_mode=on
```

## applyinfo

This utility is used to check the copied and applied status of replication logs by CUBRID HA.

```
cubrid applyinfo [option] <database-name>
```

- *database-name* : Specifies the name of a server to monitor. A node name is not included.

The following shows the [options] used on **cubrid applyinfo**.

### **-r, --remote-host-name=HOSTNAME**

Configures the name of a target node in which transaction logs are copied. Using this option will output the information of active logs (Active Info.) of a target node.

### **-a, --applied-info**

Outputs the information of replication reflection of a node executing cubrid applyinfo. The **-L** option is required to use this option.

### **-L, --copied-log-path=PATH**

Configures the location of transaction logs copied from the other node. Using this option will output the information of transaction logs copied (Copied Active Info.) from the other node.

### **-p, --pageid=ID**

Outputs the information of a specific page in the copied logs. This is available only when the **-L** option is enabled. The default is 0, it means the active page.

### **-v**

Outputs detailed information.

### **-i, --interval=SECOND**

Outputs the copied status and applied status of transaction logs per specified seconds. To see the delayed status of the replicated log, this option is mandatory.

## Example

The following example shows how to check log information (Active Info.) of the master node, the status information of log copy (Copied Active Info.) of the slave node, and the applylogdb info (Applied Info.) of the slave node by executing **applyinfo** in the slave node.

- Applied Info.: Shows the status information after the slave node applies the replication log.
- Copied Active Info.: Shows the status information after the slave node copies the replication log.
- Copied Archive Info. : Shows the status information after the slave node copies the archive log.
- Active Info.: Shows the status information after the master node records the transaction log.
- Delay in Copying Active Log: Shows the status information which the transaction logs' copy is delayed.
- Delay in Applying Copied Log: Shows the status information which the transaction logs' application is delayed.

```
[nodeB]$ cubrid applyinfo -L /home/cubrid/DB/testdb_nodeA -r nodeA -
a -p 0 -i 3 testdb
```

\*\*\* Applied Info. \*\*\*

*** Delay in Applying Copied Log ***
Delayed log page count       : 1459
Estimated Delay              : 22 second(s)

```

The items shown by each status are as follows:

- Applied Info.
  - Committed page: The information of committed pageid and offset of a transaction reflected last through replication log reflection process. The difference between this value and the EOF LSA of “Copied Active Info. represents the amount of replication delay.
  - Insert Count: The number of Insert queries reflected through replication log reflection process.
  - Update Count: The number of Update queries reflected through replication log reflection process.
  - Delete Count: The number of Delete queries reflected through replication log reflection process.
  - Schema Count: The number of DDL statements reflected through replication log reflection process.
  - Commit Count: The number of transactions reflected through replication log reflection process.
  - Fail Count: The number of DML and DDL statements in which log reflection through replication log reflection process fails.

- Copied Active Info.

- DB name: Name of a target database in which the replication log copy process copies logs
- DB creation time: The creation time of a database copied through replication log copy process
- Vol creation time: The creation time of the volume copied through replication log copy process
- EOF LSA: Information of pageid and offset copied at the last time on the target node by the replication log copy process. There will be a delay in copying logs as much as difference with the EOF LSA value of “Active Info.” and with the Append LSA value of “Copied Active Info.”
- Append LSA: Information of pageid and offset written at the last time on the disk by the replication log copy process. This value can be less than or equal to EOF LSA. There will be a delay in copying logs as much as difference between the EOF LSA value of “Copied Active Info.” and this value.
- HA server state: Status of a database server process which replication log copy process receives logs from. For details on status, see [Servers](#).

- Copied Archive Info.

- DB name: Name of a target database in which the replication log copy process copies logs
- DB creation time: The creation time of a database copied through replication log copy process
- Vol creation time: The creation time of the volume copied through replication log copy process
- Archive number: The number of archive logs copied through replication log copy process
- Log page: The information of pageid and offset of the archive log copied through replication log copy process.
- offset: The information of pageid and offset of the archive log copied through replication log copy process.

- Active Info.

- DB name: Name of a database whose node was configured in the **-r** option.
- DB creation time: Database creation time of a node that is configured in the **-r** option.
- Vol creation time: Volume creation time of a node that is configured in the **-r** option.

- EOF LSA: The last information of pageid and offset of a database transaction log of a node that is configured in the **-r** option. There will be a delay in copying logs as much as difference between the EOF LSA value of “Copied Active Info.” and this value.
- Append LSA: Information of pageid and offset written at the last time on the disk by the database whose node was configured in the **-r** option.
- HA server state: The server status of a database server whose node was configured in the **-r** option.
- Delay in Copying Active Log
  - Delayed log page count: the count of transaction log pages which the copy is delayed.
  - Estimated Delay: the expected time which the logs copying is completed.
- Delay in Applying Copied Log
  - Delayed log page count: the count of transaction log pages which the application is delayed.
  - Estimated Delay: the expected time which the logs applying is completed.

When you run this command in replica node, if “ha\_replica\_delay=30s” is specified in cubrid.conf, the following information is printed out additionally.

```
*** Replica-specific Info. ***
Deliberate lag           : 30 second(s)
Last applied log record time : 2013-06-20 11:20:10
```

Each item of the status information is as below.

- Replica-specific Info.
  - Deliberate lag: delayed time a user defined by ha\_replica\_delay parameter
  - Last applied log record time: the time where the replication log of being applied in the replica node recently was actually applied in the master node.

When you run this command in replica node, if “ha\_replica\_delay=30s” and “ha\_replica\_time\_bound=2013-06-20 11:31:00” are specified in cubrid.conf, “ha\_replica\_delay=30s” is ignored and the following information is printed out additionally.

```
*** Replica-specific Info. ***
Last applied log record time : 2013-06-20 11:25:17
Will apply log records up to : 2013-06-20 11:31:00
```

Each item of the status information is as below.

- Replica-specific Info.
  - Last applied log record time: the time where the replication log of being applied in the replica node recently was actually applied in the master node.
  - Will apply log records up to: the replica node will apply the master node's logs replicated up to this time.

When `applylogdb` stops the replication after the time of being specified by **`ha_replica_time_bound`**, the error message which is printed out in the file, **`$CUBRID/log/db-name@local-node-name_applylogdb_db-name_remote-node-name.err`** is as below.

```
Time: 06/20/13 11:51:05.549 - ERROR *** file ../../src/transaction/
log_applier.c, line 7913 ERROR CODE = -1040 Tran = 1, EID = 3
HA generic: applylogdb paused since it reached a log record
committed on master at 2013-06-20 11:31:00 or later.
Adjust or remove ha_replica_time_bound and restart applylogdb to
resume.
```

## cubrid changemode

This utility is used to check and change the server status of CUBRID HA.

```
cubrid changemode [options] <database-name@node-name>
```

- *database-name@node-name*: Specifies the name of a server to be checked or changed and separates each node name by using @. If [options] is omitted, server status is displayed.

The following shows [options] used in **`cubrid changemode`**.

### **-m, --mode=MODE**

Changes the server status. You can enter one of the following:

**standby, maintenance or active.**

- You can change a mode as **maintenance** if a server's status is **standby**.
- You can change a mode as **standby** if a server's status is **maintenance**.
- You can change a mode as **active** if a server's status is **to-be-active**. However, this should be used together with **--force** option. See the below description regarding **--force** option.

### **-f, --force**

Configures whether or not to forcibly change the server status. This option must be configured if you want to change the server status from to-be-active to active. |

If it is not configured, the status will not be changed to active. Forcibly change may cause data inconsistency among replication nodes; so it is not recommended. |

### **-t, --timeout=SECOND**

The default is 5(seconds). Configures the waiting time for the normal completion of the transaction that is being processed when the node status switches from **standby** to **maintenance**.

If the transaction is still in progress beyond the configured time, it will be forced to terminate and switch to **maintenance** status; if all transactions have completed normally within the configured time, it will switch to **maintenance** status immediately.

### **Status Changeable**

This table shows changeable modes depending on current status.

|                |               | Changeable |         |             |
|----------------|---------------|------------|---------|-------------|
|                |               | active     | standby | maintenance |
| Current Status | standby       | X          | O       | O           |
|                | to-be-standby | X          | X       | X           |
|                | active        | O          | X       | X           |
|                | to-be-active  | O*         | X       | X           |
|                | maintenance   | X          | O       | O           |

\* When the server status is to-be-active, forcibly change may cause data inconsistency among replication nodes. It is not recommended if you are not skilled enough.

### **Example**

The following example shows how to switch the *testdb* server status in the localhost node to maintenance. The waiting time for all transactions in progress to complete normally is 5 seconds,

which is the default value for the **-t** option. If all transactions are complete within this time limit, the status will be switched immediately. However, if there are transactions still being processed after this time limit, they will be rolled back before changing the status.

```
$ cubrid changemode -m maintenance testdb@localhost
The server 'testdb@localhost''s current HA running mode is
maintenance.
```

The following example shows how to retrieve status of the *testdb* server in the localhost node.

```
$ cubrid changemode testdb@localhost
The server 'testdb@localhost''s current HA running mode is active.
```

## Monitoring CUBRID Manager HA

CUBRID Manager is a dedicated CUBRID database management tool that provides the CUBRID database management and query features in a GUI environment. CUBRID Manager provides the HA dashboard, which shows the relationship diagram for the CUBRID HA group and server status. For details, see CUBRID Manager manual.

## Structures of HA

There are four possible structures for CUBRID HA: The default structure, multiple-slave node structure, load balancing structure, and multiple-standby server structure. In the table below, M stands for a master node, S for a slave node, and R for a replica node.

| Structure                     | Node structure (M:S:R) | Characteristic                                                                                                                                         |
|-------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Structure             | 1:1:0                  | The most basic structure of CUBRID HA consists of one master node and one slave node and provides availability which is a unique feature of CUBRID HA. |
| Multiple-Slave Node Structure | 1:N:0                  | This is a structure in which availability is increased by several slave nodes. However, note that there                                                |

| Structure                  | Node structure (M:S:R) | Characteristic                                                                                                                                                                                                   |
|----------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                        | may be a situation in which data is inconsistent in the CUBRID HA group when multiple failures occur.                                                                                                            |
| Load Balancing Structure   | 1:1:N                  | Several replica nodes are added in the basic structure. Read service load can be distributed, and the HA load is reduced, comparing to a multiple-slave node structure. Note that replica nodes do not failover. |
| Multiple-Standby Structure | Server 1:1:0           | Basically, this structure is the same as the basic structure. However, several slave nodes are installed on a single physical server.                                                                            |

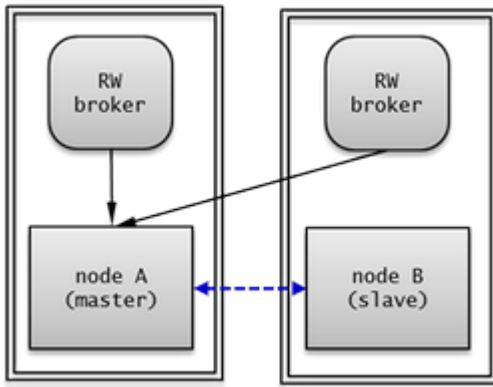

In the following description, it is assumed that there is no data in the testdb database on each node. To build HA feature as replicating database, see [Building Replication](#) or [Rebuilding Replication Script](#).

## Basic Structure of HA

The most basic structure of CUBRID HA consists of one master node and one slave node.

The default configuration is one master node and one slave node. To distribute the write load, a multi-slave node or load-distributed configuration is recommended. In addition, to access a specific node such as a slave node or replica node in read-only mode, configure the Read Only broker or the Preferred Host Read Only broker. For details about broker configuration, see [Duplexing Brokers](#).

## An Example of Node Configuration

You can configure each node in the basic structure of HA as shown below:

- **node A** (master node)
  - Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**:

```
ha_port_id=59901
ha_node_list=cubrid@nodeA:nodeB
ha_db_list=testdb
```

- **node B** (slave node): Configure this node in the same manner as *node A*.

For the **databases.txt** file of a broker node, it is necessary to configure the list of hosts configured as HA in **db-host** according to their priority. The following example shows the **databases.txt** file.

```
#db-name      vol-path          db-host      log-
path          lob-base-path
testdb        /home/cubrid/DB/testdb  nodeA:nodeB  /home/cubrid/DB/
testdb/log    file:/home/cubrid/DB/testdb/lob
```

The **cubrid\_broker.conf** file can be set in a variety of ways according to configuration of the broker. It can also be configured as separate equipment with the **databases.txt** file.

The example below shows that the RW broker is set in each node, and *node A* and *node B* have the same value.

```
[%RW_broker]
...
```

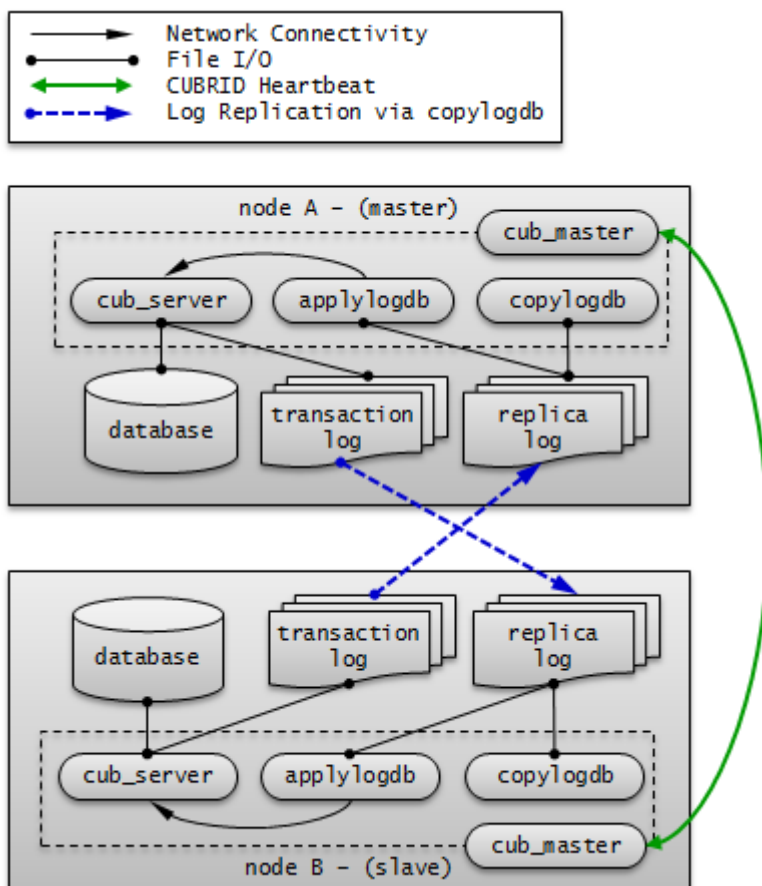

```
# Broker mode setting parameter
ACCESS_MODE          =RW
```

## Connection Configuration of Applications

See [JDBC Configuration](#), [CCI Configuration](#), and [PHP Configuration](#) in Environment Configuration.

### Remark

The moving path of a transaction log in these configurations is as follows:

## Multiple-Slave Node Structure

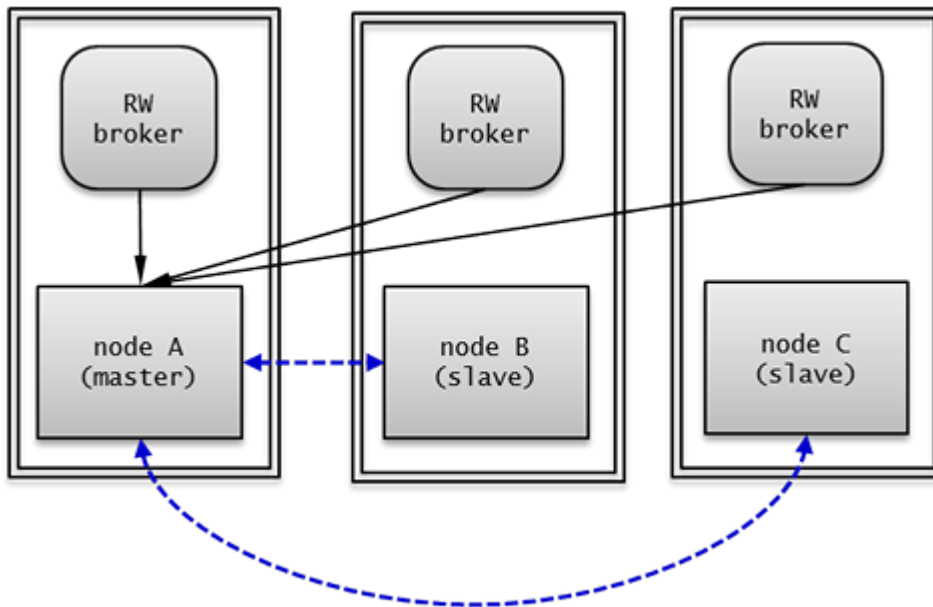

In multiple-slave node structure, there is one master node and several slave nodes to improve the service availability of CUBRID.

Because replication log copy process and replication log reflection process are running at all nodes in the CUBRID HA group, a load of copying replication log occurs. Therefore, all nodes in the CUBRID HA group have high network and disk usage.

Because there are many nodes with HA enabled, read and write services never fail as long as a single node is alive.

In the multiple-slave node structure, the node becoming a master node when failover occurs is determined by the order specified in **ha\_node\_list**. If the value of **ha\_node\_list** is node1:node2:node3 and the master node is *node A*, *node B* will become a new master node when the master node fails.

### An Example of Node Configuration

You can configure each node in the basic structure of HA as shown below:

- **node A** (master node)
  - Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**:

```
ha_port_id=59901
ha_node_list=cubrid@nodeA:nodeB:nodeC
ha_db_list=testdb
ha_copy_sync_mode=sync:sync:sync
```

- **node B, node C** (slave node): Configure this node in the same manner as *node A*.

You must enter the list of hosts configured in HA in order of priority in the **databases.txt** file of a broker node. The following is an example of the **databases.txt** file.

```
#db-name      vol-path      db-host      log-
path          lob-base-path
```

```
testdb      /home/cubrid/DB/testdb      nodeA:nodeB:nodeC      /home/
cubrid/DB/testdb/log file:/home/cubrid/DB/testdb/lob
```

The **cubrid\_broker.conf** file can be set in a variety of ways according to configuration of the broker. It can also be configured as separate equipment with the **databases.txt** file. In this example, the RW broker is configured in *node A*, *node B*, and *node C*.

The following is an example of the **databases.txt** file in *node A*, *node B*, and *node C*.

```
[%RW_broker]
...

# Broker mode setting parameter
ACCESS_MODE          =RW
```

## Connection Configuration of Applications

Connect the application to access to the broker of *node A*, *node B*, or *node C*.

```
Connection connection = DriverManager.getConnection(
    "jdbc:CUBRID:nodeA:33000:testdb:::?charSet=utf-8&altHosts=nodeB:
33000,nodeC:33000", "dba", "");
```

For details, see [JDBC Configuration](#), [CCI Configuration](#), and [PHP Configuration](#) in Environment Configuration.

### Note

The data in the CUBRID HA group may lose integrity when there are multiple failures in this structure and the example is shown below.

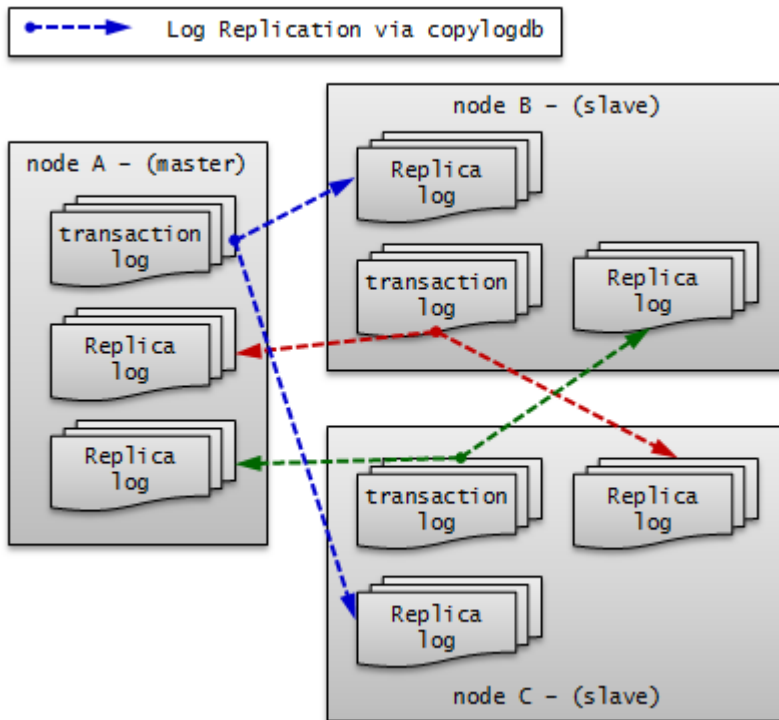

- In a situation where a failover occurs in the first slave node while replication in the second slave node is being delayed due to restart
- In a situation where a failover re-occurs before replication reflection of a new master node is not complete due to frequent failover

In addition, if the mode of replication log copy process is ASYNC, the data in the CUBRID HA group may lose integrity.

If the data in the CUBRID HA group loses integrity for any of the reasons above, all data in the CUBRID HA group should be fixed as the same by using [Building Replication](#) or [Rebuilding Replication Script](#).

### Remark

The moving path of a transaction log in these configurations is as follows:

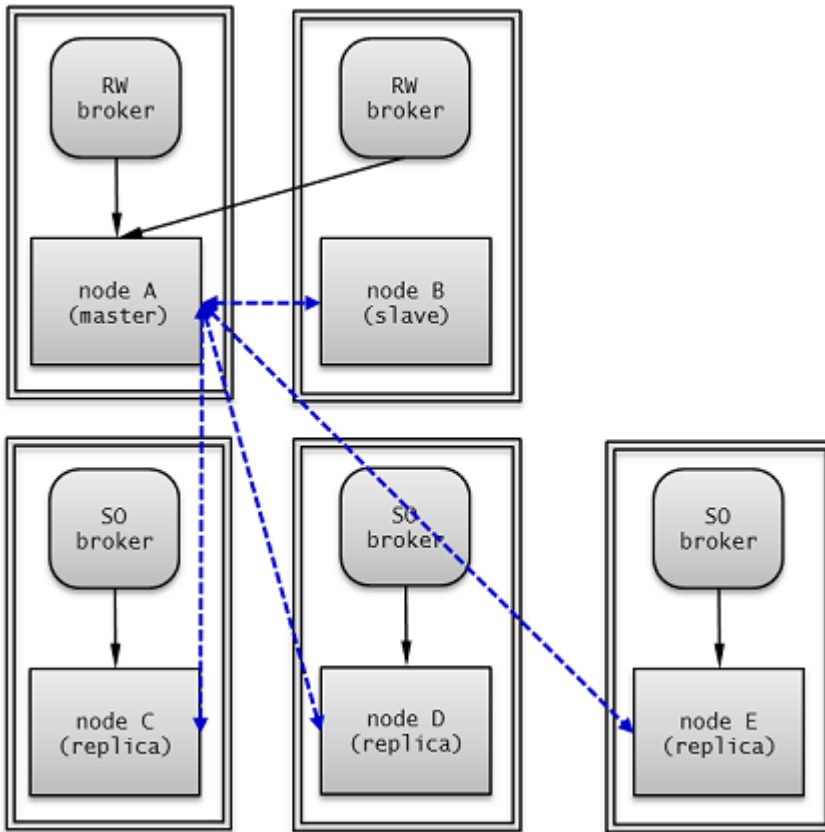

## Load Balancing Structure

The load balancing structure increases the availability of the CUBRID service by placing several nodes in the HA configuration (one master node and one slave node) and distributes read-load.

Because the replica nodes receive replication logs from the master node in the HA configuration and maintain the same data, and because the master node in the HA configuration does not receive replication logs from the replica nodes, its network and disk usage rate is lower than that of the multiple-slave structure.

Because replica nodes are not included in the HA structure, they provide read service without failover, even when all other nodes in the HA structure fail.

### An Example of Node Configuration

You can configure each node in load balancing structure as shown below:

- **node A** (master node)
  - Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**:

```
ha_port_id=59901
ha_node_list=cubrid@nodeA:nodeB
ha_replica_list=cubrid@nodeC:nodeD:nodeE
ha_db_list=testdb
ha_copy_sync_mode=sync:sync
```

- **node B** (slave node): Configure this node in the same manner as *node A*.
- **node C, node D, node E** (replica node)
  - Configure the **ha\_mode** of the **cubrid.conf** file to **replica**.

```
ha_mode=replica
```

- You can configure the **cubrid\_ha.conf** file in the same manner as *node A*.

The **cubrid\_broker.conf** can be set in a variety of ways according to configuration of the broker. It can also be configured as separate equipment with the **databases.txt** file.

In this example, broker and DB server exist on the same machine; the RW broker is configured in *node A* and *node B*; the SO broker with “CONNECT\_ORDER=RANDOM” and “PREFERRED\_HOSTS=localhost” is configured in *node C*, *node D* and *node E*. each of *node C*, *node D* or *node E* tries to connect to local DB server first because they are set as “PREFERRED\_HOSTS=localhost”. When it is failed to connect to localhost, it tries to connect to one of **db-hosts** in **databases.txt** randomly because they are set as “CONNECT\_ORDER=RANDOM”.

The following is an example of **cubrid\_broker.conf** in *node A* and *node B*.

```
[%RW_broker]
...

# Broker mode setting parameter
ACCESS_MODE          =RW
```

The following is an example **cubrid\_broker.conf** in *node C*, *node D* and *node E*.

```
[%PHRO_broker]
...

# Broker mode setting parameter
ACCESS_MODE          =SO
PREFERRED_HOSTS      =localhost
```

You must enter the list of DB server hosts in the order so that each broker can be connected appropriate HA or load balancing server in the **databases.txt** file of a broker node.

The following is an example of the **databases.txt** file in *node A* and *node B*.

```
#db-name      vol-path          db-host      log-
path          lob-base-path
testdb        /home/cubrid/DB/testdb  nodeA:nodeB  /home/cubrid/DB/
testdb/log    file:/home/cubrid/CUBRID/testdb/lob
```

The following is an example of the **databases.txt** file in *node C*, *node D* and *node E*.

```
#db-name      vol-path          db-host      log-
path          lob-base-path
testdb        /home/cubrid/DB/testdb  nodeC:nodeD:nodeE  /home/cubrid/
DB/testdb/log  file:/home/cubrid/CUBRID/testdb/lob
```

## Connection Configuration of Applications

Connect the application to access in read/write mode to the broker of *node A* or *node B*. The following is an example of a JDBC application.

```
Connection connection = DriverManager.getConnection(
    "jdbc:CUBRID:nodeA:33000:testdb:::charset=utf-8&altHosts=nodeB:33000", "dba", "");
```

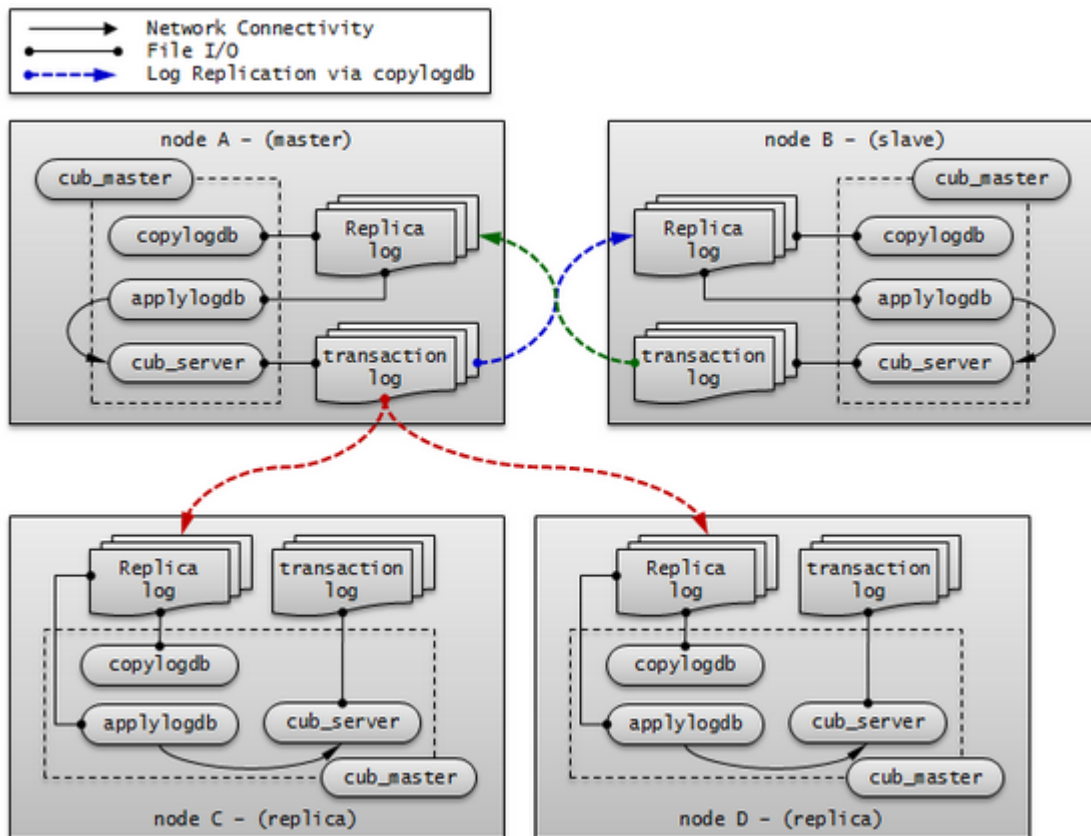

Connect the application to access in read-only mode to the broker of *node C*, *node D* or *node E*. The following is an example of a JDBC application. Configure “**loadBalance=sh**” on the URL to connect randomly to the main host and hosts which are specified by **altHosts**.

```
Connection connection = DriverManager.getConnection(
    "jdbc:CUBRID:nodeC:33000:testdb:::charset=utf-8&loadBalance=sh&altHosts=nodeD:33000,nodeE:33000",
    "dba", "");
```

For details, see [JDBC Configuration](#), [CCI Configuration](#), and [PHP Configuration](#) in Environment Configuration.

### Remark

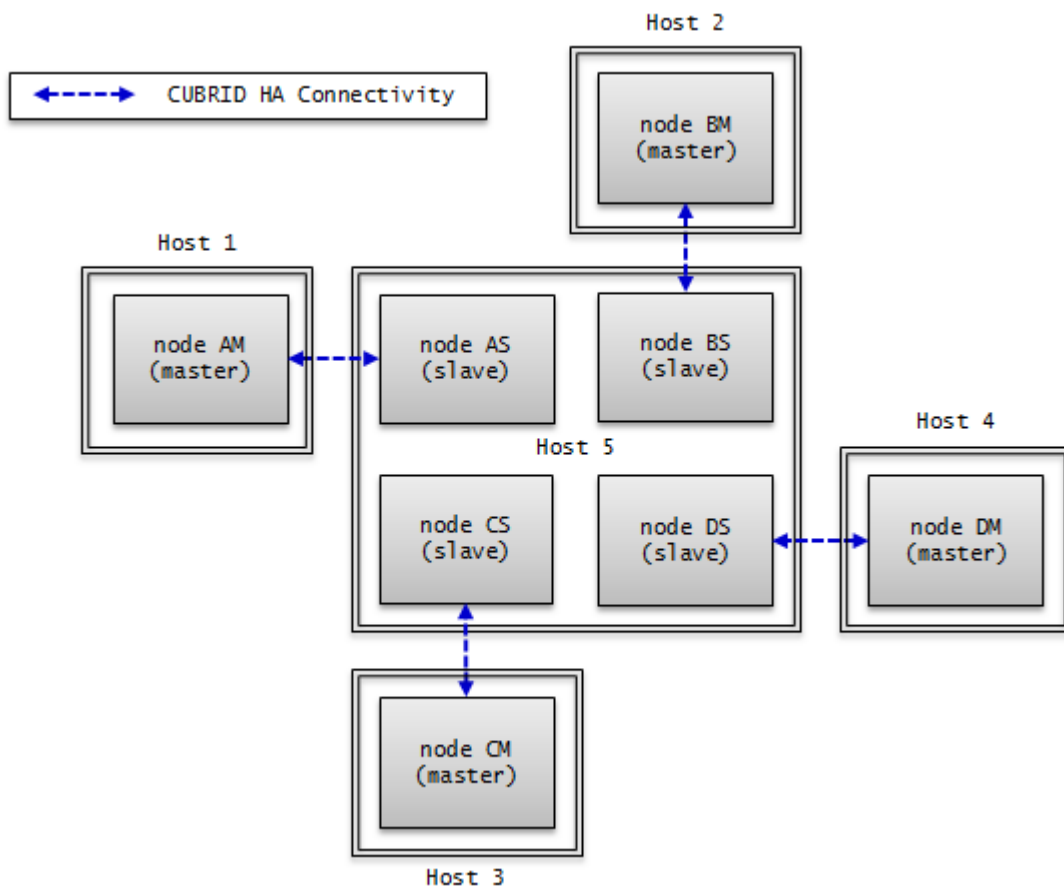

The path of a transaction log in these configurations is as follows:

## Multiple-Standby Server Structure

Although its node structure has a single master node and a single slave node, many slave nodes from different services are physically configured in a single server.

This structure is for very small services in which the reading load of slave nodes is light. It is strictly for the availability of the CUBRID service. For this reason, when a master node that failed after a failover has been restored, the load must be moved back to the original master node to minimize the load of the server with multiple-slave nodes.

### An Example of Node Configuration

You can configure each node in the basic structure of HA as shown below:

- **node AM, node AS** : Configure them in the same manner.
  - Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**.

```
ha_port_id=10000
ha_node_list=cubridA@Host1:Host5
ha_db_list=testdbA1,testdbA2
ha_copy_sync_mode=sync:sync
```

- **node BM, node BS** : Configure them in the same manner.
  - Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**.

```
ha_port_id=10001
ha_node_list=cubridB@Host2:Host5
ha_db_list=testdbB1,testdbB2
ha_copy_sync_mode=sync:sync
```

- **node CM, node CS** : Configure them in the same manner.

- Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following example shows how to configure **cubrid\_ha.conf**.

```
ha_port_id=10002
ha_node_list=cubridC@Host3:Host5
ha_db_list=testdbC1,testdbC2
ha_copy_sync_mode=sync:sync
```

- **node DM, node DS** : Configure them in the same manner.

- Configure the **ha\_mode** of the **cubrid.conf** file to **on**.

```
ha_mode=on
```

- The following is an example of the **cubrid\_ha.conf** configuration.

```
ha_port_id=10003
ha_node_list=cubridD@Host4:Host5
ha_db_list=testdbD1,testdbD2
ha_copy_sync_mode=sync:sync
```

## HA Constraints

### Supported Platforms

Currently, CUBRID HA is supported by Linux only. All nodes within CUBRID HA groups must be configured on the same platforms.

### Table Primary Key

CUBRID HA synchronizes data among nodes with the following method (as known as transaction log shipping): It replicates the primary key-based replication logs generated from the server of a master node to a slave node and then reflects the replication logs to the slave node.

If data of the specific table within CUBRID HA groups is not synchronized, you should check whether the appropriate primary key has specified for the table.

On the partitioned table, the table which has promoted some partitions by the **PROMOTE** statement replicates all data to the slave. However, since the table does not have the primary key, the data changes on the table made by the master are not applied to the slave.

#### Note

The data replication of tables without a primary key is supported by **USE\_SBR** hint. For more information, see [Using SQL Hint](#).

## Stored Procedure

In CUBRID HA, **PL/CSQL stored procedures** are replicated, but **Java stored procedures** only replicate the declaration, not the execution program. Therefore, the execution program must be manually copied to all nodes in the HA.

To execute stored procedures, the CUBRID procedural language server must be running, which is automatically started when the database server starts.

However, the **cubrid.conf** configuration for running the CUBRID language server is not replicated, so you must ensure that **stored\_procedure** is set to **yes** (default) on both the master and slave nodes.

## Method

CUBRID HA synchronizes data among nodes within CUBRID HA groups based on replication logs, So using method that does not generate replication logs may cause data inconsistency among nodes within CUBRID HA groups.

Therefore, in CUBRID HA environment, it is not recommended to use method. (e.g. CALL login('dba', '') ON CLASS dbuser;)

## Standalone Mode

The replication logs are not generated as for tasks performed in standalone mode. For this reason, data inconsistency among nodes within CUBRID HA groups may occur when performing tasks in standalone mode.

## Serial Cache

To enhance performance, a serial cache does not access Heap and does not generate replication logs when retrieving or updating serial information. Therefore, if you use a serial cache, the current values of serial caches will be inconsistent among the nodes within CUBRID HA groups.

### **cubrid backupdb -r**

This command is used to back up a specified database. If the **-r** option is used, logs that are not required for recovery will be deleted. This deletion may result in data inconsistency among nodes within CUBRID HA groups. Therefore, you must not use the **-r** option.

### **On-line backup**

If you want to perform on-line backup in HA environment, add `@hostname` after the database name. *hostname* is a name defined in `$CUBRID_DATABASES/databases.txt`. Specify “@localhost” because you generally perform on-line backup on the local database.

```
cubrid backupdb -C -D ./ -l 0 -z testdb@localhost
```

Backup during running database may occur disk I/O load. Therefore, it is recommended to run backup on slave DB than master DB.

### **INCR/DECR Functions**

If you use **INCR** / **DECR** (click counter functions) in a slave node of HA configuration, an error is returned.

### **LOB (BLOB/CLOB) Type**

In a CUBRID HA environment, the meta data (Locator) of a **LOB** column is replicated and **LOB** data is not replicated. Therefore, if storage of a **LOB** type is located on the local machine, no tasks corresponding to columns are allowed in slave nodes or master nodes after failover.

#### **Note**

On previous version of CUBRID 9.1, using triggers in CUBRID HA can cause duplicate executions. This may cause data inconsistency among nodes within CUBRID HA groups. Therefore, you should not use triggers on the previous version of 9.1.

#### **Note**

### **UPDATE STATISTICS**

From 10.0, UPDATE STATISTICS statement is replicated.

In the previous version of 10.0, UPDATE STATISTICS statement is not replicated; therefore, as a separated operation, you should run this statement in the slave/replica node. When you want to apply UPDATE STATISTICS on the slave/replica node in the previous version of 10.0, you should run this in the CSQL with **--sysadm** and **--write\_on\_slave** options.

## Operational Scenarios

### Operation Scenario during Read/Write Service

The operation scenario written in this page is not affected by read/write services. Therefore, its impact on the services caused by CUBRID operation is very limited. There can be two types of operation scenarios in which failover occurs or it does not occur.

#### When Failover Does Not Occur

You can perform the following operations without stopping and restarting nodes in CUBRID HA groups.

| General Operation                                                              | Scenario                                                                                                   | Consideration                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Online Backup                                                                  | Operation task is performed at each master node and slave node each during operation.                      | Note that there may be a delay in the transaction of master node due to the operation task.                                                                                                                                                                                                                                                                                                              |
| Schema change (excluding basic key change), index change, authorization change | When an operation task occurs at a master node, it is automatically replication reflected to a slave node. | Because replication log is copied and reflected to a slave node after an operation task is completed in a master node, operation task time is doubled. Changing schema must be processed without any failover. Index change and authority change other than the schema change can be performed by stopping each node and executing standalone mode (ex: the <b>-S</b> option of the <b>csql</b> utility) |

| General Operation   |        |        | Scenario                                                                                                                                                                                                          | Consideration                                                                                                                                                                                                                                                                  |
|---------------------|--------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     |        |        |                                                                                                                                                                                                                   | when the operation time is important.                                                                                                                                                                                                                                          |
| Add volume          |        |        | Operation task is performed at each DB regardless of HA structure.                                                                                                                                                | Note that there may be a delay in the transaction of master node due to the operation task. If operation task time is an issue, operation task can be performed by stopping each node and executing standalone mode (ex: the <b>-S</b> of the <b>cubrid addvoldb</b> utility). |
| Failure replacement | node   | server | It can be replaced without restarting the CUBRID HA group when a failure occurs.                                                                                                                                  | The failure node must be registered in the <code>ha_node_list</code> of CUBRID HA group, and the node name must not be changed during replacement.                                                                                                                             |
| Failure replacement | broker | server | It can be replaced without restarting the broker when a failure occurs.                                                                                                                                           | The connection to a broker replaced at a client can be made by <code>rcTime</code> which is configured in URL string.                                                                                                                                                          |
| DB server expansion |        |        | You can execute <b>cubrid heartbeat reload</b> in each node after configuration change ( <code>ha_node_list</code> , <code>ha_replica_list</code> ) without restarting the previously configured CUBRID HA group. | Starts or stops the <b>copylogdb/applylogdb</b> processes which were added or deleted by loading changed configuration information.                                                                                                                                            |

Broker server expansion

| General Operation | Scenario                                                    | Consideration                                                         |
|-------------------|-------------------------------------------------------------|-----------------------------------------------------------------------|
|                   | Run additional brokers without restarting existing brokers. | Modify the URL string to connect to a broker where a client is added. |

### When Failover Occurs

You must stop nodes in CUBRID HA group and complete operation before performing the following operations.

| General Operation                                           | Scenario                                                                                                             | Consideration                                                                               |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| DB server configuration change                              | A node whose configuration is changed is restarted when the configuration in <b>cubrid.conf</b> is changed.          |                                                                                             |
| Change broker configuration, add broker , and delete broker | A broker whose configuration is changed is restarted when the configuration in <b>cubrid_broker.conf</b> is changed. |                                                                                             |
| DBMS version patch                                          | Restart nodes and brokers in HA group after version patch.                                                           | Version patch means there is no change in the internal protocol, volume, and log of CUBRID. |

### Operation Scenario during Read Service

The operation scenario written in this page is only applied to read service. It is required to allow read service only or dynamically change mode configuration of broker to Read Only. There can be two types of operation scenarios in which failover occurs or it does not occur.

### When Failover Does Not Occur

You can perform the following operations without stopping and restarting nodes in CUBRID HA groups.

| General Operation                                                              | Scenario                                                                                                 | Consideration                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Schema change (primary key change)                                             | When an operation task is performed at the master node, it is automatically reflected to the slave node. | In order to change the primary key, the existing key must be deleted and a new one added. For this reason, replication reflection may not occur due to the HA internal structure which reflects primary key-based replication logs. Therefore, operation tasks must be performed during the read service.                                                                                                                                                         |
| Schema change (excluding basic key change), index change, authorization change | When an operation task is performed at the master node, it is automatically reflected to the slave node. | Because replication log is copied and reflected to a slave node after an operation task is completed in a master node, operation task time is doubled. Changing schema must be processed without any failover. Index change and authority change other than the schema change can be performed by stopping each node and executing standalone mode(ex: the <code>span class="nkeyword"&gt;-S</code> option of <b>csql</b> ) when the operation time is important. |

### When Failover Occurs

You must stop nodes in CUBRID HA group and complete operation before performing the following operations.

| General Operation                              | Scenario                                                                                  | Consideration                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------|-------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBMS version upgrade                           | Restart each node and broker in the CUBRID HA group after they are upgraded.              | A version upgrade means that there have been changed in the internal protocol, volume, or log of CUBRID. Because there are two different versions of the protocols, volumes, and logs of a broker and server during an upgrade, an operation task must be performed to make sure that each client and broker (before/after upgrade) are connected to the corresponding counterpart in the same version. |
| Massive data processing (INSERT/UPDATE/DELETE) | Stop the node that must be changed, perform an operation task, and then execute the node. | This processes massive data that cannot be segmented.                                                                                                                                                                                                                                                                                                                                                   |

## Operation Scenario after Stopping a Service

You must stop all nodes in CUBRID HA group before performing the following operation.

| General Operation                            | Scenario                                                                          | Consideration                                                                                                                                            |
|----------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Changing the host name and IP of a DB server | Stop all nodes in the CUBRID HA group, and restart them after the operation task. | When a host name has been changed, change the <b>databases.txt</b> file of each broker and reset the broker connection with <b>cubrid broker reset</b> . |

## Setting Replica Replication Delay

This scenario delays the replication of the master node data in replica node, and stops the replication of the master node data at the specific time, to detect the case which someone deleted the data by mistake and stop the replication at the specified time.

| General Operation                                | Scenario                                                                                                 | Consideration                                                                   |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Setting the delay of replication in replica node | Specify the term of replicated delay to replica node, and let the replication stop on the specified time | specify <b>ha_replica_delay</b> and <b>ha_replica_time_bound</b> in cubrid.conf |

## Building Replication

### restoreslave

**cubrid restoreslave** is the same as **cubrid restoredb** which restores a database from a backup but it includes several convenient features when rebuilding a slave or a replica. With **cubrid restoreslave**, user does not need to manually collect replication-related information from a backup output to create a replication catalog which is stored in **\_db\_ha\_apply\_info**. It automatically reads any necessary information from a backup image and an active log and then it adds the relevant replication catalog into **\_db\_ha\_apply\_info**. All you need to do is to provide two mandatory options: the state of the node where the backup image was created, and the hostname of the current master node. Please also refer **restoredb** for more details.

```
cubrid restoreslave [OPTION] database-name
```

#### **-s, --source-state=STATE**

You need to specify the state of the node where the backup image was created. STATE may be 'master', 'slave', or 'replica'

#### **-m, --master-host-name=NAME**

You need to specify the hostname of the current master node.

#### **--list**

This option displays information on backup files of a database; restoration procedure is not performed. For further information, see **--list** of **restoredb**

**-B, --backup-file-path=PATH**

You can specify the directory where backup files are to be located by using the -B option. For further information, see -B of [restoredb](#)

**-o, --output-file=FILE**

You can specify a filename to store output messages. For further information, see -o of [restoredb](#)

**-u, --use-database-location-path**

This option restores a database to the path specified in the database location file(databases.txt). For further information, see -u of [restoredb](#)

**-k, --keys-file-path=PATH**

This option specifies the path of the key file required to restore. For more information, see [restoredb](#).

## Example Scenarios of Building Replication

In this section, we will see various scenarios regarding adding a new node or removing a node during HA service.

**Note**

- Please note that only tables which have a primary key can be replicated.
- Please note that volume paths between a master node and a slave (or replica) node must be the same.
- A node includes replication processing information for all other nodes. For example, let's consider HA architecture with a master *nodeA*, and two slaves *nodeB* and *nodeC*. *nodeA* has the replication process information for *nodeB* and *nodeC*; *nodeB* has information for *nodeB* and *nodeC*; *nodeC* has information for *nodeA* and *nodeC*.
- Under the assumption of no failover, add a new node. If failover occurs during building replication, it is recommended to rebuild replication from the beginning.

**• Add a Slave after Stopping a Service**

Add a new slave node after the service stops when operating a database with only a machine.

**• Build Another Slave during HA Service**

Add a new slave using the existing slave node in the HA environment which one master and one slave are built.

- [Remove a Slave during Service](#)

Remove a slave when one master and two slaves are built.

- [Add a Replica during Service](#)

Add a new replica node using the existing slave in the environment which a master and a slave are built.

- [Rebuild a Slave during Service](#)

Rebuild the slave using the existing master in the environment which a master, a slave and a replica are built. A new information should be updated by a user in the `_db_ha_apply_info` catalog table.

Now let's see in detail about the above scenarios.

When you want to rebuild only the abnormal node in the HA environment, see [Rebuilding Replication Script](#).

#### Note

- During building a replication, please note that added or rebuilt node's replication information and replication logs should be updated or removed when you add, rebuild or remove a certain node. Replication information is saved on the `_db_ha_apply_info` table, and it has other nodes' replication process information.

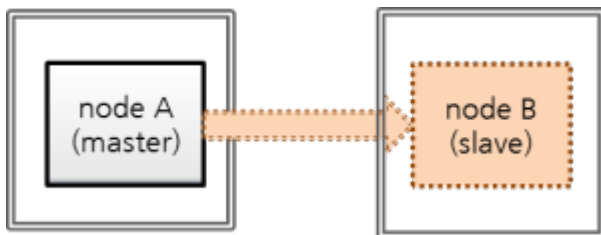

However, because role change does not occur in a replica node, the other node is not required to have replication information and a replication logs about the replica node. On the other hand, the replica node has all information about a master and a slave.

- When you run a scenario of [Rebuild a Slave during Service](#), you should update `_db_ha_apply_info`'s information directly.
- When you run a scenario of [Add a Slave after Stopping a Service](#), a slave is newly built; therefore, you can use the automatically added information.
- When you run a a scenario of [Build Another Slave during HA Service](#) or [Add a Replica during Service](#), backed-up database from the existing slave is used; you can use as it exists because master's `_db_ha_apply_info` information is included in the existing slave.

- When you run a scenario of **Remove a Slave during Service**, you must remove replication information about a removed slave. However, this information does not make a problem even if this is left.

## Add a Slave after Stopping a Service

Now let's see the case of building a new slave node with a single master node - making a 1:1 master-slave composition.

- nodeA: a master node's host name
- nodeB: a slave node's host name to be added newly

This scenario assumes that the database has been created by below commands. When you run `createdb`, a locale name and a charset should be the same between a master node and a slave node.

```
export CUBRID_DATABASES=/home/cubrid/DB
mkdir $CUBRID_DATABASES/testdb
mkdir $CUBRID_DATABASES/testdb/log
cd $CUBRID_DATABASES/testdb
cubrid createdb testdb -L $CUBRID_DATABASES/testdb/log en_US.utf8
```

The backup file is saved in the `$CUBRID_DATABASES/testdb` directory by default if the location is not specified.

URL's change in an application is not required if a broker node is composed of a separated machine and if adding a new broker is not considered.

### **Note**

If a broker's machine is not separated from a database's, to prepare a fault of a master node's machine, broker's access on a slave machine should be possible, too. To do this, `altHosts` should be added on an application's access URL and `databases.txt`'s configuration should be changed for broker duplexing.

For broker's configuration on HA environment, see [cubrid\\_broker.conf](#).

In this scenario, we assume that broker's node is not installed on a separated machine.

With the above in mind, let's work as follows.

1. Configure HA of master node and slave node.

- Set the **\$CUBRID/conf/cubrid.conf** identically on master and slave nodes.

```
[service]
service=server,broker,manager

# Add the database name to run when starting the service
server=testdb

[common]
...

# Add when configuring the HA (Logging parameters)
force_remove_log_archives=no

# Add when configuring the HA (HA mode)
ha_mode=on
```

- Set the **\$CUBRID/conf/cubrid\_ha.conf** identically on master and slave nodes.

```
[common]
ha_port_id=59901

# cubrid is a group name of HA system, nodeA and nodeB are host
names.
ha_node_list=cubrid@nodeA:nodeB

ha_db_list=testdb
ha_copy_sync_mode=sync:sync
ha_apply_max_mem_size=500
```

- Set the **\$CUBRID\_DATABASES/databases.txt** identically on master and slave nodes.

| #db-name      | vol-path                        | db-host       | log-          |
|---------------|---------------------------------|---------------|---------------|
| path          |                                 | lob-base-path |               |
| testdb        | /home/cubrid/DB/testdb          | nodeA:nodeB   | /home/cubrid/ |
| DB/testdb/log | file:/home/cubrid/DB/testdb/lob |               |               |

- Set brokers and applications in HA environment.

For broker setting and adding altHosts into URL, see [cubrid\\_broker.conf](#).

- Set locale library identically on master and slave nodes.

```
[nodeA]$ scp $CUBRID/conf/cubrid_locales.txt cubrid_usr@nodeB:
$CUBRID/conf/.
[nodeB]$ make_locale.sh -t64
```

- Create a directory to a slave node.

```
[nodeB]$ cd $CUBRID_DATABASES
[nodeB]$ mkdir testdb
```

- Create a log directory to a slave node. (create this on the same path with a master node.)

```
[nodeB]$ cd $CUBRID_DATABASES/testdb
[nodeB]$ mkdir log
```

## 2. Stop a master node, backup a master database.

```
[nodeA]$ cubrid service stop
```

Back up the database of the master node and copy the backup file to the slave node.

If the location where the backup file will be saved in the master node is not specified, the location is set as the log directory of *testdb* by default. Copy the backup file to the same location in the slave node. *testdb\_bk0v000* is the backup volume file and *testdb\_bkvinf* is the backup volume information file.

```
[nodeA]$ cubrid backupdb -z -S testdb
Backup Volume Label: Level: 0, Unit: 0, Database testdb, Backup
Time: Thu Apr 19 16:05:18 2012
[nodeA]$ cd $CUBRID_DATABASES/testdb/log
[nodeA]$ scp testdb_bk* cubrid_usr@nodeB:$CUBRID_DATABASES/testdb/
log
cubrid_usr@nodeB's password:
testdb_bk0v000                100% 6157KB   6.0MB/s
00:00
testdb_bkvinf                 100%   66      0.1KB/s
00:00
```

## 3. Restore a database from a slave node.

Restore the database in the slave node. At this time, the volume path of the master node must be identical to that of the slave node.

```
[nodeB]$ cubrid restoredb -B $CUBRID_DATABASES/testdb/log demodb
```

4. Start a master node, start a slave node.

```
[nodeA]$ cubrid heartbeat start
```

After confirming that the master node has been started, start the slave node.

If *nodeA's* state is changed from *registered\_and\_to\_be\_active* to *registered\_and\_active*, it means that the master node has been successfully started.

```
[nodeA]$ cubrid heartbeat status
@ cubrid heartbeat status

HA-Node Info (current nodeA, state master)
  Node nodeB (priority 2, state unknown)
  Node nodeA (priority 1, state master)

HA-Process Info (master 123, state master)

  Applylogdb testdb@localhost:/home1/cubrid/DB/tdb01_nodeB (pid
234, state registered)
  Copylogdb testdb@nodeB:/home1/cubrid/DB/tdb01_nodeB (pid 345,
state registered)
  Server tdb01 (pid 456, state registered_and_to_be_active)

[nodeB]$ cubrid heartbeat start
```

Confirm that the HA configurations of the master node and the slave node are successfully running

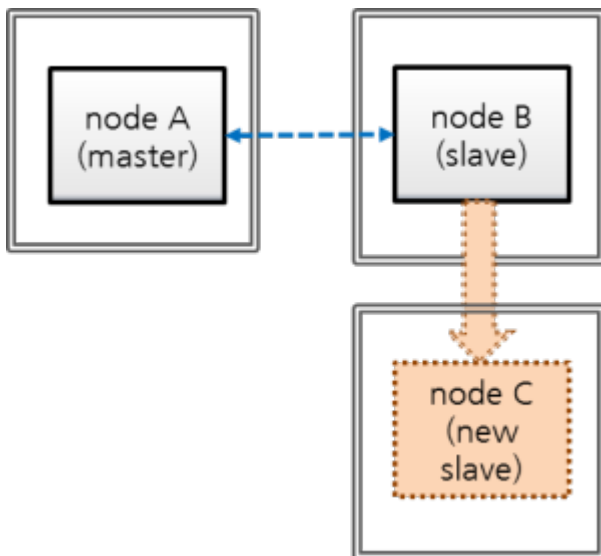

```
[nodeA]$ csql -u dba testdb@localhost -c"create table tbl(i int
primary key);insert into tbl values (1),(2),(3)"

[nodeB]$ csql -u dba testdb@localhost -c"select * from tbl"

          i
=====
          1
          2
          3
```

## Build Another Slave during HA Service

The following is a scenario to add a new slave from an existing slave during a HA service. “Master:Slave” will be from 1:1 to 1:2.

- nodeA: a master node's host name
- nodeB: a slave node's host name
- nodeC: a slave node's host name to be added

You can use an existing master or slave if you want to add a new slave during HA service. In this scenario, let's add a new slave by using an existing slave because we assume that slave's disk I/O is less than master's.

### **Note**

#### **Why possible to use a slave instead of a master when adding a node**

The reason to use a slave instead of a master is that master's transaction log (active log + archive log) is replicated to a slave as it is, and master node's transaction logs and slave node's replication logs (replicated transaction logs) are the same in format and content.

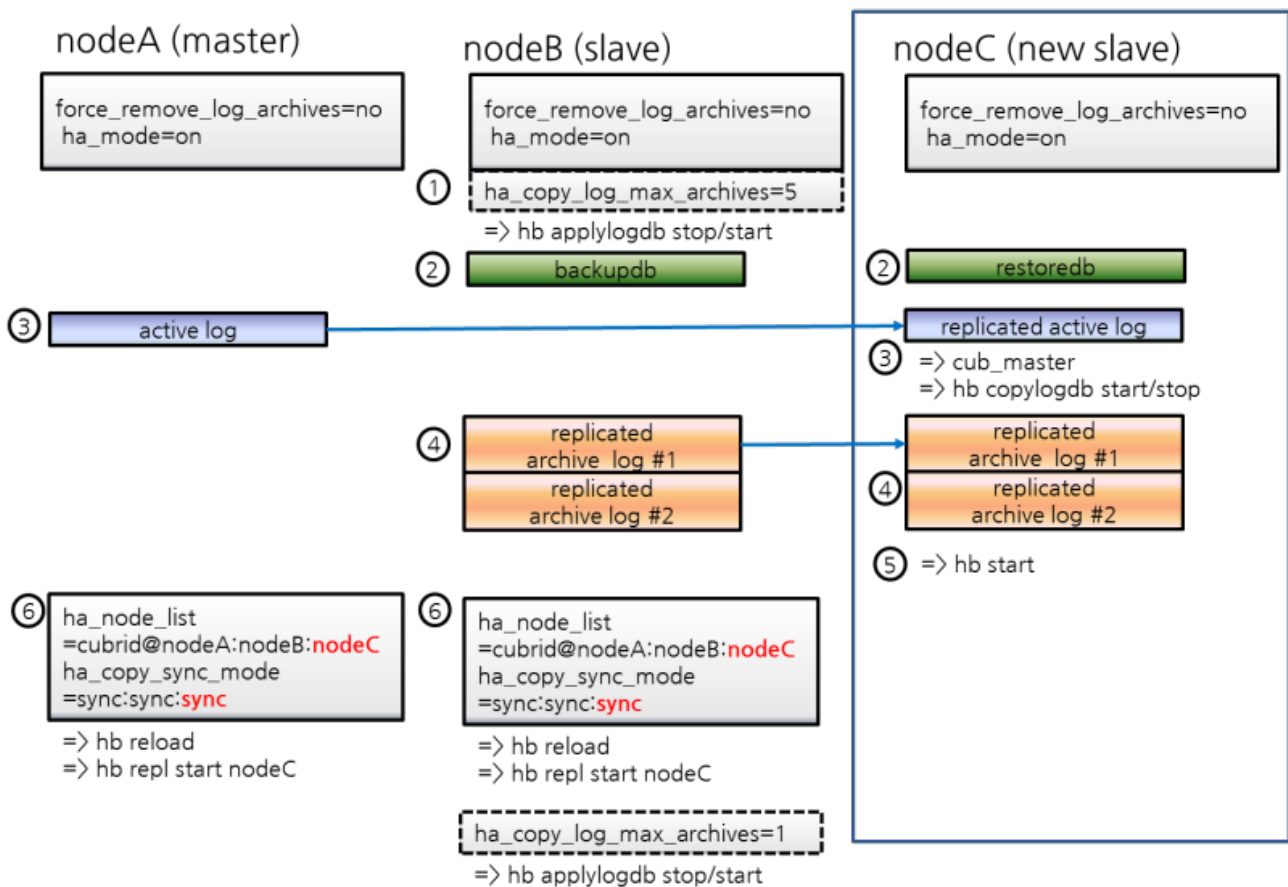

### **Note**

#### **Build an initial database**

It assumes that the database is already created with the below command. a locale name and a charset should be the same between a master and a slave when you run “createdb”.

```
export CUBRID_DATABASES=/home/cubrid/DB
mkdir $CUBRID_DATABASES/testdb
mkdir $CUBRID_DATABASES/testdb/log
cd $CUBRID_DATABASES/testdb
cubrid createdb testdb -L $CUBRID_DATABASES/testdb/log en_US.utf8
```

At this time, if you don't specify backup files' saving path as an option, backup files are saved on the log directory specified in databases.txt.

## 1. HA configuration of nodeC

- Set **\$CUBRID/conf/cubrid.conf** of nodeC identically with nodeB's.

"force\_remove\_log\_archives=no" should be set not to let no-replicated logs be deleted during HA service.

```
[service]
service=server,broker,manager

[common]
...
```

```
# Add when configuring the HA (Logging parameters)
force_remove_log_archives=no

# Add when configuring the HA (HA mode)
ha_mode=on
```

- Set **\$CUBRID/conf/cubrid\_ha.conf** of *nodeC* identically with *nodeB*'s.

However, add *nodeC* into *ha\_node\_list*, and add one more “sync” into *ha\_copy\_sync\_mode*.

```
[common]
ha_port_id=59901

# cubrid is a group name of HA system, nodeA, nodeB, and nodeC
# are host names.
ha_node_list=cubrid@nodeA:nodeB:nodeC

ha_db_list=testdb
ha_copy_sync_mode=sync:sync:sync
ha_apply_max_mem_size=500
```

- Set a locale library of *nodeC* identically with that of *nodeA* or *nodeB*.

```
[nodeB]$ scp $CUBRID/conf/cubrid_locales.txt cubrid_usr@nodeC:
$CUBRID/conf/.
[nodeC]$ make_locale.sh -t64
```

- Add *nodeA*, *nodeB*, and *nodeC* into db-host of **\$CUBRID\_DATABASES/databases.txt** in *nodeC*.

| #db-name | vol-path                  | lob-base-path                   | db-host           | log-path |
|----------|---------------------------|---------------------------------|-------------------|----------|
| testdb   | /home/cubrid/DB/testdb    |                                 | nodeA:nodeB:nodeC | /        |
|          | home/cubrid/DB/testdb/log | file:/home/cubrid/DB/testdb/lob |                   |          |

**db-host** of **databases.txt** is related to the access order to the database server by a broker; therefore, you can change the value as you want. For example, you can write only *nodeA:nodeB* or *localhost* into **db-host**. However, by considering the local machine access, (e.g. `csql -u dba testdb@localhost`) you should add at least *localhost* or the name of *localhost* into **db-host**.

2. Apply configuration for preventing from deleting replication logs of *nodeB* during restoring after backup

Replication logs of *nodeB* can be added if service continues after restoring a database from the *nodeB* backup file to *nodeC*. By the way, slave's replication logs can be deleted before being

copied to *nodeC* by configuration. To prevent this case, you can configure system parameters as follows.

- Change the value of **ha\_copy\_log\_max\_archives** bigger without restarting *nodeB*'s database.

From backup of *nodeB*, transactions which have been executed after backup of *nodeB* should be kept; then transactions after backup can be applied to *nodeC*.

Therefore, added replication logs of *nodeB* after backup should be kept.

Here, let's assume the number of replication logs as 5, which can sufficiently save executed transactions during building *nodeC*.

Edit **\$CUBRID/conf/cubrid\_ha.conf**

```
ha_copy_log_max_archives=5
```

Apply the change of the parameter **ha\_copy\_log\_max\_archives** to the applylogdb process of *nodeB*.

```
[nodeB]$ cubrid heartbeat applylogdb stop testdb nodeA
[nodeB]$ cubrid heartbeat applylogdb start testdb nodeA
```

#### Note

If you build *nodeC* with only *nodeA*, a master node, to change the value of **ha\_copy\_log\_max\_archives** from *nodeB* is needless because copying replication logs from *nodeB* is needless.

Instead, you should apply the changed **log\_max\_archives** to *nodeA*.

The value of **log\_max\_archives** parameter of cubrid.conf can be changed during service by using "SET SYSTEM PARAMETERS" syntax.

```
[nodeA]$ csqll -u dba -c "SET SYSTEM PARAMETERS
'log_max_archives=5'" testdb@localhost
```

### 3. Backup from *nodeB*, restore into *nodeC*

- Backup a database from *nodeB*.

```
[nodeB]$ cd $CUBRID_DATABASES/testdb/log
[nodeB]$ cubrid backupdb --sleep-msecs=10 -C -o output.txt
testdb@localhost
```

### Note

**--sleep-msecs** is an option to set the rest time in each cycle when 1MB is written in a backup file. The unit is millisecond. Consider setting this option if the disk I/O overhead of a machine to back up is severe; however, it is recommended to set this value as small as possible and do backup when backup overhead is small enough because if this value is bigger, backup time takes longer.

If there is no I/O overhead on *nodeB*, you can omit this option.

On the file specified in -o option, the backup result information is written.

- Copy backup files to *nodeC*.

```
[nodeB]$ cd $CUBRID_DATABASES/testdb/log
[nodeB]$ scp -l 131072 testdb_bk* cubrid_usr@nodeC:
$CUBRID_DATABASES/testdb/log
```

### Note

scp command's -l option is an option to control the amount of copying file; when you copy files between nodes, use this value properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

- Restore the database into *nodeC*.

At this time, the volume path of the slave must be the same with the master.

```
[nodeC]$ cubrid restoredb -B $CUBRID_DATABASES/testdb/log testdb
```

## 4. Copy the active log of *nodeA* into *nodeC*

In *nodeA*'s active log, there exists a number information of the archive log which is recently created. This information is needed for archive logs, which has been created after the time in which the active log had been copied, to be automatically copied by copylogdb process after

the start of HA service of *nodeC*; therefore, the user just needs to manually copy archive logs which has been created before copying an active log.

- Start *cub\_master* which manages HA connection in *nodeC*.

```
[nodeC]$ cub_master
```

- Start *copylogdb* process for *nodeA*.

```
[nodeC]$ cubrid heartbeat copylogdb start testdb nodeA
```

- Check if *nodeA*'s active log was copied.

To copy the current active log means to obtain the number information of the last archive log. Archive logs after this time are automatically copied after the process [5. Start HA server in *nodeC*].

```
[nodeC]$ cd $CUBRID_DATABASES/testdb_nodeA
[nodeC]$ ls
testdb_lgar_t  testdb_lgat  testdb_lgat__lock
```

- Stop *copylogdb* process for *nodeA* on *nodeC*.

```
[nodeC]$ cubrid heartbeat copylogdb stop testdb nodeA
```

- Stop *cub\_master* of *nodeC*.

```
[nodeC]$ cubrid service stop
```

## 5. Copy required log files after restoring a database into *nodeC*

- Copy all replicated archive logs of *nodeB* into *nodeC*.

```
[nodeC]$ cd $CUBRID_DATABASES/testdb_nodeA
[nodeC]$ scp -l 131072 cubrid@nodeB:$CUBRID_DATABASES/
testdb_nodeA/testdb_lgar0* .
```

In this process, please note that all replicated archive logs which are required for replication should exist.

**Note**

scp command's `-l` option is an option to control the amount of copying file; when you copy files between nodes, use this value properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

**Note**

Copy files of which the names end with a number. Here, we copied with `"testdb_lgar0*"` because numbers of names of all replication log files are started with 0.

**Note****Preparation plan when the required replication logs are already deleted**

Replication logs which are created between backup time and active log creation time can be deleted if the value of **ha\_copy\_log\_max\_archives** is not large enough; in this case, an error can occur when running the below process, [5. Start HA service on *nodeC*].

When an error occurs, start HA service of *nodeC* by adding archive logs in master if the required logs exist in master node. For example, you can copy an archive log #1 from master if there are archive logs #1, #2, and #3 in master; and there are only replicated archive logs #2, and #3 in slave and #1 is required additionally. However, the case in which master's archive log files are left more can happen only when the value of **log\_max\_archives** of master is big enough.

If there is no wanted number's archive log in master's archive logs, change the value of **ha\_copy\_log\_max\_archives** big enough and do backup-and-restore procedure from the beginning.

**Note****Check if required replication logs are deleted**

You can check if required replication logs are deleted or not by watching the `testdb_lginf` file.

1. If this is the case of restoring a database from a slave backup file, you can check what pages are required, from the page of master by watching the value of `required_lsa_pageid` in the `_db_ha_apply_info` catalog table.
2. Watch the contents of the `testdb_lginf` file located in `$CUBRID_DATABASES/testdb/log` directory from bottom to top.

```
Time: 03/16/15 17:44:23.767 - COMMENT: CUBRID/LogInfo for
database /home/cubrid/DB/databases/testdb/testdb
Time: 03/16/15 17:44:23.767 - ACTIVE: /home/cubrid/DB/
databases/testdb/log/testdb_lgat 1280 pages
Time: 03/16/15 17:54:40.892 - ARCHIVE: 0 /home/cubrid/DB/
databases/testdb/log/testdb_lgar000 0 1277
Time: 03/16/15 17:57:29.451 - COMMENT: Log archive /home/
cubrid/DB/databases/testdb/log/testdb_lgar000 is not
needed any longer unless a database media crash occurs.
Time: 03/16/15 18:03:08.166 - ARCHIVE: 1 /home/cubrid/DB/
databases/testdb/log/testdb_lgar001 1278 2555
Time: 03/16/15 18:03:08.167 - COMMENT: Log archive /home/
cubrid/DB/databases/testdb/log/testdb_lgar000, which contains
log pages before 2556, is not needed any longer by any HA
utilities.
Time: 03/16/15 18:03:29.378 - COMMENT: Log archive /home/
cubrid/DB/databases/testdb/log/testdb_lgar001 is not
needed any longer unless a database media crash occurs.
```

When the contents of `testdb_lginf` is written as the above, the last two numbers in “Time: 03/16/15 17:54:40.892 - ARCHIVE: 0 /home/cubrid/DB/databases/testdb/log/testdb\_lgar000 0 1277” are the start and end IDs of pages which this file store.

For example, if the page ID at backup is 2300, we can see this ID is between no. 1278 and no. 2555 by watching “testdb\_lgar001 1278 2555”; therefore, we can know that the archive logs of master (or replicated archive logs of slave) are required from no. 1 when restoring a database.

## 6. Start HA service on *nodeC*

```
[nodeC]$ cubrid heartbeat start
```

## 7. Change HA configuration of *nodeA* and *nodeB*

- Turn back the value of `ha_copy_log_max_archive` of *nodeB*.

```
[nodeB]$ vi cubrid_ha.conf  
ha_copy_log_max_archives=1
```

- Apply the changed value of `ha_copy_log_max_archives` to the `applylogdb` process of *nodeB*.

```
[nodeB]$ cubrid heartbeat applylogdb stop testdb nodeA  
[nodeB]$ cubrid heartbeat applylogdb start testdb nodeA
```

- In `cubrid_ha.conf`, add *nodeC* into `ha_node_list`, and add one “sync” more to *nodeA* and *nodeB*.

```
$ cd $CUBRID/conf  
$ vi cubrid_ha.conf  
  
ha_node_list=cubrid@nodeA:nodeB:nodeC  
ha_copy_sync_mode=sync:sync:sync
```

- Apply changed `ha_node_list`.

```
[nodeA]$ cubrid heartbeat reload  
[nodeB]$ cubrid heartbeat reload
```

- Start `copylogdb` and `applylogdb` for *nodeC*.

```
[nodeA]$ cubrid heartbeat repl start nodeC  
[nodeB]$ cubrid heartbeat repl start nodeC
```

## 8. Add a broker and add this broker's host name into `altHosts` of application URL

Add a broker if needed, and add this broker's host name into `altHosts`, the property of application URL to access this broker.

If you are not considering to add a broker, you do not need to do this job.

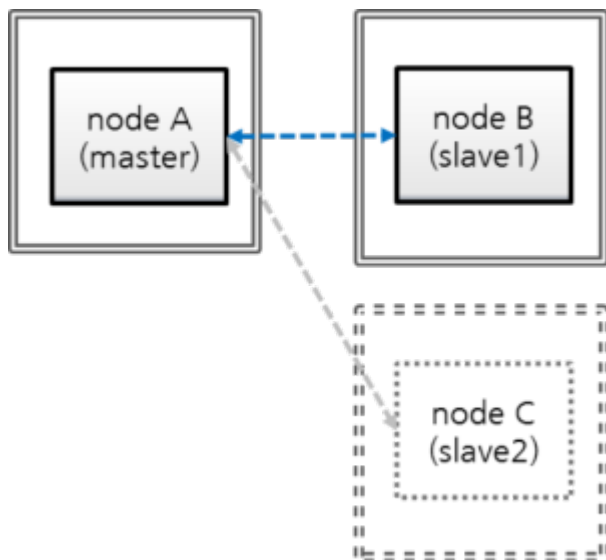

- From all of *nodeA* and *nodeB*, add *nodeC* into `db-host` of **`$CUBRID_DATABASES/databases.txt`**.

```
#db-name      vol-path      db-host      log-
path          lob-base-path
testdb       /home/cubrid/DB/testdb  nodeA:nodeB:nodeC  /home/
cubrid/DB/testdb/log    file:/home/cubrid/DB/testdb/lob
```

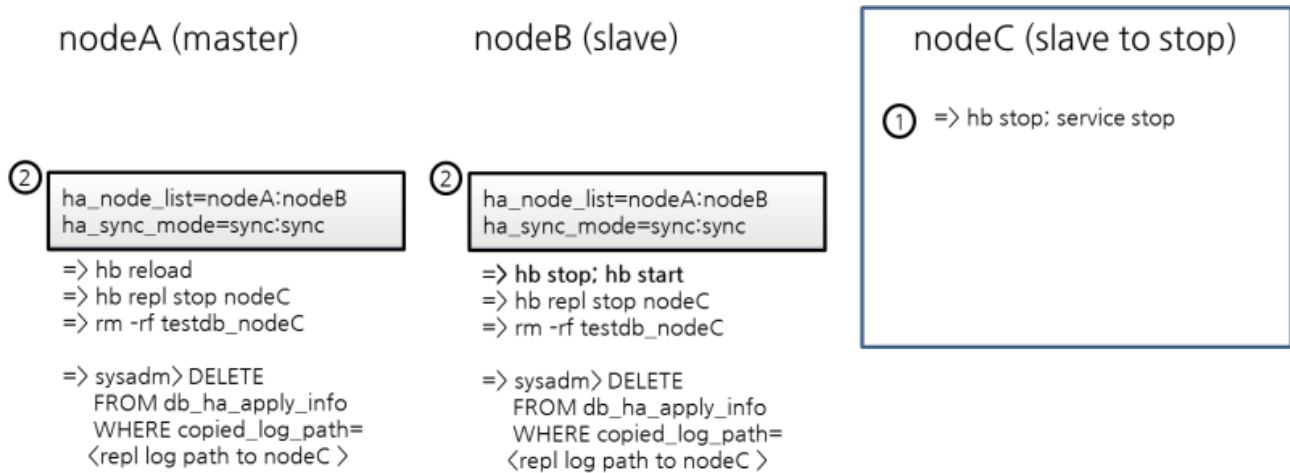

**db-host** of **databases.txt** is a configuration parameter related to the order of access from a broker to database servers; therefore, you can change as you want. For example, you can write only “nodeA:nodeB” or “localhost” into **db-host**. However, if you access database from a local machine (e.g. `csql -u dba testdb@localhost`), you should include “localhost” or the localhost name into **db-host**.

## Remove a Slave during Service

Let's remove a slave when the HA environment is composed of “master:slave = 1:2”.

- nodeA: a master node's host name
- nodeB: a slave node's host name
- nodeC: a slave node's host name to be removed

### 1. Stop the service of *nodeC*

```
$ cubrid heartbeat stop      # Processes related to heartbeat
                             (applylogdb, copylogdb, cub_server) are stopped.
$ cubrid service stop       # Processes such as cub_master,
                             cub_broker, and cub_manager are stopped.
```

### 2. Remove *nodeC* from the configuration of *nodeA*, and *nodeB*

- Remove *nodeC* in *ha\_node\_list* from *cubrid\_ha.conf* of *nodeA* and *nodeB*; remove one “sync” in *ha\_copy\_sync\_mode*.

```
$ vi cubrid_ha.conf

ha_node_list=cubrid@nodeA:nodeB
ha_copy_sync_mode=sync:sync
```

- Apply the changed *ha\_node\_list*.

Run “reload” command at the master, *nodeA*.

```
[nodeA]$ cubrid heartbeat reload
```

Run “stop” and “start” commands at the slave, *nodeB*.

```
[nodeB]$ cubrid heartbeat stop
[nodeB]$ cubrid heartbeat start
```

- Stop *copylogdb* and *applylogdb* for *nodeC*.

```
[nodeA]$ cubrid heartbeat repl stop nodeC
[nodeB]$ cubrid heartbeat repl stop nodeC
```

- Remove replication logs about *nodeC* from *nodeA* and *nodeB*.

```
$ cd $CUBRID_DATABASES
$ rm -rf testdb_nodeC
```

- Remove replication information about *nodeC* from *nodeA* and *nodeB*.

You can run DELETE operation from a slave node only if you add **--sysadm** and **--write-on-standby** options on running csql.

```
$ csql -u dba --sysadm --write-on-standby testdb@localhost

sysadm> DELETE FROM _db_ha_apply_info WHERE
copied_log_path='/home/cubrid/DB/databases/testdb_nodeC';
```

`copied_log_path` is the path in which replication log files are stored.

#### 1. Remove *nodeC* from broker's configuration

- Remove *nodeC* if this exists in `db-host` of `databases.txt` from *nodeA* and *nodeB*.

```
$ cd $CUBRID_DATABASES
$ vi databases.txt

#db-name      vol-path      db-host      log-
path          lob-base-path
testdb        /home/cubrid/DB/testdb  nodeA:nodeB  /
home/cubrid/DB/testdb/log  file:/home/cubrid/DB/testdb/lob
```

- Restart brokers of *nodeA* and *nodeB*.

```
$ cubrid broker restart
```

#### Note

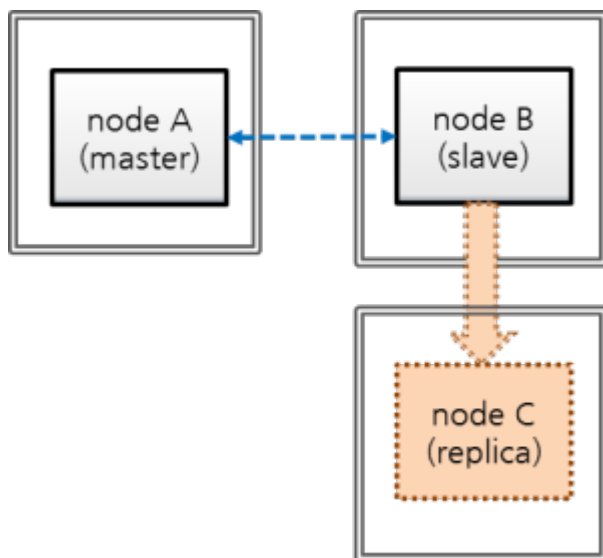

You don't need to hurry to restart these brokers because *nodeC* is already stopped and an application will not access the *nodeC* database. If you restart these brokers, you should consider that the applications connected to these brokers can be disconnected.

Moreover, if multiple brokers with the same configuration exist, one broker can substitute others; therefore, restart a broker one by one.

For example, on the above, *nodeA* and *nodeB* are the same configuration; therefore, you can restart *nodeB* first then restart *nodeA*.

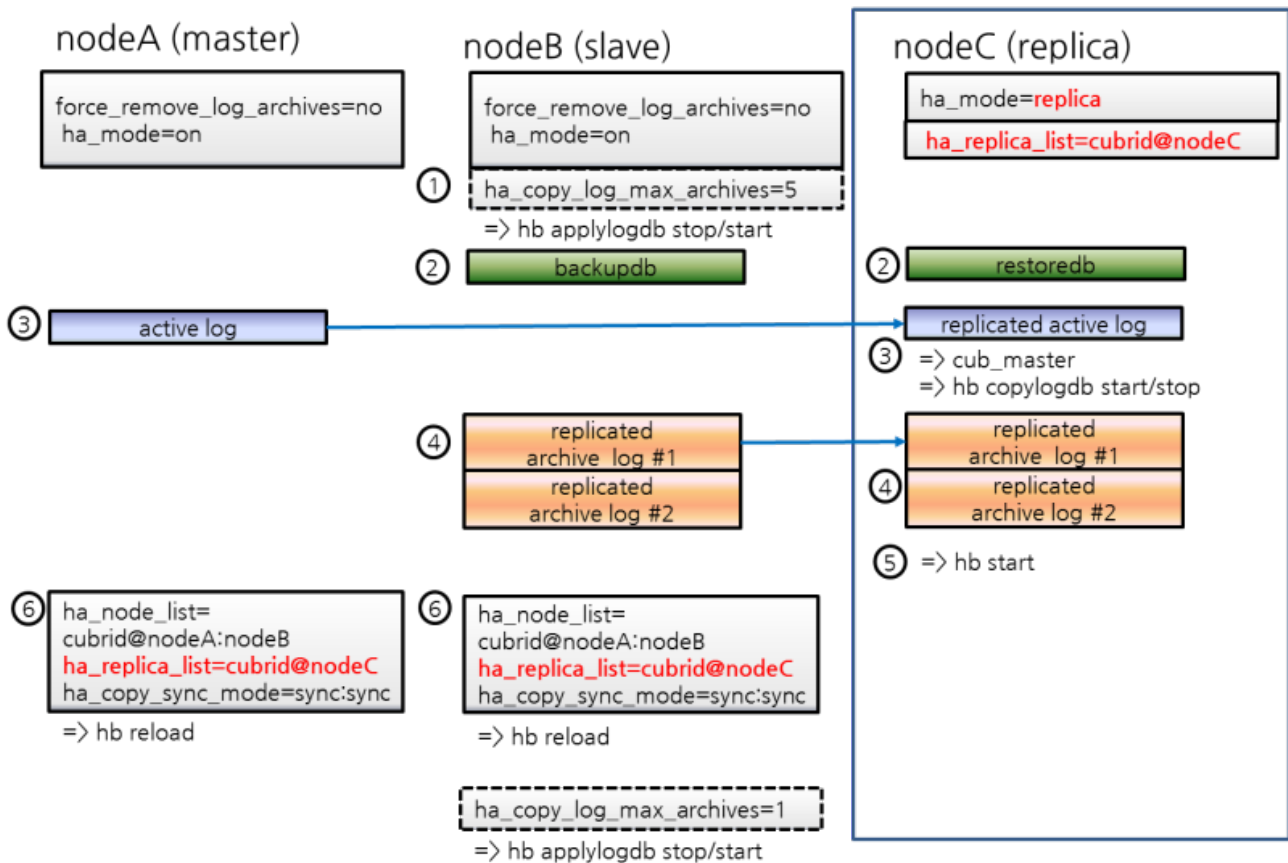

## Add a Replica during Service

Now let's add a replica when HA environment is set as "master:slave=1:1". The beginning database setting is the same as the setting in [Build an initial database](#) of [Build Another Slave during HA Service](#).

- nodeA: a master node's host name
- nodeB: a slave node's host name
- nodeC: a replica node's host name to be added newly

### 1. Configure HA parameter of *nodeC*

- Set *nodeC*'s **\$CUBRID/conf/cubrid.conf** as the same with *nodeB* except for `ha_mode`.

Set "`ha_mode=replica`".

```
[service]
service=server,broker,manager

[common]

# Add this when doing HA configuration (HA mode)
ha_mode=replica
```

#### **Note**

Replica node's transaction logs are not used to replication; therefore, whatever the value of `force_remove_log_archives` is set to, it works as yes.

- Configure *nodeC*'s **\$CUBRID/conf/cubrid\_ha.conf**

Add *nodeC* into `ha_replica_list`.

```
[common]
ha_port_id=59901

# cubrid is a group name of HA system, nodeA, nodeB, and nodeC
# are host names.
ha_node_list=cubrid@nodeA:nodeB

ha_replica_list=cubrid@nodeC

ha_db_list=testdb
ha_copy_sync_mode=sync:sync
ha_apply_max_mem_size=500
```

- Set a locale library of *nodeC* identically with that of *nodeA* or *nodeB*.

```
[nodeB]$ scp $CUBRID/conf/cubrid_locales.txt cubrid_usr@nodeC:
$CUBRID/conf/.
[nodeC]$ make_locale.sh -t64
```

- Add *nodeC* into db-host of **\$CUBRID\_DATABASES/databases.txt** in *nodeC*.

| #db-name   | vol-path               | lob-base-path                   | db-host | log-path         |
|------------|------------------------|---------------------------------|---------|------------------|
| testdb     | /home/cubrid/DB/testdb |                                 | nodeC   | /home/cubrid/DB/ |
| testdb/log |                        | file:/home/cubrid/DB/testdb/lob |         |                  |

**db-host** of **databases.txt** is related to the access order to the database server by a broker; therefore, you can change the value as you want. For example, you can write only *nodeA:nodeB* or *localhost* into **db-host**. However, by considering the local machine access, (e.g. `csql -u dba testdb@localhost`) you should add at least *localhost* or the name of *localhost* into **db-host**.

2. Apply configuration for preventing from deleting replication logs of *nodeB* during restoring after backup

*nodeB*'s replication logs can be added after restoring if a service keeps going during restoring on *nodeC* after backup of *nodeB*; at this time, some replication logs which are needed for *nodeC* can be deleted by the configuration. To protect this, configure nodes as following.

- Change the value of **ha\_copy\_log\_max\_archives** larger without restarting a database on *nodeB*.

To apply transactions after backup time to *nodeC*, transactions should be kept until the *nodeC*'s data which restore *nodeB*'s backup data become the same with master(*nodeA*)'s.

Therefore, *nodeB*'s replication logs which are added after backup should be kept.

Here, let's assume the number of replication log files which can sufficiently store transactions executed during *nodeC*'s building as 5.

Edit **\$CUBRID/conf/cubrid\_ha.conf**

```
ha_copy_log_max_archives=5
```

Apply the change of `ha_copy_log_max_archives` to *nodeB*'s `applylogdb` process.

```
[nodeB]$ cubrid heartbeat applylogdb stop testdb nodeA
[nodeB]$ cubrid heartbeat applylogdb start testdb nodeA
```

#### Note

If you build *nodeC* with *nodeA*, a master node only, copying replication logs from *nodeB* is not needed; therefore, changing the value of **ha\_copy\_log\_max\_archives** from *nodeB* is also needless.

Instead, it requires to apply a changed value of **log\_max\_archives** to *nodeA*.

The value of **log\_max\_archives** parameter in `cubrid.conf` can be changed during service with the "SET SYSTEM PARAMETERS" syntax.

```
[nodeA]$ csql -u dba -c "SET SYSTEM PARAMETERS
'log_max_archives=5'" testdb@localhost
```

### 3. Backup *nocdB* and restore on *nodeC*

- Backup a database from *nodeB*.

```
[nodeB]$ cd $CUBRID_DATABASES/testdb/log
[nodeB]$ cubrid backupdb --sleep-msecs=10 -C -o output.txt
testdb@localhost
```

#### Note

Please refer to the explanation of `--sleep-msecs` within [Build Another Slave during HA Service](#).

- Copy backup files to *nodeC*.

```
[nodeB]$ cd $CUBRID_DATABASES/testdb/log
[nodeB]$ scp -l 131072 testdb_bk* cubrid_usr@nodeC:
$CUBRID_DATABASES/testdb/log
```

#### Note

scp command's `-l` option is an option to control the amount of copying file; when you copy files between nodes, use this value properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

- Restore the database into *nodeC*.

At this time, volume paths between a master and a slave should be the same.

```
[nodeC]$ cubrid restoredb -B $CUBRID_DATABASES/testdb/log testdb
```

#### 4. Copy *nodeA*'s active log to *nodeC*

In *nodeA*'s active log, there exists a number information of the archive log which is recently created. This information is needed for archive logs, which has been created after the time in which the active log had been copied, to be automatically copied by copylogdb process after the start of HA service of *nodeC*; therefore, the user just needs to manually copy archive logs which has been created before copying an active log.

- Start `cub_master`, which manages HA connections, on *nodeC*.

```
[nodeC]$ cub_master
```

- Start copylogdb process for *nodeA*.

```
[nodeC]$ cubrid heartbeat copylogdb start testdb nodeA
```

- Check if *nodeA*'s active log was copied.

To copy the current active log means to obtain the number information of the last archive log. Archive logs after this time are automatically copied after the process [5. Start HA server in *nodeC*].

```
[nodeC]$ cd $CUBRID_DATABASES/testdb_nodeA
[nodeC]$ ls
testdb_lgar_t  testdb_lgat  testdb_lgat__lock
```

- Stop copylogdb process for *nodeA* on *nodeC*.

```
[nodeC]$ cubrid heartbeat copylogdb stop testdb nodeA
```

- Stop cub\_master of *nodeC*.

```
[nodeC]$ cubrid service stop
```

#### 5. Copy required log files after restoring a database into *nodeC*

- Copy all replicated archive logs of *nodeB* into *nodeC*.

```
[nodeC]$ cd $CUBRID_DATABASES/testdb_nodeA
[nodeC]$ scp -l 131072 cubrid@nodeB:$CUBRID_DATABASES/
testdb_nodeA/testdb_lgar0* .
```

In this process, please note that all replicated archive logs which are required for replication should exist.

#### Note

scp command's -l option is an option to control the amount of copying file; when you copy files between nodes, use this properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

#### Note

Copy files of which the names end with a number. Here, we copied with "testdb\_lgar0\*" because numbers of the names of all replication log files are started with 0.

#### Note

Replication logs which are created between backup time and active log creation time can be deleted if the value of **ha\_copy\_log\_max\_archives** is not large enough; in this case, an error can occur when running the below process, [5. Start HA service on *nodeC*].

When an error occurs, take actions by referring to [Preparation plan when the required replication logs are already deleted](#) described on the above.

## 6. Start HA service on *nodeC*

```
[nodeC]$ cubrid heartbeat start
```

## 7. Change HA configuration of *nodeA* and *nodeB*

- Turn back `ha_copy_log_max_archive` of *nodeB*.

```
[nodeB]$ vi cubrid_ha.conf
ha_copy_log_max_archives=1
```

- Apply the changed value of `ha_copy_log_max_archives` to the `applylogdb` process of *nodeB*.

```
[nodeB]$ cubrid heartbeat applylogdb stop testdb nodeA
[nodeB]$ cubrid heartbeat applylogdb start testdb nodeA
```

- In `cubrid_ha.conf`, add *nodeC* into `ha_node_list`, and add one “sync” more to *nodeA* and *nodeB*.

```
$ cd $CUBRID/conf
$ vi cubrid_ha.conf

ha_replica_list=cubrid@nodeC
```

- Apply changed `ha_node_list`.

```
[nodeA]$ cubrid heartbeat reload
[nodeB]$ cubrid heartbeat reload
```

At this time, `copylogdb` and `applylogdb` processes for *nodeC* on *nodeA* and *nodeB* are needless to start because *nodeC* is a replica node.

## 8. Add a broker and add this broker's host name into `altHosts` of application URL

Add a broker if needed, and add this broker's host name into `altHosts`, the property of application URL to access this broker.

If you are not considering to add a broker, you do not need to do this job.

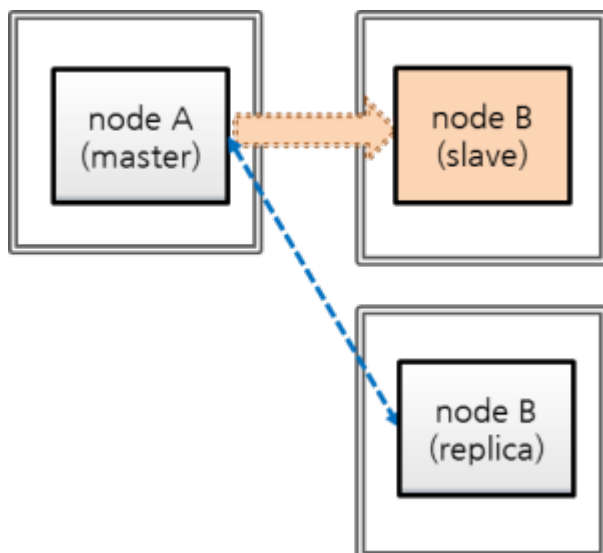

- From all of *nodeA* and *nodeB*, add *nodeC* into `db-host` of **\$CUBRID\_DATABASES/databases.txt**.

```
#db-name      vol-path      db-host      log-
path          lob-base-path
testdb        /home/cubrid/DB/testdb  nodeA:nodeB:nodeC  /home/
cubrid/DB/testdb/log  file:/home/cubrid/DB/testdb/lob
```

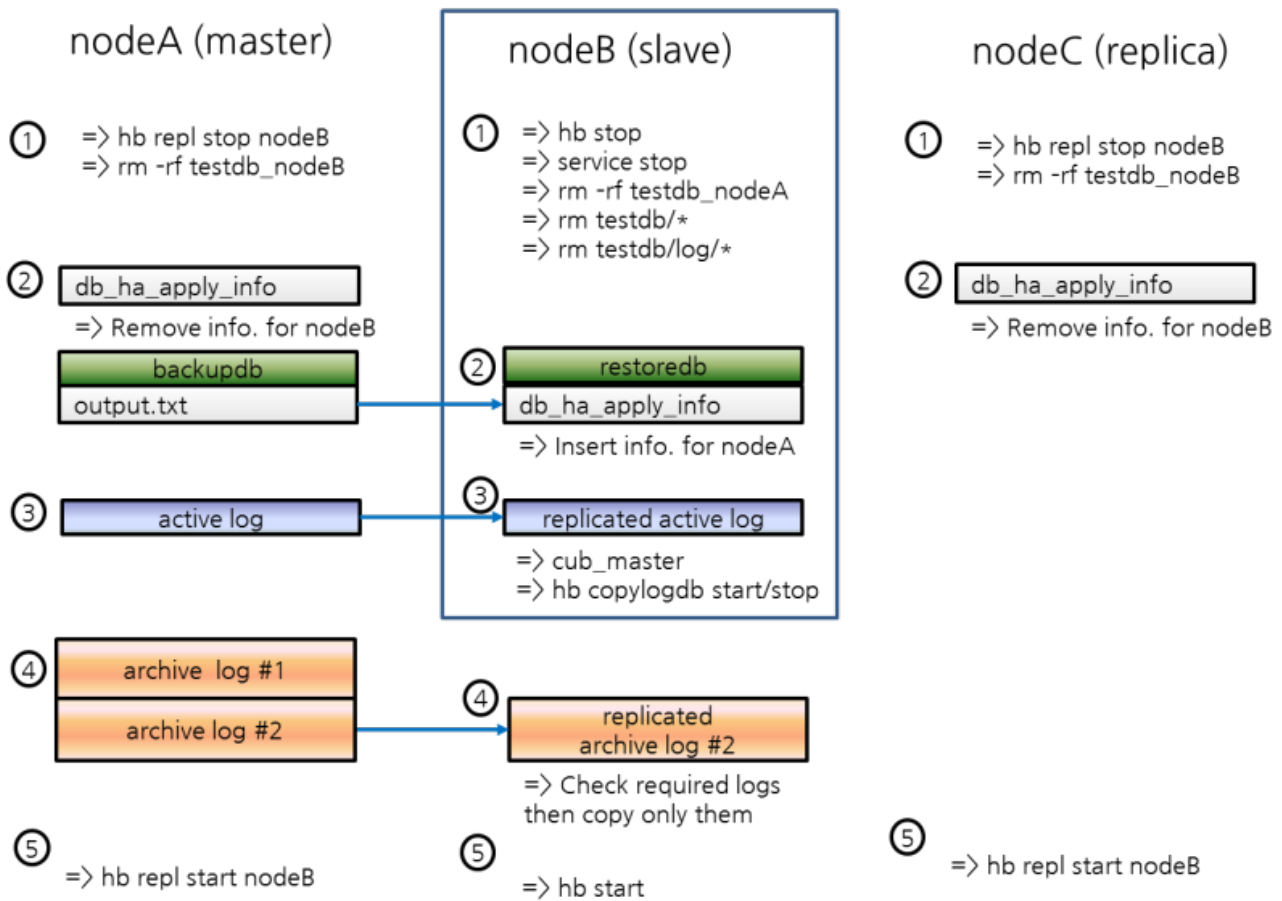

**db-host** of **databases.txt** is a configuration parameter related to the order of access from a broker to database servers; therefore, you can change as you want. For example, you can write only “nodeA:nodeB” or “localhost” into **db-host**. However, if you access database from a local machine (e.g. `csql -u dba testdb@localhost`), you should include “localhost” or the localhost name into **db-host**.

## Rebuild a Slave during Service

Now let's see the case of rebuilding a existing slave node during a service in a composition of “master:slave:relica = 1:1:1”. The beginning database setting is the same as the setting in [Build an initial database](#) of [Build Another Slave during HA Service](#).

- nodeA: a host name of a master node
- nodeB: a host name of a slave node to be rebuilt
- nodeC: a host name of a replica node

### 1. Stop *nodeB*'s service and remove this database

After stopping *nodeB*'s service, remove *nodeB*'s database volumes and *nodeB*'s replication logs located in *nodeA* and *nodeC*.

- Stop *nodeB*'s service.

```
[nodeB]$ cubrid heartbeat stop
[nodeB]$ cubrid service stop
```

- Remove *nodeB*'s database volumes and replication logs.

```
[nodeB]$ cd $CUBRID_DATABASES
[nodeB]$ rm testdb/*
[nodeB]$ rm testdb/log/*

[nodeB]$ rm -rf testdb_nodeA
[nodeB]$ rm $CUBRID/var/APPLYLOGDB/testdb
```

- Stop log replication processes of *nodeB* on *nodeA* and *nodeC*.

```
[nodeA]$ cubrid heartbeat repl stop nodeB
[nodeC]$ cubrid heartbeat repl stop nodeB
```

- Remove replication logs for *nodeB* from *nodeA* and *nodeC*.

```
[nodeA]$ rm -rf $CUBRID_DATABASES/testdb_nodeB
[nodeC]$ rm -rf $CUBRID_DATABASES/testdb_nodeB
```

## 2. Restore *nodeB*'s database from *nodeA*'s backup, and add data to HA catalog table.

- Delete `_db_ha_apply_info` data for *nodeB* from *nodeA* and *nodeC*.

```
[nodeA]$ csql --sysadm -u dba testdb@localhost
csql> DELETE FROM _db_ha_apply_info WHERE
copied_log_path='/home/cubrid/DB/databases/testdb_nodeB';

[nodeC]$ csql --sysadm --write-on-standby -u dba
testdb@localhost
csql> DELETE FROM _db_ha_apply_info WHERE
copied_log_path='/home/cubrid/DB/databases/testdb_nodeB';
```

- Backup a database from *nodeA*.

```
[nodeA]$ cd $CUBRID_DATABASES/testdb/log
[nodeA]$ cubrid backupdb --sleep-msecs=10 -C -o output.txt
testdb@localhost
```

### Note

Please refer to `--sleep-msecs` of [Build Another Slave during HA Service](#).

- Copy backup files to *nodeB*.

```
[nodeA]$
[nodeA]$ scp testdb_bk* cubrid_usr@nodeB:$CUBRID_DATABASES/
testdb/log
```

### Note

scp command's `-l` option is an option to control the amount of copying file; when you copy files between nodes, use this properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

- Restore the database into *nodeB*.

At this time, the volume path of the master node must be identical to that of the slave node.

```
[nodeB]$ cubrid restoredb -B $CUBRID_DATABASES/testdb/log testdb
```

- Add a replication information record for *nodeA* to *nodeB*'s `_db_ha_apply_info`.

Get an update information of **`_db_ha_apply_info`** from `output.txt` file, which has backup result messages in *nodeA*. `output.txt` is saved at the directory on which a user ran "cubrid backupdb" command.

```
[nodeA]$ vi $CUBRID_DATABASES/testdb/log/output.txt
[ Database(testdb) Full Backup start ]
- num-threads: 2
- compression method: NONE
- sleep 10 millisecond per 1M read.
- backup start time: Fri Mar 20 18:18:53 2015
- number of permanent volumes: 2
- HA apply info: testdb 1426495463 12922 16192
- backup progress status
...
```

Make the below script and run. At "HA apply info" on the above output, put the first number, 1426495463 into `$db_creation`, the second number, 12922 into `$pageid`, and the third number, 16192 into `$offset`; put `testdb` into `db_name`, the database name and *nodeA* into `master_host`, the master node's host name.

```
[nodeB]$ vi update.sh

#!/bin/sh
```

```

db_creation=1426495463
page_id=12922
offset=16192
db_name=testdb
master_host=nodeA

repl_log_home_abs=$CUBRID_DATABASES

repl_log_path=$repl_log_home_abs/${db_name}_${master_host}

local_db_creation=`awk 'BEGIN { print strftime("%m/%d/%Y %H:%M:
%S", '$db_creation') }'`
csql_cmd="\
INSERT INTO \
        _db_ha_apply_info \
VALUES \
( \
        '$db_name', \
        datetime '$local_db_creation', \
        '$repl_log_path', \
        $page_id, $offset, \
        $page_id, $offset, \
        $page_id, $offset, \
        $page_id, $offset, \
        $page_id, $offset, \
        $page_id, $offset, \
        NULL, \
        NULL, \
        NULL, \
        0, \
        0, \
        0, \
        0, \
        0, \
        0, \
        0, \
        0, \
        NULL \
)"

# Insert nodeA's HA info.
csql --sysadm -u dba -c "$csql_cmd" -S testdb

```

```
[nodeB]$ sh update.sh
```

Check if the data is successfully inserted.

```
[nodeB]$ csql -u dba -S testdb
```

```
csql> ;line on  
csql> SELECT * FROM _db_ha_apply_info;
```

### 3. Copy *nodeA*'s active log into *nodeB*

In *nodeA*'s active log, there exists a number information of the archive log which is recently created. This information is needed for archive logs, which has been created after the time in which the active log had been copied, to be automatically copied by copylogdb process after the start of HA service of *nodeC*; therefore, the user just needs to manually copy archive logs which has been created before copying an active log.

- Start cub\_master which manages HA connection in *nodeB*.

```
[nodeB]$ cub_master
```

- Start copylogdb process for *nodeA* on *nodeB*.

```
[nodeB]$ cubrid heartbeat copylogdb start testdb nodeA
```

- Check if an active log of *nodeA* is copied.

To copy the current active log means to obtain the number information of the last archive log. Archive logs after this time are automatically copied after the process [5. Start HA server in *nodeB*].

```
[nodeB]$ cd $CUBRID_DATABASES/testdb_nodeA  
[nodeB]$ ls  
testdb_lgar_t  testdb_lgat  testdb_lgat__lock
```

- Stop copylogdb process for *nodeA* on *nodeB*.

```
[nodeB]$ cubrid heartbeat copylogdb stop testdb nodeA
```

- Stop *nodeB*'s cub\_master.

```
[nodeB]$ cubrid service stop
```

### 4. Copy required log files after restoring a database into *nodeB*

- Copy all archive logs of *nodeA* into *nodeB*.

```
[nodeB]$ cd $CUBRID_DATABASES/testdb_nodeA
[nodeB]$ scp -l 131072 cubrid@nodeA:$CUBRID_DATABASES/testdb/log/
testdb_lgar0* .
```

In this process, please note that all replicated archive logs which are required for replication should exist.

#### Note

scp command's -l option is an option to control the amount of copying file; when you copy files between nodes, use this properly as considering I/O overhead. The unit is Kbits. 131072 is 16MB.

#### Note

Copy files of which the names end with a number. Here, we copied with "testdb\_lgar0\*" because numbers of names of all replication log files are started with 0.

#### Note

##### **When required logs are already deleted**

Archive logs which are created between backup time and active log creation time can be deleted if the value of **log\_max\_archives** is not large enough; in this case, an error can occur when running the below process, [5. Start HA service on *nodeB* ...].

When an error occurs, enlarge the value of **log\_max\_archives** enough and proceed again backup-and-restore from the beginning.

5. Start HA service on *nodeB*; restart copylogdb and applylogdb processes on *nodeA* and *nodeC*

```
[nodeB]$ cubrid heartbeat start
```

```
[nodeA]$ cubrid heartbeat applylogdb start testdb nodeB
[nodeA]$ cubrid heartbeat copylogdb start testdb nodeB
```

```
[nodeC]$ cubrid heartbeat applylogdb start testdb nodeB
[nodeC]$ cubrid heartbeat copylogdb start testdb nodeB
```

## Detection of Replication Mismatch

### How to Detect Replication Mismatch

Replication mismatch between replication nodes, indicating that data of the master node and the slave node (or the replica node) is not identical, can be detected to some degree by the following process. You can also use `checksumdb` utility to detect a replication inconsistency. However, please note that there is no more accurate way to detect a replication mismatch than by directly comparing the data of the master node to the data of the slave node (or the replica node). If it is determined that there has been a replication mismatch, you should rebuild the database of the master node to the slave node (or the replica node) (see [Rebuilding Replication Script](#).)

- Execute **cubrid statdump** command and check **Time\_ha\_replication\_delay**. When this value is bigger, replication latency can be larger; the bigger latency time shows the possibility of the larger replication mismatch.
- On the slave node (or the replica node), execute **cubrid applyinfo** to check the “Fail count” value. If the “Fail count” is 0, it can be determined that no transaction has failed in replication (see [applyinfo](#).)

```
[nodeB]$ cubrid applyinfo -L /home/cubrid/DB/testdb_nodeA -r nodeA -
a testdb

*** Applied Info. ***
Committed page           : 1913 | 2904
Insert count              : 645
Update count              : 0
Delete count              : 0
Schema count              : 60
Commit count              : 15
Fail count                : 0
...
```

- To check whether copying replication logs has been delayed or not on the slave node (or the replica node), execute **cubrid applyinfo** and compare the “Append LSA” value of “Copied Active Info.” to the “Append LSA” value of “Active Info.”. If there is a big difference between the two values, it means that delay has occurred while copying the replication logs to the slave node (or the replica node) (see [applyinfo](#).)

```
[nodeB]$ cubrid applyinfo -L /home/cubrid/DB/testdb_nodeA -r nodeA -
a testdb
```

...

\*\*\* Copied Active Info. \*\*\*

```
DB name                : testdb
DB creation time       : 11:28:00.000 AM 12/17/2010
(1292552880)
Vol creation time      : 11:28:10.000 AM 12/17/2010
(1292552890)
EOF LSA                : 1913 | 2976
Append LSA             : 1913 | 2976
HA server state        : active
```

\*\*\* Active Info. \*\*\*

```
DB name                : testdb
DB creation time       : 11:28:00.000 AM 12/17/2010
(1292552880)
Vol creation time      : 11:28:10.000 AM 12/17/2010
(1292552890)
EOF LSA                : 1913 | 2976
Append LSA             : 1913 | 2976
HA server state        : active
```

- If a delay seems to occur when copying the replication logs, check whether the network line speed is slow, whether there is sufficient free disk space, disk I/O is normal, etc.
- To check the delay in applying the replication log in the slave node (or the replica node), execute **cuprid applyinfo** and compare the “Committed page” value of “Applied Info.” to the “EOF LSA” value of “Copied Active Info.”. If there is a big difference between the two values, it means that a delay has occurred while applying the replication logs to the slave database (or the replica database) (see [applyinfo](#).)

```
[nodeB]$ cuprid applyinfo -L /home/cuprid/DB/testdb_nodeA -r nodeA -
a testdb
```

\*\*\* Applied Info. \*\*\*

```
Committed page         : 1913 | 2904
Insert count           : 645
Update count           : 0
Delete count           : 0
Schema count           : 60
Commit count           : 15
Fail count             : 0
```

\*\*\* Copied Active Info. \*\*\*

```
DB name                : testdb
DB creation time       : 11:28:00.000 AM 12/17/2010
(1292552880)
Vol creation time      : 11:28:10.000 AM 12/17/2010
```

```
(1292552890)
EOF LSA                : 1913 | 2976
Append LSA             : 1913 | 2976
HA server state        : active
...
```

- If the delay in applying the replication logs is too long, it may be due to a transaction with a long execution time. If the transaction is performed normally, a delay in applying the replication logs may normally occur. To determine whether it is normal or abnormal, continuously execute **cubrid applyinfo** and check whether applylogdb continuously applies replication logs to the slave node (or the replica node) or not.
- Check the error log message created by the copylogdb process and the applylogdb process (see the error message).
- Compare the number of records on the master database table to that on the slave (or the replica) database table.

## checksumdb

**checksumdb** provides a simple way to check replication integrity. Basically, it divides each table from a master node into fixed-size chunks and then calculates CRC32 values. The calculation itself, not the calculated value, is then replicated through CUBRID HA. Consequently, by comparing CRC32 values calculated on master and slave nodes (or replica nodes), **checksumdb** can report the replication integrity. Note that **checksumdb** might affect master's performance even though it is designed to minimize the performance degradation.

```
cubrid checksumdb [options] <database-name>@<hostname>
```

- *<hostname>* : When you initiate checksum calculation, you need to specify the hostname of a master node. When you need to get the result after the calculation is completed, specify the hostname of a node you want to check.

### **-c, --chunk-size=NUMBER**

You can specify the number of rows to select for each CRC32 calculation. (default: 500 rows, minimum: 100 rows)

### **-s, --sleep=NUMBER**

checksumdb sleeps the specified amount of time after calculating each chunk (default: 100 ms)

### **-i, --include-class-file=FILE**

You can specify tables to check the replication mismatch by specifying the `-i FILE` option. If it is not specified, entire tables will be checked. Empty string, tab, carriage return and comma are separators among table names in the file.

#### **-e, --exclude-class-file=FILE**

You can specify tables to exclude from checking the replication mismatch by specifying the `-e FILE` option. Note that either `-i` or `-e` can be used, not both.

#### **-t, --timeout=NUMBER**

You can specify a calculation timeout with this option. (default: 1000 ms) If the timeout is reached, the calculation will be cancelled and will be resumed after a short period of time.

#### **-n, --table-name=STRING**

You can specify a table name to save checksum results. The table name must include the owner's name which can only be dba. (default: dba.db\_ha\_checksum)

#### **-r, --report-only**

After checksum calculation is completed, you can get a report with this option.

#### **--resume**

When checksum calculation is aborted, you can resume the calculation using this option.

#### **--schema-only**

When this option is given, checksumdb does not calculate CRC32 but only check schema of each table

#### **--cont-on-error**

Without this option, checksumdb halts on errors.

The following example shows how to start checksumdb

```
cubrid checksumdb -c 100 -s 10 testdb@master
```

When no replication mismatch found,

```
$ cubrid checksumdb -r testdb@slave
=====
target DB: testdb@slave (state: standby)
report time: 2016-01-14 16:33:30
checksum table name: db_ha_checksum, db_ha_checksum_schema
=====

-----
different table schema
-----
NONE
```

```

-----

## HA Error Messages

The following are error messages about the errors which can be reasons for the replication mismatch.

## CAS process(cub\_cas)

Error messages in CAS process are written to **\$CUBRID/log/broker/error\_log/<broker\_name>\_<app\_server\_num>.err**. The following table shows connection error messages in the HA environment.

### Error messages for handshaking between a broker and a DB server

| Error Code | Error message                                                                       | Severity | Description                                                                                                                      | Solution |
|------------|-------------------------------------------------------------------------------------|----------|----------------------------------------------------------------------------------------------------------------------------------|----------|
| -1139      | Handshake error (peer host ?): incompatible read/write mode. (client: ?, server: ?) | error    | ACCESS_MODE of broker and the status of server (active/standby) is not the same (see <b>Broker Mode</b> ).                       |          |
| -1140      | Handshake error (peer host ?): HA replication delayed.                              | error    | Replication is delayed in the server which set <b>ha_delay_limit</b> .                                                           |          |
| -1141      | Handshake error (peer host ?): replica-only client to non-replica server.           | error    | A broker(CAS) which can access only a replica attempts to connect to the server which is not a replica(see <b>Broker Mode</b> ). |          |
| -1142      | Handshake error (peer host ?): remote access to                                     | error    | It attempts to connect to a server with HA maintenance                                                                           |          |

| Error Code | Error message       | Severity | Description                         | Solution |
|------------|---------------------|----------|-------------------------------------|----------|
|            | server not allowed. |          | mode(see <a href="#">Servers</a> ). |          |

|       |                                                             |       |                                 |  |
|-------|-------------------------------------------------------------|-------|---------------------------------|--|
| -1143 | Handshake error (peer host ?): unidentified server version. | error | Server version is unidentified. |  |
|-------|-------------------------------------------------------------|-------|---------------------------------|--|

### Connection Error Messages

| Error Code | Error message | Severity | Description | Solution |
|------------|---------------|----------|-------------|----------|
|------------|---------------|----------|-------------|----------|

|      |                                                    |       |                               |  |
|------|----------------------------------------------------|-------|-------------------------------|--|
| -353 | Cannot make connection to master server on host ?. | error | cub_master process went down. |  |
|------|----------------------------------------------------|-------|-------------------------------|--|

|       |                                                              |       |                        |  |
|-------|--------------------------------------------------------------|-------|------------------------|--|
| -1144 | Timed out attempting to connect to ?.<br>(timeout: ? sec(s)) | error | The machine went down. |  |
|-------|--------------------------------------------------------------|-------|------------------------|--|

### Replication Log Copy Process(copylogdb)

The error messages from the replication log copy process are stored in **\$CUBRID/log/<db-name>@<remote-node-name>\_copylogdb.err**. The severity levels of error messages found in the replication log copy process are as follows: fatal, error, and notification. The default level is error. Therefore, to record notification error messages, it is necessary to change the value of **error\_log\_level** in the **cubrid.conf** file. For details, see [Error Message-Related Parameters](#).

### Initialization Error Messages

The error messages that can be found in initialization stage of replication log copy process are as follows:

| Error Code | Error Message                                                                                 | Severity | Description                                                                                                                         | Solution                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -10        | Cannot mount the disk volume ?.                                                               | error    | Fails to open a replication log file.                                                                                               | Check if replication logs exist. For the location of replication logs, see <a href="#">Default Environment Configuration</a> .                                 |
| -78        | Internal error: an I/O error occurred while reading logical log page ? (physical page ?) of ? | fatal    | Fails to read a replication log.                                                                                                    | Check the replication log by using the cubrid applyinfo utility.                                                                                               |
| -81        | Internal error: logical log page ? may be corrupted.                                          | fatal    | A replication log page error, in which the replication log copy process has been copied from the connected database server process. | Check the error log of the database server process to which the replication log copy process is connected. This error log can be found in \$CUBRID/log/server. |
| -1039      | log writer: log writer has been started. mode: ?                                              | error    | The replication log copy process has been successfully                                                                              | No action is required because this error message is recorded to display the start                                                                              |

| Error Code | Error Message | Severity | Description              | Solution                                                                                                                                                                                                                                                                   |
|------------|---------------|----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |               |          | initialized and started. | information of the replication log copy process. Ignore any error messages which are displayed between the start of replication log copy process and output of this error message since there is a possibility that an error message is shown up even in normal situation. |

### Replication Log Request and Reception Error Messages

The replication log copy process requests a replication log from the connected database server and receives the corresponding replication log. Error messages that can be found in this stage are as follows:

| Error Code | Error Message                                | Severity | Description                                                               | Solution                                                                                                 |
|------------|----------------------------------------------|----------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| -89        | Log ? is not included in the given database. | error    | The previously replicated log and the log to be replication do not match. | Check information of the database server/host to which the replication log copy process is connected. If |

| Error Code | Error Message                       | Severity | Description                                                                                                              | Solution                                                                                                                               |
|------------|-------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|            |                                     |          |                                                                                                                          | you need to change the database server/host information, reinitialize it by deleting the existing replication log and then restarting. |
| -186       | Data receiver error from the server | error    | Incorrect information has been received from the database server to which the replication log copy process is connected. | It will be internally recovered.                                                                                                       |
| -199       | The server is not responding.       | error    | The connection to the database server has been terminated.                                                               | It will be internally recovered.                                                                                                       |

### Replication Log Write Error Messages

The replication log copy process copies the replication log that was received from the connected database server process to the location (**ha\_copy\_log\_base**) specified in the **cubrid\_ha.conf** file. Error messages that can be found in this stage are as follows:

| Error Code | Error Message                                                                                                                                                     | Severity | Description                                                             | Solution                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-------------------------------------------------------------------------|----------------------------------------------------------------|
| -10        | Cannot mount the disk volume ?.                                                                                                                                   | error    | Fails to open a replication log file.                                   | Check if replication logs exist.                               |
| -79        | Internal error: an I/O error occurred while writing logical log page ? (physical page ?) of ?.                                                                    | fatal    | Fails to write a replication log.                                       | It will be internally recovered.                               |
| -80        | An error occurred due to insufficient space in operating system device while writing logical log page ?(physical page ?) of ?. Up to ? bytes in size are allowed. | fatal    | Fails to write a replication log due to insufficient file system space. | Check if there is sufficient space left in the disk partition. |

### Replication Log Archive Error Messages

The replication log copy process periodically archives the replication logs that have been received from the connected database server process. Error messages that can be found in this stage are as follows:

| Error Code | Error Message                               | Severity | Description                     | Solution                               |
|------------|---------------------------------------------|----------|---------------------------------|----------------------------------------|
| -78        | Internal error: an I/O error occurred while | fatal    | Fails to read a replication log | Check the replication log by using the |

| Error Code | Error Message                                                                                  | Severity     | Description                                             | Solution                                                                                                   |
|------------|------------------------------------------------------------------------------------------------|--------------|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
|            | reading logical log page ? (physical page ?) of ?.                                             |              | during archiving.                                       | cubrid applyinfo utility.                                                                                  |
| -79        | Internal error: an I/O error occurred while writing logical log page ? (physical page ?) of ?. | fatal        | Fails to write an archive log.                          | It will be internally recovered.                                                                           |
| -81        | Internal error: logical log page ? may be corrupted.                                           | fatal        | Found an error on the replication log during archiving. | Check the replication log by using the cubrid applyinfo utility.                                           |
| -98        | Cannot create an archive log ? to archive pages from ? to ?.                                   | fatal        | Fails to create an archive log file.                    | Check if there is sufficient space left in the disk partition.                                             |
| -974       | An archive log ? to archive pages from ? to ? has been created.                                | notification | Information on an archive log file                      | No action is required because this error message is recorded to keep information on newly created archive. |

### Stop and Restart Error Messages

Error messages that can be found in this stage are as follows:

| Error Code | Error Message                                   | Severity | Description                                                      | Solution                         |
|------------|-------------------------------------------------|----------|------------------------------------------------------------------|----------------------------------|
| -1037      | log writer: log writer is terminated by signal. | error    | The copylogdb process has been terminated by a specified signal. | It will be internally recovered. |

### Replication Log Reflection Process(applylogdb)

The error messages from the replication log reflection process are stored in **\$CUBRID/log/db-name@local-node-name\_applylogdb\_db-name\_remote-node-name.err**. The severity levels of error message found in the replication log reflection process are as follow: fatal, error, and notification. The default level is error. Therefore, to record notification error messages, it is necessary to change the value of **error\_log\_level** in the **cubrid.conf** file. For details, see [Error Message-Related Parameters](#).

### Initialization Error Messages

The error messages that can be found in initialization stage of replication log reflection process are as follows:

| Error Code | Error Message                                                                | Severity | Description                                                                          | Solution                                                                                    |
|------------|------------------------------------------------------------------------------|----------|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| -10        | Cannot mount the disk volume ?.                                              | error    | An applylogdb that is trying to reflect the same replication log is already running. | Check if there is an applylogdb process that is trying to reflect the same replication log. |
| -1038      | log applier: log applier has been started. required LSA: ? ?. last committed | error    | It will be started normally after initialization of                                  | No action is required because this error is recorded to display the                         |

| Error Code | Error Message                          | Severity | Description          | Solution                                                     |
|------------|----------------------------------------|----------|----------------------|--------------------------------------------------------------|
|            | LSA: ? ?. last committed repl LSA: ? ? |          | applylogdb succeeds. | start information of the replication log reflection process. |

### Log Analysis Error Messages

The replication log reflection process reads, analyzes, and reflects the replications logs that have been copied by the replication log copy process. The error message that can be found in this stage are as follows:

| Error Code | Error Message                                                                          | Severity | Description                                                                                                  | Solution                                                         |
|------------|----------------------------------------------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| -13        | An I/O error occurred while reading page ? in volume ?.                                | error    | Fails to read a log page to be reflected.                                                                    | Check the replication log by using the cubrid applyinfo utility. |
| -17        | Internal error: Trying to read page ? of the volume ? which has been already released. | fatal    | Trying to read a log page that does not exist in the replication log.                                        | Check the replication log by using the cubrid applyinfo utility. |
| -81        | Internal error: logical log page ? may be corrupted.                                   | fatal    | There is an inconsistency between an old log under replication reflection and the current log, or there is a | Check the replication log by using the cubrid applyinfo utility. |

| Error Code | Error Message                                                               | Severity | Description                                     | Solution                                                                                          |

| -1036      | log applier: log applier is terminated by signal. | error    | The replication log reflection process has been terminated by a specified signal. | It will be recovered internally. |

## Determine the Cause of Failover

### Fail-over, Fail-back messages

In an HA environment, messages for fail-over and fail-back are prefixed with [Failover], [Failback], respectively. These messages can be categorized into diagnosis messages, which are logged when fail-over or fail-back is determined, and result messages, which are logged when fail-over or fail-back is either canceled or successfully completed.

Diagnosis messages indicate the reason why the fail-over or fail-back was initiated and are prefixed with [Diagnosis]. Result messages include the prefix [Cancelled] along with the reason if fail-over or fail-back is canceled, and the prefix [Success] along with the result if fail-over or fail-back is successfully completed.

Fail-over and fail-back messages enable to determine the cause of fail-over. Below is a list of situations in which fail-over occurs and the corresponding fail-over and fail-back messages that may be logged. Fail-over messages are logged on the slave node, while fail-back messages are logged on the master node.

## Isolation of master node

### Isolation of master node

When the master node determines that it is isolated from the network due to failing to receive heartbeat messages from all slave nodes, the fail-back of the master node and the fail-over of the slave nodes are decided. The **ha\_ping\_hosts** are used to verify whether the network of the master node is truly partitioned. Fail-back is successfully completed only if the master node's network partition is confirmed through this verification.

Similarly, for slave nodes, fail-over is successfully completed only when a ping check using **ha\_ping\_hosts** confirms that there is no current network partition. Below is a list of fail-over and fail-back messages that could be logged when the master node is isolated.

| Diagnosis Messages                                                                                                                                             | Description                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Failback] [Diagnosis] The master node has failed to receive heartbeat messages from all other slave nodes, resulting in a network partition.                  | Fail-over has been initiated since master node failed to received heartbeat messages from every slave nodes                                                                    |
| [Failover] [Diagnosis] The current node has failed to receive heartbeat messages from the master node (master_node_name).                                      | Fail-back has been initiated since slave node failed to received heartbeat messages from master node                                                                           |
| Result Messages                                                                                                                                                | Description                                                                                                                                                                    |
| [Failback] [Cancelled] Ping check succeeded for the hosts registered in ha_ping_hosts, determining that it is not a network partition.                         | Fail-back has been cancelled since master node succeeded ping check to ha_ping_hosts                                                                                           |
| [Failback] [Cancelled] No hosts are registered in ha_ping_hosts, or all registered hosts are invalid, making it impossible to determine the network partition. | Fail-back has been cancelled due to the inability to determine the network partition of the master node, as the hosts registered in ha_ping_hosts are either empty or invalid. |
| [Failback] [Success] Current node has been successfully demoted to slave.                                                                                      | Fail-back is successfully completed, and the master node has been demoted to a slave node                                                                                      |
| [Failover] [Cancelled] Ping check has been failed to all hosts registered in ha_ping_hosts, indicating a network partition.                                    | Fail-over has been cancelled because the slave node determined a network partition due to a failed ping check and is unable to assume the master role.                         |
| [Failover] [Success] Current node has been successfully promoted to master.                                                                                    | Fail-over is successfully completed, and the slave node has been promoted to a master node                                                                                     |

## Loss of the master node's role

### Loss of the master node's role

When the master node loses its role due to reasons such as the failure to restart `cub_server` or disk errors, a fail-back of the master node and a fail-over of the slave node are initiated. If a disk failure has been detected, an error message like "Disk failure has occurred: prev\_eof\_lsa(4096, 128), eof\_lsa(4096, 128)" is logged in the server error log.

For the slave node, fail-over is successfully completed only when a ping check using **ha\_ping\_hosts** confirms that there is no current network partition. Below is a list of fail-over and fail-back messages that could be logged when the master node loses its role.

| Diagnosis Messages                                                                                                               | Description                                                                                                                                |
|----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| [Failback] [Diagnosis] The master node failed to restart the server process.                                                     | Fail-back has been initiated since the master node failed to restart a <code>cub_server</code> process that has been terminated abnormally |
| [Failback] [Diagnosis] The master node has lost its role due to server process problem, such as disk failure.                    | Fail-back has been initiated since the master node lost its role due to a disk failure or similar reasons.                                 |
| [Failover] [Diagnosis] The master node (master_node_name) has lost its role due to server process problem, such as disk failure. | Fail-over has been initiated as the slave node determined that the master node has lost its role due to a disk failure or similar reasons. |

| Result Messages                                                           | Description                                                                               |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| [Failback] [Success] Current node has been successfully demoted to slave. | Fail-back is successfully completed, and the master node has been demoted to a slave node |

| Result Messages                                                                                                             | Description                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Failover] [Cancelled] Ping check has been failed to all hosts registered in ha_ping_hosts, indicating a network partition. | Fail-over has been cancelled because the slave node determined a network partition due to a failed ping check and is unable to assume the master role. |
| [Failover] [Success] Current node has been successfully promoted to master.                                                 | Fail-over is successfully completed, and the slave node has been promoted to a master node                                                             |

## Multiple master node (split-brain)

### Multiple master node (split-brain)

When there is an abnormal situation where two or more servers assume the master role in an HA environment, it is referred to as a “split-brain” scenario. In such cases, all master nodes, except for the one designated to perform the master role, will fail-back to slave nodes to resolve the split-brain situation. Below is a list of fail-back messages that may be logged during a split-brain scenario.

| Diagnosis Messages                                                                                | Description                                                                                                                             |
|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| [Failback] [Diagnosis] Multiple master nodes (master_node_name1, master_node_name2) are detected. | Fail-back of the master nodes has been initiated to resolve the split-brain situation caused by the detection of multiple master nodes. |

| Result Messages                                                           | Description                                                                               |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| [Failback] [Success] Current node has been successfully demoted to slave. | Fail-back is successfully completed, and the master node has been demoted to a slave node |

## Rebuilding Replication Script

Replication rebuilding is required in CUBRID HA when data in the CUBRID HA group is inconsistent because of multiple failures in multiple-slave node structure, or because of a generic error. Rebuilding replications in CUBRID HA is performed through a **ha\_make\_slavedb.sh** script. With the **cubrid applyinfo** utility, you can check the replication progress; however replication inconsistency is not detected. If you want to determine whether replication is inconsistent correctly, you must examine data of the master and slave nodes yourself.

When you rebuild only a slave because the slave is abnormal in the environment of master-slave composition, the process is as follows.

1. Backup the master database.
2. Restore the database from slave.
3. Save backup time into the slave's HA meta table (`_db_ha_apply_info`).
4. Start HA service from slave. (`cubrid hb start`)

For rebuilding replications, the following environment must be the same in master, slave and replica nodes.

- CUBRID version
- Environmental variable (`$CUBRID`, `$CUBRID_DATABASES`, `$LD_LIBRARY_PATH`, `$PATH`, `$CUBRID_TMP`, `$TMPDIR`)
- The paths of database volume, log, and replication
- Username and password of the Linux server
- HA-related parameters except for **ha\_mode**, **ha\_copy\_sync\_mode**, **ha\_ping\_hosts** and **ha\_tcp\_ping\_hosts**

You can rebuild replication by running **ha\_make\_slavedb.sh** script only in these cases.

- *from-master-to-slave*
- *from-slave-to-replica*
- *from-replica-to-replica*
- *from-replica-to-slave*

For the other cases, you should build manually. For the manual building scenarios, see [Building Replication](#).

If the case is not for rebuilding but for newly building, configure `cubrid.conf`, `cubrid_ha.conf`, and `databases.txt` files as the same with master's.

In the below description, first, we will look over the cases to use **ha\_make\_slavedb.sh** script, which is used to rebuilding replication.

As a reference, you cannot use **ha\_make\_slavedb.sh** script when you want to build multiple slave nodes.

## ha\_make\_slavedb.sh Script

To rebuild replications, use the **ha\_make\_slavedb.sh** script. This script is located in **\$CUBRID/share/scripts/ha**. Before rebuilding replications, the following items must be configured for the environment of the user. This script is supported since the version 2008 R2.2 Patch 9 and its configuration is different from 2008 R4.1 Patch 2 or earlier. This document describes it in CUBRID 2008 R4.1 Patch 2 or later.

- **target\_host** : The host name of the source node (master node in general) for rebuilding replication. It should be registered in **/etc/hosts**. A slave node can rebuild replication by using the master node or the replica node as the source. A replica node can rebuild replication by using the slave node or another replica node as the source.
- **repl\_log\_home** : Specifies the home directory of the replication log of the master node. It is usually the same as **\$CUBRID\_DATABASES**. You must enter an absolute path and should not use a symbolic link. You also cannot use a slash (/) after the path.

The following are optional items:

- **db\_name** : Specifies the name of the database to be replicated. If not specified, the first name that appears in **ha\_db\_list** in **\$CUBRID/conf/cubrid\_ha.conf** is used.
- **backup\_dest\_path** : Specifies the path in which the backup volume is created when executing **backupdb** in source node for rebuilding replication.
- **backup\_option** : Specifies necessary options when executing **backupdb** in the source node in which replication will be rebuilt.
- **restore\_option** : Specifies necessary options when executing **restoredb** in the target node in which replication will be rebuilt.
- **scp\_option** : Specifies the **scp** option which enables backup of source node in which replication is rebuilt to copy into the target node. The default option is **-l 131072**, which does not impose an overload on network (limits the transfer rate to 16 MB).
- **ssh\_port** : Specifies the **port** number of the ssh and scp used in the script. This option also applies to **expect** run from the script. The default port number is **22**.

Once the script has been configured, execute the **ha\_make\_slavedb.sh** script in the target node in which replication will be rebuilt. When the script is executed, rebuilding replication happens in a number of phases. To move to the next stage, the user must enter an appropriate value. The following are the descriptions of available values.

- **yes** : Keeps going.
- **no** : Does not move forward with any stages from now on.
- **skip**: Skips to the next stage. This input value is used to ignore a stage that has not necessarily been executed when retrying the script after it has failed.

#### Warning

- **ha\_make\_slavedb.sh** script executes the connection command into the remote node by **expect** and **ssh**; therefore, **expect** command should be installed('yum install expect' in root account) and **ssh** should be possible in remote connection.

#### Note

- Backup volumes are required for rebuilding replication

To replicate, you must copy the physical image of the database volume in the target node to the database of the node to be replicated. However, **cubrid unloaddb** backs up only logical images so replication using **cubrid unloaddb** and **cubrid loaddb** is unavailable. Because **cubrid backupdb** backs up physical images, replication is possible by using this utility. The **ha\_make\_slavedb.sh** script performs replication by using **cubrid backupdb**.

- Online-backup of a source node and restoration of a rebuilding node during rebuilding replication.

**ha\_make\_slavedb.sh** script executes online backup about a source node during DB operation, and restore to the being-rebuilt node. To apply added transactions after backup to the being-rebuilt node, **ha\_make\_slavedb.sh** script use the archive logs of “master” node by copying(in all cases, archive logs of “master” are used; all cases include how to build slave from master, how to build replica from slave and how to build replica from replica).

Therefore, so as not to remove archive logs which have been added to the source node during the execution of the online backup, there is a need to properly set **force\_remove\_log\_max\_archives** and **log\_max\_archives** in cubrid.conf from the master node. For details, see the below building examples.

### · Error while executing the rebuilding replication script

The rebuilding replication script is not automatically rolled back to its previous stage even when an error occurs during the execution. This is because the slave node cannot provide normal service before rebuilding replication script is executed. To return to the phase before rebuilding replication script is executed, you must back up the existing replication logs and **\_db\_ha\_apply\_info** information which is internal catalog of the master and slave nodes before building replication is executed.

## CUBRID Security

This chapter describes the CUBRID security features. CUBRID provides Packet Encryption, ACL(Access Control List), authorization, and TDE(Transparent Data Encryption) features to protect the user database.

### Packet Encryption

#### Requirements of secure communication

Without an encrypted connection between the client and the server, a hacker with access to the network can monitor all traffic and steal and exploit data exchanged between the client and the server. In this way, a third party (middle-man) steals and makes bad use of information, it is called a man in the middle (MITM) attack. This MITM attack can be prevented by adding a secure authentication procedure to the connection between the client and the server.

#### Packet encryption method

CUBRID uses SSL/TLS (Secure Socket Layer/Transport Layer Security) protocol to encrypt data transmitted between the client and the server. The CUBRID server uses OpenSSL for encryption, and the client can make an encrypted connection using JDBC or CCI Driver. The encryption protocols supported between the client and server are SSLv3, TLSv1, TLSv1.1, and TLSv1.2.

#### Note

##### **SSL/TLS**

SSL was first developed by Netscape as an encryption protocol that provides authentication and data encryption between a client and server working over a network. Netscape released

version 3.0, which improved security flaws in 1996; Since then, the SSL 3.0 version became the basis for TLS 1.0; and it was defined by the IETF in January 1999 as the [RFC2246](#) standard. The last update is [RFC5246](#). TLS is defined based on SSL 3.0, and it is almost similar to SSL 3.0.

SSL/TLS provides Server Authentication, Client Authentication, and Data Encryption functions. Authentication refers to a procedure to verify that the other party is correct, and encryption refers to preventing access to contents even if data is stolen.

## Server setup for packet encryption

### Setting encryption mode and non-encryption mode

CUBRID can set either an encryption mode or a non-encryption mode, and the default is non-encryption mode. To change to the encryption mode, you can set the encryption mode by changing the SSL parameter value in `cubrid_broker.conf`. If you change the SSL parameter value of `cubrid_broker.conf`, you must restart the broker. For detailed configuration method, refer to [Broker Configuration](#).

### Certificate and Private Key

In order to exchange an encrypted symmetric session key which will be used in a secure communication session, a public key and a private key are required in the server.

The public key used by the server is included in the certificate 'cas\_ssl\_cert.crt', and the private key is included in 'cas\_ssl\_cert.key'. The certificate and private key are located in the `$CUBRID/conf` directory.

This certificate, 'self-signed' certificate, was created with the OpenSSL command tool utility and can be replaced with another certificate issued by a public CA (Certificate Authorities, for example, IdenTrust or DigiCert) if desired. Or, the existing certificate/private key can be replaced by generating a new one using the OpenSSL command utility as shown below.

```
$ openssl genrsa -out my_cert.key
2048                                     # create 2048 bit
size RSA private key
$ openssl req -new -key my_cert.key -out
my_cert.csr                            # create CSR
(Certificate Signing Request)
$ openssl x509 -req -days 365 -in my_cert.csr -signkey my_cert.key -
out my_cert.crt # create a certificate valid for 1 year.
```

And replace `my_cert.key` and `my_cert.crt` with `$CUBRID/conf/cas_ssl_cert.key` and `$CUBRID/conf/cas_ssl_cert.crt` respectively.

## Supported driver

CUBRID provides various drivers. Currently, the drivers that support packet encryption feature are JDBC and CCI.

### Encrypted connection method

The client can make an encrypted connection with the server by using the `useSSL` property of `db-url` during driver connection setup. For more information on how to use it, refer to [Configuration Connection](#) of the JDBC driver or [cci\\_connect\\_with\\_url](#) of the CCI driver.

## ACL (Access Control List)

CUBRID supports the ACL function that can be accessed only for users or applications authorized in two layers: the broker layer and the database server layer. The ACL of the broker layer is mainly used to control the access of application programs such as WEB and WAS, and the ACL of the database server layer is mainly used to control the access of the brokers and csqIs.

For more details, see [Limiting Broker Access](#) and [Limiting Database Server Access](#).

## Authorization

CUBRID can create users(or groups) and provide a function to control the access of the other users(or groups) to tables created by a user.

If you want to allow other users(or groups) to access your tables, you could provide access privileges to the users(or groups) by **GRANT**. Also, to revoke access privileges of other users, you can use **REVOKE**. Access to the (virtual) table created by a PUBLIC user is allowed to all users.

For more details, see [User Management](#).

## TDE (Transparent Data Encryption)

### CUBRID TDE Concept

CUBRID supports **Transparent Data Encryption (henceforth, TDE)**. TDE means transparently encrypting data from the user's point of view. This allows users to encrypt data stored on disk with little to no application change.

CUBRID TDE provides encryption and decryption at the engine level to minimize performance degradation due to encryption. When a user creates an encrypted table, all relevant user data stored on disk (data at rest) is automatically encrypted. By providing TDE, CUBRID helps users to comply with security regulations and guidelines required in various sites.

## Table Encryption

In CUBRID, a **table** is the unit for TDE-encryption. To use the TDE feature, create a table using the **ENCRYPT** option as follows. For more information, see [Table Encryption \(TDE\)](#).

```
CREATE TABLE tde_tbl (att1 INT, att2 VARCHAR(20)) ENCRYPT=AES;
```

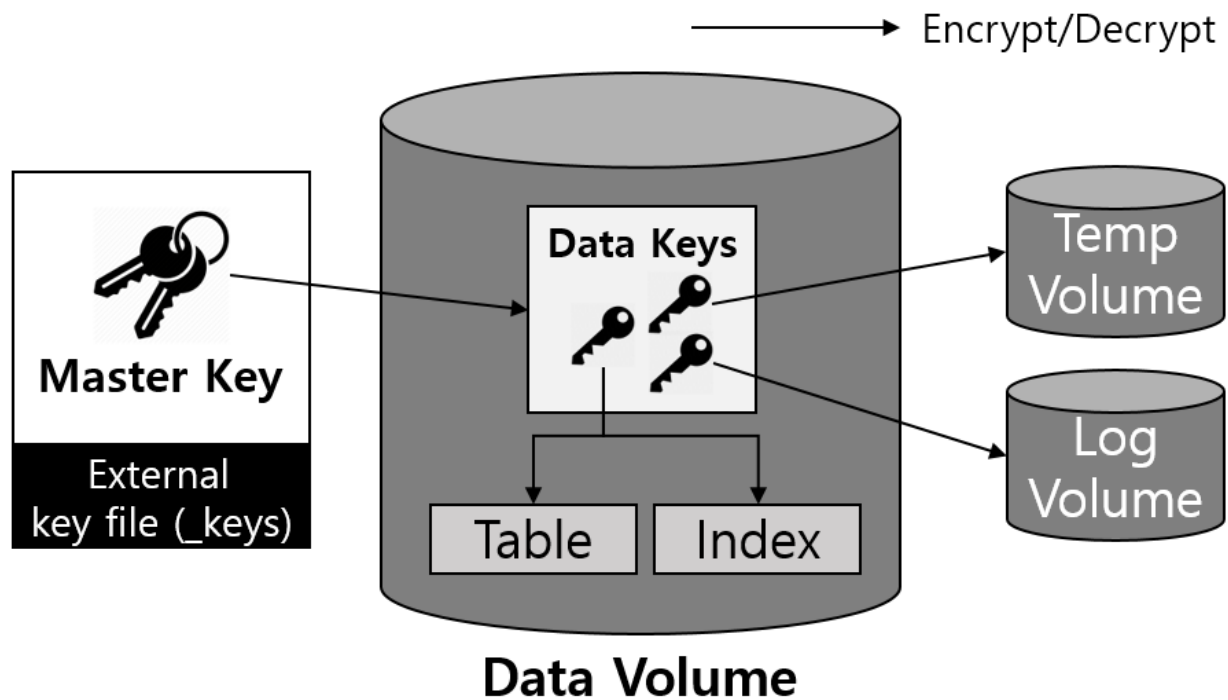

When an encrypted table is created, all data related to the table is automatically encrypted when written to disk; and decrypted when read into memory. Related data includes not only tables but also indexes created on the table, temporary data created while executing queries related to the table, logs created when data is changed, DWB, and backups. For more details, see [Encryption Target](#) and [TDE Restriction](#).

## Key Management

CUBRID uses symmetric key algorithms to encrypt the data. Keys used for encryption are managed in two levels consisting of master keys and data keys for efficiency. Master keys managed by the user are stored in a separate file, and CUBRID provides a utility to manage it.

### 2-Level Key Management

CUBRID TDE manages keys in two levels as follows:

- **Master key:** A key used when encrypting and decrypting data keys, and it is managed by DBA user.
- **Data Key:** A key used when encrypting user data such as table and log, and it is managed by CUBRID Engine.

Data keys are stored within the data volume and are always securely encrypted using a master key when written to disk. The master key is stored in a separate file, and it must be managed safely according to the security policy users comply with.

Managing keys in two levels makes it possible to perform the key change operation efficiently. If there is only a key that encrypts the user data, it takes a long time to work when you change the key. All the data that has been encrypted has to be read, decrypted, and re-encrypted. Also, the overall performance of the database may be degraded during this process.

#### Warning

##### **Loss of Master Key**

If the master key is lost, data encrypted by TDE cannot be read or changed.

## File-based Master Key Management

Master keys are separately stored and managed as a separate key file so that the user can manage master keys in various ways according to individual security requirements. This key file contains all the information of master keys, so if it is leaked, there may be a security problem, and if it is lost, the encrypted data cannot be read (When TDE is unavailable). So, be careful to manage this key file.

By default, the key file is created with the name of **<database-name>\_keys** at the location where the data volume is created when creating a database using **cubrid createdb** utility. Without additional configuration for the key file, this key file is automatically used. The location of the key file to be used can be changed by a system parameter. For more information, see [Disk-Related Parameters](#).

The key file can contain several master keys (up to 128). A master key among those keys is set on the database to encrypt the database, data keys technically. One master key is created and set by default when the key file is created, and DBA can add, delete, change, and search keys using the TDE utility (TDE utility). When deleting a key, the key to delete must exist in the key file, and the key set on the database currently cannot be removed. When changing a key to set to encrypt a database, both the previously key set on the database and the key to be set must exist in the key file. Through key inquiry, you can check the number of keys and creation time of them, and you can check the current key set on the database and setting time.

```
$ cubrid tde --show-keys testdb
Key File: /home/usr/CUBRID/databases/testdb/testdb_keys

The current key set on testdb:
Key Index: 2
Created on Fri Nov 27 11:14:54 2020
Set      on Fri Nov 27 11:15:30 2020

Keys Information:
Key Index: 0 created on Fri Nov 27 11:11:27 2020
Key Index: 1 created on Fri Nov 27 11:14:47 2020
Key Index: 2 created on Fri Nov 27 11:14:54 2020
Key Index: 3 created on Fri Nov 27 11:14:55 2020

The number of keys: 4
```

### Note

#### Creating a database using an existing key file

If you want to create a new database using a key file that was previously managed for reasons such as security policy, copy or move the key file to the directory where the database will be created before creating it. The name of the key file must be changed to

**<database\_name>\_keys**. If you're using the **tde\_keys\_file\_path** system parameter, you have to copy the key file to the path.

## Encryption Target

### Permanent Data Encryption

The encrypted table data and all index data created on the table are encrypted. For more information on the encrypted table, see [Table Encryption \(TDE\)](#).

### Temporary Data Encryption

In addition to persistent data such as tables, temporary data created during queries related to encrypted tables are also encrypted. For example, all temporary data created in executing a query such as *SELECT \* FROM tde\_tbl ORDER BY att1* or creating an index on *tde\_tbl* are encrypted when it is written to disk. For more information on temporary data, see [Temporary Volume](#).

### Log Data Encryption

Since the data which has to be encrypted may be included in the REDO and UNDO log records generated when the encrypted table is manipulated, all log data related to the encrypted table is encrypted. Encryption is applied to both the active log and the archive log. For more information on log volumes, see [Database Volume](#).

### DWB Encryption

Persistent data is temporarily written to the Double Write Buffer (DWB) before being written to the data volume. It may be encrypted even at this time because the data for the encrypted table can be included. For more information on DWB, see [Database Volume](#).

### Backup Encryption

If there are encrypted data in data volumes and log volumes, they are also stored as encrypted in backup volumes. For more information on backup, see [backupdb](#).

### Backup Key File

The backup volume contains the key file by default. If the backup volume, including the key file, is leaked, meaning the master key is also leaked. There may be a security problem even though the data in the volume is encrypted. To prevent this, you can backup the key file separately by using the **--separate-keys** option. However, in the case of separating the key file, it must be managed carefully to prevent losing the key file for database restore. The separated backup key file is created in the same directory path as the backup volume and has the name **<database\_name>\_bk<backup\_level>\_keys**.

```
$ cubrid backupdb -S --separate-keys testdb
Backup Volume Label: Level: 0, Unit: 0, Database testdb, Backup
Time: Mon Nov 30 14:34:49 2020
$ ls
lob testdb testdb_bk0_keys testdb_bk0v000 testdb_bkvinf
testdb_keys
testdb_lgar_t testdb_lgat testdb_lginf testdb_vinf
```

### The key file used to restore

The key file separated during backup can be given as the key file for restoration by using the **--keys-file-path** option (restoredb). If the valid key file does not exist in the specified path, restore fails.

If the **--keys-file-path** option is not given, the key file to be used is searched according to the following priority. If the valid key file cannot be found, restore fails.

#### Key file classification

- Server key file: A key file that is generally used when running the server. It can be set with the `tde_keys_file_path` system parameter or in the default path same as the data volume.
- Backup key file: A key file created during backup included in the backup volume or separated by **--separate-keys** option.

#### The priority of the key file to use for restore

1. The backup key file that the backup volume contains.
2. The backup key file created with the **--separate-keys** option during backup (e.g. `testdb_bk0_keys`). This key file must exist in the same path as the backup volume.
3. The server key file in the path specified by the **tde-keys-file-path** system parameter.
4. The server key file in the same path as the data volume (e.g., `testdb_keys`).

#### Note

In the case of (1), If the backup volume contains a backup key file, the backup key file is copied with the same name as the one created by **--separate-keys** during restore.

Even if the valid key file is not found, restore could be successful if there is no encrypted data in the backup volume. However, since the key file does not exist, you cannot use TDE functions later.

#### Note

##### **Incremental Backup**

When performing restoration using multiple level backup volumes by incremental backup, the backup key file of the level specified by the **--level** option is used. If the **--level** option is not specified, the highest level backup key file is used. If only the key file to be used exists, restore can succeed.

#### Note

##### **Loss of the backup key file**

If the backup key file is lost, the restore would fail. However, if the key is not changed, the backup key file of the previous volume can be used by using the **--keys-file-path** option. Also, if the key at the backup time exists in the server key, it can be used for backup recovery. Generally, restore can succeed if any key file that has the key intactly at the backup time is given.

#### Note

##### **The case in which the key is changed automatically after restore**

Suppose the key set on the database does not exist in the server key file at the end of the restoration process. In that case, the backup key file is copied to the server key file, and the first key in the key file is arbitrarily set on the database for encrypting the database. This is because the key set on the database may not exist in any key file after the restore is complete.

## Encryption Algorithm

CUBRID supports the following encryption algorithms for TDE.

### TDE Encryption Algorithm

| Algorithm                    | Key Size | Option Name |
|------------------------------|----------|-------------|
| Advanced Encryption Standard | 256 bits | AES         |
| ARIA                         | 256 bits | ARIA        |

Advanced Encryption Algorithm (AES) is a specification established by the National Institute of Standards and Technology (NIST) and is widely used worldwide. It has high stability and many optimizations are supported by many platforms such as hardware acceleration, so there is little performance degradation during encryption/decryption. ARIA is one of Korea's national standard encryption algorithms and is optimized for lightweight environments and hardware implementation.

#### Note

#### Default Encryption Algorithm for TDE

If the algorithm is not specified when creating the TDE encryption table, AES is used by default. If you want to change the default encryption algorithm, you can specify it by the system parameter **tde\_default\_algorithm**. This default encryption algorithm is used to encrypt logs or temporary data in addition to tables. For details on specifying the encryption algorithm when creating a table, see [Table Encryption \(TDE\)](#).

## Table Encryption Checking

You can check whether the table is encrypted by following three ways.

### SHOW CREATE TABLE

```
csql> show create table tde_tbl1;

=== <Result of SELECT Command in Line 1> ===
```

```

TABLE                                CREATE TABLE
=====
'tde_tbl1'                          'CREATE TABLE [tde_tbl1] ([a] INTEGER)
REUSE_OID, COLLATE iso88591_bin ENCRYPT=AES'

1 row selected. (0.144627 sec) Committed.

1 command(s) successfully processed.

```

## Inquiry to db\_class

Encryption of each table and encryption algorithm can be checked by the **tde\_algorithm** column of the system catalog **db\_class** or **\_db\_class**. For more information on the system catalog, see [System Catalog](#).

```

csql> select class_name, tde_algorithm from db_class where
class_name like '%tde%';

=== <Result of SELECT Command in Line 1> ===

  class_name          tde_algorithm
=====
'tde_tbl1'           'AES'
'tde_tbl2'           'ARIA'
'not_tde_tbl'        'NONE'

3 rows selected. (0.057243 sec) Committed.

1 command(s) successfully processed.

```

## Using cubrid diagdb utility

You can check by referring to **tde\_algorithm** among the file header information of encrypted tables and index files from the result by **cubrid diagdb** utility with the -d1 (dump file tables) option. For more details, see [diagdb](#).

```

$ cubrid diagdb -d1 testdb
...
Dumping file 0|3520
  file header:
    vfid = 0|3520
    permanent
    regular
    tde_algorithm: AES
    page: total = 64, user = 1, table = 1, free = 62

```

```
... sector: total = 1, partial = 1, full = 0, empty = 0
```

## TDE on HA

In a HA environment, TDE is applied independently to each node. This means that for each node, the key file and TDE-related system parameters can be managed independently.

However, the TDE information of the replicated table is shared and the same. So, if the TDE module of the slave node is not loaded, the replication will stop when attempting to manipulate an encrypted table from the master node. In this case, not only the changes to a TDE-encrypted table, but also any subsequent changes cannot be replicated. Afterward, if the slave node's TDE configuration is correct and restarted, replication resumes from the stopped point.

## When TDE is unavailable

In the following cases, the TDE feature cannot be used, and an error occurs because the TDE module cannot be loaded correctly.

- When the valid key file cannot be found
- When the key set on the database cannot be found in the key file

Even if the TDE module is not loaded, the server can start normally, and users can access unencrypted tables. This means that all DML and DDL such as SELECT and INSERT only for TDE-encrypted tables cannot be executed.

However, the case log data has been encrypted is different. If the log data is encrypted when the TDE module is not loaded and the log is accessed by recovery, HA, VACUUM, etc., the system cannot be properly executed, and the entire server has no option but to stop running the server.

## TDE Restriction

In addition to the restrictions described above, there are the following.

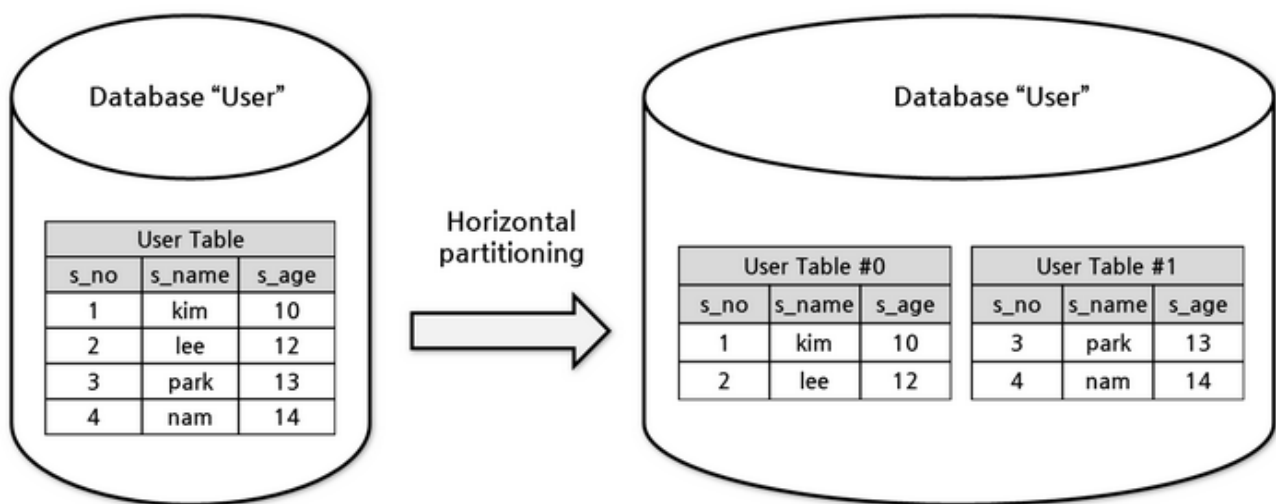

1. The replication log is not encrypted in HA.
2. CUBRID does not support the **ALTER TABLE** statement to change the TDE table option, which means you cannot set TDE to existing tables. If you want to do that, you need to move the data to the new table created with the TDE table option.
3. SQL log is not encrypted. For more information on the SQL log, see [Managing the SQL Log](#).

# CUBRID SHARD

## Database Sharding

### Horizontal partitioning

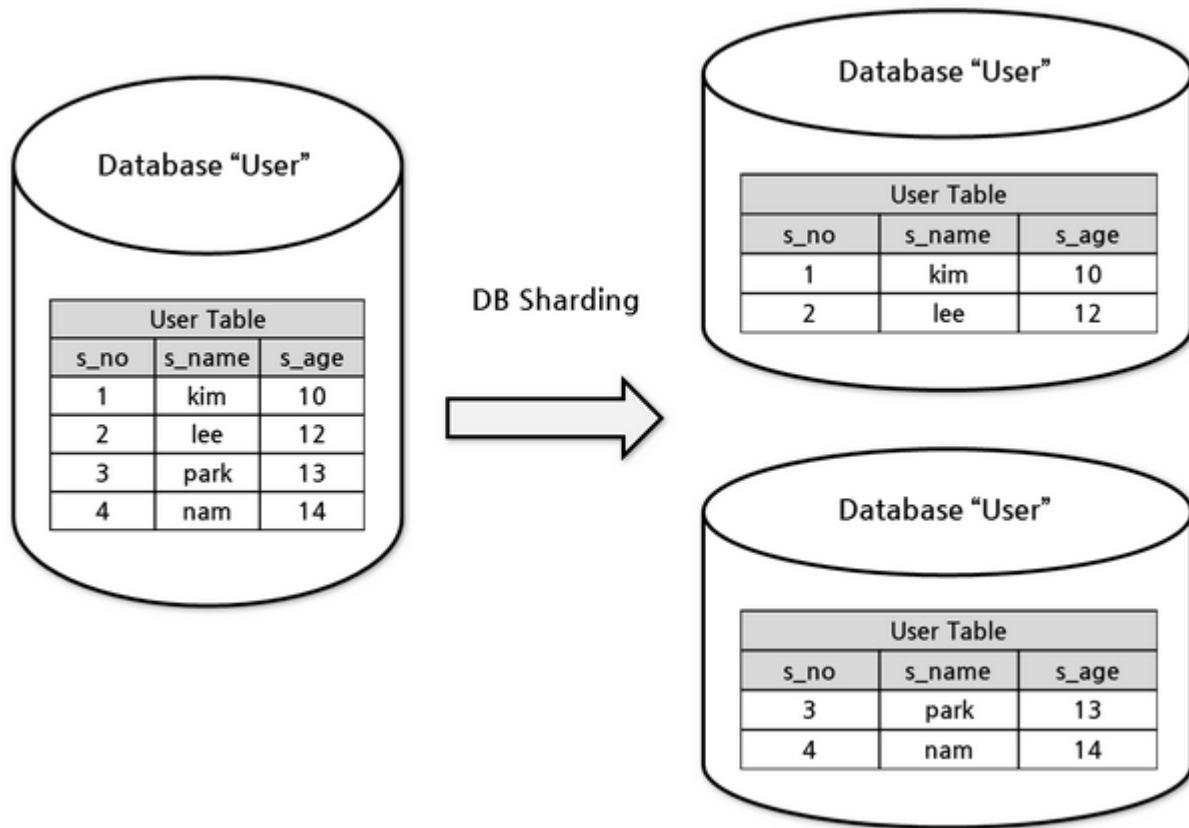

Horizontal partition is a design to partition the data for which schema is identical, based on the row, into multiple tables and store them. For example, 'User Table' with identical schema can be divided into 'User Table #0' in which users less than 13 years are stored and 'User Table #1' in which users 13 or greater than 13 years old.

### Database sharding

Database sharding is to store data into physically separate databases through horizontal partitioning and to retrieve them. For example, it is a method to store users less than 13 years old in database 0 and store users 13 or greater than 13 years old in database 1 when 'User Table' is located through multiple database. In addition to performance, database sharding is used to distribute and save large data which cannot be saved into one database instance.

Each partitioned database is called a shard or database shard.

## CUBRID SHARD

The CUBRID SHARD is middleware for database sharding and its characteristics are as follows:

- Middleware that is used to minimize changes in existing applications, allowing access to transparently sharded data by using Java Database Connectivity (JDBC), a popular choice, or CUBRID C Interface (CCI), which is CUBRID C API.
- In this function, a hint may be added to an existing query to indicate a shard in which the query would be executed.
- It guarantees the unique characteristics of certain transactions.

## CUBRID SHARD Terminologies

The terminologies used to describe CUBRID SHARD are as follows:

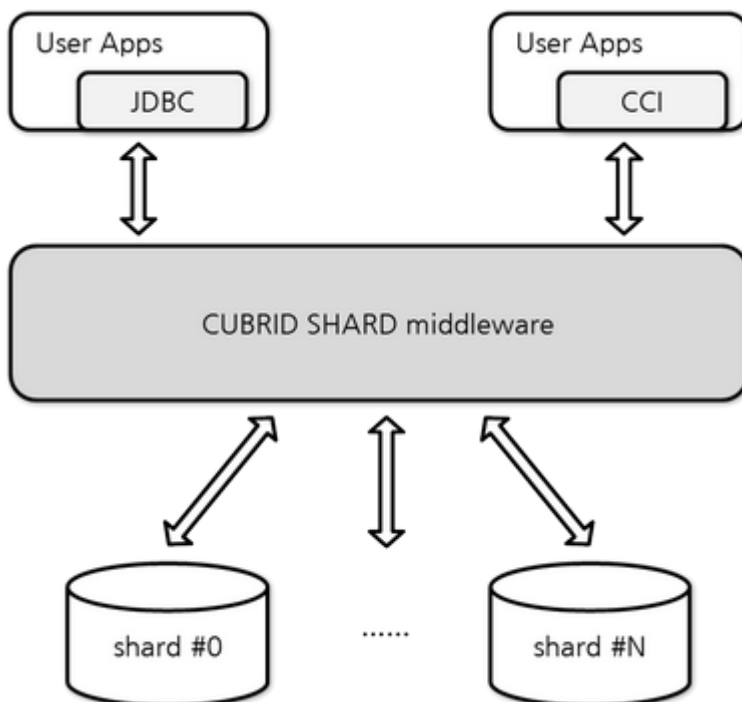

- **shard DB** : A database that includes a split table and data and processes user requests
- **shard metadata** : Configuration information for the operation of a CUBRID SHARD. It analyzes the requested query and includes information to select a shard DB which will execute a query and to create a database session with the shard DB.
- **shard key (column)** : A column used as an identifier to select a shard in the sharding table

- **shard key data** : A shard key value that corresponds to the hint to identify the shard from the query
- **shard ID** : An identifier to identify a shard DB
- **proxy** : A CUBRID middleware process that analyzes hints included in user queries and sends requests to a shard DB which will process the query, based on the analyzed hint and the shard metadata

## CUBRID SHARD Main Features

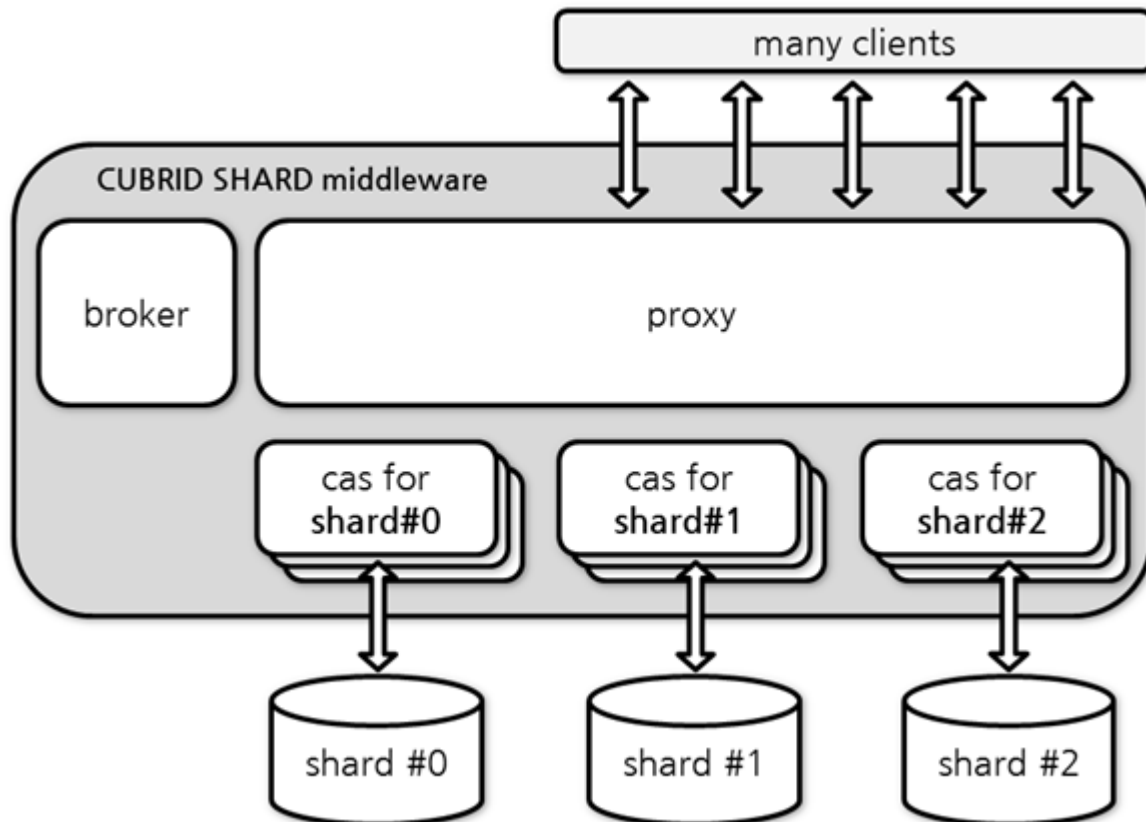

### Middleware Structure

The CUBRID SHARD is middleware, positioned between an application and logically, or physically, split shards. It keeps connection with multiple applications, sends requests from applications to the appropriate shard, and returns the results to the applications.

Generally, it uses Java Database Connectivity (JDBC) or CUBRID C Interface (CCI), an interface used to connect to the CUBRID SHARD, and processes the requests from applications. It does not require additional driver or framework, minimizing the changes in applications.

The CUBRID SHARD middleware consists of three processes (broker/proxy/CAS) and the brief features of each process are as follows:

#### • broker

- Receives the initial connection request from drivers such as JDBC/CCI and then sends the received request to the proxy based on the load balancing policy.
- Monitors and restores the status of the proxy process and the CAS process.

#### • proxy

- Sends the user request from the driver and then returns the processing result to the application.
- Manages the connection between the driver and the CAS and processes transactions.

#### • CAS

- Creates a connection with the split shard DB and processes the user request received from the proxy by using the connection.
- Processes transactions.

## Selecting a Shard DB through the Shard SQL Hint

### Shard SQL Hint

With the hints and configuration data included in a SQL hint statement, the CUBRID SHARD selects a shard DB that will process the requests from applications. The types of available SQL hints are as follows:

| SQL hint                                        | Description                                                                                                                        |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b><code>/*+ shard_key */</code></b>            | A hint to specify the position of the bind variable or literal value that corresponds to the shard key column.                     |
| <b><code>/*+ shard_val( value ) */</code></b>   | A hint to explicitly specify the shard key within the hint when there is no column that corresponds to the shard key in the query. |
| <b><code>/*+ shard_id( shard_id ) */</code></b> | A hint used when a user specifies a shard DB to process queries.                                                                   |

The terms are summarized as shown below: For more information on shard terms, see [CUBRID SHARD Terminologies](#).

- **shard key** : A column to distinguish shard DBs. In general, this column exists in all or most tables in a shard DB and has a unique value.
- **shard id** : An identifier that can be used to logically distinguish shards. For example, when one DB is split into four shard DBs, there are four shard IDs.

For more information on the query process using hints and configuration information, see [General Procedure of Executing Queries by Using Shard SQL Hint](#).

#### Note

- When more than one shard hint exist on a query, it works normally if shard hints indicate the same shards, but it fails if each of them indicates the different shard.

```
SELECT * FROM student WHERE shard_key = /*+ shard_key */ 250 OR  
shard_key = /*+ shard_key */ 22;
```

On the above case, it works normally if the shard keys 250 and 22 indicate the same shard, but it fails if they indicate the different shards.

- On some driver functions which batches the queries with an array by binding the several values(ex. PreparedStatement.executeBatch in JDBC, cci\_execute\_array in CCI), if at least the one which accesses to the other shard exists, all executions of the queries fail.
- Functions to run several statements at one time on shard environment(ex. Statement.executeBatch in JDBC, cci\_execute\_batch in CCI) will be supported later.

### shard\_key Hint

The **shard\_key** hint is to specify the position of a bind or literal variable. This hint should be positioned in front of either of them.

Ex) Specifies the position of a bind variable. Executes the query in the shard DB corresponding to the student\_no value that would be bound when executed.

```
SELECT name FROM student WHERE student_no = /** shard_key */ ?;
```

Ex) Specifies the position of a literal value. Executes the query in the shard DB corresponding to the student\_no value (the literal value) that is 123 when executed.

```
SELECT name FROM student WHERE student_no = /** shard_key */ 123;
```

### shard\_val Hint

The **shard\_val** hint is used when there is no shard column that can be used to identify the shard DB in the query. It sets the shard key column as the value of the **shard\_val** hint. The **shard\_val** hint can be positioned anywhere in an SQL statement.

Ex) When the shard key is not included in the student\_no or in the query, the query is performed in the shard DB in which the shard key (student\_no) is 123.

```
SELECT age FROM student WHERE name =? /** shard_val(123) */;
```

### shard\_id Hint

Regardless of the shard key column value, the **shard\_id** hint can be used when the user specifies a shard for query execution. The **shard\_id** hint can be positioned anywhere in an SQL statement.

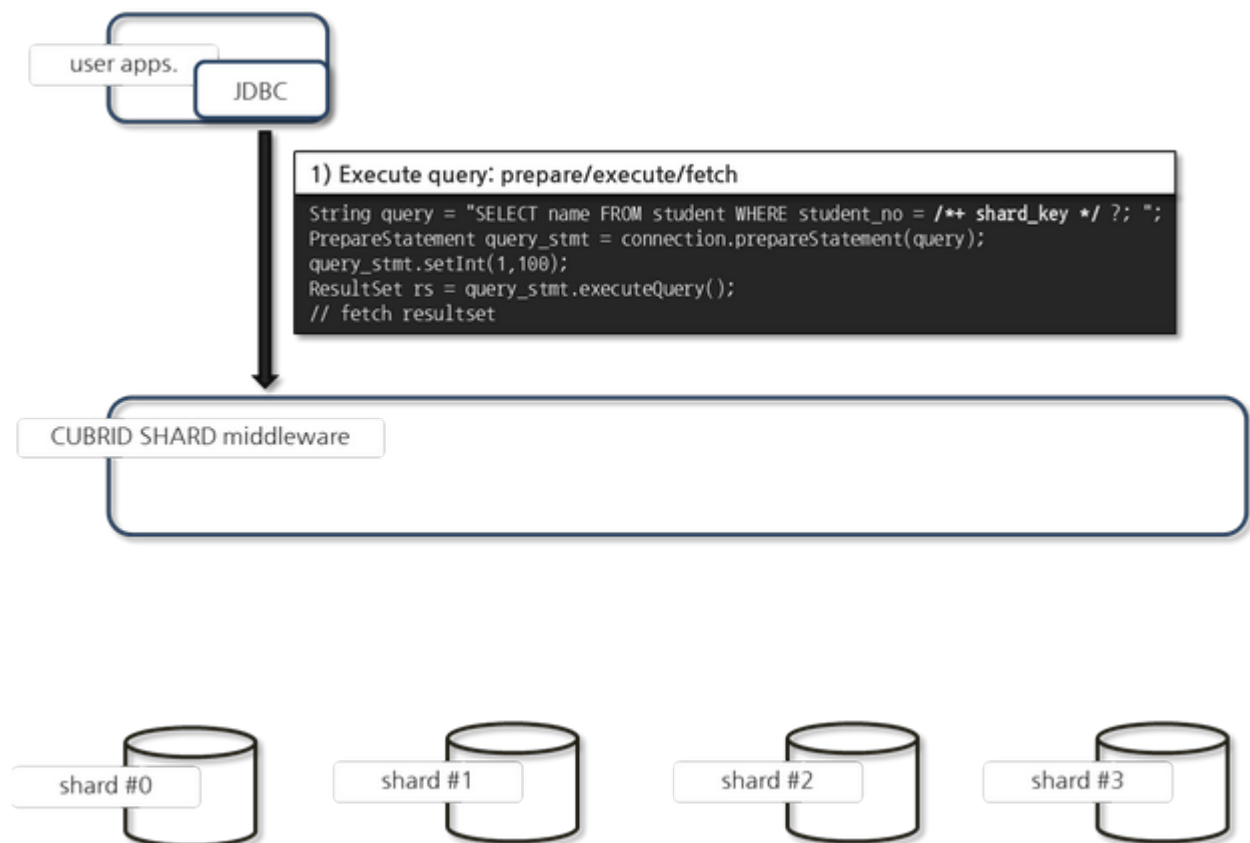

Ex) When the query is performed in shard DB #3, queries students whose value of age is greater than 17 in the shard DB #3.

```
SELECT * FROM student WHERE age > 17 /*+ shard_id(3) */;
```

## General Procedure of Executing Queries by Using Shard SQL Hint

### 1. Executing Queries

The following shows how a user-requested query is executed.

- An application makes a request for a query to the CUBRID SHARD through the JDBC interface. It adds the **shard\_key** hint to the SQL statement to specify the shard DB from where the query will be executed.
- The SQL hint, like the example above, in the SQL statement, should be positioned in front of the bind variable or literal value of the column specified by the shard key.

The shard SQL hint configured by the bind variable is as follows:

```
SELECT name FROM student WHERE student_no = /*+ shard_key */ ?
```

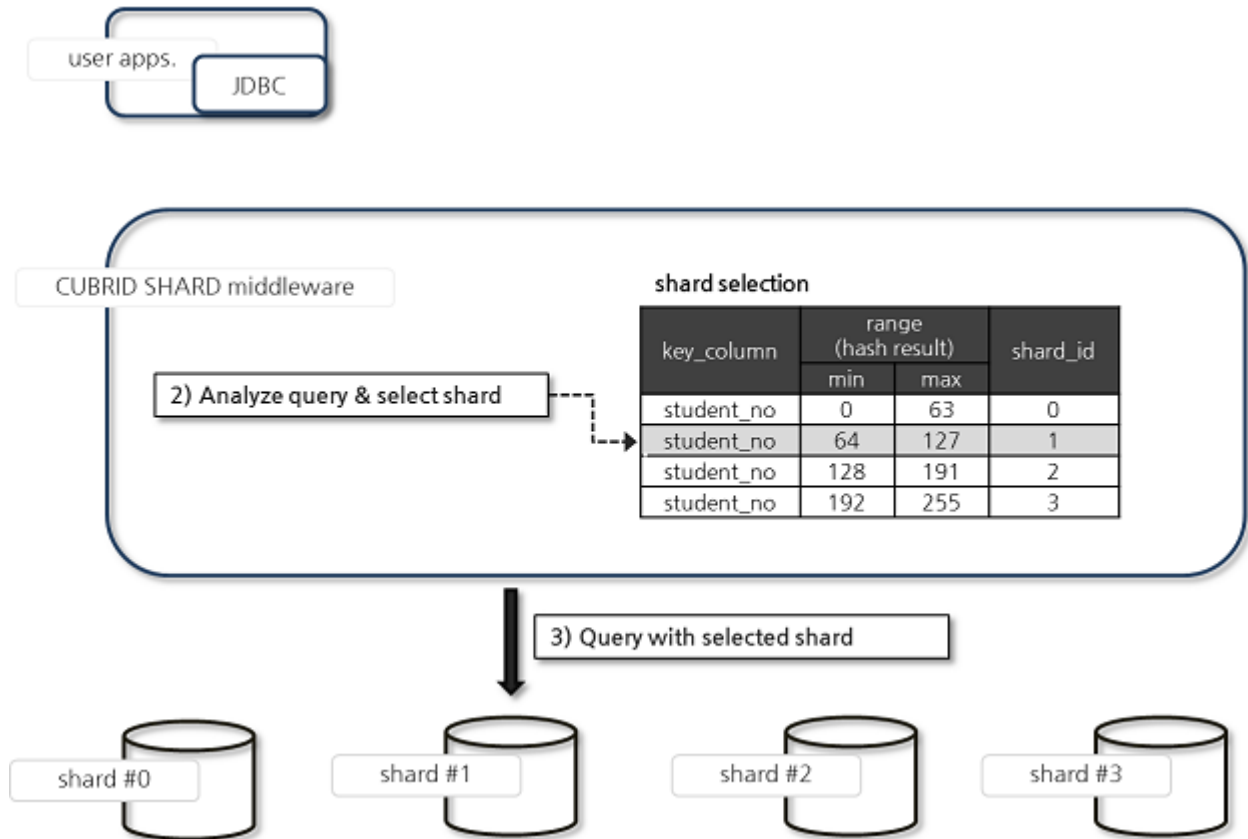

The shard SQL hint specified in the literal value is as follows:

```
SELECT name FROM student WHERE student_no = /*+ shard_key */ 100
```

shard\_key column
shard SQL Hint
literal value

## 2. Select a Shard DB to Analyze and Perform a Query

Select a shard DB to analyze and perform the query by following the steps below:

- SQL queries received from users are rewritten in the format that is appropriate for internal processing.
- Select the shard DB that executed the query by using the SQL statement and hint requested by the user.
  - When the SQL hint is set in the bind variable, select the shard DB which will execute the query by using the result of hashing the value of the shard\_key bind variable and the configuration information.
  - The hash function can be specified by the user. If not specified, the shard\_key value is hashed by using the default hash function. Default hash functions are as follows:
  - When the shard\_key is an integer

```
Default hash function (shard_key) = shard_key mod
SHARD_KEY_MODULAR parameter (default value 256)
```

- When the shard\_key is a string

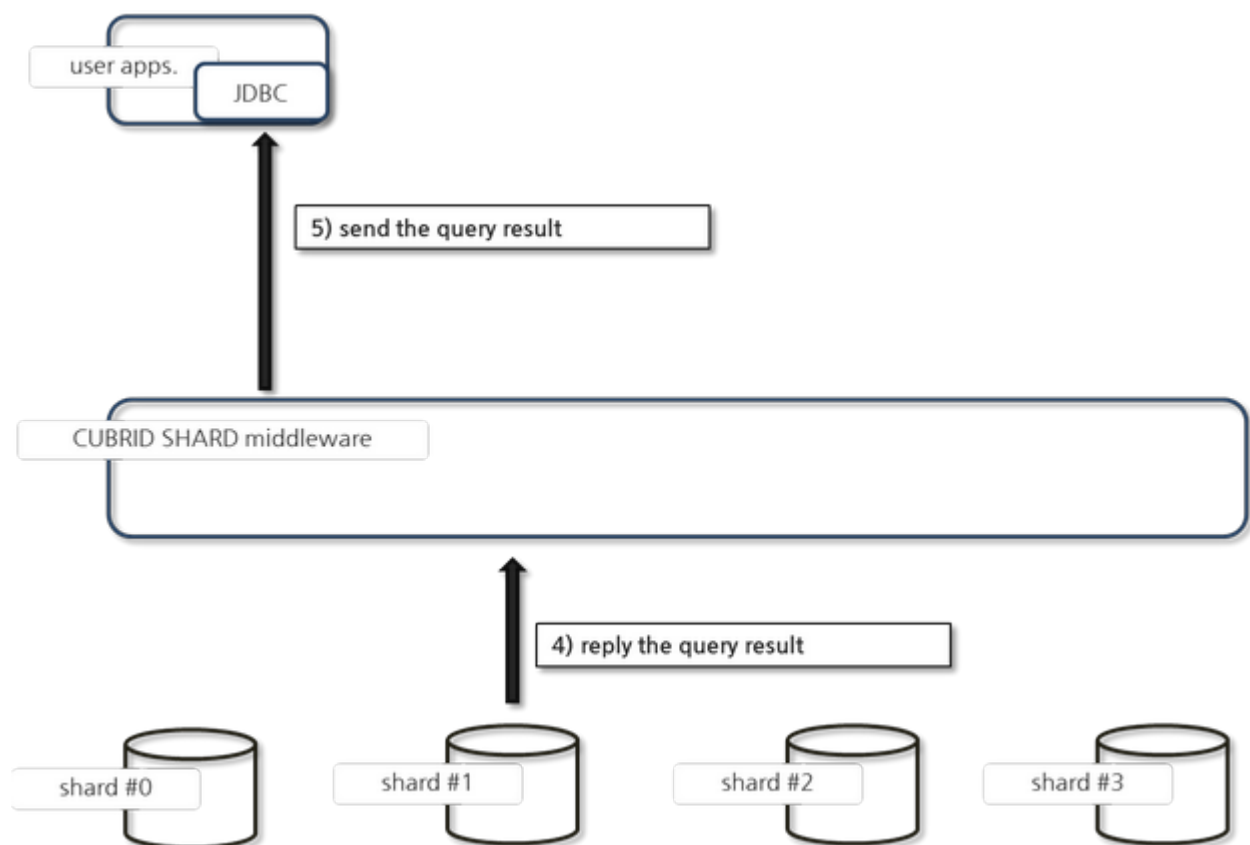

```
Default hash function (shard_key) = shard_key[0] mod
SHARD_KEY_MODULAR parameter (default value 256)
```

### Note

When the shard\_key bind variable value is 100, “Default hash function (shard\_key) = 100 % 256 = 100.” Therefore, the shard DB #1 (the hash result is 100) will be selected and then the user request will be sent to the selected shard DB #1.

### 3. Return the Query Execution Result

Return the query execution result as follows:

- Receives the query execution result from the shard DB #1 and then returns it to the requested application.

### Note

On the driver functions which do a batch query processing with the array which binds several values(ex. executeBatch in JDBC, cci\_execute\_array and cci\_execute\_batch in CCI ), they fail to run if there is a value which accesses to a different shard.

## Transaction Support

### Transaction Processing

The CUBRID SHARD executes an internal processing procedure to guarantee atomicity among ACID. For example, when an exception such as abnormal termination of an application occurs, the CUBRID SHARD sends a request to rollback to the shard DB which has been processing the request from the application in order to invalidate all changes in the transaction.

The ACID, the characteristic of general transactions, is guaranteed, based on the characteristics and settings of the backend DBMS.

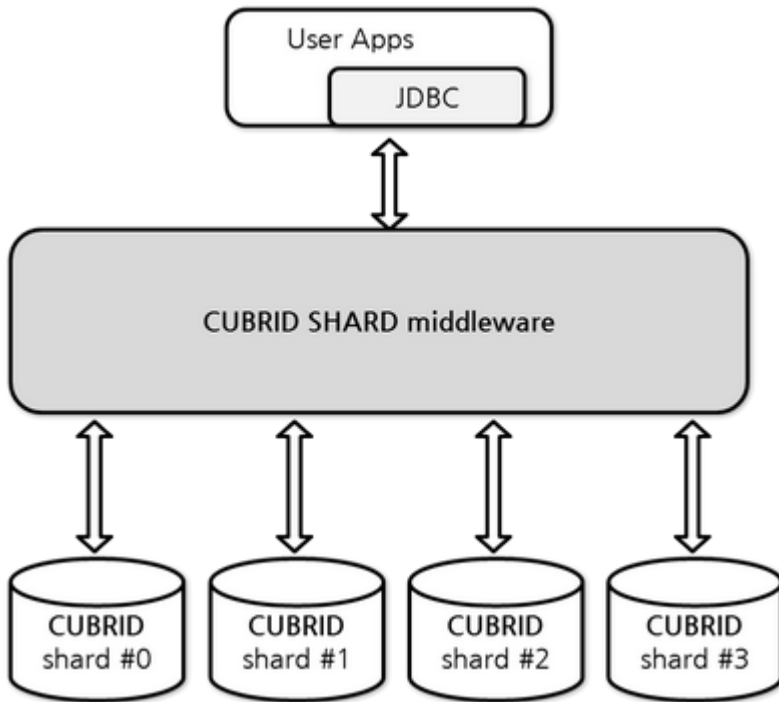

### Constraints

2 Phase Commit (2PC) is unavailable; therefore, an error occurs when a query is executed by using several shard DBs in a single transaction.

## Quick Start

### Configuration Example

The CUBRID SHARD to be explained consists of four CUBRID SHARD DBs as shown below. The application uses the JDBC interface to process user requests.

### Start after creating the shard DB and user account

As shown in the example above, after each shard DB node creates a shard DB and a user account, it starts the instance of the database.

- shard DB name: *shard1*
- shard DB user account: *shard*
- shard DB user password: *shard123*

```
sh> # Creating CUBRID SHARD DB
sh> cubrid createdb shard1 en_US

sh> # Creating CUBRID SHARD user account
sh> csql -S -u dba shard1 -c "create user shard password 'shard123'"

sh> # Starting CUBRID SHARD DB
sh> cubrid server start shard1
```

## Changing the shard Configurations

### **cubrid\_broker.conf**

Change **cubrid\_broker.conf** as shown below by referring to **cubrid\_broker.conf.shard**:

**Warning**

The port number and the shared memory identifier should be appropriately changed to the value which has not been assigned by the system.

```
[broker]
MASTER_SHM_ID           =30001
ADMIN_LOG_FILE           =log/broker/cubrid_broker.log

[%shard1]
SERVICE                 =ON
BROKER_PORT              =36000
MIN_NUM_APPL_SERVER      =20
MAX_NUM_APPL_SERVER      =40
APPL_SERVER_SHM_ID       =36000
LOG_DIR                   =log/broker/sql_log
ERROR_LOG_DIR             =log/broker/error_log
SQL_LOG                   =ON
TIME_TO_KILL              =120
SESSION_TIMEOUT          =300
KEEP_CONNECTION           =ON
MAX_PREPARED_STMT_COUNT  =1024
SHARD                     =ON
SHARD_DB_NAME             =shard1
SHARD_DB_USER             =shard
SHARD_DB_PASSWORD        =shard123
SHARD_NUM_PROXY           =1
SHARD_PROXY_LOG_DIR       =log/broker/proxy_log
SHARD_PROXY_LOG           =ERROR
SHARD_MAX_CLIENTS         =256
SHARD_PROXY_SHM_ID        =36090
SHARD_CONNECTION_FILE     =shard_connection.txt
SHARD_KEY_FILE            =shard_key.txt
```

For CUBRID, the server port number is not separately configured in the **shard\_connection.txt** but the **cubrid\_port\_id** parameter of the **cubrid.conf** configuration file is used. Therefore, set the **cubrid\_port\_id** parameter of the **cubrid.conf** identical to the server.

```
# TCP port id for the CUBRID programs (used by all clients).
cubrid_port_id=41523
```

### shard\_key.txt

Set **shard\_key.txt**, the shard DB mapping configuration file, for the shard key hash value as follows:

- [%shard\_key]: Sets the shard key section

- Executing the query at shard #0 when the shard key hash result created by default hash function is between 0 and 63
- Executing the query at shard #1 when the shard key hash result created by default hash function is between 64 and 127
- Executing the query at shard #2 when the shard key hash result created by default hash function is between 128 and 191
- Executing the query at the shard #3 when the shard key hash result created by default hash function is between 192 and 255

```
[%shard_key]
#min    max    shard_id
0        63     0
64       127     1
128      191     2
192      255     3
```

### **shard\_connection.txt**

Configure the **shard\_connection.txt** file which is shard database configuration file, as follows:

- Real database name and connection information of shard #0
- Real database name and connection information of shard #1
- Real database name and connection information of shard #2
- Real database name and connection information of shard #3

```
# shard-id  real-db-name  connection-info
#
0          shard1    HostA
1          shard1    HostB
2          shard1    HostC
3          shard1    HostD
```

## Starting Service and Monitoring

### **Starting CUBRID SHARD**

To use CUBRID SHARD feature, start the CUBRID SHARD as shown below:

```
sh> cubrid broker start
@ cubrid broker start
++ cubrid broker start: success
```

## Retrieving the CUBRID SHARD Status

Retrieve the CUBRID SHARD status as follows to check the parameter and the status of the process.

```
sh> cubrid broker status
@ cubrid broker status
% shard1
-----
ID      PID    QPS    LQS  PSIZE STATUS
-----
1-0-1  21272    0      0  53292 IDLE
1-1-1  21273    0      0  53292 IDLE
1-2-1  21274    0      0  53292 IDLE
1-3-1  21275    0      0  53292 IDLE

sh> cubrid broker status -f
@ cubrid broker status
% shard1
-----
-----
-----
ID      PID    QPS    LQS  PSIZE STATUS      LAST ACCESS
TIME                               DB          HOST      LAST CONNECT TIME
SQL_LOG_MODE
-----
-----
-----
1-0-1  21272    0      0  53292 IDLE      2013/01/31 15:00:24
shard1@HostA      HostA 2013/01/31 15:00:25 -
1-1-1  21273    0      0  53292 IDLE      2013/01/31 15:00:24
shard1@HostB      HostB 2013/01/31 15:00:25 -
1-2-1  21274    0      0  53292 IDLE      2013/01/31 15:00:24
shard1@HostC      HostC 2013/01/31 15:00:25 -
1-3-1  21275    0      0  53292 IDLE      2013/01/31 15:00:24
shard1@HostD      HostD 2013/01/31 15:00:25 -
```

## Writing a Sample

Check that the CUBRID SHARD operates normally by using a simple Java program.

### Writing a Sample Table

Write a temporary table for the example in all shard DBs.

```
sh> csql -C -u shard -p 'shard123' shard1@localhost -c "create table
student (s_no int, s_name varchar, s_age int, primary key(s_no))"
```

## Writing Code

The following example program is to enter student information from 0 to 1023 to the shard DB. Check the **cubrid\_broker.conf** modified in the previous procedure and then set the address/port information and the user information into the connection url.

```
import java.sql.DriverManager;
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.ResultSetMetaData;
import java.sql.PreparedStatement;
import java.sql.Date;
import java.sql.*;
import cubrid.jdbc.driver.*;

public class TestInsert {

    static {
        try {

Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
        } catch (ClassNotFoundException e) {
            throw new RuntimeException(e);
        }
    }

    public static void DoTest(int thread_id) throws SQLException
{
        Connection connection = null;

        try {
            connection =
DriverManager.getConnection("jdbc:cubrid:localhost:36000:shard1:::?
charSet=utf8", "shard", "shard123");
            connection.setAutoCommit(false);

            for (int i=0; i < 1024; i++) {
                String query = "INSERT INTO student
VALUES (/*+ shard_key */ ?, ?, ?)";
                PreparedStatement query_stmt =
connection.prepareStatement(query);

                String name="name_" + i;
                query_stmt.setInt(1, i);
```

```

        query_stmt.setString(2, name);
        query_stmt.setInt(3, (i%64)+10);

        query_stmt.executeUpdate();
        System.out.print(".");

        query_stmt.close();
        connection.commit();
    }

    connection.close();
} catch(SQLException e) {
    System.out.print("exception occurs : " +
e.getErrorCode() + " - " + e.getMessage());
    System.out.println();
    connection.close();
}

/**
 * @param args
 */
public static void main(String[] args) {
    // TODO Auto-generated method stub

    try {
        DoTest(1);
    } catch(Exception e){
        e.printStackTrace();
    }
}
}

```

## Executing a Sample

Execute the sample program as follows:

```

sh> javac -cp ".:$CUBRID/jdbc/cubrid_jdbc.jar" *.java
sh> java -cp ".:$CUBRID/jdbc/cubrid_jdbc.jar" TestInsert

```

## Checking the Result

Execute the query in each shard DB and check whether or not the partitioned information has been correctly entered.

- shard #0

```
sh> csql -C -u shard -p 'shard123' shard1@localhost -c "select *
from student order by s_no"
```

| s_no | s_name   | s_age |
|------|----------|-------|
| 0    | 'name_0' | 10    |
| 1    | 'name_1' | 11    |
| 2    | 'name_2' | 12    |
| 3    | 'name_3' | 13    |
| ...  |          |       |

• shard #1

```
sh> $ csql -C -u shard -p 'shard123' shard1@localhost -c "select *
from student order by s_no"
```

| s_no | s_name    | s_age |
|------|-----------|-------|
| 64   | 'name_64' | 10    |
| 65   | 'name_65' | 11    |
| 66   | 'name_66' | 12    |
| 67   | 'name_67' | 13    |
| ...  |           |       |

• shard #2

```
sh> $ csql -C -u shard -p 'shard123' shard1@localhost -c "select *
from student order by s_no"
```

| s_no | s_name     | s_age |
|------|------------|-------|
| 128  | 'name_128' | 10    |
| 129  | 'name_129' | 11    |
| 130  | 'name_130' | 12    |
| 131  | 'name_131' | 13    |
| ...  |            |       |

• shard #3

```
sh> $ csql -C -u shard -p 'shard123' shard1@localhost -c "select *
from student order by s_no"
```

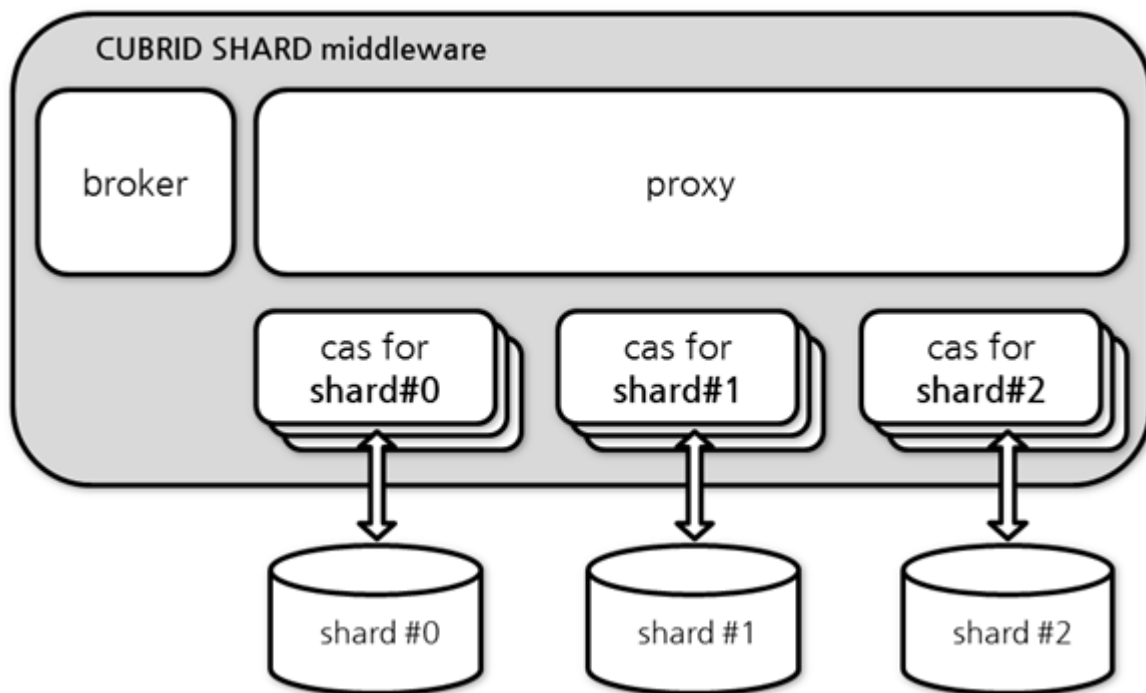

| s_no | s_name     | s_age |
|------|------------|-------|
| 192  | 'name_192' | 10    |
| 193  | 'name_193' | 11    |
| 194  | 'name_194' | 12    |

```
195 'name_195'
...
13
```

## Architecture and Configuration

### Architecture

The CUBRID SHARD is middleware, consisting of a broker, proxy, and CAS process as shown below.

### Configuration

To use the CUBRID SHARD feature, the parameters needed to run SHARD related processes, shard connection file(SHARD\_CONNECTION\_FILE) and shard key file(SHARD\_KEY\_FILE) should be configured.

#### cubrid\_broker.conf

The **cubrid\_broker.conf** file is used for setting the CUBRID SHARD feature. Refer to **cubrid\_broker.conf.shard** when configuring **cubrid\_broker.conf**. For details of **cubrid\_broker.conf**, see [Broker Configuration](#).

## Shard Connection File(SHARD\_CONNECTION\_FILE)

To connect to the backend shard DB, the CUBRID SHARD loads the shard connection configuration file specified in the **SHARD\_CONNECTION\_FILE** parameter of **cubrid\_broker.conf**.

The shard DB can be set until 256 shards.

If **SHARD\_CONNECTION\_FILE** is not specified in **cubrid\_broker.conf**, it loads the **shard\_connection.txt** file by default.

### Format

The basic example and format of a shard connection configuration file are as follows:

```
#
# shard-id      real-db-name      connection-info
#
# * cubrid : hostname, hostname, ...

# CUBRID
0      shard1      HostA
1      shard1      HostB
2      shard1      HostC
3      shard1      HostD
```

#### Note

As shown in the general CUBRID settings, the content after # is converted to comment.

### CUBRID

When the backend shard DB is CUBRID, the format of the connection configuration file is as follows:

```
# CUBRID
# shard-id      real-db-name      connection-info
# shard identifier( >0 )      The real name of backend shard DB
# host name

0      shard_db_1      host1
1      shard_db_2      host2
2      shard_db_3      host3
3      shard_db_4      host4
```

For CUBRID, a separate backend shard DB port number is not specified in the above configuration file, but the **CUBRID\_PORT\_ID** parameter in the **cubrid.conf** file is used. The **cubrid.conf** file is by default located in the **\$CUBRID/conf**.

```
$ vi cubrid.conf

...

# TCP port id for the CUBRID programs (used by all clients).
cubrid_port_id=41523
```

### Shard key file(SHARD\_KEY\_FILE)

The CUBRID SHARD loads the shard key configuration file specified in the **SHARD\_KEY\_FILE** parameter of **cubrid\_broker.conf** to determine which backend shard DB should process the user requests.

If **SHARD\_KEY\_FILE** is not specified in **cubrid\_broker.conf**, it loads the **shard\_key.txt** file by default.

### Format

The example and format of a shard key configuration file are as follows:

```
[%student_no]
#min      max      shard_id
0          31       0
32         63       1
64         95       2
96        127       3
128       159       0
160       191       1
192       223       2
224       255       3
```

- [%shard\_key\_name]: Specifies the name of the shard key.
- min: The minimum value range of the shard key hash results.
- max: The maximum range of the shard key hash results.
- shard\_id: The shard identifier

### Note

As shown in the general CUBRID settings, the content after # is converted to comment.

### Warning

- min of the shard key should always start from 0.
- max should be up to 255.
- No empty value between min and max is allowed.
- The default hash function should not exceed the value of the **SHARD\_KEY\_MODULAR** parameter(min. 1, max 256).
- The result of shard key hashing should be within a range from 0 to (**SHARD\_KEY\_MODULAR** -1).

## Setting User-Defined Hash Function

To select a shard that will perform queries, the CUBRID SHARD uses the results of hashing the shard key and the metadata configuration information. For this, users can use the default hash function or define a hash function.

### Default Hash Function

When the **SHARD\_KEY\_LIBRARY\_NAME** and **SHARD\_KEY\_FUNCTION\_NAME** parameters of **cubrid\_broker.conf** are not set, the shard key is hashed by using the default hash function. The default hash function is as follows:

- When the shard\_key is an integer

```
Default hash function (shard_key) = shard_key mod SHARD_KEY_MODULAR  
parameter (default value: 256)
```

- When the shard\_key is a string

```
Default hash function (shard_key) = shard_key[0] mod  
SHARD_KEY_MODULAR parameter (default value: 256)
```

## Setting User-Defined Hash Function

The CUBRID SHARD can hash the shard key by using the user-defined hash function, in addition to the default hash function.

### Implementing and Creating a Library

The user-defined hash function must be implemented as a **.so** library loadable at runtime. Its prototype is as shown below:

```
/*
    return value :
        success - shard key id(>0)
        fail    - invalid argument(ERROR_ON_ARGUMENT),
shard key id make fail(ERROR_ON_MAKE_SHARD_KEY)
    type        : shard key value type
    val         : shard key value
*/
typedef int (*FN_GET_SHARD_KEY) (const char *shard_key,
T_SHARD_U_TYPE type,
                                const void *val, int
val_size);
```

- The return value of the hash function should be within the range of the hash results of the **shard\_key.txt** configuration file.
- To build a library, the **\$CUBRID/include/shard\_key.h** file of the CUBRID source must be included. The file lets you know the details such as error code that can be returned.

### Changing the cubrid\_broker.conf Configuration File

To apply a user-defined hash function, the **SHARD\_KEY\_LIBRARY\_NAME** and **SHARD\_KEY\_FUNCTION\_NAME** parameters of **cubrid\_broker.conf** should be set according to the implementation.

- **SHARD\_KEY\_LIBRARY\_NAME** : The (absolute) path of the user-defined hash library.
- **SHARD\_KEY\_FUNCTION\_NAME** : The name of the user-defined hash function.

### Example

The following example shows how to use a user-defined hash. First, check the **shard\_key.txt** configuration file.

```
[%student_no]
#min      max      shard_id
0         31       0
32        63       1
64        95       2
```

|     |     |   |
|-----|-----|---|
| 96  | 127 | 3 |
| 128 | 159 | 0 |
| 160 | 191 | 1 |
| 192 | 223 | 2 |
| 224 | 255 | 3 |

To set the user-defined hash function, implement a **.so** shared library that is loadable at runtime. The result of the hash function should be within the range of hash function results defined in the **shard\_key.txt** configuration file. The following example shows a simple implementation.

- When the shard\_key is an integer
  - Select shard #0 when the shard\_key is an odd number
  - Select shard #1 when the shard\_key is an even number
- When the shard\_key is a string
  - Select shard #0 when the shard\_key string starts with 'a' or 'A'.
  - Select shard #1 when the shard\_key string starts with 'b' or 'B'.
  - Select shard #2 when the shard\_key string starts with 'c' or 'C'.
  - Select shard #3 when the shard\_key string starts with 'd' or 'D'.

```
// <shard_key_udf.c>

#include <string.h>
#include <stdio.h>
#include <unistd.h>
#include "shard_key.h"

int
fn_shard_key_udf (const char *shard_key, T_SHARD_U_TYPE
type,
                  const void *value, int value_len)
{
    unsigned int ival;
    unsigned char c;

    if (value == NULL)
    {
        return ERROR_ON_ARGUMENT;
    }

    switch (type)
    {
        case SHARD_U_TYPE_INT:
```

```

        ival = (unsigned int) (*(unsigned int *) value);
        if (ival % 2)
        {
            return 32;           // shard #1
        }
        else
        {
            return 0;           // shard #0
        }
        break;

    case SHARD_U_TYPE_STRING:
        c = (unsigned char) (((unsigned char *) value)[0]);
        switch (c)
        {
            case 'a':
            case 'A':
                return 0;           // shard #0
            case 'b':
            case 'B':
                return 32;          // shard #1
            case 'c':
            case 'C':
                return 64;          // shard #2
            case 'd':
            case 'D':
                return 96;          // shard #3
            default:
                return ERROR_ON_ARGUMENT;
        }

        break;

    default:
        return ERROR_ON_ARGUMENT;
    }
    return ERROR_ON_MAKE_SHARD_KEY;
}

```

Build the user-defined function as a shared library. The following example is Makefile for building a hash function.

```

# Makefile

CC = gcc
LIBS = $(LIB_FLAG)
CFLAGS = $(CFLAGS_COMMON) -fPIC -I$(CUBRID)/include -I$(CUBRID_SRC)/src/broker

SHARD_CC = gcc -g -shared -Wl,-soname,shard_key_udf.so

```

```
SHARD_KEY_UDF_OBJS = shard_key_udf.o

all:$(SHARD_KEY_UDF_OBJS)
    $(SHARD_CC) $(CFLAGS) -o shard_key_udf.so $
    (SHARD_KEY_UDF_OBJS) $(LIBS)

clean:
    -rm -f *.o core shard_key_udf.so
```

To include the user-defined hash function, modify the **SHARD\_KEY\_LIBRARY\_NAME** and **SHARD\_KEY\_FUNCTION\_NAME** parameters as shown in the above implementation.

```
[%student_no]
SHARD_KEY_LIBRARY_NAME = $CUBRID/conf/shard_key_udf.so
SHARD_KEY_FUNCTION_NAME = fn_shard_key_udf
```

#### Note

- When you define a user's hash function in the application, 16bit(short), 32bit(int) and 64bit(INT64) integer can be used as the value of shard key.
- The user should define a hash function when you have to use VARCHAR type.

## Running and Monitoring

By using the CUBRID SHARD utility, CUBRID SHARD function can be started or stopped and various status information can be retrieved. For more details, see [Broker](#).

## Configuration Test

With **cubrid broker test** command, you can test if the configuration works normally. For details, see [Broker to DB Connection Test](#).

## CUBRID SHARD Log

There are four types of logs that relate to starting the shard: access, proxy, error and SQL logs. Changing the directory of each log is available through **LOG\_DIR**, **ERROR\_LOG\_DIR**, and **SHARD\_PROXY\_LOG\_DIR** parameters of the shard configuration file (**cubrid\_broker.conf**).

### SHARD PROXY Log

#### Access Log

- Parameter: **ACCESS\_LOG**
- Description: Log the client access (the existing broker logs at the CAS).
- Default directory: \$CUBRID/log/broker/
- File name: <broker\_name>\_<proxy\_index>.access
- Log type: All strings, except the access log and the cas\_index at the CAS, are identical

```
10.24.18.67 - - 1340243427.828 1340243427.828 2012/06/21 10:50:27 ~
2012/06/21 10:50:27 23377 - -1 shard1      shard1
10.24.18.67 - - 1340243427.858 1340243427.858 2012/06/21 10:50:27 ~
2012/06/21 10:50:27 23377 - -1 shard1      shard1
10.24.18.67 - - 1340243446.791 1340243446.791 2012/06/21 10:50:46 ~
2012/06/21 10:50:46 23377 - -1 shard1      shard1
10.24.18.67 - - 1340243446.821 1340243446.821 2012/06/21 10:50:46 ~
2012/06/21 10:50:46 23377 - -1 shard1      shard1
```

#### Proxy Log

- Parameter: **SHARD\_PROXY\_LOG\_DIR**
- Description: Log the behavior of the inner proxy.
- Default directory: \$CUBRID/log/broker/proxy\_log
- File name: <broker\_name>\_<proxy\_index>log

```
06/21 10:50:46.822 [SRD] ../../src/broker/shard_proxy_io.c(1045):
New socket io created. (fd:50).
06/21 10:50:46.822 [SRD] ../../src/broker/shard_proxy_io.c(2517):
New client connected. client(client_id:3, is_busy:Y, fd:50, ctx_cid:
3, ctx_uid:4).
06/21 10:50:46.825 [DBG] ../../src/broker/shard_proxy_io.c(3298):
Shard status. (num_cas_in_tran=1, shard_id=2).
```

```
06/21 10:50:46.827 [DBG] ../../src/broker/shard_proxy_io.c(3385):
Shard status. (num_cas_in_tran=0, shard_id=2).
```

## Proxy Log Level

- Parameter: **SHARD\_PROXY\_LOG**
- Proxy log level policy: When the upper level is set, all logs of the lower level will be left.
  - Ex) Set SCHEDULE and then all ERROR | TIMEOUT | NOTICE | SHARD | SCHEDULE logs will be left.
- Proxy Log Level Item
  - NONE or OFF: No log is left.
  - ERROR (default): An internal error occurs and logging is not successfully processed
  - TIMEOUT: Timeout such as session timeout or query timeout
  - NOTICE: When the error is not a query without hint or other errors
  - SHARD: Scheduling that shows which shard and which CAS the client request have sent to and whether the request has responded to the client or not
  - SCHEDULE: Shard processing such as getting the shard key ID through parsing the hit or hashing
  - ALL: All logs

## SHARD CAS Log

### SQL Log

- Parameter: **SQL\_LOG**
- Description: Log queries such as prepare/execute/fetch and other cas information.
- Default directory: \$CUBRID/log/broker/sql\_log
- File name: %broker\_name%\_%proxy\_index%\_%shard\_index%\_%as\_index%.sql.log

```
13-06-21 10:13:00.005 (0) STATE idle
13-06-21 10:13:01.035 (0) CAS TERMINATED pid 31595
13-06-21 10:14:20.198 (0) CAS STARTED pid 23378
13-06-21 10:14:21.227 (0) connect db shard1@HostA user dba url
shard1 session id 3
13-06-21 10:14:21.227 (0) DEFAULT isolation_level 3, lock_timeout -1
13-06-21 10:50:28.259 (1) prepare srv_h_id 1
```

```
13-06-21 10:50:28.259 (0) auto_rollback
13-06-21 10:50:28.259 (0) auto_rollback 0
```

## Error log

- Parameter: **ERROR\_LOG\_DIR**
- Description: For CUBRID, the cs library logs EID and error strings to the corresponding file.
- Default directory: \$CUBRID/log/broker/error\_log
- File name: %broker\_name%\_%proxy\_index%\_%shard\_index%\_%cas\_index%.err

```
Time: 06/21/12 10:50:27.776 - DEBUG *** file ../../src/transaction/

```

## Constraints

### Linux only support

CUBRID SHARD feature can be used only in Linux.

### One transaction can be run on only one shard DB

One transaction should be performed within only one shard DB, so the following constraints exist.

- It is unavailable to change data in several shard DBs through changing the shard key (**UPDATE**). If necessary, use **DELETE** / **INSERT**.
- A query about more than one shard DB, such as join, sub-query, or, union, group by, between, like, in, exist, or any/some/all, is not supported.

### Session information is valid only in each shard DB

Session information is valid within each shard DB only. Therefore, the results from session-related functions such as `LAST_INSERT_ID()` may be different from the intended result.

### No support SET NAMES statement

In SHARD environment, SET NAMES statement is not recommended to use because it can work abnormally.

### **auto increment is valid only in each shard DB**

The auto increment attribute or SERIAL is valid within each shard DB only. So a result different from the intended result may be returned.

### **DDL syntax with SHARD hint syntax not supported**

Since DDL phrases such as schema creation and change in the SHARD configuration environment do not support SHARD hints, each SHARD DB must be accessed to process schema creation and change. The shard\_id (0) is normally processed, and an error is generated from the shard\_id (1).

Error example)

```
CREATE TABLE foo (col1 INT NOT NULL) /** SHARD_ID(1) /
```

```
DROP TABLE IF EXISTS foo /* SHARD_ID(1) */
```

## API Reference

This chapter covers the following API:

### JDBC Driver

#### JDBC Overview

CUBRID JDBC driver (**cubrid\_jdbc.jar**) implements an interface to enable access from applications in Java to CUBRID database server. CUBRID JDBC driver is installed in the *<directory where CUBRID is installed>/jdbc* directory. The driver has been developed based on the JDBC 2.0 specification and the default driver provided is complied with JDK 1.8.

#### **Verifying CUBRID JDBC Driver Version**

You can verify the version of JDBC driver as follows:

```
% jar -tf cubrid_jdbc.jar  
META-INF/
```

```
META-INF/MANIFEST.MF
cubrid/
cubrid/jdbc/
cubrid/jdbc/driver/
cubrid/jdbc/jci/
cubrid/sql/
cubrid/jdbc/driver/CUBRIDBlob.class
...
CUBRID-JDBC-11.3.0.0047
```

## Registering CUBRID JDBC Driver

Use the **Class.forName** (*driver-class-name*) method to register CUBRID JDBC driver. The following example shows how to load the **cubrid.jdbc.driver.CUBRIDDriver** class to register CUBRID JDBC driver.

```
import java.sql.*;
import cubrid.jdbc.driver.*;

public class LoadDriver {
    public static void main(String[] Args) {
        try {
            Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
        } catch (Exception e) {
            System.err.println("Unable to load driver.");
            e.printStackTrace();
        }
        ...
    }
}
```

## Installing and Configuring JDBC

### Requirements

- JDK 1.8 or later
- CUBRID 2008 R2.0 (8.2.0) or later
- CUBRID JDBC driver 2008 R1.0 or later

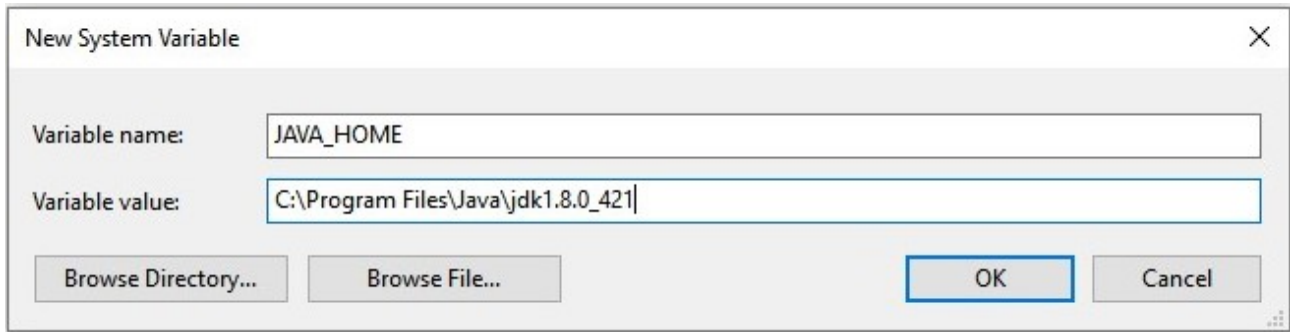

### Installing Java and Configuring Environment

You must already have Java installed and the **JAVA\_HOME** environment variable configured in your system. You can download Java from the Developer Resources for Java Technology website ( <https://www.oracle.com/java/technologies/downloads/#java8> ).

### Configuring the environment variables for Windows

After installing Java, right-click on [This PC] and select [Properties]. Then, click on [Advanced system settings] under the Related settings to open the System Properties dialog box. Click on [Environment Variables] in the [Advanced] tab to open the Environment Variables dialog box.

In the [System variables], click [New]. Enter **JAVA\_HOME** as the variable name and input the Java installation path (e.g., C:\Program Files\Java\jdk1.8.0\_421) as the variable value, then click [OK].

Of system variables, select Path and then click [Edit]. Add **%JAVA\_HOME%\bin** in the [Variable value] and then click [OK].

You can also configure **JAVA\_HOME** and **PATH** values in the shell instead of using the way described above.

```
set JAVA_HOME= C:\Program Files\Java\jdk1.8.0_421
set PATH=%PATH%;%JAVA_HOME%\bin
```

### Configuring the environment variables for Linux

Specify the directory path where Java is installed (example: /usr/java/jdk1.8.0\_421) as a **JAVA\_HOME** environment variable and add **\$JAVA\_HOME/bin** to the **PATH** environment variable.

```
export JAVA_HOME=/usr/java/jdk1.8.0_421      #bash
export PATH=$JAVA_HOME/bin:$PATH            #bash

setenv JAVA_HOME /usr/java/jdk1.8.0_421     #csh
set path = ($JAVA_HOME/bin $path)           #csh
```

### Configuring JDBC Driver

To use JDBC, you should specify the path where the CUBRID JDBC driver is located in the **CLASSPATH** environment variable.

The CUBRID JDBC driver (**cubrid\_jdbc.jar**) is located in the jdbc directory under the directory of CUBRID installation.

### Configuring the CLASSPATH environment variable for Windows

```
set CLASSPATH=C:\CUBRID\jdbc\cubrid_jdbc.jar:.
```

### Configuring the CLASSPATH environment variable for Linux

```
export CLASSPATH=$HOME/CUBRID/jdbc/cubrid_jdbc.jar:.
```

#### Warning

If a general CUBRID JDBC driver has been installed in the same library directory (**\$JAVA\_HOME/jre/lib/ext**) where the JRE is installed, it may be loaded ahead of the server-side JDBC driver used by the Java stored procedure, which causing it to malfunction. In a Java stored procedure environment, make sure not to install a general CUBRID JDBC driver in the directory where the JRE is installed (**\$JAVA\_HOME/jre/lib/ext**).

## JDBC Programming

## Configuration Connection

The **DriverManager** is an interface for managing the JDBC driver. It is used to select a driver and create new database connection. If CUBRID JDBC driver is registered, you can connect a database by calling the **DriverManager.getConnection** (*db-url*, *user-id*, *password*) method.

The **getConnection** method returns the **Connection** object and it is used to execute queries and commands, and commit and roll back transactions. The syntax below shows the *db-url* argument for configuring connection.

```
jdbc:cubrid:<host>:<port>:<db-name>:[user-id]:[password]:[?
<property> [& <property>]]

<host> ::=
hostname | ip_address

<property> ::= altHosts=<alternative_hosts>
               | rcTime=<second>
               | loadBalance=<balance_mode>
               | connectTimeout=<second>
               | queryTimeout=<second>
               | charSet=<character_set>
               | zeroDateTimeBehavior=<behavior_type>
               | logFile=<file_name>
               | logOnException=<bool_type>
               |
logSlowQueries=<bool_type>&slowQueryThresholdMillis=<millisecond>
               | useLazyConnection=<bool_type>
               | useSSL=<bool_type>
               | clientCacheSize=<unit_size>
               | usePreparedStmtCache=<bool_type>
               | preparedStmtCacheSize=<unit_size>
               | preparedStmtCacheSqlLimit=<unit_size>
               | hold_cursor=<bool_type>

<alternative_hosts> ::=
<standby_broker1_host>:<port> [,<standby_broker2_host>:<port>]
<behavior_type> ::= exception | round | convertToNull
<bool_type> ::= true | false
<unit_size> ::= multiple of mega byte
<balance_mode> ::= true | false | rr | sh
```

- *host*: IP address or host name where the CUBRID broker is running
- *port*: The CUBRID broker port number (default value: 33,000)
- *db-name*: The name of the database to connect

- **user-id**: The user ID which is connected to a database. There are two types of users in a database by default: **dba** and **public**. If this is NULL, it becomes `<db_user>` in `db-url`. If this is an empty string (`""`), it becomes a **public** user.
- **password**: The password of a user who is to be connected to a database. If this is NULL, `<db_password>` in `db-url` is used. If this is an empty string (`""`), DB password becomes an empty string. You cannot include `'` in the password of the `db-url` string.
- `<property>`
  - **altHosts**: The host IP addresses and connection ports of one or more stand by brokers which will perform failover in the HA environment.

#### Note

Even if there are **RW** and **RO** together in `ACCESS_MODE*` setting of brokers of main host and **altHosts**, application decides the target host to access without the relation for the setting of **ACCESS\_MODE**. Therefore, you should define the main host and **altHosts** as considering **ACCESS\_MODE** of target brokers.

- **rcTime**: Interval time (in seconds) to try to connect active brokers during failover in the HA environment. See the below URL example.
- **loadBalance**: When there are multiple hosts that a client can connect to, this is the property that selects the algorithm for determining the target host to connect to. Through load balancing, the client's connection requests can be distributed so that they are not concentrated on a specific server. (default value: false)

The behavior for each setting is as follows:

- **false**: This property is not applied. \* **true or rr**: Connects to the specified hosts using the **Round-Robin** method.
- **sh**: Connects to the specified hosts using the **Random(Shuffle)** method.
- **connectTimeout**: Timeout value (in seconds) for database connection. The default value is 30 seconds. If this value is 0, it means infinite waiting. This value is also applied when internal reconnection occurs after the initial connection. The **DriverManger.setLoginTimeout()** method can be used to configure it; however, the value configured in this method will be ignored if a value is configured in the connection URL.
- **queryTimeout**: Timeout value (in seconds) for query execution (default value: 0, infinite). The maximum value is 2,000,000. This value can be changed by the **DriverManger.setQueryTimeout()** method.

### Note

When you run `executeBatch()` method, the query timeout is applied in one method call, not in one query.

- **charSet:** The character set of a database to be connected
- **zeroDateTimeBehavior:** The property used to determine the way to handle an output value; because JDBC does not allow a value having zero for both date and time regardless of date and time in the object with the **java.sql.Date** type. For information about the value having zero for both date and date, see [Date/Time Types](#).

The default operation is **exception**. The operation for each configuration is as follows:

- **exception:** Default operation. It is handled as an `SQLException` exception.
- **round:** Converts to the minimum value allowed for a type to be returned. Exceptionally, when the value's type is `TIMESTAMP`, this value is rounded as '1970-01-01 00:00:00'(GST). (yyyy-mm-dd hh24:mi:ss)
- **convertToNull:** Converts to **NULL**.
- **logFile:** The name of a log file for debugging (default value: `cubrid_jdbc.log`). If a path is not configured, it is stored the location where applications are running.
- **logOnException:** Whether to log exception handling for debugging (default value: false)
- **logSlowQueries:** Whether to log slow queries for debugging (default value: false)
  - **slowQueryThresholdMillis:** Timeout value (in milliseconds) of slow queries (default value: 60,000).
- **useLazyConnection:** If this is true, it returns success without connecting to the broker when user requests the connection, and it connects to the broker after calling `prepare` or `execute` function (default: false). If this value is true, it can prevent from access delay or failure as many application clients restart simultaneously and create connection pools.
- **useSSL:** Packet Encryption mode (Default: false)
  - Packet encryption: `useSSL = true`
  - Plain text: `useSSL = false`
- **clientCacheSize:** cache size for result-cache \* the unit is multiple of mega-byte \* the range is 1 ~ 1024 (1 mega-byte to 1 giga-byte) \* the default value is 1

- **usePreparedStmtCache**: Prepared Statement Cache mode (Default: false)
- **preparedStmtCacheSize**: If usePreparedStmtCache is TRUE, the number of SQLs that can be cached (Default:25, Min:1, Max:2147483647)
- **preparedStmtCacheSqlLimit**: If usePreparedStmtCache is TRUE, length of SQL that can be cached (Default:256, Min:1, Max:2147483647)
- **hold\_cursor**: Cursor holdability setting (default: true). If this value is false, CLOSE\_CURSORS\_AT\_COMMIT is set, and if true, HOLD\_CURSORS\_OVER\_COMMIT is set. For details, see [Cursor Holdability](#).

### Example 1

```
--connection URL string when user name and password omitted
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public::

--connection URL string when zeroDateTimeBehavior property specified
URL=jdbc:CUBRID:127.0.0.1:33000:demodb:public:??
zeroDateTimeBehavior=convertToNull

--connection URL string when charSet property specified
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public:??charSet=utf-8

--connection URL string when queryTimeout and charSet property
specified
URL=jdbc:CUBRID:127.0.0.1:33000:demodb:public:??
queryTimeout=18charSet=utf-8

--connection URL string when a property(altHosts) specified for HA
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public:??
altHosts=192.168.0.2:33000,192.168.0.3:33000

--connection URL string when properties(altHosts,rcTime,
connectTimeout) specified for HA
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public:??
altHosts=192.168.0.2:33000,192.168.0.3:33000&rcTime=600&connectTimeou
t=5

--connection URL string when properties(altHosts,rcTime, charSet)
specified for HA
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public:??
altHosts=192.168.0.2:33000,192.168.0.3:33000&rcTime=600&charSet=utf-8

--connection URL string when useSSL property specified for encrypted
connection
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public:??useSSL=true
```

```
--connection URL string when clientCacheSize property specified for
result-cache
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public::?clientCacheSize=1

--connection URL string when usePreparedStmtCache property specified
for prepared stament cache
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public::?
usePreparedStmtCache=true&preparedStmtCacheSize=100&preparedStmtCache
SqlLimit=1024"

--connection URL string when hold_cursor property specified for
cursor holdability
URL=jdbc:CUBRID:192.168.0.1:33000:demodb:public::?hold_cursor=true
```

## Example 2

```
String url = "jdbc:cubrid:192.168.0.1:33000:demodb:public:";
String userid = "";
String password = "";

try {
    Connection conn =
        DriverManager.getConnection(url,userid,password);
    // Do something with the Connection

    ...

} catch (SQLException e) {
    System.out.println("SQLException: " + e.getMessage());
    System.out.println("SQLState: " + e.getSQLState());
}

...
```

### Note

- Because a colon (:) and a question mark are used as a separator in the URL string, it is not allowed to use them as parts of a password. To use them in a password, you must specify a user name (*user-id*) and a password (*password*) as a separate argument in the **getConnection** method.
- The database connection in thread-based programming must be used independently each other.
- The rollback method requesting transaction rollback will be ended after a server completes the rollback job.

- In autocommit mode, the transaction is not committed if all results are not fetched after running the SELECT statement. Therefore, although in autocommit mode, you should end the transaction by executing COMMIT or ROLLBACK if some error occurs during fetching for the resultset.

### Warning

- The **useSSL** flag must match with mode of the broker trying to connect. If the encryption mode is different from the server that trying to connect, that connection request will be rejected. Please refer the following cases that are not allowed.
  - useSSL=true, connection request will be rejected when the broker is in 'normal mode' (**cubrid\_broker.conf**: SSL = OFF)
  - useSSL=false, connection request will be rejected when the broker is in 'encryption mode' (**cubrid\_broker.conf**: SSL = ON)
- The **clientCacheSize** works only when **JDBC\_CACHE** or **JDBC\_CACHE\_ONLY\_HINT** of broker configure is **ON**.

## Connecting with DataSource

DataSource is the concept to be introduced in JDBC 2.0 API extention; it supports connection pooling and distributed transaction. CUBRID supports only connection pooling and do not supports distributed transaction and JNDI.

CUBRIDDataSource is DataSource implemented in CUBRID.

### Creating a DataSource Object

To create a DataSource object, call as follows.

```
CUBRIDDataSource ds = null;  
ds = new CUBRIDDataSource();
```

### Setting Connection Properties

**Connection properties** are used to configure connections between datasource and CUBRID DBMS. General properties are a DB name, a host name, a port number, a user name and a password.

To set or get the values of properties, use below methods which is implemented in `cubrid.jdbc.driver.CUBRIDDataSource`.

```
public PrintWriter getLogWriter();
public void setLogWriter(PrintWriter out);
public void setLoginTimeout(int seconds);
public int getLoginTimeout();
public String getDatabaseName();
public String getDatabaseName();
public String getDataSourceName();
public String getDescription();
public String getNetworkProtocol();
public String getPassword();
public int getPortNumber();
public int getPort();
public String getRoleName();
public String getServerName();
public String getUser();
public String getURL();
public String getUrl();
public void setDatabaseName(String dbName);
public void setDescription(String desc);
public void setNetworkProtocol(String netProtocol);
public void setPassword(String psswd);
public void setPortNumber(int p);
public void setPort(int p);
public void setRoleName(String rName);
public void setServerName(String svName);
public void setUser(String uName);
public void setUrl(String urlString);
public void setURL(String urlString);
```

Especially, use a `setURL()` method to set the property through a URL string. Regarding URL string, see [Configuration Connection](#).

```
import cubrid.jdbc.driver.CUBRIDDataSource;
...
CUBRIDDataSource ds = null;
ds = new CUBRIDDataSource();
ds.setUrl("jdbc:cubrid:192.168.0.1:55300:demodb::?
charset=utf8&logSlowQueries=true&slowQueryThresholdMillis=1000&logTra
ceApi=true&logTraceNetwork=true");
```

Call `getConnection` method to get a connection object from `DataSource`.

```
Connection connection = null;
connection = ds.getConnection("dba", "");
```

CUBRIDConnectionPoolDataSource is an object which connection-pool datasource is implemented in CUBRID; it includes the methods of the same names with the methods of CUBRIDDataSource.

For detail examples, see **Connecting to a DataSource Object** in [JDBC Sample Program](#).

## Checking SQL LOG

The connection URL information can be printed out by calling cubrid.jdbc.driver.CUBRIDConnection.toString() method.

```
e.g.) cubrid.jdbc.driver.CUBRIDConnection(CAS ID : 1, PROCESS ID : 22922)
```

You can find SQL log of that CAS easily by CAS ID which is printed out.

For more details, see [Checking SQL Log](#).

## Checking Foreign Key Information

You can check foreign key information by using **getImportedKeys**, **getExportedKeys**, and **getCrossReference** methods of the **DatabaseMetaData** interface. The usage and example of each method are as follows:

```
getImportedKeys(String catalog, String schema, String table)

getExportedKeys(String catalog, String schema, String table)

getCrossReference(String parentCatalog, String parentSchema, String
parentTable, String foreignCatalog, String foreignSchema, String
foreignTable)
```

- **getImportedKeys** method: Retrieves information of primary key columns which are referred by foreign key columns in a given table. The results are sorted by **PKTABLE\_NAME** and **KEY\_SEQ**.
- **getExportedKeys** method: Retrieves information of all foreign key columns which refer to primary key columns in a given table. The results are sorted by **FKTABLE\_NAME** and **KEY\_SEQ**.
- **getCrossReference** method: Retrieves information of primary key columns which are referred by foreign key columns in a given table. The results are sorted by **PKTABLE\_NAME** and **KEY\_SEQ**.

## Return Value

When the methods above are called, the ResultSet consisting of 14 columns listed in the table below is returned.

| Name          | Type   | Note                                                                                                                                                   |
|---------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| PKTABLE_CAT   | String | null without exception                                                                                                                                 |
| PKTABLE_SCHEM | String | null without exception                                                                                                                                 |
| PKTABLE_NAME  | String | The name of a primary key table                                                                                                                        |
| PKCOLUMN_NAME | String | The name of a primary key column                                                                                                                       |
| FKTABLE_CAT   | String | null without exception                                                                                                                                 |
| FKTABLE_SCHEM | String | null without exception                                                                                                                                 |
| FKTABLE_NAME  | String | The name of a foreign key table                                                                                                                        |
| FKCOLUMN_NAME | String | The name of a foreign key column                                                                                                                       |
| KEY_SEQ       | short  | Sequence of columns of foreign keys or primary keys (starting from 1)                                                                                  |
| UPDATE_RULE   | short  | The corresponding values to referring actions defined as to foreign keys when primary keys are updated. Cascade=0, Restrict=2, No action=3, Set null=4 |
| DELETE_RULE   | short  | The corresponding value to referring actions defined as                                                                                                |

| Name          | Type   | Note                                                                                          |
|---------------|--------|-----------------------------------------------------------------------------------------------|
|               |        | to foreign keys when primary keys are deleted. Cascade=0, Restrict=2, No action=3, Set null=4 |
| FK_NAME       | String | Foreign key name                                                                              |
| PK_NAME       | String | Primary key name                                                                              |
| DEFERRABILITY | short  | 6 without exception (DatabaseMetaData.importedKeyInitiallyImmediate)                          |

```

## Using Object Identifiers (OIDs) and Collections

In addition to the methods defined in the JDBC specification, CUBRID JDBC driver provides methods that handle OIDs and collections (set, multiset, and sequence).

To use these methods, you must import **cubrid.sql.\***; as well as the CUBRID JDBC driver classes which are imported by default. Furthermore, you should convert to not the **ResultSet** class, which is provided by the standard JDBC API) but the **CUBRIDResultSet** class to get result.

```

import cubrid.jdbc.driver.* ;
import cubrid.sql.* ;
...

CUBRIDResultSet urs = (CUBRIDResultSet) stmt.executeQuery(
    "SELECT city FROM location");

```

### Warning

If extended API is used, transactions won't be automatically committed even though **AUTOCOMMIT** is set to TRUE. Therefore, you must explicitly commit transactions for open connections. The extended API of CUBRID is method that handle OIDs, collections, etc.

## Using OIDs

You must follow the rules below when using OIDs.

- To use **CUBRIDOID**, you must **import cubrid.sql.\***. (a)

- You can get OIDs by specifying the class name in the **SELECT** statement. It can also be used together with other properties. (b)
- **ResultSet** for queries must be received by **CUBRIDResultSet**. (c)
- The method to get OIDs from **CUBRIDResultSet** is **getOID** (). (d)
- You can get the value from OIDs by using the **getValues** () method and the result will be **ResultSet**. (e)
- You can substitute OID with a value by using the **setValues** () method. (f)
- When you use extended API, you must always execute **commit** () for connection. (g)

### Example

```
import java.sql.*;
import cubrid.sql.*; //a
import cubrid.jdbc.driver.*;

/*
CREATE TABLE oid_test(
    id INTEGER,
    name VARCHAR(10),
    age INTEGER
);

INSERT INTO oid_test VALUES(1, 'Laura', 32);
INSERT INTO oid_test VALUES(2, 'Daniel', 39);
INSERT INTO oid_test VALUES(3, 'Stephen', 38);
*/

class OID_Sample
{
    public static void main (String args [])
    {
        // Making a connection
        String url= "jdbc:cubrid:localhost:33000:demodb:public::";
        String user = "dba";
        String passwd = "";

        // SQL statement to get OID values
        String sql = "SELECT oid_test from oid_test"; //b
        // columns of the table
        String[] attr = { "id", "name", "age" } ;

        // Declaring variables for Connection and Statement
        Connection con = null;
        Statement stmt = null;
        CUBRIDResultSet rs = null;
```

```

ResultSetMetaData rsmd = null;

try {
    Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
} catch (ClassNotFoundException e) {
    throw new IllegalStateException("Unable to load Cubrid
driver", e);
}

try {
    con = DriverManager.getConnection(url, user, passwd);
    stmt = con.createStatement();
    rs = (CUBRIDResultSet)stmt.executeQuery(sql); //c
    rsmd = rs.getMetaData();

    // Printing columns
    int numOfColumn = rsmd.getColumnCount();
    for (int i = 1; i <= numOfColumn; i++ ) {
        String ColumnName = rsmd.getColumnName(i);
        String JdbcType = rsmd.getColumnTypeName(i);
        System.out.print(ColumnName );
        System.out.print("(" + JdbcType + " ");
        System.out.print(" | ");
    }
    System.out.print("\n");

    // Printing rows
    CUBRIDResultSet rsoid = null;
    int k = 1;

    while (rs.next()) {
        CUBRIDOID oid = rs.getOID(1); //d
        System.out.print("OID");
        System.out.print(" | ");
        rsoid = (CUBRIDResultSet)oid.getValues(attr); //e

        while (rsoid.next()) {
            for( int j=1; j <= attr.length; j++ ) {
                System.out.print(rsoid.getObject(j));
                System.out.print(" | ");
            }
        }
        System.out.print("\n");

        // New values of the first row
        Object[] value = { 4, "Yu-ri", 19 };
        if (k == 1) oid.setValues(attr, value); //f

        k = 0;
    }
    con.commit(); //g

```

```

    } catch(CUBRIDException e) {
        e.printStackTrace();

    } catch(SQLException ex) {
        ex.printStackTrace();

    } finally {
        if(rs != null) try { rs.close(); } catch(SQLException e) {}
        if(stmt != null) try { stmt.close(); } catch(SQLException
e) {}
        if(con != null) try { con.close(); } catch(SQLException e
{}
    }
}
}
}

```

## Using Collections

The line “a” in the example 1 is where data of collection types (**SET**, **MULTISET**, and **LIST**) is fetched from **CUBRIDResultSet**. The results are returned as array format. Note that this can be used only when data types of all elements defined in the collection types are same.

### Example 1

```

import java.sql.*;
import java.lang.*;
import cubrid.sql.*;
import cubrid.jdbc.driver.*;

// create class collection_test(
// settest set(integer),
// multisettest multiset(integer),
// listtest list(Integer)
// );
//

// insert into collection_test values({1,2,3},{1,2,3},{1,2,3});
// insert into collection_test values({2,3,4},{2,3,4},{2,3,4});
// insert into collection_test values({3,4,5},{3,4,5},{3,4,5});

class Collection_Sample
{
    public static void main (String args [])
    {
        String url= "jdbc:cubrid:127.0.0.1:33000:demodb:public::";
        String user = "";
        String passwd = "";
        String sql = "select settest,multisettest,listtest from
collection_test";
    }
}

```

```

        try {
            Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            Connection con =
DriverManager.getConnection(url,user,passwd);
            Statement stmt = con.createStatement();
            CUBRIDResultSet rs = (CUBRIDResultSet)
stmt.executeQuery(sql);
            CUBRIDResultSetMetaData rsmd = (CUBRIDResultSetMetaData)
rs.getMetaData();
            int numbofColumn = rsmd.getColumnCount();
            while (rs.next ()) {
                for (int j=1; j<=numbofColumn; j++ ) {
                    Object[] reset = (Object[])
rs.getCollection(j); //a
                    for (int m=0 ; m < reset.length ; m++)
                        System.out.print(reset[m] +",");
                    System.out.print(" | ");
                }
                System.out.print("\n");
            }
            rs.close();
            stmt.close();
            con.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

```

## Example 2

```

import java.sql.*;
import java.io.*;
import java.lang.*;
import cubrid.sql.*;
import cubrid.jdbc.driver.*;

// create class collection_test(
// settest set(integer),
// multisettest multiset(integer),
// listtest list(Integer)
// );
//
// insert into collection_test values({1,2,3},{1,2,3},{1,2,3});
// insert into collection_test values({2,3,4},{2,3,4},{2,3,4});
// insert into collection_test values({3,4,5},{3,4,5},{3,4,5});

```

```

class SetOP_Sample {
    public static void main(String args[]) {
        String url = "jdbc:cubrid:
127.0.0.1:33000:demodb:public: ";
        String user = "";
        String passwd = "";
        String sql = "select collection_test from
collection_test";
        try {

        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            CUBRIDConnection con = (CUBRIDConnection)
DriverManager.getConnection(url, user, passwd);
            Statement stmt = con.createStatement();
            CUBRIDResultSet rs = (CUBRIDResultSet)
stmt.executeQuery(sql);
            while (rs.next()) {
                CUBRIDOID oid = rs.getOID(1);
                oid.addToSet("settest",
Integer.valueOf(10));
                oid.addToSet("multisettest",
Integer.valueOf(20));
                oid.addToSequence("listtest", 1,
Integer.valueOf(30));
                oid.addToSequence("listtest", 100,
Integer.valueOf(100));
                oid.putIntoSequence("listtest", 99,
Integer.valueOf(99));
                oid.removeFromSet("settest",
Integer.valueOf(1));
                oid.removeFromSet("multisettest",
Integer.valueOf(2));
                oid.removeFromSequence("listtest",
99);
                oid.removeFromSequence("listtest",
1);
            }
            con.commit();
            rs.close();
            stmt.close();
            con.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

```

## Getting Auto Increment Column Value

Auto increment (**AUTO\_INCREMENT**) is a column-related feature that increments the numeric value of each row. For more information, see [Column Definition](#). It can be defined only for numeric domains (**SMALLINT**, **INTEGER**, **DECIMAL** ( $p, 0$ ), and **NUMERIC** ( $p, 0$ )).

Auto increment is recognized as automatically created keys in the JDBC programs. To retrieve the key, you need to specify the time to insert a row from which the automatically created key value is to be retrieved. To perform it, you must set the flag by calling **Connection.prepareStatement** and **Statement.execute** methods. In this case, the command executed should be the **INSERT** statement or **INSERT** within **SELECT** statement. For other commands, the JDBC driver ignores the flag-setting parameter.

### Steps

- Use one of the following to indicate whether or not to return keys created automatically. The following method forms are used for tables of the database server that supports the auto increment columns. Each method form can be applied only to a single-row **INSERT** statement.
  - Write the **PreparedStatement** object as shown below.

```
Connection.prepareStatement(sql statement,  
Statement.RETURN_GENERATED_KEYS);
```

- To insert a row by using the **Statement.execute** method, use the **Statement.execute** method as shown below.

```
Statement.execute(sql statement,  
Statement.RETURN_GENERATED_KEYS);
```

- Get the **ResultSet** object containing automatically created key values by calling the **PreparedStatement.getGeneratedKeys** or **Statement.getGeneratedKeys** method. Note that the data type of the automatically created keys in **ResultSet** is **DECIMAL** regardless of the data type of the given domain.

### Example

The following example shows how to create a table with auto increment, enter data into the table so that automatically created key values are entered into auto increment columns, and check whether the key values are successfully retrieved by using the **Statement.getGeneratedKeys** () method. Each step is explained in the comments for commands that correspond to the steps above.

```
import java.sql.*;  
import java.math.*;
```

```

import cubrid.jdbc.driver.*;

Connection con;
Statement stmt;
ResultSet rs;
java.math.BigDecimal idColVar;
...
stmt = con.createStatement();    // Create a Statement object

// Create table with identity column
stmt.executeUpdate(
    "CREATE TABLE EMP_PHONE (EMPNO CHAR(6), PHONENO CHAR(4), " +
    "IDENTCOL INTEGER AUTO_INCREMENT)");

stmt.execute(
    "INSERT INTO EMP_PHONE (EMPNO, PHONENO) " +
    "VALUES ('000010', '5555')",           // Insert a row
    Statement.RETURN_GENERATED_KEYS);    // Indicate you want
    automatically

rs = stmt.getGeneratedKeys();    // generated keys

// Retrieve the automatically <Step 2>
// generated key value in a ResultSet.
// Only one row is returned.
// Create ResultSet for query
while (rs.next()) {
    java.math.BigDecimal idColVar = rs.getBigDecimal(1);
    // Get automatically generated key value
    System.out.println("automatically generated key value = " +
    idColVar);
}

rs.close();                        // Close ResultSet
stmt.close();                      // Close Statement

```

## Using BLOB/CLOB

The interface that handles **LOB** data in JDBC is implemented based on JDBC 4.0 specification. The constraints of the interface are as follows:

- Only sequential write is supported when creating **BLOB** or **CLOB** object. Writing to arbitrary locations is not supported.
- You cannot change **BLOB** or **CLOB** data by calling methods of **BLOB** or **CLOB** object fetched from **ResultSet**.
- **Blob.truncate**, **Clob.truncate**, **Blob.position**, and **Clob.position** methods are supported.

- You cannot bind the LOB data by calling **PreparedStatement.setAsciiStream**, **PreparedStatement.setBinaryStream**, and **PreparedStatement.setCharacterStream** methods for **BLOB/CLOB** type columns.
- To use **BLOB / CLOB** type in the environment where JDBC 4.0 is not supported such as JDK versions 1.5 or earlier, you must do explicit type conversion for the conn object to **CUBRIDConnection**. See example below.

```
//JDK 1.6 or higher

import java.sql.*;

Connection conn = DriverManager.getConnection(url, id, passwd);
Blob blob = conn.createBlob();

//JDK 1.5 or lower

import java.sql.*;
import cubrid.jdbc.driver.*;

Connection conn = DriverManager.getConnection(url, id, passwd);
Blob blob = ((CUBRIDConnection)conn).createBlob();
```

### Storing LOB Data

You can bind the **LOB** type data in the following ways.

- Create **java.sql.Blob** or **java.sql.Clob** object, store file content in the object, use **setBlob ()** or **setClob ()** of **PreparedStatement** (example 1).
- Execute a query, get **java.sql.Blob** or **java.sql.Clob** object from the **ResultSet** object, and bind the object in **PreparedStatement** (example 2).

### Example 1

```
Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
Connection conn = DriverManager.getConnection
("jdbc:cubrid:localhost:33000:image_db:user1:password1:", "", "");

PreparedStatement pstmt1 = conn.prepareStatement("INSERT INTO
doc(image_id, doc_id, image) VALUES (?, ?, ?)");
pstmt1.setString(1, "image-21");
pstmt1.setString(2, "doc-21");

//Creating an empty file in the file system
Blob bImage = conn.createBlob();
byte[] bArray = new byte[256];
```

```

...

//Inserting data into the external file. Position is start with 1.
bImage.setBytes(1, bArray);
//Appending data into the external file
bImage.setBytes(257, bArray);
...

pstmt1.setBlob(3, bImage);
pstmt1.executeUpdate();
...

```

## Example 2

```

Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
Connection conn = DriverManager.getConnection
("jdbc:cubrid:localhost:33000:image_db:user1:password1:", "", "");
conn.setAutoCommit(false);

PreparedStatement pstmt1 = conn.prepareStatement("SELECT image FROM
doc WHERE image_id = ? ");
pstmt1.setString(1, "image-21");
ResultSet rs = pstmt1.executeQuery();

while (rs.next())
{
    Blob bImage = rs.getBlob(1);
    PreparedStatement pstmt2 = conn.prepareStatement("INSERT INTO
doc(image_id, doc_id, image) VALUES (?, ?, ?)");
    pstmt2.setString(1, "image-22");
    pstmt2.setString(2, "doc-22");
    pstmt2.setBlob(3, bImage);
    pstmt2.executeUpdate();
    pstmt2.close();
}

pstmt1.close();
conn.commit();
conn.setAutoCommit(true);
conn.close();
...

```

## Getting LOB Data

You can get the **LOB** type data in the following ways.

- Get data directly from **ResultSet** by using **getBytes ()** or **getString ()** method (example 1).

- Get the java.sql.Blob or java.sql.Clob object from **ResultSet** by calling **getBlob ()** or **getClob ()** method and get data for this object by using the **getBytes ()** or **getSubString ()** method (example 2).

### Example 1

```
Connection conn = DriverManager.getConnection
("jdbc:cubrid:localhost:33000:image_db:user1:password1:", "", "");

// Getting data directly from ResultSet
PreparedStatement pstmt1 = conn.prepareStatement("SELECT content FROM
doc_t WHERE doc_id = ? ");
pstmt1.setString(1, "doc-10");
ResultSet rs = pstmt1.executeQuery();

while (rs.next())
{
    String sContent = rs.getString(1);
    System.out.println("doc.content= "+sContent.);
}
```

### Example 2

```
Connection conn = DriverManager.getConnection
("jdbc:cubrid:localhost:33000:image_db:user1:password1:", "", "");

// Getting BLOB data from ResultSet and getting data from the BLOB
object
PreparedStatement pstmt2 = conn.prepareStatement("SELECT image FROM
image_t WHERE image_id = ?");
pstmt2.setString(1, "image-20");
ResultSet rs = pstmt2.executeQuery();

while (rs.next())
{
    Blob bImage = rs.getBlob(1);
    Bytes[] bArray = bImage.getBytes(1, (int)bImage.length());
}
```

#### Note

If a string longer than defined max length is inserted (**INSERT**) or updated (**UPDATE**), the string will be truncated.

## setBoolean

### **prepareStatement.setBoolean(1, true) will set**

- 1 for numeric types
- '1' for string types

### **prepareStatement.setBooelan(1, false) will set**

- 0 for numeric types
- '0' for string types

#### **Note**

Behavior of legacy versions

#### **prepareStatement.setBoolean(1, true) set**

- as 2008 R4.1, 9.0, 1 of BIT(1) type
- as 2008 R4.3, 2008 R4.4, 9.1, 9.2, 9.3, -128 of SHORT type

## JDBC Error Codes and Error Messages

JDBC error codes which occur in SQLException are as follows.

- All error codes are negative.
- After SQLException, error number can be shown by SQLException.getErrorCode() and error message can be shown by SQLException.getMessage().
- If the value of error code is between -21001 and -21999, it is caused by CUBRID JDBC methods.
- If the value of error code is between -10000 and -10999, it is caused by CAS and transferred by JDBC methods. For CAS errors, see [CAS Error](#).
- If the value of error code is between 0 and -9999, it is caused by database server. For database server errors, see [Database Server Errors](#).

| Error Number | Error Message                |
|--------------|------------------------------|
| -21001       | Index's Column is Not Object |

| Error Number | Error Message                                                       |
|--------------|---------------------------------------------------------------------|
| -21002       | Server error                                                        |
| -21003       | Cannot communicate with the broker                                  |
| -21004       | Invalid cursor position                                             |
| -21005       | Type conversion error                                               |
| -21006       | Missing or invalid position of the bind variable provided           |
| -21007       | Attempt to execute the query when not all the parameters are binded |
| -21008       | Internal Error: NULL value                                          |
| -21009       | Column index is out of range                                        |
| -21010       | Data is truncated because receive buffer is too small               |
| -21011       | Internal error: Illegal schema type                                 |
| -21012       | File access failed                                                  |
| -21013       | Cannot connect to a broker                                          |
| -21014       | Unknown transaction isolation level                                 |
| -21015       |                                                                     |

| Error Number | Error Message                                                 |
|--------------|---------------------------------------------------------------|
|              | Internal error: The requested information is not available    |
| -21016       | The argument is invalid                                       |
| -21017       | Connection or Statement might be closed                       |
| -21018       | Internal error: Invalid argument                              |
| -21019       | Cannot communicate with the broker or received invalid packet |
| -21020       | No More Result                                                |
| -21021       | This ResultSet do not include the OID                         |
| -21022       | Command is not insert                                         |
| -21023       | Error                                                         |
| -21024       | Request timed out                                             |
| -21101       | Attempt to operate on a closed Connection.                    |
| -21102       | Attempt to access a closed Statement.                         |
| -21103       | Attempt to access a closed PreparedStatement.                 |
| -21104       | Attempt to access a closed ResultSet.                         |

| Error Number | Error Message                                                                       |
|--------------|-------------------------------------------------------------------------------------|
| -21105       | Not supported method                                                                |
| -21106       | Unknown transaction isolation level.                                                |
| -21107       | invalid URL -                                                                       |
| -21108       | The database name should be given.                                                  |
| -21109       | The query is not applicable to the executeQuery(). Use the executeUpdate() instead. |
| -21110       | The query is not applicable to the executeUpdate(). Use the executeQuery() instead. |
| -21111       | The length of the stream cannot be negative.                                        |
| -21112       | An IOException was caught during reading the inputstream.                           |
| -21113       | Not supported method, because it is deprecated.                                     |
| -21114       | The object does not seem to be a number.                                            |
| -21115       | Missing or invalid position of the bind variable provided.                          |
| -21116       | The column name is invalid.                                                         |

| Error Number | Error Message                                                                  |
|--------------|--------------------------------------------------------------------------------|
| -21117       | Invalid cursor position.                                                       |
| -21118       | Type conversion error.                                                         |
| -21119       | Internal error: The number of attributes is different from the expected.       |
| -21120       | The argument is invalid.                                                       |
| -21121       | The type of the column should be a collection type.                            |
| -21122       | Attempt to operate on a closed DatabaseMetaData.                               |
| -21123       | Attempt to call a method related to scrollability of non-scrollable ResultSet. |
| -21124       | Attempt to call a method related to sensitivity of non-sensitive ResultSet.    |
| -21125       | Attempt to call a method related to updatability of non-updatable ResultSet.   |
| -21126       | Attempt to update a column which cannot be updated.                            |
| -21127       | The query is not applicable to the executeInsert().                            |
| -21128       | The argument row can not be zero.                                              |

| Error Number | Error Message                                                                     |
|--------------|-----------------------------------------------------------------------------------|
| -21129       | Given InputStream object has no data.                                             |
| -21130       | Given Reader object has no data.                                                  |
| -21131       | Insertion query failed.                                                           |
| -21132       | Attempt to call a method related to scrollability of TYPE_FORWARD_ONLY Statement. |
| -21133       | Authentication failure                                                            |
| -21134       | Attempt to operate on a closed PooledConnection.                                  |
| -21135       | Attempt to operate on a closed XAConnection.                                      |
| -21136       | Illegal operation in a distributed transaction                                    |
| -21137       | Attempt to access a CUBRIDOID associated with a Connection which has been closed. |
| -21138       | The table name is invalid.                                                        |
| -21139       | Lob position to write is invalid.                                                 |
| -21140       | Lob is not writable.                                                              |
| -21141       | Request timed out.                                                                |

## JDBC Sample Program

The following sample shows how to connect to CUBRID by using the JDBC driver, and retrieve and insert data. To run the sample program, make sure that the database you are trying to connect to and the CUBRID broker are running. In the sample, you will use the *demodb* database that is automatically created during the installation.

### Loading JDBC Driver

To connect to CUBRID, load the JDBC driver by using the **forName** () method of the **Class**. For more information, see [JDBC Overview](#) of the JDBC driver.

```
Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
```

### Connecting to Database

After loading the JDBC driver, use the **getConnection** () method of the **DriverManager** to connect to the database. To create a **Connection** object, you must specify information such as the URL which indicates the location of a database, user name, password, etc. For more information, see [Configuration Connection](#).

```
String url = "jdbc:cubrid:localhost:33000:demodb::";  
String userid = "dba";  
String password = "";  
  
Connection conn = DriverManager.getConnection(url,userid,password);
```

To connect to a database, it is possible to use a **DataSource** object, too. If you want to include connection properties to a connection URL string, **setURL** method implemented in **CUBRIDDataSource** can be used.

```
import cubrid.jdbc.driver.CUBRIDDataSource;  
...  
  
ds = new CUBRIDDataSource();  
ds.setURL("jdbc:cubrid:127.0.0.1:33000:demodb::?  
charset=utf8&logSlowQueries=true&slowQueryThresholdMillis=1000&logTraceApi=true&logTraceNetwork=true");
```

For details about **CUBRIDDataSource**, see [Connecting with DataSource](#).

### Connecting to a DataSource Object

The following is an example to execute SELECT statements in multiple threads; they connect to DB with the setURL of CUBRIDDataSource, which is a DataSource implemented in CUBRID. Codes are separated with DataSourceMT.java and DataSourceExample.java.

- DataSourceMT.java includes a main() function. After a CUBRIDDataSource object is created and a setURL method is called to connect to DB, multiple threads run DataSourceExample.test method.
- In DataSourceExample.java, DataSourceExample.test is implemented; it is run on the threads in DataSourceMT.java.

DataSourceMT.java

```
import cubrid.jdbc.driver.*;

public class DataSourceMT {
    static int num_thread = 20;

    public static void main(String[] args) {
        CUBRIDDataSource ds = null;
        thrCPDSMT thread[];

        ds = new CUBRIDDataSource();
        ds.setURL("jdbc:cubrid:127.0.0.1:33000:demodb::?
charset=utf8&logSlowQueries=true&slowQueryThresholdMillis=1000&logTraceApi=true&logTraceNetwork=true");

        try {
            thread = new thrCPDSMT[num_thread];

            for (int i = 0; i < num_thread; i++) {
                Thread.sleep(1);
                thread[i] = new thrCPDSMT(i, ds);
                try {
                    Thread.sleep(1);
                    thread[i].start();
                } catch (Exception e) {
                }
            }

            for (int i = 0; i < num_thread; i++) {
                thread[i].join();
                System.err.println("join thread : " + i);
            }

        } catch (Exception e) {
            e.printStackTrace();
            System.exit(-1);
        }
    }
}
```

```

}

            System.exit(-1);
        }
    }
}

```

*DataSourceExample.java*

```

import java.sql.*;
import javax.sql.*;
import cubrid.jdbc.driver.*;

public class DataSourceExample {

    public static void printdata(ResultSet rs) throws SQLException {
        try {
            ResultSetMetaData rsmd = null;

            rsmd = rs.getMetaData();
            int numberOfColumn = rsmd.getColumnCount();

            while (rs.next()) {
                for (int j = 1; j <= numberOfColumn; j++)
                    System.out.print(rs.getString(j) + " ");
                System.out.println("");
            }
        } catch (SQLException e) {
            System.out.println("SQLException : " + e.getMessage());
            throw e;
        }
    }

    public static void test(CUBRIDDataSource ds) throws Exception {
        Connection connection = null;
    }
}

```

```

Statement statement = null;
ResultSet resultSet = null;

for (int i = 1; i <= 20; i++) {
    try {
        connection = ds.getConnection("dba", "");
        statement = connection.createStatement();
        String SQL = "SELECT * FROM code";
        resultSet = statement.executeQuery(SQL);

        while (resultSet.next()) {
            printdata(resultSet);
        }

        if (i % 5 == 0) {
            System.gc();
        }
    } catch (Exception e) {
        e.printStackTrace();
    } finally {
        closeAll(resultSet, statement, connection);
    }
}

public static void closeAll(ResultSet resultSet, Statement
statement,
    Connection connection) {
    if (resultSet != null) {
        try {
            resultSet.close();
        } catch (SQLException e) {
        }
    }
    if (statement != null) {
        try {
            statement.close();
        } catch (SQLException e) {
        }
    }
    if (connection != null) {
        try {
            connection.close();
        } catch (SQLException e) {
        }
    }
}
}

```

To send a query statement to the connected database and execute it, create **Statement**, **PreparedStatement**, and **CallableStatement** objects. After the **Statement** object is created, execute the query statement by using **executeQuery ()** or **executeUpdate ()** method of the **Statement** object. You can use the **next ()** method to process the next row from the **ResultSet** that has been returned as a result of executing the **executeQuery ()** method.

### Note

In the version of 2008 R4.x or before, if you execute commit after query execution, **ResultSet** will be automatically closed. Therefore, you must not use **ResultSet** after commit. Generally CUBRID is executed in auto-commit mode; if you do not want for CUBRID being executed in auto-commit mode, you should specify **conn.setAutoCommit(false);** in the code.

From 9.1, **Cursor holdability** is supported; therefore, you can use **ResultSet** after commit.

## Disconnecting from Database

You can disconnect from a database by executing the **close ()** method for each object.

## CREATE, INSERT

The following is an example which connects to *demodb*, creates a table, executes a query with prepared statement and rolls back the query.

```
import java.util.*;
import java.sql.*;

public class Basic {
    public static Connection connect() {
        Connection conn = null;
        try {
            Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
            conn = DriverManager.getConnection("jdbc:cubrid:localhost:
33000:demodb::", "dba", "");
            conn.setAutoCommit (false) ;
        } catch ( Exception e ) {
            System.err.println("SQLException : " + e.getMessage());
        }
        return conn;
    }

    public static void printdata(ResultSet rs) {
        try {
            ResultSetMetaData rsmd = null;

            rsmd = rs.getMetaData();
```

```

        int numberOfColumn = rsmd.getColumnCount();

        while (rs.next ()) {
            for(int j=1; j<=numberOfColumn; j++ )
                System.out.print(rs.getString(j) + "  " );
            System.out.println("");
        }
    } catch ( Exception e ) {
        System.err.println("SQLException : " + e.getMessage());
    }
}

public static void main(String[] args) throws Exception {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;
    PreparedStatement preStmt = null;

    try {
        conn = connect();

        stmt = conn.createStatement();
        stmt.executeUpdate("CREATE TABLE xoo ( a INT, b INT, c
CHAR(10))");

        preStmt = conn.prepareStatement("INSERT INTO xoo
VALUES(?,?, '100')");
        preStmt.setInt (1, 1) ;
        preStmt.setInt (2, 1*10) ;
        int rst = preStmt.executeUpdate () ;

        rs = stmt.executeQuery("select a,b,c from xoo" );

        printdata(rs);

        conn.rollback();
        stmt.close();
        conn.close();
    } catch ( Exception e ) {
        conn.rollback();
        System.err.println("SQLException : " + e.getMessage());
    } finally {
        if ( conn != null ) conn.close();
    }
}
}

```

## SELECT

The following example shows how to execute the **SELECT** statement by connecting to *demodb* which is automatically created when installing CUBRID.

```

import java.sql.*;

public class SelectData {
    public static void main(String[] args) throws Exception {
        Connection conn = null;
        Statement stmt = null;
        ResultSet rs = null;

        try {
            Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
            conn =
DriverManager.getConnection("jdbc:cubrid:localhost:
33000:demodb::", "dba", "");

            String sql = "SELECT name, players FROM event";
            stmt = conn.createStatement();
            rs = stmt.executeQuery(sql);

            while(rs.next()) {
                String name = rs.getString("name");
                String players = rs.getString("players");
                System.out.println("name ==> " + name);
                System.out.println("Number of players==> " + players);

System.out.println("\n=====");
            }

            rs.close();
            stmt.close();
            conn.close();
        } catch ( SQLException e ) {
            System.err.println(e.getMessage());
        } catch ( Exception e ) {
            System.err.println(e.getMessage());
        } finally {
            if ( conn != null ) conn.close();
        }
    }
}

```

## INSERT

The following example shows how to execute the **INSERT** statement by connecting to *demodb* which is automatically created when installing CUBRID. You can delete or update data the same way as you insert data so you can reuse the code below by simply modifying the query statement in the code.

```

import java.sql.*;

```

```

public class insertData {
    public static void main(String[] args) throws Exception {
        Connection conn = null;
        Statement stmt = null;

        try {
            Class.forName("cubrid.jdbc.driver.CUBRIDDriver");
            conn = DriverManager.getConnection("jdbc:cubrid:localhost:
33000:demodb:::", "dba", "");
            String sql = "insert into olympic(host_year, host_nation,
host_city, opening_date, closing_date) values (2008, 'China',
'Beijing', to_date('08-08-2008','mm-dd-yyyy'),
to_date('08-24-2008','mm-dd-yyyy'))";
            stmt = conn.createStatement();
            stmt.executeUpdate(sql);
            System.out.println("A row is inserted.");
            stmt.close();
        } catch ( SQLException e ) {
            System.err.println(e.getMessage());
        } catch ( Exception e ) {
            System.err.println(e.getMessage());
        } finally {
            if ( conn != null ) conn.close();
        }
    }
}

```

## JDBC API

For details about JDBC API, see Java API Specification (<https://docs.oracle.com/javase/7/docs/api/>) and for details about Java, see Java SE Documentation (<https://www.oracle.com/java/technologies/javase-documentation.html>).

If **cursor holdability** is not configured, a cursor is maintained by default.

The following table shows the JDBC standard and extended interface supported by CUBRID. Note that some methods are not supported even though they are included in the JDBC 2.0 specification.

### Supported JDBC Interface by CUBRID

| JDBC Standard Interface    | JDBC Extended Interface | Supported |
|----------------------------|-------------------------|-----------|
| java.sql.Blob              |                         | Supported |
| java.sql.CallableStatement |                         | Supported |

| JDBC Standard Interface    | JDBC Extended Interface          | Supported                                               |
|----------------------------|----------------------------------|---------------------------------------------------------|
| java.sql.Clob              |                                  | Supported                                               |
| java.sql.Connection        |                                  | Supported                                               |
| java.sql.DatabaseMetaData  |                                  | Supported                                               |
| java.sql.Driver            |                                  | Supported                                               |
| java.sql.PreparedStatement | java.sql.CUBRIDPreparedStatement | Supported                                               |
| java.sql.ResultSet         | java.sql.CUBRIDResultSet         | Supported                                               |
| java.sql.ResultSetMetaData | java.sql.CUBRIDResultSetMetaData | Supported                                               |
| N/A                        | CUBRIDOID                        | Supported                                               |
| java.sql.Statement         | java.sql.CUBRIDStatement         | The getGeneratedKeys() method of JDBC 3.0 is supported. |
| java.sql.DriverManager     |                                  | Supported                                               |
| Java.sql.SQLException      | Java.sql.CUBRIDException         | Supported                                               |
| java.sql.Array             |                                  | Not Supported                                           |
| java.sql.ParameterMetaData |                                  | Not Supported                                           |

| JDBC Standard Interface | JDBC Extended Interface | Supported     |
|-------------------------|-------------------------|---------------|
| java.sql.Ref            |                         | Not Supported |
| java.sql.Savepoint      |                         | Not Supported |
| java.sql.SQLData        |                         | Not Supported |
| java.sql.SQLInput       |                         | Not Supported |
| java.sql.Struct         |                         | Not Supported |

#### Note

- If **cursor holdability** is not specified, cursor is hold in default.
- From CUBRID 2008 R4.3 version, the behavior of batching the queries on the autocommit mode was changed. The methods that batch the queries are PreparedStatement.executeBatch and Statement.executeBatch. Until 2008 R4.1 version, these methods had committed the transaction after executing all queries on the array. From 2008 R4.3, they commit each query on the array.
- In autocommit mode off, if the general error occurs during executing one of the queries in the array on the method which does a batch processing of the queries, the query with an error is ignored and the next query is executed continuously. But if the deadlock occurs, the error occurs as rolling back the transaction.

## CCI Driver

### CCI Overview

CUBRID CCI (C Client Interface) driver implements an interface to enable access from C-based application to CUBRID database server through broker. It is also used as back-end infrastructure

for creating tools (PHP, ODBC, etc.) which use the CAS application servers. In this environment, the CUBRID broker sends queries received from applications to a database and transfers the result to applications.

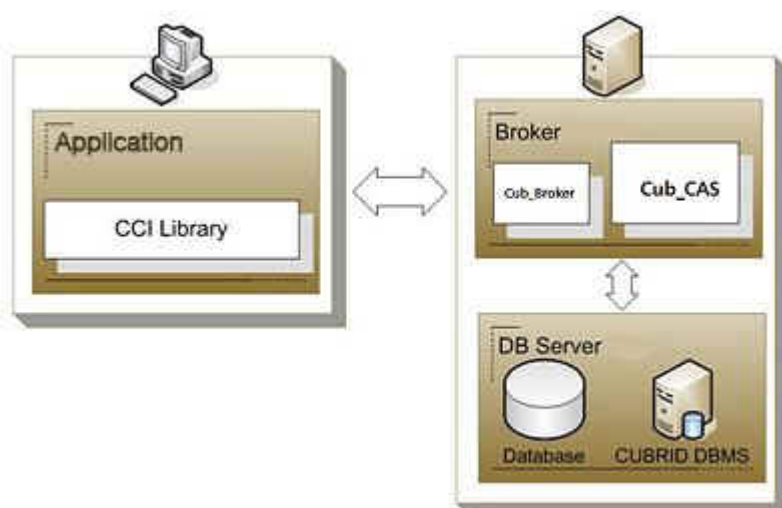

It is automatically installed upon CUBRID installation and can be found in the **\$CUBRID/lib** directory. A header file as well as library files is required to use the driver.

|                 | Windows               | UNIX/Linux            |
|-----------------|-----------------------|-----------------------|
| C header file   | cci/include/cas_cci.h | cci/include/cas_cci.h |
| Static library  | cci/lib/cascci.lib    | cci/lib/libcascci.a   |
| Dynamic library | cci/bin/cascci.dll    | cci/lib/libcascci.so  |

#### **Note**

- For Windows, Microsoft Visual C++ 2015 Redistributable (x86 or x64) must be installed to use the CCI Driver.
- From 11.2 Version, the path to the CCI driver has been changed. (cci/include, cci/lib, cci/bin)

Because CUBRID CCI driver is connected through the CUBRID broker, you can manage it the same way as other interfaces such as JDBC, PHP, ODBC, etc. In fact, CCI provides back-end infrastructure to implement PHP, ODBC, Python, and Ruby interfaces.

## CCI Programming

### Writing CCI Applications

The applications using CCI interact with CUBRID in the process of connecting to CAS, preparing queries, executing queries, handling response, and disconnecting. In each process, CCI communicates with applications through connection handle, query handle, and response handle.

The default value of auto-commit mode can be configured by using `CCI_DEFAULT_AUTOCOMMIT` which is a broker parameter. If it is omitted, the default value is set to **ON**. To change auto-commit mode within applications, you should use the `cci_set_autocommit()` function. If auto-commit mode is **OFF**, you should explicitly commit or roll back transactions by using the `cci_end_tran()` function.

General process for writing applications is as follows. For using the prepared statement, additional step binding data to a variable is required; the examples 1 and 2 show the way to implement this.

- Opening a database connection handle (related functions: `cci_connect()`, `cci_connect_with_url()` )
- Getting the request handle for the prepared statement (related function: `cci_prepare()` )
- Binding data to the prepared statement (related function: `cci_bind_param()` )
- Executing the prepared statement (related function: `cci_execute()` )
- Processing the execution result (related functions: `cci_cursor()`, `cci_fetch()`, `cci_get_data()`, `cci_get_result_info()` )
- Closing the request handle (related function: `cci_close_req_handle()` )
- Closing the database connection handle (related function: `cci_disconnect()` )
- Using database connection pool (related functions: `cci_property_create()`, `cci_property_destroy()`, `cci_property_set()`, `cci_datasource_create()`, `cci_datasource_destroy()`, `cci_datasource_borrow()`, `cci_datasource_release()`, `cci_datasource_change_property()` )

#### Note

- If you want to compile the CCI application on Windows, "WINDOWS" should be defined. Therefore, "-DWINDOWS" option should be defined on the compiler.
- The database connection in thread-based programming must be used independently each other.

- In autocommit mode, the transaction is not committed if all results are not fetched after running the SELECT statement. Therefore, although in autocommit mode, you should end the transaction by calling `cci_end_tran()` if some error occurs during fetching for the resultset.

### Example 1

```
// Example to execute a simple query
// In Linux: gcc -o simple simple.c -m64 -I${CUBRID}/cci/include -
lnsl ${CUBRID}/cci/lib/libcascci.so -lpthread

#include <stdio.h>
#include "cas_cci.h"
#define BUFSIZE (1024)

int
main (void)
{
    int con = 0, req = 0, col_count = 0, i, ind;
    int error;
    char *data;
    T_CCI_ERROR cci_error;
    T_CCI_COL_INFO *col_info;
    T_CCI_CUBRID_STMT stmt_type;
    char *query = "select * from code";

    //getting a connection handle for a connection with a server
    con = cci_connect ("localhost", 33000, "demodb", "dba", "");
    if (con < 0)
    {
        printf ("cannot connect to database\n");
        return 1;
    }

    //preparing the SQL statement
    req = cci_prepare (con, query, 0, &cci_error);
    if (req < 0)
    {
        printf ("prepare error: %d, %s\n", cci_error.err_code,
                cci_error.err_msg);
        goto handle_error;
    }

    //getting column information when the prepared statement is the
    SELECT query
    col_info = cci_get_result_info (req, &stmt_type, &col_count);
    if (col_info == NULL)
    {
```

```

        printf ("get_result_info error: %d, %s\n",
cci_error.err_code,
                cci_error.err_msg);
        goto handle_error;
    }

    //Executing the prepared SQL statement
    error = cci_execute (req, 0, 0, &cci_error);
    if (error < 0)
    {
        printf ("execute error: %d, %s\n", cci_error.err_code,
                cci_error.err_msg);
        goto handle_error;
    }
    while (1)
    {

        //Moving the cursor to access a specific tuple of results
        error = cci_cursor (req, 1, CCI_CURSOR_CURRENT, &cci_error);
        if (error == CCI_ER_NO_MORE_DATA)
        {
            break;
        }
        if (error < 0)
        {
            printf ("cursor error: %d, %s\n", cci_error.err_code,
                    cci_error.err_msg);
            goto handle_error;
        }

        //Fetching the query result into a client buffer
        error = cci_fetch (req, &cci_error);
        if (error < 0)
        {
            printf ("fetch error: %d, %s\n", cci_error.err_code,
                    cci_error.err_msg);
            goto handle_error;
        }
        for (i = 1; i <= col_count; i++)
        {

            //Getting data from the fetched result
            error = cci_get_data (req, i, CCI_A_TYPE_STR, &data,
&ind);
            if (error < 0)
            {
                printf ("get_data error: %d, %d\n", error, i);
                goto handle_error;
            }
            printf ("%s\t|", data);
        }
        printf ("\n");
    }

```

```

    }

    //Closing the request handle
    error = cci_close_req_handle (req);
    if (error < 0)
    {
        printf ("close_req_handle error: %d, %s\n",
cci_error.err_code,
                cci_error.err_msg);

        if (error == CCI_ER_NO_MORE_DATA)
        {
            break;
        }
        if (error < 0)
        {
            printf ("cursor error: %d, %s\n", err.err_code, err.err_msg);
            goto cci_work_end;
        }

        error = cci_fetch (req, &err);
        if (error < 0)
        {
            printf ("fetch error: %d, %s\n", err.err_code, err.err_msg);
            goto cci_work_end;
        }
    }
}
```

```
error = cci_get_data (req, 1, CCI_A_TYPE_INT, &data, &ind);
if (error < 0)
{
    printf ("get data error: %d\n", error);
    goto cci_work_end;
}
printf ("%d\n", data);
}

error = 1;
cci_work_end:
cci_close_req_handle (req);
return error;
}
```

## Configuring Library

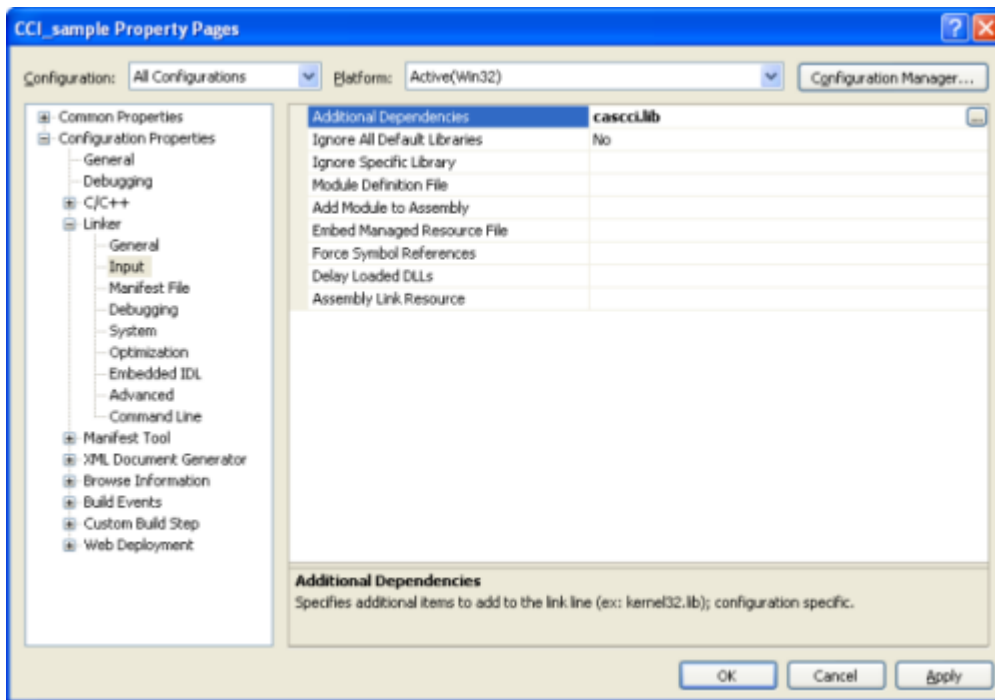

Once you have written applications using CCI, you should decide, according to its features, whether to execute CCI as static or dynamic link before you build it. See the table in [CCI Overview](#) to decide which library will be used.

The following is an example of Makefile, which makes a link by using the dynamic library on UNIX/Linux.

```
CC=gcc
CFLAGS = -g -Wall -I. -I$(CUBRID)/cci/include
LDFLAGS = -L$(CUBRID)/cci/lib -lcascci -lnsl

TEST_OBJS = test.o
EXES = test
all: $(EXES)
test: $(TEST_OBJS)
    $(CC) -o $@ $(TEST_OBJS) $(LDFLAGS)
```

The following image shows configuration to use static library on Windows.

## Using BLOB/CLOB

### Storing LOB Data

You can create **LOB** data file and bind the data by using the functions below in CCI applications.

- Creating **LOB** data files (related functions: `cci_blob_new()` , `cci_blob_write()` )
- Binding **LOB** data (related function: `cci_bind_param()` )
- Freeing memory for **LOB** struct (related function: `cci_blob_free()` )

### Example

```
int con = 0; /* connection handle */
int req = 0; /* request handle */
int res;
int n_executed;
int i;
T_CCI_ERROR error;
T_CCI_BLOB blob = NULL;
char data[1024] = "bulabula";

con = cci_connect ("localhost", 33000, "tdb", "PUBLIC", "");
if (con < 0) {
    goto handle_error;
}
req = cci_prepare (con, "insert into doc (doc_id, content) values
(?,?)", 0, &error);
if (req < 0)
```

```

{
    goto handle_error;
}

res = cci_bind_param (req, 1 /* binding index*/, CCI_A_TYPE_STR,
"doc-10", CCI_U_TYPE_STRING, CCI_BIND_PTR);

/* Creating an empty LOB data file */
res = cci_blob_new (con, &blob, &error);
res = cci_blob_write (con, blob, 0 /* start position */, 1024 /*
length */, data, &error);

/* Binding BLOB data */
res = cci_bind_param (req, 2 /* binding index*/, CCI_A_TYPE_BLOB,
(void *)blob, CCI_U_TYPE_BLOB, CCI_BIND_PTR);

n_executed = cci_execute (req, 0, 0, &error);
if (n_executed < 0)
{
    goto handle_error;
}

/* Commit */
if (cci_end_tran(con, CCI_TRAN_COMMIT, &error) < 0)
{
    goto handle_error;
}

/* Memory free */
cci_blob_free(blob);
return 0;

handle_error:
if (blob != NULL)
{
    cci_blob_free(blob);
}
if (req > 0)
{
    cci_close_req_handle (req);
}
if (con > 0)
{
    cci_disconnect(con, &error);
}
return -1;

```

## Retrieving LOB Data

You can retrieve **LOB** data by using the following functions in CCI applications. Note that if you enter data in the **LOB** type column, the actual **LOB** data is stored in the file located in external

storage and Locator value is stored in the **LOB** type column. Thus, to retrieve the **LOB** data stored in the file, you should call the `cci_blob_read()` function but the `cci_get_data()` function.

- Retrieving meta data (Locator) in the the **LOB** type column (related function: `cci_get_data()` )
- Retrieving the **LOB** data (related function: `cci_blob_read()` )
- Freeing memory for the **LOB** struct: (related function: `cci_blob_free()` )

### Example

```
int con = 0; /* connection handle */
int req = 0; /* request handle */
int ind; /* NULL indicator, 0 if not NULL, -1 if NULL*/
int res;
int i;
T_CCI_ERROR error;
T_CCI_BLOB blob;
char buffer[1024];

con = cci_connect ("localhost", 33000, "image_db", "PUBLIC", "");
if (con < 0)
{
    goto handle_error;
}
req = cci_prepare (con, "select content from doc_t", 0 /*flag*/,
&error);
if (req< 0)
{
    goto handle_error;
}

res = cci_execute (req, 0/*flag*/, 0/*max_col_size*/, &error);

while (1) {
    res = cci_cursor (req, 1/* offset */, CCI_CURSOR_CURRENT/*
cursor position */, &error);
    if (res == CCI_ER_NO_MORE_DATA)
    {
        break;
    }
    res = cci_fetch (req, &error);

    /* Fetching CLOB Locator */
    res = cci_get_data (req, 1 /* colume index */, CCI_A_TYPE_BLOB,
(void *)&blob /* BLOB handle */, &ind /* NULL indicator */);
    /* Fetching CLOB data */
    res = cci_blob_read (con, blob, 0 /* start position */, 1024 /*
length */, buffer, &error);
    printf ("content = %s\n", buffer);
}
```

```
/* Memory free */
cci_blob_free(blob);
res=cci_close_req_handle(req);
res = cci_disconnect (con, &error);
return 0;

handle_error:
if (req > 0)
{
    cci_close_req_handle (req);
}
if (con > 0)
{
    cci_disconnect(con, &error);
}
return -1;
```

## CCI Error Codes and Error Messages

CCI API functions return a negative number as CCI or CAS (broker application server) error codes when an error occurs. The CCI error codes occur in CCI API functions and CAS error codes occur in CAS.

- All error codes are negative.
- All error codes and error messages of functions which have “T\_CCI\_ERROR err\_buf” as a parameter can be found on err\_buf.err\_code and err\_buf.err\_msg.
- All error messages of functions which have no “T\_CCI\_ERROR err\_buf” as a parameter can output by using `cci_get_err_msg()`.
- If the value of error code is between -20002 and -20999, it is caused by CCI API functions.
- If the value of error code is between -10000 and -10999, it is caused by CAS and transferred by CCI API functions. For CAS errors, see [CAS Error](#).
- If the value of error code is **CCI\_ER\_DBMS** (-20001), it is caused by database server. You can check server error codes in err\_buf.err\_code of the database error buffer (err\_buf). For database server errors, see [Database Server Errors](#).

### Warning

If an error occurs in server, the value of **CCI\_ER\_DBMS**, which is error code returned by a function may be different from the value of the `err_buf.err_code`. Except server errors, every error code stored in `err_buf` is identical to that returned by a function.

### Note

CCI and CAS error codes have different values between the earlier version of CUBRID 9.0 and the version of CUBRID 9.0 or later. Therefore, the users who developed the applications by using the error code names must recompile them and the users who developed them by directly assigning error code numbers must recompile them after changing the number values.

The database error buffer (`err_buf`) is a struct variable of `T_CCI_ERROR` defined in the **cas\_cci.h** header file. For how to use it, see the example below.

CCI error codes which starting with **CCI\_ER** are defined in enum called **T\_CCI\_ERROR\_CODE** under the **\$CUBRID/include/cas\_cci.h** file. Therefore, to use this error code name in program code, you should include a header file in the upper side of code by entering **#include "cas\_cci.h"**.

The following example shows how to display error messages. In the example, the error code value (`req`) returned by `cci_prepare()` is **CCI\_ER\_DBMS**. -493 (server error code) is stored in **cci\_error.err\_code** and the error message, 'Syntax: Unknown class "notable". select \* from notable' is stored in **cci\_error.err\_msg** of the database error buffer.

```
// gcc -o err err.c -m64 -I${CUBRID}/cci/include -lnsl ${CUBRID}/cci/
lib/libcascci.so -lpthread
#include <stdio.h>
#include "cas_cci.h"

#define BUFSIZE (1024)

int
main (void)
{
    int con = 0, req = 0, col_count = 0, i, ind;
    int error;
    char *data;
    T_CCI_ERROR err_buf;
    char *query = "select * from notable";

    //getting a connection handle for a connection with a server
    con = cci_connect ("localhost", 33000, "demodb", "dba", "");
    if (con < 0)
    {
```

```

        printf ("cannot connect to database\n");
        return 1;
    }

    //preparing the SQL statement
    req = cci_prepare (con, query, 0, &err_buf);
    if (req < 0)
    {
        if (req == CCI_ER_DBMS)
        {
            printf ("error from server: %d, %s\n", err_buf.err_code,
err_buf.err_msg);
        }
        else
        {
            printf ("error from cci or cas: %d, %s\n",
err_buf.err_code, err_buf.err_msg);
        }
        goto handle_error;
    }
    // ...
}

```

The following list shows CCI error codes. For CAS errors, see [CAS Error](#).

| Error Code (Error Number)      | Error Message                  | Note                                                                                                                                                                 |
|--------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCI_ER_DBMS (-20001)           | CUBRID DBMS Error              | Error codes returned by functions when an error occurs in server. The causes of the error can be checked with err_code and err_msg stored in the T_CCI_ERROR struct. |
| CCI_ER_CON_HANDLE (-20002)     | Invalid connection handle      |                                                                                                                                                                      |
| CCI_ER_NO_MORE_MEMORY (-20003) | Memory allocation error        | Insufficient memory                                                                                                                                                  |
| CCI_ER_COMMUNICATION (-20004)  | Cannot communicate with server |                                                                                                                                                                      |

| Error Code (Error Number)          | Error Message                   | Note                                                                                                                            |
|------------------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| CCI_ER_NO_MORE_DATA<br>(-20005)    | Invalid cursor position         |                                                                                                                                 |
| CCI_ER_TRAN_TYPE (-20006)          | Unknown transaction type        |                                                                                                                                 |
| CCI_ER_STRING_PARAM<br>(-20007)    | Invalid string argument         | An error occurred when <code>sql_stmt</code> is NULL in <code>cci_prepare()</code> , and <code>cci_prepare_and_execute()</code> |
| CCI_ER_TYPE_CONVERSION<br>(-20008) | Type conversion error           | Cannot convert the given value into an actual data type.                                                                        |
| CCI_ER_BIND_INDEX (-20009)         | Parameter index is out of range | Index that binds data is not valid.                                                                                             |
| CCI_ER_ATYPE (-20010)              | Invalid T_CCI_A_TYPE value      |                                                                                                                                 |
| CCI_ER_NOT_BIND (-20011)           |                                 | Not available                                                                                                                   |
| CCI_ER_PARAM_NAME (-20012)         | Invalid T_CCI_DB_PARAM value    |                                                                                                                                 |
| CCI_ER_COLUMN_INDEX<br>(-20013)    | Column index is out of range    |                                                                                                                                 |
| CCI_ER_SCHEMA_TYPE (-20014)        |                                 | Not available                                                                                                                   |

| Error Code (Error Number)               | Error Message                                                       | Note |
|-----------------------------------------|---------------------------------------------------------------------|------|
| CCI_ER_DATASOURCE_TIMEOUT<br>(-20036)   |                                                                     |      |
| CCI_ER_DATASOURCE_TIMEDWAIT<br>(-20037) | pthread_cond_timedwait<br>error                                     |      |
| CCI_ER_LOGIN_TIMEOUT<br>(-20038)        | Connection timed out                                                |      |
| CCI_ER_QUERY_TIMEOUT<br>(-20039)        | Request timed out                                                   |      |
| CCI_ER_RESULT_SET_CLOSED<br>(-20040)    |                                                                     |      |
| CCI_ER_INVALID_HOLDABILITY<br>(-20041)  | Invalid holdability mode.<br>The only accepted values<br>are 0 or 1 |      |
| CCI_ER_NOT_UPDATABLE<br>(-20042)        | Request handle is not<br>updatable                                  |      |
| CCI_ER_INVALID_ARGS (-20043)            | Invalid argument                                                    |      |
| CCI_ER_USED_CONNECTION<br>(-20044)      | This connection is used<br>already.                                 |      |

## C Type Definition

The following shows the structs used in CCI API functions.

| Name          | Type   | Member             | Description                                                |
|---------------|--------|--------------------|------------------------------------------------------------|
| T_CCI_ERROR   | struct | char err_msg[1024] | Representation of database error info                      |
|               |        | int err_code       |                                                            |
| T_CCI_BIT     | struct | int size           | Representation of bit type                                 |
|               |        | char *buf          |                                                            |
| T_CCI_DATE    | struct | short yr           | Representation of datetime, timestamp, date, and time type |
|               |        | short mon          |                                                            |
|               |        | short day          |                                                            |
|               |        | short hh           |                                                            |
|               |        | short mm           |                                                            |
|               |        | short ss           |                                                            |
| T_CCI_DATE_TZ | struct | short ms           | Representation of date/time types with timezone            |
|               |        | short yr           |                                                            |
|               |        | short mon          |                                                            |
|               |        | short day          |                                                            |
|               |        | short hh           |                                                            |

| Name                      | Type   | Member                          | Description                                                          |
|---------------------------|--------|---------------------------------|----------------------------------------------------------------------|
|                           |        | short mm                        |                                                                      |
|                           |        | short ss                        |                                                                      |
|                           |        | short ms                        |                                                                      |
|                           |        | char tz[64]                     |                                                                      |
| <b>T_CCI_SET</b>          | void*  |                                 | Representation of set type                                           |
| <b>T_CCI_COL_INFO</b>     | struct | <b>T_CCI_U_EXT_TYPE</b><br>type | Representation of column information for the <b>SELECT</b> statement |
|                           |        | char is_non_null                |                                                                      |
|                           |        | short scale                     |                                                                      |
|                           |        | int precision                   |                                                                      |
|                           |        | char *col_name                  |                                                                      |

**Note**

If a string longer than defined max length is inserted (**INSERT**) or updated (**UPDATE**), the string will be truncated.

## CCI Sample Program

The sample program shows how to write a CCI application by using the *demodb* database which is included with the CUBRID installation package. You can practice the ways to connect to CAS, prepare queries, execute queries, handle response, disconnect from CAS, etc. by following sample program below. In the sample program, the dynamic link on Linux environment is used.

The code below shows information about *olympic* table schema in the *demodb* database which is used for sample program.

```

csql> ;sc olympic

=== <Help: Schema of a Class> ===

<Class Name>

    olympic

<Attributes>

    host_year          INTEGER NOT NULL
    host_nation        CHARACTER VARYING(40) NOT NULL
    host_city          CHARACTER VARYING(20) NOT NULL
    opening_date       DATE NOT NULL
    closing_date       DATE NOT NULL
    mascot             CHARACTER VARYING(20)
    slogan             CHARACTER VARYING(40)
    introduction       CHARACTER VARYING(1500)

<Constraints>

    PRIMARY KEY pk_olympic_host_year ON olympic (host_year)

```

## Preparing

Make sure that the *demodb* database and the broker are running before you execute the sample program. You can start the *demodb* database and the broker by executing the **cubrid** utility. The code below shows how to run a database server and broker by executing the **cubrid** utility.

```
[tester@testdb ~]$ cubrid server start demodb
@ cubrid master start
++ cubrid master start: success
@ cubrid server start: demodb
```

This may take a long time depending on the amount of recovery works to do.

CUBRID 9.2

```
++ cubrid server start: success
[tester@testdb ~]$ cubrid broker start
@ cubrid broker start
++ cubrid broker start: success
```

## Building

With the program source and the Makefile prepared, executing **make** will create an executable file named *test*. If you use a static library, there is no need to deploy additional files and the execution will be faster. However, it increases the program size and memory usage. If you use a dynamic library, there will be some performance overhead but the program size and memory usage can be optimized.

The code below a command line that makes a test program build by using a dynamic library instead of using **make** on Linux.

```
cc -o test test.c -I$CUBRID/cci/include -L$CUBRID/cci/lib -lnsl -
lcascci
```

## Sample Code

```
#include <stdio.h>
#include <cas_cci.h>
char *cci_client_name = "test";
int main (int argc, char *argv[])
{
    int con = 0, req = 0, col_count = 0, res, ind, i;
    T_CCI_ERROR error;
    T_CCI_COL_INFO *res_col_info;
    T_CCI_CUBRID_STMT stmt_type;
    char *buffer, db_ver[16];
    printf("Program started!\n");
    if ((con=cci_connect("localhost", 30000, "demodb", "PUBLIC",
    ""))<0) {
        printf(" %s(%d): cci_connect fail\n", __FILE__, __LINE__);
        return -1;
    }
}
```

```

    if ((res=cci_get_db_version(con, db_ver, sizeof(db_ver)))<0) {
        printf( "%s(%d): cci_get_db_version fail\n", __FILE__,
__LINE__);
        goto handle_error;
    }
    printf("DB Version is %s\n",db_ver);
    if ((req=cci_prepare(con, "select * from event", 0,&error))<0) {
        if (req < 0) {
            printf( "%s(%d): cci_prepare fail(%d)\n", __FILE__,

## cci\_bind\_param

int cci\_bind\_param(int req\_handle, int index, T\_CCI\_A\_TYPE a\_type, void \*value, T\_CCI\_U\_TYPE u\_type, char flag)

The **cci\_bind\_param** function binds data in the *bind* variable of prepared statement. This function converts *value* of the given *a\_type* to an actual binding type and stores it. Subsequently, whenever `cci_execute()` is called, the stored data is sent to the server. If **cci\_bind\_param** () is called multiple times for the same *index*, the latest configured value is valid.

### Parameters:

- **req\_handle** – (IN) Request handle of a prepared statement
- **index** – (IN) Location of binding; it starts with 1.
- **a\_type** – (IN) Data type of *value*
- **value** – (IN) Data value to bind

- **u\_type** – (IN) Data type to be applied to the database
- **flag** – (IN) bind\_flag(**CCI\_BIND\_PTR**).

Returns:

Error code (0: success)

- **CCI\_ER\_BIND\_INDEX**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_TYPE\_CONVERSION**
- **CCI\_ER\_USED\_CONNECTION**

To bind **NULL** to the database, choose one of below settings.

- Set the value of *value* to a **NULL** pointer
- Set the value of *u\_type* to **CCI\_U\_TYPE\_NULL**

The following shows a part of code to bind NULL.

```
res = cci_bind_param (req, 2 /* binding index*/, CCI_A_TYPE_STR,
NULL, CCI_U_TYPE_STRING, CCI_BIND_PTR);
```

or

```
res = cci_bind_param (req, 2 /* binding index*/, CCI_A_TYPE_STR,
data, CCI_U_TYPE_NULL, CCI_BIND_PTR);
```

can be used.

If **CCI\_BIND\_PTR** is configured for *flag*, the pointer of *value* variable is copied (shallow copy), but no value is copied. If it is not configured for *flag*, the value of *value* variable is copied (deep copy) by allocating memory. If multiple columns are bound by using the same memory buffer, **CCI\_BIND\_PTR** must not be configured for the *flag*.

**T\_CCI\_A\_TYPE** is a C language type that is used in CCI applications for data binding, and consists of primitive types such as int and float, and user-defined types defined by CCI such

as **T\_CCI\_BIT** and **T\_CCI\_DATE**. The identifier for each type is defined as shown in the table below.

| <b>a_type</b>            | <b>value type</b>                  |
|--------------------------|------------------------------------|
| <b>CCI_A_TYPE_STR</b>    | char *                             |
| <b>CCI_A_TYPE_INT</b>    | int *                              |
| <b>CCI_A_TYPE_FLOAT</b>  | float *                            |
| <b>CCI_A_TYPE_DOUBLE</b> | double *                           |
| <b>CCI_A_TYPE_BIT</b>    | <b>T_CCI_BIT</b> *                 |
| <b>CCI_A_TYPE_SET</b>    | <b>T_CCI_SET</b>                   |
| <b>CCI_A_TYPE_DATE</b>   | <b>T_CCI_DATE</b> *                |
| <b>CCI_A_TYPE_BIGINT</b> | int64_t * (For Windows: __int64 *) |
| <b>CCI_A_TYPE_BLOB</b>   | <b>T_CCI_BLOB</b>                  |
| <b>CCI_A_TYPE_CLOB</b>   | <b>T_CCI_CLOB</b>                  |

**T\_CCI\_U\_TYPE** is a column type of database and data bound though the *value* argument is converted into this type. The **cci\_bind\_param** () function uses two kinds of types to send information which is used to convert U-type data from A-type data; the U-type data can be interpreted by database language and the A-type data can be interpreted by C language.

There are various A-type data that are allowed by U-type data. For example, **CCI\_U\_TYPE\_INT** can receive **CCI\_A\_TYPE\_STR** as A-type data including **CCI\_A\_TYPE\_INT**. For information on type conversion, see [Implicit Type Conversion](#).

Both **T\_CCI\_A\_TYPE** and **T\_CCI\_U\_TYPE** enum(s) are defined in the **cas\_cci.h** file. The definition of each identifier is described in the table below.

| <b>u_type</b>               | <b>Corresponding a_type (default)</b> |
|-----------------------------|---------------------------------------|
| <b>CCI_U_TYPE_CHAR</b>      | <b>CCI_A_TYPE_STR</b>                 |
| <b>CCI_U_TYPE_STRING</b>    | <b>CCI_A_TYPE_STR</b>                 |
| <b>CCI_U_TYPE_BIT</b>       | <b>CCI_A_TYPE_BIT</b>                 |
| <b>CCI_U_TYPE_VARBIT</b>    | <b>CCI_A_TYPE_BIT</b>                 |
| <b>CCI_U_TYPE_NUMERIC</b>   | <b>CCI_A_TYPE_STR</b>                 |
| <b>CCI_U_TYPE_INT</b>       | <b>CCI_A_TYPE_INT</b>                 |
| <b>CCI_U_TYPE_SHORT</b>     | <b>CCI_A_TYPE_INT</b>                 |
| <b>CCI_U_TYPE_FLOAT</b>     | <b>CCI_A_TYPE_FLOAT</b>               |
| <b>CCI_U_TYPE_DOUBLE</b>    | <b>CCI_A_TYPE_DOUBLE</b>              |
| <b>CCI_U_TYPE_DATE</b>      | <b>CCI_A_TYPE_DATE</b>                |
| <b>CCI_U_TYPE_TIME</b>      | <b>CCI_A_TYPE_DATE</b>                |
| <b>CCI_U_TYPE_TIMESTAMP</b> | <b>CCI_A_TYPE_DATE</b>                |
| <b>CCI_U_TYPE_OBJECT</b>    | <b>CCI_A_TYPE_STR</b>                 |
| <b>CCI_U_TYPE_BIGINT</b>    | <b>CCI_A_TYPE_BIGINT</b>              |
| <b>CCI_U_TYPE_DATETIME</b>  | <b>CCI_A_TYPE_DATE</b>                |

| <b>u_type</b>          | <b>Corresponding a_type (default)</b> |
|------------------------|---------------------------------------|
| <b>CCI_U_TYPE_BLOB</b> | <b>CCI_A_TYPE_BLOB</b>                |
| <b>CCI_U_TYPE_CLOB</b> | <b>CCI_A_TYPE_CLOB</b>                |
| <b>CCI_U_TYPE_ENUM</b> | <b>CCI_A_TYPE_STR</b>                 |

When the string including the date is used as an input parameter of **DATE**, **DATETIME**, or **TIMESTAMP**, “YYYY/MM/DD” or “YYYY-MM-DD” is allowed for the date string type. Therefore, “2012/01/31” or “2012-01-31” is valid, but “01/31/2012” is invalid. The following is an example of having the string that includes the date as an input parameter of the date type.

```
// "CREATE TABLE tbl(aa date, bb datetime)";

char *values[][3] =
{
    {"1994/11/30", "1994/11/30 20:08:08"},
    {"2008-10-31", "2008-10-31 20:08:08"}
};

req = cci_prepare(conn, "insert into tbl (aa, bb) values
( ?, ?)", CCI_PREPARE_INCLUDE_OID, &error);

for(i=0; i< 2; i++)
{
    res = cci_bind_param(req, 1, CCI_A_TYPE_STR, values[i][0],
CCI_U_TYPE_DATE, (char)NULL);
    res = cci_bind_param(req, 2, CCI_A_TYPE_STR, values[i][1],
CCI_U_TYPE_DATETIME, (char)NULL);
    cci_execute(req, CCI_EXEC_QUERY_ALL, 0, err_buf);
}
```

## cci\_bind\_param\_array

int cci\_bind\_param\_array(int req\_handle, int index, T\_CCI\_A\_TYPE a\_type, void \*value, int \*null\_ind, T\_CCI\_U\_TYPE u\_type)

The **cci\_bind\_param\_array** function binds a parameter array for a prepared `cci_execute_array()` is called, data is sent to the server by the stored *value* pointer. If **cci\_bind\_param\_array** () is called multiple times for the same *index*, the last configured value is valid. If **NULL** is bound to the data, a non-zero value is configured in *null\_ind*. If

*value* is a **NULL** pointer, or *u\_type* is **CCI\_U\_TYPE\_NULL**, all data are bound to **NULL** and the data buffer used by *value* cannot be reused. For the data type of *value* for *a\_type*, see the `cci_bind_param()` function description.

#### Parameters:

- **req\_handle** – (IN) Request handle of the prepared statement
- **index** – (IN) Binding location
- **a\_type** – (IN) Data type of *value*
- **value** – (IN) Data value to be bound
- **null\_ind** – (IN) **NULL** indicator array (0 : not **NULL**, 1 : **NULL**)
- **u\_type** – (IN) Data type to be applied to the database.

#### Returns:

Error code (0: success)

- **CCI\_ER\_BIND\_INDEX**
- **CCI\_ER\_BIND\_ARRAY\_SIZE**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_TYPE\_CONVERSION**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_bind\_param\_array\_size

`int cci_bind_param_array_size(int req_handle, int array_size)`

The **cci\_bind\_param\_array\_size** function determines the size of the array to be used in `cci_bind_param_array()`. **cci\_bind\_param\_array\_size** () must be called first before `cci_bind_param_array()` is used.

**Parameters:**

- **req\_handle** – Request handle of a prepared statement
- **array\_size** – (IN) binding array size

**Returns:**

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_bind\_param\_ex

int cci\_bind\_param\_ex(int req\_handle, int index, T\_CCI\_A\_TYPE a\_type, void \*value, int length, T\_CCI\_U\_TYPE u\_type, char flag)

The **cci\_bind\_param\_ex** function works as the same with `cci_bind_param()`. However, it has an additional argument, *length*, which specifies the byte length of a string if bound data is a string.

**Parameters:**

- **req\_handle** – (IN) Request handle of the prepared statement
- **index** – (IN) Binding location, starting from 1
- **a\_type** – (IN) Data type of *value*
- **value** – (IN) Data value to be bound
- **length** – (IN) Byte length of a string to be bound
- **u\_type** – (IN) Data type to be applied to the database.
- **flag** – (IN) bind\_flag( `CCI_BIND_PTR` ).

**Returns:**

Error code(0: success)

The *length* argument can be used for binding a string which includes '\0' as below.

```
cci_bind_param_ex(statement, 1, CCI_A_TYPE_STR, "aaa\0bbb", 7,
CCI_U_TYPE_STRING, 0);
```

## cci\_blob\_free

int cci\_blob\_free(T\_CCI\_BLOB blob)

The **cci\_blob\_free** function frees memory of *blob* struct.

Returns:

Error code (0: success)

- **CCI\_ER\_INVALID\_LOB\_HANDLE**

## cci\_blob\_new

int cci\_blob\_new(int conn\_handle, T\_CCI\_BLOB \*blob, T\_CCI\_ERROR \*error\_buf)

The **cci\_blob\_new** function creates an empty file where **LOB** data is stored and returns locator referring to the data to *blob* struct.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **blob** – (OUT) **LOB** locator
- **error\_buf** – (OUT) Error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**

- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**
- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_blob\_read

int cci\_blob\_read(int conn\_handle, T\_CCI\_BLOB blob, long start\_pos, int length, char \*buf, T\_CCI\_ERROR \*error\_buf)

The **cci\_blob\_read** function reads as much as data from *start\_pos* to *length* of the **LOB** data file specified in *blob*; then it stores it in *buf* and returns it.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **blob** – (OUT) **LOB** locator
- **start\_pos** – (IN) Index location of **LOB** data file
- **length** – (IN) **LOB** data length from buffer
- **buf** – (IN) Data buffer to read
- **error\_buf** – (OUT) Error buffer

Returns:

Size of read value ( $\geq 0$ : success), Error code ( $< 0$ : error)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**
- **CCI\_ER\_INVALID\_LOB\_READ\_POS**

- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_blob\_size

long long cci\_blob\_size(T\_CCI\_BLOB \*blob)

The **cci\_blob\_size** function returns data file size that is specified in *blob*.

Parameters:

- **blob** – (OUT) **LOB** locator

Returns:

Size of **BLOB** data file (>= 0: success), Error code (< 0: error)

- **CCI\_ER\_INVALID\_LOB\_HANDLE**

## cci\_blob\_write

int cci\_blob\_write(int conn\_handle, T\_CCI\_BLOB blob, long start\_pos, int length, const char \*buf, T\_CCI\_ERROR \*error\_buf)

The **cci\_blob\_write** function reads as much as data from *buf* to *length* and stores it from *start\_pos* of the **LOB** data file specified in *blob*.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **blob** – (OUT) **LOB** locator
- **start\_pos** – (IN) Index location of **LOB** data file
- **length** – (IN) Data length from buffer
- **buf** – (OUT) Data buffer to write
- **error\_buf** – (OUT) Error buffer

#### Returns:

Size of written value ( $\geq 0$ : success), Error code ( $< 0$ : error)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**
- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_cancel

**int cci\_cancel(int conn\_handle)**

Cancel the running query on the other thread. This function executes the same behavior as `Statement.cancel()` method in JAVA.

#### Parameters:

- **conn\_handle** – (IN) Connection handle

Returns:

Error code

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**

The following shows how to cancel the query execution of a thread.

```
/* gcc -o pthr pthr.c -m64 -I${CUBRID}/include -lnsl ${CUBRID}/
lib/libcascci.so -lpthread
*/

#include <stdio.h>
#include <cas_cci.h>
#include <unistd.h>
#include <pthread.h>
#include <string.h>
#include <time.h>

#define QUERY "select * from db_class A, db_class B, db_class C,
db_class D, db_class E"

static void *thread_main (void *arg);
static void *execute_statement (int con, char *sql_stmt);

int
main (int argc, char *argv[])
{
    int thr_id = 0, conn_handle = 0, res = 0;
    void *jret;
    pthread_t th;
    char url[1024];
    T_CCI_ERROR error;
    snprintf (url, 1024, "cci:CUBRID:localhost:
33000:demodb:PUBLIC::");

    conn_handle = cci_connect_with_url_ex (url, NULL, NULL,
&error);

    if (conn_handle < 0)
    {
        printf ("ERROR: %s\n", error.err_msg);
        return -1;
    }
}
```

```
    res = pthread_create (&th, NULL, &thread_main, (void *)
&conn_handle);

    if (res < 0)
    {
        printf ("thread fork failed.\n");
        return -1;
    }
    else
    {
        printf ("thread started\n");
    }
    sleep (5);
    // If thread_main is still running, below cancels the query
of thread_main.
    res = cci_cancel (conn_handle);
    if (res < 0)
    {
        printf ("cci_cancel failed\n");
        return -1;

}

```

## cci\_clob\_free

int cci\_clob\_free(T\_CCI\_CLOB clob)

The **cci\_clob\_free** function frees memory of **CLOB** struct.

Parameters:

- **clob** – (IN) **LOB** locator

Returns:

Error code (0: success)

- **CCI\_ER\_INVALID\_LOB\_HANDLE**

## cci\_clob\_new

int cci\_clob\_new(int conn\_handle, T\_CCI\_CLOB \*clob, T\_CCI\_ERROR \*error\_buf)

The **cci\_clob\_new** function creates an empty file where **LOB** data is stored and returns locator referring to the data to *clob* struct.

Parameters:

- **conn\_handle** – ((IN) Connection handle
- **clob** – (OUT) **LOB** locator
- **error\_buf** – (OUT) Error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**
- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_clob\_read

int cci\_clob\_read(int conn\_handle, T\_CCI\_CLOB clob, long start\_pos, int length, char \*buf, T\_CCI\_ERROR \*error\_buf)

The **cci\_clob\_read** function reads as much as data from *start\_pos* to *length* in the **LOB** data file specified in *clob*; then it stores it in *buf* and returns it.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **clob** – (IN) **LOB** locator
- **start\_pos** – (IN) Index location of **LOB** data file
- **length** – (IN) **LOB** data length from buffer
- **buf** – (IN) Data buffer to read
- **error\_buf** – (OUT) Error buffer

Returns:

Size of read value ( $\geq 0$ : success), Error code ( $< 0$ : Error)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**
- **CCI\_ER\_INVALID\_LOB\_READ\_POS**
- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_clob\_size

long long cci\_clob\_size(T\_CCI\_CLOB \*clob)

The **cci\_clob\_size** function returns data file size that is specified in *clob*.

Parameters:

- **clob** – (IN) **LOB** locator

Returns:

Size of **CLOB** data file ( $\geq 0$ : success), Error code ( $< 0$ : error)

- **CCI\_ER\_INVALID\_LOB\_HANDLE**

## cci\_clob\_write

int cci\_clob\_write(int conn\_handle, T\_CCI\_CLOB clob, long start\_pos, int length, const char \*buf, T\_CCI\_ERROR \*error\_buf)

The **cci\_clob\_write** function reads as much as data from *buf* to *length* and then stores the value from *start\_pos* in **LOB** data file specified in *clob*.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **clob** – (IN) **LOB** locator
- **start\_pos** – (IN) Index location of **LOB** data file
- **length** – (IN) Data length from buffer
- **buf** – (OUT) Data buffer to write
- **error\_buf** – (OUT) Error buffer

Returns:

Size of written value ( $\geq 0$ : success), Error code ( $< 0$ : Error)

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_INVALID\_LOB\_HANDLE**

- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_close\_query\_result

int cci\_close\_query\_result(int req\_handle, T\_CCI\_ERROR \*err\_buf)

The **cci\_close\_query\_result** function closes the resultset returned by `cci_execute()`, `cci_execute_array()` or `cci_execute_batch()`. If you run `cci_prepare()` repeatedly without closing the request handle(`req_handle`), it is recommended to call this function before calling `cci_close_req_handle()`.

Parameters:

- **req\_handle** – (IN) Request handle
- **err\_buf** – (OUT) Error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_RESULT\_SET\_CLOSED**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_close\_req\_handle

int cci\_close\_req\_handle(int req\_handle)

The **cci\_close\_req\_handle** function closes the request handle obtained by `cci_prepare()`.

Parameters:

- **req\_handle** – (IN) Request handle

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_col\_get

```
int cci_col_get(int conn_handle, char *oid_str, char *col_attr, int *col_size, int *col_type,  
T_CCI_ERROR *err_buf)
```

The **cci\_col\_get** function gets an attribute value of collection type. If the name of the class is C, and the domain of *set\_attr* is set (multiset, sequence), the query looks like as follows:

```
SELECT a FROM C, TABLE(set_attr) AS t(a) WHERE C = oid;
```

That is, the number of members becomes the number of records.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) Collection attribute name
- **col\_size** – (OUT) Collection size (-1 : null)

- **col\_type** – (OUT) Collection type (set, multiset, sequence: u\_type)
- **err\_buf** – (OUT) Database error buffer

Returns:

Request handle

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

## cci\_col\_seq\_drop

int cci\_col\_seq\_drop(int conn\_handle, char \*oid\_str, char \*col\_attr, int index, T\_CCI\_ERROR \*err\_buf)

The **cci\_col\_seq\_drop** function drops the index-th (base: 1) member of the sequence attribute values. The following example shows how to drop the first member of the sequence attribute values.

```
cci_col_seq_drop(conn_handle, oid_str, seq_attr, 1, err_buf);
```

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) Collection attribute name
- **index** – (IN) Index
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

## cci\_col\_seq\_insert

int cci\_col\_seq\_insert(int conn\_handle, char \*oid\_str, char \*col\_attr, int index, char \*value, T\_CCI\_ERROR \*err\_buf)

The **cci\_col\_seq\_insert** function inserts one member at the index-th (base: 1) position of the sequence attribute values. The following example shows how to insert "a" at the first position of the sequence attribute values.

```
cci_col_seq_insert(conn_handle, oid_str, seq_attr, 1, "a",  
err_buf);
```

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) Collection attribute name
- **index** – (IN) Index
- **value** – (IN) Sequential element (string)
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**

## • CCI\_ER\_DBMS

### cci\_col\_seq\_put

```
int cci_col_seq_put(int conn_handle, char *oid_str, char *col_attr, int index, char *value,  
T_CCI_ERROR *err_buf)
```

The **cci\_col\_seq\_put** function replaces the index-th (base: 1) member of the sequence attribute values with a new value. The following example shows how to replace the first member of the sequence attributes values with "a".

```
cci_col_seq_put(conn_handle, oid_str, seq_attr, 1, "a", err_buf);
```

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) Collection attribute name
- **index** – (IN) Index
- **value** – (IN) Sequential value
- **err\_buf** – (OUT) Database error buffer

#### Returns:

#### Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

### cci\_col\_set\_add

```
int cci_col_set_add(int conn_handle, char *oid_str, char *col_attr, char *value, T_CCI_ERROR  
*err_buf)
```

The **cci\_col\_set\_add** function adds one member to the set attribute values. The following example shows how to add “a” to the set attribute values.

```
cci_col_set_add(conn_handle, oid_str, set_attr, "a", err_buf);
```

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) collection attribute name
- **value** – (IN) set element
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

## cci\_col\_set\_drop

```
int cci_col_set_drop(int conn_handle, char *oid_str, char *col_attr, char *value, T_CCI_ERROR *err_buf)
```

The **cci\_col\_set\_drop** function drops one member from the set attribute values. The following example shows how to drop “a” from the set attribute values.

```
cci_col_set_drop(conn_handle, oid_str, set_attr, "a", err_buf);
```

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid

- **col\_attr** – (IN) collection attribute name
- **value** – (IN) set element (string)
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_LOGIN\_TIMEOUT**
- **CCI\_ER\_COMMUNICATION**

## cci\_col\_size

int cci\_col\_size(int conn\_handle, char \*oid\_str, char \*col\_attr, int \*col\_size, T\_CCI\_ERROR \*err\_buf)

The **cci\_col\_size** function gets the size of the set (seq) attribute.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **col\_attr** – (IN) Collection attribute name
- **col\_size** – (OUT) Collection size (-1: NULL)
- **err\_buf** – Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**

---

- **CCI\_ER\_DBMS**

## cci\_connect

int cci\_connect(char \*ip, int port, char \*db\_name, char \*db\_user, char \*db\_password)

A connection handle to the database server is assigned and it tries to connect to the server. If it has succeeded, the connection handle ID is returned; if fails, an error code is returned.

### Parameters:

- **ip** – (IN) A string that represents the IP address of the server (host name)
- **port** – (IN) Broker port (The port configured in the **\$CUBRID/conf/cubrid\_broker.conf** file)
- **db\_name** – (IN) Database name
- **db\_user** – (IN) Database user name
- **db\_passwd** – (IN) Database user password

### Returns:

Success: Connection handle ID (int), Failure: Error code

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_HOSTNAME**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## cci\_connect\_ex

int cci\_connect\_ex(char \*ip, int port, char \*db\_name, char \*db\_user, char \*db\_password, T\_CCI\_ERROR \*err\_buf)

The **cci\_connect\_ex** function returns **CCI\_ER\_DBMS** error and checks the error details in the database error buffer (*err\_buf*) at the same time. In that point, it is different from **cci\_connect()** and the others are the same as the **cci\_connect()** function.

Parameters:

- **ip** – (IN) A string that represents the IP address of the server (host name)
- **port** – (IN) Broker port (The port configured in the **\$CUBRID/conf/cubrid\_broker.conf** file)
- **db\_name** – (IN) Database name
- **db\_user** – (IN) Database user name
- **db\_passwd** – (IN) Database user password
- **err\_buf** – Database error buffer

Returns:

Success: Connection handle ID (int), Failure: Error code

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_HOSTNAME**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## cci\_connect\_with\_url

**int cci\_connect\_with\_url(char \*url, char \*db\_user, char \*db\_password)**

The **cci\_connect\_with\_url** function connects a database by using connection information passed with a *url* argument. If broker's HA feature is used in CCI, you must specify the connection information of the standby broker server with *altHosts* property, which is used for the failover, in the *url* argument of this function. It returns the ID of a connection handle

on success; it returns an error code on failure. For details about HA features of broker, see [Duplexing Brokers](#).

#### Parameters:

- **url** – (IN) A string that contains server connection information.
- **db\_user** – (IN) Database user name. If this is NULL, it becomes `<db_user>` in `url`. If this is an empty string ("" ) or `<db_user>` in `url` is not specified, DB user name becomes **PUBLIC**.
- **db\_passwd** – (IN) Database user password. If this is NULL, `<db_password>` in `url` is used. If `<db_password>` in `url` is not specified, DB password becomes an empty string ("" ).

#### Returns:

Success: Connection handle ID (int), Failure: Error code

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_HOSTNAME**
- **CCI\_ER\_INVALID\_URL**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_LOGIN\_TIMEOUT**

```
<url> ::=
cci:CUBRID:<host>:<port>:<db_name>:<db_user>:<db_password>:[?
<properties>]

<properties> ::= <property> [&<property>]
<property> ::= altHosts=<alternative_hosts> [ &rcTime=<time>]
[ &loadBalance=true|false]
                |{login_timeout|loginTimeout}=<milli_sec>
                |{query_timeout|queryTimeout}=<milli_sec>
```

```

        | {disconnect_on_query_timeout|
disconnectOnQueryTimeout}=true|false
        | logFile=<file_name>
        | logBaseDir=<dir_name>
        | logSlowQueries=true|
false[&slowQueryThresholdMillis=<milli_sec>]
        | logTraceApi=true|false
        | logTraceNetwork=true|false
        | useSSL=true|false

<alternative_hosts> ::= <host>:<port> [,<host>:<port>]

<host> := HOSTNAME | IP_ADDR
<time> := SECOND
<milli_sec> := MILLI SECOND

```

**altHosts** is the property related to connection target and **loginTimeout**, **queryTimeout**, and **disconnectOnQueryTimeout** are the properties related to timeout; **logSlowQueries**, **logTraceApi**, and **logTraceNetwork** are the properties related to log information configuration for debugging. Note that a property name which is a value to be entered in the *url* argument is not case sensitive.

- *host*: A host name or IP address of the master database
- *port*: A port number
- *db\_name*: A name of the database
- *db\_user*: A name of the database user
- *db\_password*: A database user password. You cannot include ‘:’ in the password of the *url* string.
- **altHosts** = *standby\_broker1\_host, standby\_broker2\_host, ...*: Specifies the broker information of the standby server, which is used for failover when it is impossible to connect to the active server. You can specify multiple brokers for failover, and the connection to the brokers is attempted in the order listed in **alhosts**.

#### Note

Even if there are **RW** and **RO** together in *ACCESS\_MODE\** setting of brokers of main host and **altHosts**, application decides the target host to access without the relation for the setting of **ACCESS\_MODE**. Therefore, you should define the main host and **altHosts** as considering **ACCESS\_MODE** of target brokers.

- **rcTime**: After the failure occurred on the first connected broker, the application connects to the broker specified by **altHosts**(broker failover). Then it attempts to reconnect to the first connected broker at every **rcTime**(default value: 600 seconds).
- **loadBalance**: When this value is true, the applications try to connect to the main host and alternative hosts specified with the **altHosts** property as a random order. (default value: false).
- **login\_timeout** | **loginTimeout**: Timeout value (unit: msec.) for database login. Upon timeout, a **CCI\_ER\_LOGIN\_TIMEOUT** (-38) error is returned. The default value is **30,000**(30 sec.). If this value is 0, it means infinite waiting. This value is also applied when internal reconnection occurs after the initial connection.
- **query\_timeout** | **queryTimeout**: If time specified in these properties has expired when calling `cci_prepare()`, `cci_execute()`, etc. a cancellation message for query request which was sent to a server will be delivered and called function returns a **CCI\_ER\_QUERY\_TIMEOUT** (-39) error. The default value is 0. If this value is 0, it means infinite waiting. The value returned upon timeout may vary depending on a value specified in **disconnect\_on\_query\_timeout**. For details, see **disconnect\_on\_query\_timeout**.

#### Note

If you use `cci_execute_batch()` or `cci_execute_array()` function, or set **CCI\_EXEC\_QUERY\_ALL** in `cci_execute()` function to run multiple queries at once, query timeout is applied to one function, not to one query. In other words, if query timeout occurs after the start of a function, a function running is quit.

- **disconnect\_on\_query\_timeout** | **disconnectOnQueryTimeout**: Whether to disconnect socket immediately after time for query request has expired. It determines whether to terminate a socket connection immediately or wait for server response after sending cancellation message for query request to a server when calling `cci_prepare()`, `cci_execute()`, etc. The default value is **false**, meaning that it will wait for server response. If this value is true, a socket will be closed immediately after sending a cancellation message to a server upon timeout and returns the **CCI\_ER\_QUERY\_TIMEOUT** (-39) error. (If an error occurs on database server side, not on broker side, it returns -1. If you want to view error details, see error codes in “database error buffer.” You can get information how to check error codes in [CCI Error Codes and Error Messages](#).) Please note that there is a possibility that a database server does not get a cancellation message and execute a query even after an error is returned.
- **logFile**: A log file name for debugging (default value: **cci\_<handle\_id>.log**). **<handle\_id>** indicates the ID of a connection handle returned by this function.

- **logBaseDir**: A directory where a debug log file is created. The file name including the path will be logBaseDir/logFile, and the relative path is possible.
- **logSlowQueries**: Whether to log slow query for debugging (default value: **false**)
- **slowQueryThresholdMillis**: Timeout for slow query logging if slow query logging is enabled (default value: **60000**, unit: milliseconds)
- **logTraceApi**: Whether to log the start and end of CCI functions
- **logTraceNetwork**: Whether to log network data content transferred of CCI functions
- **useSSL**: Packet Encryption mode (Default: false)
  - Packet encryption: useSSL = true
  - Plain text: useSSL = false

### Example

```
--connection URL string when a property(altHosts) is specified
for HA
URL=cci:CUBRID:192.168.0.1:33000:demodb:::?
altHosts=192.168.0.2:33000,192.168.0.3:33000

--connection URL string when properties(altHosts,rcTime) is
specified for HA
URL=cci:CUBRID:192.168.0.1:33000:demodb:::?
altHosts=192.168.0.2:33000,192.168.0.3:33000&rcTime=600

--connection URL string when
properties(logSlowQueries,slowQueryThresholdMills, logTraceApi,
logTraceNetwork) are specified for interface debugging
URL = "cci:cubrid:192.168.0.1:33000:demodb:::?
logSlowQueries=true&slowQueryThresholdMillis=1000&logTraceApi=tru
e&logTraceNetwork=true"

--connection URL string when useSSL property specified for
encrypted connection
URL = "cci:cubrid:192.168.0.1:33000:demodb:::?useSSL=true"
```

### Warning

- The **useSSL** flag must match with the mode of the broker trying to connect. If encryption mode is different from the server that trying to connect, that connection request will be rejected. Please refer to the following cases that are not allowed.
  - useSSL=true, connection request will be rejected when the broker is in 'normal mode' (**cubrid\_broker.conf**: SSL = OFF)
  - useSSL=false, connection request will be rejected when the broker is in 'encryption mode' (**cubrid\_broker.conf**: SSL = ON)

## cci\_connect\_with\_url\_ex

int cci\_connect\_with\_url\_ex(char \*url, char \*db\_user, char \*db\_password, T\_CCI\_ERROR \*err\_buf)

The **cci\_connect\_with\_url\_ex** function returns **CCI\_ER\_DBMS** error and checks the error details in the database error buffer (*err\_buf*) at the same time. In that point, it is different from `cci_connect_with_url()` and the others are the same as the `cci_connect_with_url()` function.

Parameters:

- **err\_buf** – Database error buffer

int cci\_cursor(int req\_handle, int offset, T\_CCI\_CURSOR\_POS origin, T\_CCI\_ERROR \*err\_buf)

The **cci\_cursor** function moves the cursor specified in the request handle to access the specific record in the query result executed by `cci_execute()`. The position of cursor is moved by the values specified in the *origin* and *offset* values. If the position to be moved is not valid, **CCI\_ER\_NO\_MORE\_DATA** is returned.

## Parameters:

- **req\_handle** – (IN) Request handle
- **offset** – (IN) Offset to be moved
- **origin** – (IN) Variable to represent a position. The type is **T\_CCI\_CURSOR\_POS**. **T\_CCI\_CURSOR\_POS** enum consists of **CCI\_CURSOR\_FIRST**, **CCI\_CURSOR\_CURRENT** and **CCI\_CURSOR\_LAST**.
- **err\_buf** – (OUT) Database error buffer

## Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_NO\_MORE\_DATA**
- **CCI\_ER\_COMMUNICATION**

## Example

```
//the cursor moves to the first record
cci_cursor(req, 1, CCI_CURSOR_FIRST, &err_buf);

//the cursor moves to the next record
cci_cursor(req, 1, CCI_CURSOR_CURRENT, &err_buf);

//the cursor moves to the last record
cci_cursor(req, 1, CCI_CURSOR_LAST, &err_buf);

//the cursor moves to the previous record
cci_cursor(req, -1, CCI_CURSOR_CURRENT, &err_buf);
```

**cci\_cursor\_update**

**int cci\_cursor\_update(int req\_handle, int cursor\_pos, int index, T\_CCI\_A\_TYPE a\_type, void \*value, T\_CCI\_ERROR \*err\_buf)**

The **cci\_cursor\_update** function updates *cursor\_pos* from the value of the *index* -th column to *value*. If the database is updated to **NULL**, *value* becomes **NULL**. For update conditions, see `cci_prepare()`. The data types of *value* for *a\_type* are shown in the table below.

## Parameters:

- **req\_handle** – (IN) Request handle
- **cursor\_pos** – (IN) Cursor position
- **index** – (IN) Column index
- **a\_type** – (IN) *value* Type
- **value** – (IN) A new value
- **err\_buf** – (OUT) Database error buffer

## Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_TYPE\_CONVERSION**
- **CCI\_ER\_ATYPE**

Data types of *value* for *a\_type* are as below.

| <b>a_type</b>            | <b>value type</b>  |
|--------------------------|--------------------|
| <b>CCI_A_TYPE_STR</b>    | char *             |
| <b>CCI_A_TYPE_INT</b>    | int *              |
| <b>CCI_A_TYPE_FLOAT</b>  | float *            |
| <b>CCI_A_TYPE_DOUBLE</b> | double *           |
| <b>CCI_A_TYPE_BIT</b>    | <b>T_CCI_BIT</b> * |
| <b>CCI_A_TYPE_SET</b>    | <b>T_CCI_SET</b>   |

| a_type            | value type                         |
|-------------------|------------------------------------|
| CCI_A_TYPE_DATE   | T_CCI_DATE *                       |
| CCI_A_TYPE_BIGINT | int64_t * (For Windows: __int64 *) |
| CCI_A_TYPE_BLOB   | T_CCI_BLOB                         |
| CCI_A_TYPE_CLOB   | T_CCI_CLOB                         |

### cci\_datasource\_borrow

T\_CCI\_CONN cci\_datasource\_borrow(T\_CCI\_DATASOURCE \*datasource, T\_CCI\_ERROR \*err\_buf)

The **cci\_datasource\_borrow** function obtains CCI connection to be used in **T\_CCI\_DATASOURCE** struct.

Parameters:

- **datasource** – (IN) **T\_CCI\_DATASOURCE** struct pointer in which CCI connection exists
- **err\_buf** – (OUT) Error code and message returned upon error occurrence

Returns:

Success: CCI connection handler identifier, Failure: -1

#### See also

cci\_property\_create(), cci\_property\_destroy(), cci\_property\_get(), cci\_property\_set(),  
 cci\_datasource\_create(), cci\_datasource\_destroy(), cci\_datasource\_release(),  
 cci\_datasource\_change\_property()

## cci\_datasource\_change\_property

```
int cci_datasource_change_property(T_CCI_DATASOURCE *datasource, const char *key, const char *val)
```

A property name of a DATASOURCE is specified in *key*, a value in *val*. The changed property value by this function is applied to all connections in the *datasource*.

### Parameters:

- **datasource** – (IN) T\_CCI\_DATASOURCE struct pointer to obtain CCI connections.
- **key** – (IN) A pointer to the string of a property name
- **val** – (IN) A pointer to the string of a property value

### Returns:

Error code(0: success)

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_NO\_PROPERTY**
- **CCI\_ER\_PROPERTY\_TYPE**

The following shows names and values of changeable properties.

| Property name        | Type | Value      | Description                                                                                                               |
|----------------------|------|------------|---------------------------------------------------------------------------------------------------------------------------|
| default_autocommit   | bool | true/false | Whether auto-commit or not. The default is CCI_DEFAULT_AUTO COMMIT in cubrid_broker.conf; the default of this is ON(true) |
| default_lock_timeout | msec | number     | lock timeout                                                                                                              |

| Property name     | Type   | Value                                            | Description                                                                                                                                           |
|-------------------|--------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| default_isolation | string | See the table of <code>cci_property_set()</code> | isolation level. The default is isolation_level in cubrid.conf; the default of this is "READ COMMITTED".                                              |
| login_timeout     | msec   | number                                           | login timeout. The default is 0(infinite wait). It can also be used when you call prepare or execute functions; at this time reconnection can happen. |

### Example

```
...
ps = cci_property_create ();
...
ds = cci_datasource_create (ps, &err);
...
cci_datasource_change_property(ds, "login_timeout", "5000");
cci_datasource_change_property(ds, "default_lock_timeout",
"2000");
cci_datasource_change_property(ds, "default_isolation",
"TRAN_REP_CLASS_COMMIT_INSTANCE");
cci_datasource_change_property(ds, "default_autocommit", "true");
...
```

### See also

```

cci_datasource_create(),    cci_datasource_borrow(),    cci_datasource_destroy(),  
cci_datasource_release()
```

## cci\_datasource\_create

T\_CCI\_DATASOURCE \*cci\_datasource\_create(T\_CCI\_PROPERTIES \*properties, T\_CCI\_ERROR \*err\_buf)

The **cci\_datasource\_create** function creates DATASOURCE of CCI.

Parameters:

- **properties** – (IN) **T\_CCI\_PROPERTIES** struct pointer in which configuration of struct pointer is stored. Values of properties will be set with `cci_property_set()`.
- **err\_buf** – (OUT) Error buffer. Error code and message returned upon error occurrence

Returns:

Success: **T\_CCI\_DATASOURCE** struct pointer created, Failure: **NULL**

### ! See also

cci_property_create(),    cci_property_destroy(),    cci_property_get(),    cci_property_set(),  
cci_datasource_borrow(),    cci_datasource_destroy(),    cci_datasource_release(),  
cci_datasource_change_property()
```

## cci\_datasource\_destroy

void cci\_datasource\_destroy(T\_CCI\_DATASOURCE \*datasource)

The **cci\_datasource\_destroy** function destroys DATASOURCE of CCI.

**Parameters:**

- **datasource** – (IN) **T\_CCI\_DATASOURCE** struct pointer to be deleted

**Returns:**

void

**See also**

`cci_property_create()` , `cci_property_destroy()` , `cci_property_get()` , `cci_property_set()` ,  
`cci_datasource_create()` , `cci_datasource_borrow()` , `cci_datasource_release()` ,  
`cci_datasource_change_property()`

## `cci_datasource_release`

`int cci_datasource_release(T_CCI_DATASOURCE *datasource, T_CCI_CONN conn, T_CCI_ERROR *err_buf)`

The **cci\_datasource\_release** function returns CCI connection released in **T\_CCI\_DATASOURCE** struct. If you want to reuse the connection after calling this function, recall `cci_datasource_borrow()` .

**Parameters:**

- **datasource** – (IN) **T\_CCI\_DATASOURCE** struct pointer which returns CCI connection
- **conn** – (IN) CCI connection handler identifier released
- **err\_buf** – (OUT) Error buffer(returns error code and error message when an error occurs)

**Returns:**

Success: 1, Failure: 0

**See also**

```
cci_property_create() ,    cci_property_destroy() ,    cci_property_get() ,    cci_property_set() ,  
cci_datasource_create() ,    cci_datasource_destroy() ,    cci_datasource_borrow() ,  
cci_datasource_change_property()
```

## cci\_disconnect

int cci\_disconnect(int conn\_handle, T\_CCI\_ERROR \*err\_buf)

The **cci\_disconnect** function disconnects all request handles created for *conn\_handle*. If a transaction is being performed, the handles are disconnected after `cci_end_tran()` is executed.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**

## cci\_end\_tran

int cci\_end\_tran(int conn\_handle, char type, T\_CCI\_ERROR \*err\_buf)

The **cci\_end\_tran** function performs commit or rollback on the current transaction. At this point, all open request handles are terminated and the connection to the database server is disabled. However, even after the connection to the server is disabled, the connection handle remains valid.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **type** – (IN) **CCI\_TRAN\_COMMIT** or **CCI\_TRAN\_ROLLBACK**

- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_TRAN\_TYPE**

You can configure the default value of auto-commit mode by using **CCI\_DEFAULT\_AUTOCOMMIT** broker parameter upon startup of an application. If configuration on broker parameter is omitted, the default value is **ON**; use the `cci_set_autocommit()` function to change auto-commit mode within an application. If auto-commit mode is **OFF**, you must explicitly commit or roll back transaction by using the `cci_end_tran()` function.

## cci\_escape\_string

long cci\_escape\_string(int conn\_handle, char \*to, const char \*from, unsigned long length, T\_CCI\_ERROR \*err\_buf)

Converts the input string to a string that can be used in the CUBRID query. The following parameters are specified in this function: connection handle or **no\_backslash\_escapes** setting value, output string pointer, input string pointer, the length of the input string, and the address of the **T\_CCI\_ERROR** struct variable.

Parameters:

- **conn\_handle** – (IN) connection handle or **no\_backslash\_escapes** setting value. When a connection handle is given, the **no\_backslash\_escapes** parameter value is read to determine how to convert. Instead of the connection handle, **CCI\_NO\_BACKSLASH\_ESCAPES\_TRUE** or **CCI\_NO\_BACKSLASH\_ESCAPES\_FALSE** value can be sent to determine how to convert.
- **to** – (OUT) Result string
- **from** – (IN) Input string

- **length** – (IN) Maximum byte length of the input string
- **err\_buf** – (OUT) Database error buffer

Returns:

Success: Byte length of the changed string, Failure: Error Code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_COMMUNICATION**

When the system parameter **no\_backslash\_escapes** is yes (default) or when the **CCI\_NO\_BACKSLASH\_ESCAPES\_TRUE** value is sent to the connection handle location, the string is converted to the following characters.

- ' (single quote) => ' + ' (escaped single quote)

When the system parameter **no\_backslash\_escapes** is no or when the **CCI\_NO\_BACKSLASH\_ESCAPES\_FALSE** value is sent to the connection handle location, the string is converted to the following characters:

- \n (new line character, ASCII 10) => \ + n (backslash + Alphabet n)
- \r (carriage return, ASCII 13) => \ + r (backslash + Alphabet r)
- \0 (ASCII 0) => \ + 0 (backslash + 0(ASCII 48))
- \ (backslash) => \ + \

You can assign the space where the result string will be saved by using the *length* parameter. It will take as much as the byte length of the maximum input string \* 2 + 1.

## cci\_execute

**int cci\_execute(int req\_handle, char flag, int max\_col\_size, T\_CCI\_ERROR \*err\_buf)**

The **cci\_execute** function executes the SQL statement (prepared statement) that has executed **cci\_prepare()**. A request handle, *flag*, the maximum length of a column to be fetched, and the address of a **T\_CCI\_ERROR** construct variable in which error information being stored are specified as arguments.

**Parameters:**

- **req\_handle** – (IN) Request handle of the prepared statement
- **flag** – (IN) exec flag ( **CCI\_EXEC\_QUERY\_ALL** )
- **max\_col\_size** – (IN) The maximum length of a column to be fetched when it is a string data type in bytes. If this value is 0, full length is fetched.
- **err\_buf** – (OUT) Database error buffer

**Returns:**

- **SELECT** : Returns the number of results
- **INSERT, UPDATE** : Returns the number of rows reflected
- Others queries : 0
- Failure : Error code
  - **CCI\_ER\_REQ\_HANDLE**
  - **CCI\_ER\_BIND**
  - **CCI\_ER\_DBMS**
  - **CCI\_ER\_COMMUNICATION**
  - **CCI\_ER\_QUERY\_TIMEOUT**
  - **CCI\_ER\_LOGIN\_TIMEOUT**

Through a *flag*, the way of query execution can be set as all queries or the first one.

**Note**

In 2008 R4.4 and from 9.2, CUBRID does not support setting the *flag* as **CCI\_EXEC\_ASYNC**, which brings the results as an asynchronous method.

If the *flag* is set to **CCI\_EXEC\_QUERY\_ALL**, all prepared queries(separated by semicolon) are executed. If not, only the first query is executed.

If the *flag* is set to **CCI\_EXEC\_QUERY\_ALL**, the following rules are applied.

- The return value is the result of the first query.
- If an error occurs in any query, the execution is processed as a failure.
- For a query composed of in a query composed of q1; q2; q3, even if an error occurs in q2 after q1 succeeds the execution, the result of q1 remains valid. That is, the previous successful query executions are not rolled back when an error occurs.
- If a query is executed successfully, the result of the second query can be obtained using `cci_next_result()`.

*max\_col\_size* is a value that is used to determine the maximum length of a column to be sent to a client when the columns of the prepared statement are **CHAR**, **VARCHAR**, **BIT** or **VARBIT**. If this value is 0, full length is fetched.

## cci\_execute\_array

```
int cci_execute_array(int req_handle, T_CCI_QUERY_RESULT **query_result, T_CCI_ERROR
*err_buf)
```

If more than one value is bound to the prepared statement, this gets the values of the variables to be bound and executes the query by binding each value to the variable.

### Parameters:

- **req\_handle** – (IN) Request handle of the prepared statement
- **query\_result** – (OUT) Query results
- **err\_buf** – (OUT) Database error buffer

### Returns:

- Success: The number of executed queries (it has nothing to do with query execution success/failure.)
- Failure: Negative number
  - **CCI\_ER\_REQ\_HANDLE**
  - **CCI\_ER\_BIND**
  - **CCI\_ER\_DBMS**

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_LOGIN\_TIMEOUT**

To bind the data, call the `cci_bind_param_array_size()` function to specify the size of the array, bind each value to the variable by using the `cci_bind_param_array()` function, and execute the query by calling the `cci_execute_array()` function. The query result will be stored on the array of **T\_CCI\_QUERY\_RESULT** structure.

`cci_execute_array()` function returns the results of queries to the *query\_result* variable. You can use below macros to get the result of each query. In the macro, note that the validation check for each parameter entered is not performed.

After using the *query\_result* variable, you must delete the *query\_result* by using the `cci_query_result_free()` function.

| Macro                                   | Return Type                         | Description                                                                     |
|-----------------------------------------|-------------------------------------|---------------------------------------------------------------------------------|
| <code>CCI_QUERY_RESULT_RESULT</code>    | int                                 | the number of affected rows or error identifier (-1: CAS error, -2: DBMS error) |
| <code>CCI_QUERY_RESULT_ERR_NO</code>    | int                                 | error number about a query                                                      |
| <code>CCI_QUERY_RESULT_ERR_MSG</code>   | char *                              | error message about a query                                                     |
| <code>CCI_QUERY_RESULT_STMT_TYPE</code> | int( <b>T_CCI_CUBRID_STMT</b> enum) | type of a query statement                                                       |

If autocommit mode is on, each query in the array is committed after executing.

#### Note

- In the previous version of 2008 R4.3, if the autocommit mode is on, all queries in the array were committed after all of them are executed. From 2008 R4.3 version, the transaction is committed every time when a query is executed.

- In autocommit mode off, if the general error occurs during executing one of the queries in the array on the cci\_execute\_array function which does a batch processing of the queries, the query with an error is ignored and the next query is executed continuously. But if the deadlock occurs, the error occurs as rolling back the transaction.

```

char *query =
    "update participant set gold = ? where host_year = ? and
nation_code = 'KOR'";
int gold[2];
char *host_year[2];
int null_ind[2];
T_CCI_QUERY_RESULT *result;
int n_executed;
...

req = cci_prepare (con, query, 0, &cci_error);
if (req < 0)
{
    printf ("prepare error: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
    goto handle_error;
}

gold[0] = 20;
host_year[0] = "2004";

gold[1] = 15;
host_year[1] = "2008";

null_ind[0] = null_ind[1] = 0;
error = cci_bind_param_array_size (req, 2);
if (error < 0)
{
    printf ("bind_param_array_size error: %d\n", error);
    goto handle_error;
}

error =
    cci_bind_param_array (req, 1, CCI_A_TYPE_INT, gold,
null_ind, CCI_U_TYPE_INT);
if (error < 0)
{
    printf ("bind_param_array error: %d\n", error);
    goto handle_error;
}

error =
    cci_bind_param_array (req, 2, CCI_A_TYPE_STR, host_year,

```

```

null_ind, CCI_U_TYPE_INT);
if (error < 0)
{
    printf ("bind_param_array error: %d\n", error);
    goto handle_error;
}

n_executed = cci_execute_array (req, &result, &cci_error);
if (n_executed < 0)
{
    printf ("execute error: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
    goto handle_error;
}
for (i = 1; i <= n_executed; i++)
{
    printf ("query %d\n", i);
    printf ("result count = %d\n", CCI_QUERY_RESULT_RESULT
(result, i));
    printf ("error message = %s\n", CCI_QUERY_RESULT_ERR_MSG
(result, i));
    printf ("statement type = %d\n",
        CCI_QUERY_RESULT_STMT_TYPE (result, i));
}
error = cci_query_result_free (result, n_executed);
if (error < 0)
{
    printf ("query_result_free: %d\n", error);
    goto handle_error;
}
error = cci_end_tran(con, CCI_TRAN_COMMIT, &cci_error);
if (error < 0)
{
    printf ("end_tran: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
    goto handle_error;
}

```

## cci\_execute\_batch

```

int cci_execute_batch(int conn_handle, int num_sql_stmt, char **sql_stmt, T_CCI_QUERY_RESULT
**query_result, T_CCI_ERROR *err_buf)

```

In CCI, multiple jobs can be processed simultaneously when using DML queries such as **INSERT / UPDATE / DELETE**. `CCI_QUERY_RESULT_RESULT` and `cci_execute_batch()` functions can be used to execute such batch jobs. Note that prepared statements cannot be used in the `cci_execute_batch()` function. The query result will be stored on the array of `T_CCI_QUERY_RESULT` structure.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **num\_sql\_stmt** – (IN) The number of *sql\_stmt*
- **sql\_stmt** – (IN) SQL statement array
- **query\_result** – (OUT) The results of *sql\_stmt*
- **err\_buf** – (OUT) Database error buffer

#### Returns:

- Success: The number of executed queries (it has nothing to do with query execution success/failure.)
- Failure: Negative number
  - **CCI\_ER\_CON\_HANDLE**
  - **CCI\_ER\_DBMS**
  - **CCI\_ER\_COMMUNICATION**
  - **CCI\_ER\_NO\_MORE\_MEMORY**
  - **CCI\_ER\_CONNECT**
  - **CCI\_ER\_QUERY\_TIMEOUT**
  - **CCI\_ER\_LOGIN\_TIMEOUT**

Executes *sql\_stmt* as many times as *num\_sql\_stmt* specified as a parameter and returns the number of queries executed with the *query\_result* variable. You can use `CCI_QUERY_RESULT_RESULT`, `c:macro:CCI_QUERY_RESULT_ERR_NO`, `CCI_QUERY_RESULT_ERR_MSG` and `CCI_QUERY_RESULT_STMT_TYPE` macros to get the result of each query. Regarding the summary of these macros, see the `cci_execute_array()` function.

Note that the validity check is not performed for each parameter entered in the macro.

After using the *query\_result* variable, you must delete the query result by using the `cci_query_result_free()` function.

If autocommit mode is on, each query in the array is committed after executing.

**Note**

- In the previous version of 2008 R4.3, if the autocommit is on, all queries in the array were committed after all of them are executed. From 2008 R4.3 version, each query in the array is committed right after each running.
- If autocommit mode is off, after the general error occurs during executing one of the queries in the array on the cci\_execute\_batch function which does a batch processing of the queries, the query with an error is ignored and the next query is executed. But if the deadlock occurs, the error occurs as rolling back the transaction.

```

...
char **queries;
T_CCI_QUERY_RESULT *result;
int n_queries, n_executed;
...
count = 3;
queries = (char **) malloc (count * sizeof (char *));
queries[0] =
    "insert into athlete(name, gender, nation_code, event)
values('Ji-sung Park', 'M', 'KOR', 'Soccer')";
queries[1] =
    "insert into athlete(name, gender, nation_code, event)
values('Joo-young Park', 'M', 'KOR', 'Soccer')";
queries[2] =
    "select * from athlete order by code desc limit 2";

//calling cci_execute_batch()
n_executed = cci_execute_batch (con, count, queries, &result,
&cci_error);
if (n_executed < 0)
{
    printf ("execute_batch: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
    goto handle_error;
}
printf ("%d statements were executed.\n", n_executed);

for (i = 1; i <= n_executed; i++)
{
    printf ("query %d\n", i);
    printf ("result count = %d\n", CCI_QUERY_RESULT_RESULT
(result, i));
    printf ("error message = %s\n", CCI_QUERY_RESULT_ERR_MSG
(result, i));
    printf ("statement type = %d\n",

```

```

        CCI_QUERY_RESULT_STMT_TYPE (result, i));
    }

    error = cci_query_result_free (result, n_executed);
    if (error < 0)
    {
        printf ("query_result_free: %d\n", error);
        goto handle_error;
    }
    ...

```

## cci\_execute\_result

int cci\_execute\_result(int req\_handle, T\_CCI\_QUERY\_RESULT \*\*query\_result, T\_CCI\_ERROR \*err\_buf)

The **cci\_execute\_result** function stores the execution results (e.g. statement type, result count) performed by `cci_execute()` to the array of **T\_CCI\_QUERY\_RESULT** structure. You can use `CCI_QUERY_RESULT_RESULT`, `CCI_QUERY_RESULT_ERR_NO`, `CCI_QUERY_RESULT_ERR_MSG`, `CCI_QUERY_RESULT_STMT_TYPE` macros to get the results of each query. Regarding the summary of these macros, see the `cci_execute_array()` function.

Note that the validity check is not performed for each parameter entered in the macro.

The memory of used query results must be released by the `cci_query_result_free()` function.

### Parameters:

- **req\_handle** – (IN) Request handle of the prepared statement
- **query\_result** – (OUT) Query results
- **err\_buf** – (OUT) Database error buffer

### Returns:

Success: The number of queries, Failure: Negative number

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_COMMUNICATION**

```

...
T_CCI_QUERY_RESULT *qr;

```

```

...

cci_execute( ... );
res = cci_execute_result(req_h, &qr, &err_buf);
if (res < 0)
{
    /* error */
}
else
{
    for (i=1 ; i <= res ; i++)
    {
        result_count = CCI_QUERY_RESULT_RESULT(qr, i);
        stmt_type = CCI_QUERY_RESULT_STMT_TYPE(qr, i);
    }
    cci_query_result_free(qr, res);
}
...

```

## cci\_fetch

int cci\_fetch(int req\_handle, T\_CCI\_ERROR \*err\_buf)

The **cci\_fetch** function fetches the query result executed by `cci_execute()` from the server-side CAS and stores it to the client buffer. The `cci_get_data()` function can be used to identify the data of a specific column from the fetched query result.

Parameters:

- **req\_handle** – (IN) Request handle
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CAS\_ER\_HOLDABLE\_NOT\_ALLOWED**
- **CCI\_ER\_NO\_MORE\_DATA**
- **CCI\_ER\_RESULT\_SET\_CLOSED**
- **CCI\_ER\_DELETED\_TUPLE**
- **CCI\_ER\_COMMUNICATION**

- **CCI\_ER\_NO\_MORE\_MEMORY**

## cci\_fetch\_buffer\_clear

int cci\_fetch\_buffer\_clear(int req\_handle)

The **cci\_fetch\_buffer\_clear** function clears the records temporarily stored in the client buffer.

Parameters:

- **req\_handle** – Request handle

Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**

## cci\_fetch\_sensitive

int cci\_fetch\_sensitive(int req\_handle, T\_CCI\_ERROR \*err\_buf)

The **cci\_fetch\_sensitive** function sends changed values for sensitive column when the **SELECT** query result is delivered. If the results by *req\_handle* are not sensitive, they are same as the ones by `cci_fetch()`. The return value of **CCI\_ER\_DELETED\_TUPLE** means that the given row has been deleted.

Parameters:

- **req\_handle** – (IN) Request handle
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_NO\_MORE\_DATA**
- **CCI\_ER\_COMMUNICATION**

- **CCI\_ER\_DBMS**

- **CCI\_ER\_DELETED\_TUPLE**

sensitive column means the item that can provide updated value in the **SELECT** list when you re-request the results. For example, if a column is directly used as an item of the **SELECT** list without aggregation operation, this column can be called a sensitive column.

When you fetch the result again, the sensitive result receive the data from the server, not from the client buffer.

### cci\_fetch\_size

int cci\_fetch\_size(int req\_handle, int fetch\_size)

This function is deprecated. Even if it's called, there will be ignored.

### cci\_get\_autocommit

CCI\_AUTOCOMMIT\_MODE cci\_get\_autocommit(int conn\_handle)

The **cci\_get\_autocommit** function returns the auto-commit mode currently configured.

Parameters:

- **conn\_handle** – (IN) Connection handle

Returns:

- **CCI\_AUTOCOMMIT\_TRUE**: Auto-commit mode is ON
- **CCI\_AUTOCOMMIT\_FALSE**: Auto-commit mode is OFF
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

### cci\_get\_bind\_num

int cci\_get\_bind\_num(int req\_handle)

The **cci\_get\_bind\_num** function gets the number of input bindings. If the SQL statement used during preparation is composed of multiple queries, it represents the number of input bindings used in all queries.

**Parameters:**

- **req\_handle** – (IN) Request handle for the prepared statement

**Returns:**

The number of input bindings

- **CCI\_ER\_REQ\_HANDLE**

## cci\_get\_cas\_info

**int cci\_get\_cas\_info(int conn\_handle, char \*info\_buf, int buf\_length, T\_CCI\_ERROR \*err\_buf)**

Retrieve CAS information which is connected to conn\_handle. The string of the below format is returned to the info\_buf.

```
<host>:<port>,<cas id>,<cas process id>
```

The below is an example.

```
127.0.0.1:33000,1,12916
```

Through CAS ID, you can check the SQL log file of this CAS easily.

For details, see [Checking SQL Log](#).

**Parameters:**

- **conn\_handle** – (IN) connection handle
- **info\_buf** – (OUT) connection information buffer
- **buf\_length** – (IN) buffer length of the connection information
- **err\_buf** – (OUT) Error buffer

**Returns:**

error code

- **CCI\_ER\_INVALID\_ARGS**
- **CCI\_ER\_CON\_HANDLE**

## cci\_get\_class\_num\_objs

int cci\_get\_class\_num\_objs(int conn\_handle, char \*class\_name, int flag, int \*num\_objs, int \*num\_pages, T\_CCI\_ERROR \*err\_buf)

The **cci\_get\_class\_num\_objs** function gets the number of objects of the *class\_name* class and the number of pages being used. If the flag is configured to 1, an approximate value is fetched; if it is configured to 0, an exact value is fetched.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **class\_name** – (IN) Class name
- **flag** – (IN) 0 or 1
- **num\_objs** – (OUT) The number of objects
- **num\_pages** – (OUT) The number of pages
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## CCI\_GET\_COLLECTION\_DOMAIN

### CCI\_GET\_COLLECTION\_DOMAIN(*u\_type*)

If *u\_type* is set, multiset, or sequence type, this macro gets the domain of the set, multiset or sequence. If *u\_type* is not a set type, the return value is the same as *u\_type*.

**Parameters:**

- **u\_type** (Type) – (IN)

**Returns:**

Type (CCI\_U\_TYPE)

**cci\_get\_cur\_oid**

int cci\_get\_cur\_oid(int req\_handle, char \*oid\_str\_buf)

The **cci\_get\_cur\_oid** function gets OID of the currently fetched records if **CCI\_INCLUDE\_OID** is configured in execution. The OID is represented in string for a page, slot, or volume.

**Parameters:**

- **conn\_handle** – (IN) Request handle
- **oid\_str\_buf** – (OUT) OID string

**Returns:**

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**

**cci\_get\_data**

int cci\_get\_data(int req\_handle, int col\_no, int type, void \*value, int \*indicator)

The **cci\_get\_data** function gets the *col\_no* -th value from the currently fetched result.

**Parameters:**

- **req\_handle** – (IN) Request handle
- **col\_no** – (IN) One-based column index. It starts with 1.
- **type** – (IN) Data type (defined in the **T\_CCI\_A\_TYPE**) of *value* variable

- **value** – (OUT) Variable address for data to be stored. If *type* is one of (CCI\_A\_TYPE\_STR, CCI\_A\_TYPE\_SET, CCI\_A\_TYPE\_BLOB or CCI\_A\_TYPE\_CLOB) and the value of a column is NULL, the *value* will be NULL, too.

- **indicator** –

(OUT) **NULL** indicator. (-1 : **NULL**)

- If *type* is **CCI\_A\_TYPE\_STR** : -1 is returned in case of **NULL**; the length of string stored in *value* is returned, otherwise.
- If *type* is not **CCI\_A\_TYPE\_STR** : -1 is returned in case of **NULL**, 0 is returned, otherwise.

Returns:

Error code (0: success)

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_TYPE\_CONVERSION**
- **CCI\_ER\_COLUMN\_INDEX**
- **CCI\_ER\_ATYPE**

The *type* of the *value* variable is determined based on the given *type* argument, and the value or the pointer is copied to the *value* variable accordingly. For a value to be copied, the memory for the address to be transferred to the *value* variable must have been previously assigned. Note that if a pointer is copied, a pointer in the application client library is returned, so the value becomes invalid next time the `cci_get_data()` function is called.

In addition, the pointer returned by the pointer copy must not be freed. However, if the *type* is **CCI\_A\_TYPE\_SET**, the memory must be freed by using the `cci_set_free()` function after using the set because the set is returned after the **T\_CCI\_SET** type memory is allocated. The following table shows the summary of *type* arguments and data types of their corresponding *value* values.

| type              | value Type                         | Meaning                                   |
|-------------------|------------------------------------|-------------------------------------------|
| CCI_A_TYPE_STR    | char **                            | pointer copy                              |
| CCI_A_TYPE_INT    | int *                              | value copy                                |
| CCI_A_TYPE_FLOAT  | float *                            | value copy                                |
| CCI_A_TYPE_DOUBLE | double *                           | value copy                                |
| CCI_A_TYPE_BIT    | <b>T_CCI_BIT</b> *                 | value copy (pointer copy for each member) |
| CCI_A_TYPE_SET    | <b>T_CCI_SET</b> *                 | memory allocation and value copy          |
| CCI_A_TYPE_DATE   | <b>T_CCI_DATE</b> *                | value copy                                |
| CCI_A_TYPE_BIGINT | int64_t * (For Windows: __int64 *) | value copy                                |
| CCI_A_TYPE_BLOB   | <b>T_CCI_BLOB</b> *                | memory allocation and value copy          |
| CCI_A_TYPE_CLOB   | <b>T_CCI_CLOB</b> *                | memory allocation and value copy          |

### Remark

- For **LOB** type, if the `cci_get_data()` function is called, meta data with the **LOB** type column (locator) is displayed. To call data of the **LOB** type column, the `cci_blob_read()` function should be called.

The below example shows a part of a code to print out the fetched result with `cci_get_data()`.

```

...

if ((res=cci_get_data(req, i, CCI_A_TYPE_INT, &buffer, &ind))<0)
{
    printf( "%s(%d): cci_get_data fail\n", __FILE__, __LINE__);
    goto handle_error;
}
if (ind != -1)
    printf("%d \t|", buffer);
else
    printf("NULL \t|");
...

```

### cci\_get\_db\_parameter

int cci\_get\_db\_parameter(int conn\_handle, T\_CCI\_DB\_PARAM param\_name, void \*value, T\_CCI\_ERROR \*err\_buf)

The **cci\_get\_db\_parameter** function gets a parameter value specified in the database.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **param\_name** – (IN) System parameter name
- **value** – (OUT) Parameter value
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_PARAM\_NAME**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

The data type of *value* for *param\_name* is shown in the table below.

| param_name                         | value Type | note     |
|------------------------------------|------------|----------|
| <b>CCI_PARAM_ISOLATION_LEVEL</b>   | int *      | get/set  |
| <b>CCI_PARAM_LOCK_TIMEOUT</b>      | int *      | get/set  |
| <b>CCI_PARAM_MAX_STRING_LENGTH</b> | int *      | get only |
| <b>CCI_PARAM_AUTO_COMMIT</b>       | int *      | get only |

In `cci_get_db_parameter()` and `cci_set_db_parameter()`, the input/output unit of **CCI\_PARAM\_LOCK\_TIMEOUT** is milliseconds.

#### Warning

In the earlier version of CUBRID 9.0, you should be careful that the output unit of **CCI\_PARAM\_LOCK\_TIMEOUT** is second.

**CCI\_PARAM\_MAX\_STRING\_LENGTH** is measured in bytes and it gets a value defined in the **MAX\_STRING\_LENGTH** broker parameter.

## cci\_get\_db\_version

```
int cci_get_db_version(int conn_handle, char *out_buf, int out_buf_size)
```

The **cci\_get\_db\_version** function gets the Database Management System (DBMS) version.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **out\_buf** – (OUT) Result buffer
- **out\_buf\_size** – (IN) *out\_buf* size

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## cci\_get\_err\_msg

int cci\_get\_err\_msg(int err\_code, char \*msg\_buf, int msg\_buf\_size)

The **cci\_get\_err\_msg** function stores error messages corresponding to the error code in the error message buffer. For details on error codes and error messages, see [CCI Error Codes and Error Messages](#).

Parameters:

- **err\_code** – (IN) Error code
- **msg\_buf** – (OUT) Error message buffer
- **msg\_buf\_size** – (IN) *msg\_buf* size

Returns:

0: Success, -1: Failure

note:: From CUBRID 9.1, CUBRID ensures that all functions which have err\_buf parameter store an error value into err\_buf parameter, so you don't need to use cci\_get\_err\_msg function if a function has err\_buf parameter.

```
req = cci_prepare (con, query, 0, &err_buf);
if (req < 0)
{
    printf ("error: %d, %s\n", err_buf.err_code,
err_buf.err_msg);
    goto handle_error;
}
```

On the previous version of 9.1, an err\_buf value was stored only when CCI\_ER\_DBMS error occurred. So printing an error message should have been separated by CCI\_ER\_DBMS error.

```
req = cci_prepare (con, query, 0, &err_buf);
if (req < 0)
{
    if (req == CCI_ER_DBMS)
    {
        printf ("error: %s\n", err_buf.err_msg);
    }
    else
    {
        char msg_buf[1024];
        cci_get_err_msg(req, msg_buf, 1024);
        printf ("error: %s\n", msg_buf);
    }
    goto handle_error;
}
```

From 9.1, you can simplify the branch of the above code by using `cci_get_error_msg` function.

```
req = cci_prepare (con, query, 0, &err_buf);
if (req < 0)
{
    char msg_buf[1024];
    cci_get_error_msg(req, err_buf, msg_buf, 1024);
    printf ("error: %s\n", msg_buf);
    goto handle_error;
}
```

## `cci_get_error_msg`

`int cci_get_error_msg(int err_code, T_CCI_ERROR *err_buf, char *msg_buf, int msg_buf_size)`

Saves the error messages corresponding to the CCI error codes in the message buffer. If the value of CCI error code is **CCI\_ER\_DBMS**, the database error buffer (*err\_buf*) receives the error message sent from the data server and saves it in the message buffer(*msg\_buf*). For details on error codes and messages, see [CCI Error Codes and Error Messages](#).

Parameters:

- **err\_code** – (IN) Error code
- **err\_buf** – (IN) Database error buffer
- **msg\_buf** – (OUT) Error message buffer
- **msg\_buf\_size** – (IN) *msg\_buf* size

**Returns:**

0: Success, -1: Failure

## cci\_get\_holdability

### int cci\_get\_holdability(int conn\_handle)

Returns the cursor holdability setting value about the result set from the connection handle. When it is 1, the connection is disconnected or the cursor is holdable until the result set is intentionally closed regardless of commit. When it is 0, the result set is closed when committed and the cursor is not holdable. For more details on cursor holdability, see Cursor Holdability.

**Parameters:**

- **conn\_handle** – (IN) Connection handle

**Returns:**

0 (not holdable), 1 (holdable)

- **CCI\_ER\_CON\_HANDLE**

## cci\_get\_last\_insert\_id

### int cci\_get\_last\_insert\_id(int conn\_handle, void \*value, T\_CCI\_ERROR \*err\_buf)

Gets the primary key of the INSERT statement which executed at the last time.

**Parameters:**

- **conn\_handle** – (IN) Request handle
- **value** – (OUT) The pointer of the result buffer pointer(char \*\*). It stores the last primary key of INSERT statement executed on the last time. The memory which this pointer indicates doesn't need to be released, because it is the fixed buffer inside the connection handle.
- **err\_buf** – (OUT) Error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**
- **CCI\_ER\_INVALID\_ARGS**

```
#include <stdio.h>
#include "cas_cci.h"

int main ()
{
    int con = 0;
    int req = 0;

    int error;
    T_CCI_ERROR cci_error;

    char *query = "insert into t1 values(NULL);";
    char *value = NULL;

    con = cci_connect ("localhost", 33000, "demodb", "dba", "");

    if (con < 0)
    {
        printf ("con error\n");
        return;
    }

    req = cci_prepare (con, query, 0, &cci_error);
    if (req < 0)
    {
        printf ("cci_prepare error: %d\n", req);
        printf ("cci_error: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
        return;
    }
    error = cci_execute (req, 0, 0, &cci_error);
    if (error < 0)
    {
        printf ("cci_execute error: %d\n", error);
        return;
    }

    error = cci_get_last_insert_id (con, &value, &cci_error);
```

```
    if (error < 0)
    {
        printf ("cci_get_last_insert_id error: %d\n", error);
        return;
    }

    printf ("## last insert id: %s\n", value);

    error = cci_close_req_handle (req);
    error = cci_disconnect (con, &cci_error);
    return 0;
}
```

## cci\_get\_login\_timeout

int cci\_get\_login\_timeout(int conn\_handle, int \*timeout, T\_CCI\_ERROR \*err\_buf)

Return login timeout value to *timeout*.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **timeout** – (OUT) A pointer to login timeout value(unit: millisecond)
- **err\_buf** – (OUT) Error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_INVALID\_ARGS**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_get\_query\_plan

int cci\_get\_query\_plan(int req\_handle, char \*\*out\_buf\_p)

Saves the query plan to the result buffer; the query plan about the request handle which the cci\_prepare function returned. You can call this function whether to call the cci\_execute function or not.

After calling the `cci_get_query_plan` function, if the use of a result buffer ends, you should call the `cci_query_info_free()` function to release the result buffer created by `cci_get_query_plan` function.

```
char *out_buf;
...
req = cci_prepare (con, query, 0, &cci_error);
...
ret = cci_get_query_plan(req, &out_buf);
...
printf("plan = %s", out_buf);
cci_query_info_free(out_buf);
```

Parameters:

- **req\_handle** – (IN) Request handle
- **out\_buf\_p** – (OUT) The pointer of a result buffer pointer

Returns:

Error code

- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

#### ! See also

`cci_query_info_free()`

## cci\_query\_info\_free

`int cci_query_info_free(char *out_buf)`

Releases the result buffer memory allocated from the `cci_get_query_plan()` function.

**Parameters:**

- **req\_handle** – (IN) Request handle
- **out\_buf** – (OUT) Result buffer pointer

**Returns:**

Error code

- **CCI\_ER\_NO\_MORE\_MEMORY**

 **See also**

`cci_get_query_plan()`

## cci\_get\_query\_timeout

**int cci\_get\_query\_timeout(int req\_handle)**

The **cci\_get\_query\_timeout** function returns timeout configured for query execution.

**Parameters:**

- **req\_handle** – (IN) Request handle

**Returns:**

Success: Timeout value configured in current request handle (unit: msec.), Failure: Error code

- **CCI\_ER\_REQ\_HANDLE**

## cci\_get\_result\_info

**T\_CCI\_COL\_INFO \*cci\_get\_result\_info(int req\_handle, T\_CCI\_CUBRID\_STMT \*stmt\_type, int \*num)**

If the prepared statement is **SELECT**, the **T\_CCI\_COL\_INFO** struct that stores the column information about the execution result can be obtained by using this function. If it is not **SELECT**, **NULL** is returned and the *num* value becomes 0.

**Parameters:**

- **req\_handle** – (IN) Request handle for the prepared statement
- **stmt\_type** – (OUT) Command type
- **num** – (OUT) The number of columns in the **SELECT** statement (if *stmt\_type* is **CUBRID\_STMT\_SELECT**)

**Returns:**

Success: Result info pointer, Failure: **NULL**

You can access the **T\_CCI\_COL\_INFO** struct directly to get the column information from the struct, but you can also use a macro to get the information, which is defined as follows. The address of the **T\_CCI\_COL\_INFO** struct and the column index are specified as parameters for each macro. The macro can be called only for the **SELECT** query. Note that the validity check is not performed for each parameter entered in each macro. If the return type of the macro is `char*`, do not free the memory pointer.

| Macro                                        | Return Type         | Meaning                  |
|----------------------------------------------|---------------------|--------------------------|
| <code>CCI_GET_RESULT_INFO_TYPE</code>        | <b>T_CCI_U_TYPE</b> | column type              |
| <code>CCI_GET_RESULT_INFO_SCALE</code>       | short               | column scale             |
| <code>CCI_GET_RESULT_INFO_PRECISION</code>   | int                 | column precision         |
| <code>CCI_GET_RESULT_INFO_NAME</code>        | char *              | column name              |
| <code>CCI_GET_RESULT_INFO_ATTR_NAME</code>   | char *              | column attribute name    |
| <code>CCI_GET_RESULT_INFO_CLASS_NAME</code>  | char *              | column class name        |
| <code>CCI_GET_RESULT_INFO_IS_NON_NULL</code> | char (0 or 1)       | whether a column is NULL |

```

col_info = cci_get_result_info (req, &stmt_type, &col_count);
if (col_info == NULL)
{
    printf ("get_result_info error\n");
    goto handle_error;
}

for (i = 1; i <= col_count; i++)
{
    printf ("%12s = %d\n", "type", CCI_GET_RESULT_INFO_TYPE
(col_info, i));
    printf ("%12s = %d\n", "scale",
        CCI_GET_RESULT_INFO_SCALE (col_info, i));
    printf ("%12s = %d\n", "precision",
        CCI_GET_RESULT_INFO_PRECISION (col_info, i));
    printf ("%12s = %s\n", "name", CCI_GET_RESULT_INFO_NAME
(col_info, i));
    printf ("%12s = %s\n", "attr_name",
        CCI_GET_RESULT_INFO_ATTR_NAME (col_info, i));
    printf ("%12s = %s\n", "class_name",
        CCI_GET_RESULT_INFO_CLASS_NAME (col_info, i));
    printf ("%12s = %s\n", "is_non_null",
        CCI_GET_RESULT_INFO_IS_NON_NULL (col_info,i) ?
"true" : "false");
}

```

## CCI\_GET\_RESULT\_INFO\_ATTR\_NAME

### CCI\_GET\_RESULT\_INFO\_ATTR\_NAME(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_ATTR\_NAME** macro gets the actual attribute name of the *index*-th column of a prepared **SELECT** list. If there is no name for the attribute (constant, function, etc), " " (empty string) is returned. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid. You cannot delete the returned memory pointer with **free()**.

#### Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) A pointer to the column information fetched by `cci_get_result_info()`
- **index** (int) – (IN) Column index

#### Returns:

Attribute name (char \*)

## CCI\_GET\_RESULT\_INFO\_CLASS\_NAME

### CCI\_GET\_RESULT\_INFO\_CLASS\_NAME(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_CLASS\_NAME** macro gets the *index*-th column's class name of a prepared **SELECT** list. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid. You cannot delete the returned memory pointer with **free** (). The return value can be **NULL**.

#### Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) Column info pointer by `cci_get_result_info()`
- **index** (int) – (IN) Column index

#### Returns:

Class name (char \*)

## CCI\_GET\_RESULT\_INFO\_IS\_NON\_NULL

### CCI\_GET\_RESULT\_INFO\_IS\_NON\_NULL(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_IS\_NON\_NULL** macro gets a value indicating whether the *index*-th column of a prepared **SELECT** list is nullable. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid.

When a column of a **SELECT** list is not a column but an expression, CUBRID cannot judge it's NON\_NULL or not; therefore, CCI\_GET\_RESULT\_INFO\_IS\_NON\_NULL macro always returns 0.

#### Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) Column info pointer by `cci_get_result_info()`
- **index** (int) – (IN) Column index

#### Returns:

0: nullable, 1: non **NULL**

## CCI\_GET\_RESULT\_INFO\_NAME

### CCI\_GET\_RESULT\_INFO\_NAME(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_NAME** macro gets the *index*-th column's name of a prepared **SELECT** list. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid. You cannot delete the returned memory pointer with **free** ().

Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) Column info pointer to `cci_get_result_info()`
- **index** (int) – (IN) Column index

Returns:

Column name (char \*)

## CCI\_GET\_RESULT\_INFO\_PRECISION

### CCI\_GET\_RESULT\_INFO\_PRECISION(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_PRECISION** macro gets the *index*-th column's precision of a prepared **SELECT** list. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid.

Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) Column info pointer by `cci_get_result_info()`
- **index** (int) – (IN) Column index

Returns:

precision (int)

## CCI\_GET\_RESULT\_INFO\_SCALE

### CCI\_GET\_RESULT\_INFO\_SCALE(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_SCALE** macro gets the *index*-th column's scale of a prepared **SELECT** list. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid.

Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) Column info pointer by `cci_get_result_info()`
- **index** (int) – (IN) Column index

Returns:

scale (int)

## CCI\_GET\_RESULT\_INFO\_TYPE

### CCI\_GET\_RESULT\_INFO\_TYPE(res\_info, index)

The **CCI\_GET\_RESULT\_INFO\_TYPE** macro gets the *index*-th column's type of a prepared **SELECT** list. It does not check whether the specified argument, *res\_info*, is **NULL** and whether *index* is valid.

If you want to check which column is a SET type or not, use `CCI_IS_SET_TYPE`.

Parameters:

- **res\_info** (T\_CCI\_COL\_INFO\*) – (IN) pointer to the column information fetched by `cci_get_result_info()`
- **index** (int) – (IN) Column index

Returns:

Column type (**T\_CCI\_U\_TYPE**)

## CCI\_IS\_SET\_TYPE

### CCI\_IS\_SET\_TYPE(u\_type)

The `CCI_IS_SET_TYPE` macro check whether *u\_type* is set type.

Parameters:

· **u\_type** (Type) – (IN)

Returns:

1 : set, 0 : not set

## CCI\_IS\_MULTISSET\_TYPE

### CCI\_IS\_MULTISSET\_TYPE(u\_type)

The CCI\_IS\_SET\_TYPE macro check whether *u\_type* is multiset type.

Parameters:

· **u\_type** (Type) – (IN)

Returns:

1 : multiset, 0 : not multiset

## CCI\_IS\_SEQUENCE\_TYPE

### CCI\_IS\_SEQUENCE\_TYPE(u\_type)

The CCI\_IS\_SET\_TYPE macro check whether *u\_type* is sequence type.

Parameters:

· **u\_type** (Type) – (IN)

Returns:

1 : sequence, 0 : not sequence

## CCI\_IS\_COLLECTION\_TYPE

### CCI\_IS\_COLLECTION\_TYPE(u\_type)

The CCI\_IS\_SET\_TYPE macro check whether *u\_type* is collection (set, multiset, sequence) type.

**Parameters:**

- **u\_type** (Type) – (IN)

**Returns:**

1 : collection (set, multiset, sequence), 0 : not collection

## cci\_get\_version

**int cci\_get\_version(int \*major, int \*minor, int \*patch)**

The cci\_get\_version function gets the version of CCI library. In case of version “9.2.0.0001”, 9 is the major version, 2 is the minor version, and 0 is the patch version.

**Parameters:**

- **major** – (OUT) major version
- **minor** – (OUT) minor version
- **patch** – (OUT) patch version

**Returns:**

Zero without exception (success)

**Note**

In CUBRID for Linux, you can check the file version of CCI library by using the **strings** command.

```
$ strings /home/usr1/CUBRID/lib/libcascci.so | grep VERSION  
VERSION=9.2.0.0001
```

## cci\_init

**void cci\_init()**

If you compile the CCI application program for Windows with static linking library(.lib), this function should be called always. In the other cases, this does not need to be called.

## cci\_is\_holdable

int cci\_is\_holdable(int req\_handle)

The **cci\_is\_holdable** function returns whether the request handle(req\_handle) is holdable or not.

### Parameters:

- **req\_handle** – (IN) Request handle for the prepared statement

### Returns:

- 1: holdable
- 0: not holdable
- **CCI\_ER\_REQ\_HANDLE**

### See also

[cci\\_prepare\(\)](#)

## cci\_is\_updatable

int cci\_is\_updatable(int req\_handle)

The **cci\_is\_updatable** function checks the SQL statement executing [cci\\_prepare\(\)](#) can make updatable result set (which means CCI\_PREPARE\_UPDATABLE is configured in *flag* when executing [cci\\_prepare\(\)](#) ).

### Parameters:

- **req\_handle** – (IN) Request handle for the prepared statement

### Returns:

- 1 : updatable
- 0 : not updatable

## · CCI\_ER\_REQ\_HANDLE

### cci\_next\_result

int cci\_next\_result(int req\_handle, T\_CCI\_ERROR \*err\_buf)

The **cci\_next\_result** function gets results of next query if **CCI\_EXEC\_QUERY\_ALL** flag is set upon `cci_execute()`. The information about the query fetched by next\_result can be obtained with `cci_get_result_info()`. If next\_result is executed successfully, the database is updated with the information of the current query.

You can execute multiple queries in the written order when **CCI\_EXEC\_QUERY\_ALL** flag is set on `cci_execute()`. At this time, CUBRID brings the first query's result after calling `cci_execute()`; CUBRID brings the second and the other queries' results after calling **cci\_next\_result** function. At this time, the column information about the query result can be brought by calling `cci_get_result_info()` function whenever `cci_execute()` function or **cci\_next\_result** function is called.

In other words, when you run Q1, Q2, and Q3 at once with calling `cci_prepare()` function, the result of Q1 is brought by calling `cci_execute()`; the result of Q2 or Q3 is brought by calling **cci\_next\_result**. The result of Q1, Q2 or Q3 is brought by calling `cci_get_result_info()` function for each time.

```
sql = "SELECT * FROM athlete; SELECT * FROM nation; SELECT *
FROM game";
req = cci_prepare (con, sql, 0, &error);
...
ret = cci_execute (req, CCI_EXEC_QUERY_ALL, 0, &error);
res_col_info = cci_get_result_info (req, &cmd_type, &col_count);
...
ret = cci_next_result (req, &error);
res_col_info = cci_get_result_info (req, &cmd_type, &col_count);
...
ret = cci_next_result (req, &error);
res_col_info = cci_get_result_info (req, &cmd_type, &col_count);
```

#### Parameters:

- **req\_handle** – (IN) Request handle of a prepared statement
- **err\_buf** – (OUT) Database error buffer

#### Returns:

- **SELECT** : The number of results
- **INSERT, UPDATE** : The number of records reflected
- Others : 0
- Failure : Error code
  - **CCI\_ER\_REQ\_HANDLE**
  - **CCI\_ER\_DBMS**
  - **CCI\_ER\_COMMUNICATION**

The error code **CAS\_ER\_NO\_MORE\_RESULT\_SET** means that no more result set exists.

## cci\_oid

**int cci\_oid(int conn\_handle, T\_CCI\_OID\_CMD cmd, char \*oid\_str, T\_CCI\_ERROR \*err\_buf)**

By the value of *cmd* argument, it executes the following behavior.

- **CCI\_OID\_DROP**: Deletes the given oid.
- **CCI\_OID\_IS\_INSTANCE**: Checks whether the given oid is an instance oid.
- **CCI\_OID\_LOCK\_READ**: Sets read lock on the given oid.
- **CCI\_OID\_LOCK\_WRITE**: Sets write lock on the given oid.

### Parameters:

- **conn\_handle** – (IN) Connection handle
- **cmd** – (IN) CCI\_OID\_DROP, CCI\_OID\_IS\_INSTANCE, CCI\_OID\_LOCK\_READ, CCI\_OID\_LOCK\_WRITE
- **oid\_str** – (IN) oid
- **err\_buf** – (OUT) Database error buffer

### Returns:

- when *cmd* is CCI\_OID\_IS\_INSTANCE
  - 0 : Non-instance

- 1 : Instance
- < 0 : error
- when *cmd* is CCI\_OID\_DROP, CCI\_OID\_LOCK\_READ or CCI\_OID\_LOCK\_WRITE

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OID\_CMD**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

## cci\_oid\_get

int cci\_oid\_get(int conn\_handle, char \*oid\_str, char \*\*attr\_name, T\_CCI\_ERROR \*err\_buf)

The **cci\_oid\_get** function gets the attribute values of the given oid. *attr\_name* is an array of the attributes, and it must end with **NULL**. If *attr\_name* is NULL, the information of all attributes is fetched. The request handle has the same form as when the SQL statement "SELECT attr\_name FROM oid\_class WHERE oid\_class = oid" is executed.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **attr\_name** – (IN) A list of attributes
- **err\_buf** – (OUT) Database error buffer

Returns:

Success: Request handle, Failure: Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_CONNECT**

## cci\_oid\_get\_class\_name

```
int cci_oid_get_class_name(int conn_handle, char *oid_str, char *out_buf, int out_buf_len,  
T_CCI_ERROR *err_buf)
```

The **cci\_oid\_get\_class\_name** function gets the class name of the given oid.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **out\_buf** – (OUT) Out buffer
- **out\_buf\_len** – (IN) *out\_buf* length
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_OBJECT**
- **CCI\_ER\_DBMS**

## cci\_oid\_put

```
int cci_oid_put(int conn_handle, char *oid_str, char **attr_name, char **new_val_str,  
T_CCI_ERROR *err_buf)
```

The **cci\_oid\_put** function configures the *attr\_name* attribute values of the given oid to *new\_val\_str*. The last value of *attr\_name* must be **NULL**. Any value of any type must be represented as a string. The value represented as a string is applied to the database after being converted depending on the attribute type on the server. To insert a **NULL** value, configure the value of *new\_val\_str* [i] to **NULL**.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **oid\_str** – (IN) oid
- **attr\_name** – (IN) The list of attribute names
- **new\_val\_str** – (IN) The list of new values
- **err\_buf** – (OUT) Database error buffer

#### Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**

## cci\_oid\_put2

```
int cci_oid_put2(int conn_handle, char *oidstr, char **attr_name, void **new_val, int *a_type,
T_CCI_ERROR *err_buf)
```

The **cci\_oid\_put2** function sets the *attr\_name* attribute values of the given oid to *new\_val*. The last value of *attr\_name* must be **NULL**. To insert a **NULL** value, set the value of *new\_val* [i] to **NULL**.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **oidstr** – (IN) oid
- **attr\_name** – (IN) A list of attribute names
- **new\_val** – (IN) A new value array
- **a\_type** – (IN) *new\_val* type array

- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**

The type of *new\_val* [i] for *a\_type* is shown in the table below.

#### Type of *new\_val*[i] for *a\_type*

| Type                     | value type                         |
|--------------------------|------------------------------------|
| <b>CCI_A_TYPE_STR</b>    | char **                            |
| <b>CCI_A_TYPE_INT</b>    | int *                              |
| <b>CCI_A_TYPE_FLOAT</b>  | float *                            |
| <b>CCI_A_TYPE_DOUBLE</b> | double *                           |
| <b>CCI_A_TYPE_BIT</b>    | <b>T_CCI_BIT</b> *                 |
| <b>CCI_A_TYPE_SET</b>    | <b>T_CCI_SET</b> *                 |
| <b>CCI_A_TYPE_DATE</b>   | <b>T_CCI_DATE</b> *                |
| <b>CCI_A_TYPE_BIGINT</b> | int64_t * (For Windows: __int64 *) |

```
char *attr_name[array_size]
void *attr_val[array_size]
int a_type[array_size]
int int_val
```

```

...

attr_name[0] = "attr_name0"
attr_val[0] = &int_val
a_type[0] = CCI_A_TYPE_INT
attr_name[1] = "attr_name1"
attr_val[1] = "attr_val1"
a_type[1] = CCI_A_TYPE_STR

...
attr_name[num_attr] = NULL

res = cci_put2(con_h, oid_str, attr_name, attr_val, a_type,
&error)

```

## cci\_prepare

**int cci\_prepare(int conn\_handle, char \*sql\_stmt, char flag, T\_CCI\_ERROR \*err\_buf)**

The `cci_prepare()` function prepares SQL execution by acquiring request handle for SQL statements. If a SQL statement consists of multiple queries, the preparation is performed only for the first query. With the parameter of this function, an address to **T\_CCI\_ERROR** where connection handle, SQL statement, *flag*, and error information are stored.

### Parameters:

- **conn\_handle** – (IN) Connection handle
- **sql\_stmt** – (IN) SQL statement
- **flag** – (IN) prepare flag (CCI\_PREPARE\_UPDATABLE, CCI\_PREPARE\_INCLUDE\_OID, CCI\_PREPARE\_CALL or CCI\_PREPARE\_HOLDABLE)
- **err\_buf** – (OUT) Database error buffer

### Returns:

Success: Request handle ID (int), Failure: Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_STR\_PARAM**

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_LOGIN\_TIMEOUT**

**CCI\_PREPARE\_UPDATABLE**, **CCI\_PREPARE\_INCLUDE\_OID**, **CCI\_PREPARE\_CALL** or **CCI\_PREPARE\_HOLDABLE** can be configured in *flag*. If **CCI\_PREPARE\_UPDATABLE** is configured, updatable resultset is created and **CCI\_PREPARE\_INCLUDE\_OID** is automatically configured. **CCI\_PREPARE\_UPDATABLE** and **CCI\_PREPARE\_HOLDABLE** cannot be used simultaneously in *flag*. If you want to call the Java Stored Procedure, specify **CCI\_PREPARE\_CALL** flag into the **cci\_prepare** function. You can see an related example on `cci_register_out_param()`.

The default value of whether to keep result set after commit is cursor holdability. Thus, if you want to configure **CCI\_PREPARE\_UPDATABLE** in *flag* of `cci_prepare()`, you should call `cci_set_holdability()` first before calling `cci_prepare()` so that cursor cannot be maintained.

However, not all updatable resultsets are created even though **CCI\_PREPARE\_UPDATABLE** is configured. So you need to check if the results are updatable by using `cci_is_updatable()` after preparation. You can use `cci_oid_put()` or `cci_oid_put2()` to update result sets.

The conditions of updatable queries are as follows:

- Must be **SELECT**.
- OID can be included in the query result.
- The column to be updated must be the one that belongs to the table specified in the **FROM** clause.

If **CCI\_PREPARE\_HOLDABLE** is set, a cursor is held as long as result set is closed or connection is disconnected after the statement is committed(see [Cursor Holdability](#)).

## cci\_prepare\_and\_execute

```
int cci_prepare_and_execute(int conn_handle, char *sql_stmt, int max_col_size, int *exec_retval,
T_CCI_ERROR *err_buf)
```

The **cci\_prepare\_and\_execute** function executes the SQL statement immediately and returns a request handle for the SQL statement. A request handle, SQL statement, the maximum length of a column to be fetched, error code, and the address of a **T\_CCI\_ERROR** construct variable in which error information being stored are specified as arguments. *max\_col\_size* is a value to configure the maximum length of a column to be sent to a client

when the column of a SQL statement is **CHAR**, **VARCHAR**, **BIT**, or **VARBIT**. If this value is 0, full length is fetched.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **sql\_stmt** – (IN) SQL statement
- **max\_col\_size** – (IN) The maximum length of a column to be fetched when it is a string data type in bytes. If this value is 0, full length is fetched.
- **exec\_retval** – (OUT) Success: Affected rows, Failure: Error code
- **err\_buf** – (OUT) Database error buffer

#### Returns:

Success: Request handle ID (int), Failure: Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_STR\_PARAM**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_QUERY\_TIMEOUT**

## cci\_property\_create

T\_CCI\_PROPERTIES \*cci\_property\_create()

The **cci\_property\_create** function creates **T\_CCI\_PROPERTIES** struct to configure DATASOURCE of CCI.

#### Returns:

Success: **T\_CCI\_PROPERTIES** struct pointer in which memory is allocated, Failure: **NULL**

#### ! See also

`cci_property_create()` , `cci_property_destroy()` , `cci_property_get()` , `cci_property_set()` ,  
`cci_datasource_create()` , `cci_datasource_destroy()` , `cci_datasource_release()`

## cci\_property\_destroy

`void cci_property_destroy(T_CCI_PROPERTIES *properties)`

The **cci\_property\_destroy** function destroys **T\_CCI\_PROPERTIES** struct.

Parameters:

- **properties** – **T\_CCI\_PROPERTIES** struct pointer to be destroyed

#### ! See also

`cci_property_create()` , `cci_property_destroy()` , `cci_property_get()` , `cci_property_set()` ,  
`cci_datasource_create()` , `cci_datasource_destroy()` , `cci_datasource_release()`

## cci\_property\_get

`char *cci_property_get(T_CCI_PROPERTIES *properties, char *key)`

The **cci\_property\_get** function retrieves the property value configured in the **T\_CCI\_PROPERTIES** struct.

Parameters:

- **properties** – **T\_CCI\_PROPERTIES** struct pointer which gets value corresponding to *key*
- **key** – Name of property to be retrieved (For name and description available properties, see the `cci_property_set()` )

**Returns:**

Success: String pointer of value corresponding to *key*,

Failure: NULL

**See also**

`cci_property_create()` , `cci_property_destroy()` , `cci_property_get()` , `cci_property_set()` ,  
`cci_datasource_create()` , `cci_datasource_destroy()` , `cci_datasource_release()`

**cci\_property\_set**

**int cci\_property\_set(T\_CCI\_PROPERTIES \*properties, char \*key, char \*value)**

It configures a property value in **T\_CCI\_PROPERTIES** struct.

**Parameters:**

- **properties** – **T\_CCI\_PROPERTIES** struct pointer in which *key* and *value* are stored
- **key** – String pointer of property name
- **value** – String pointer of property value

**Returns:**

Success: 1, Failure: 0

The property names and its meanings that can be configured in the struct are as follows:

| Property name | Type   | Default | Description                                      |
|---------------|--------|---------|--------------------------------------------------|
| user          | string |         | DB user name.                                    |
| password      | string |         | DB user password.                                |
| url           | string |         | Connection URL.<br>For specifying connection URL |

| Property name                   | Type | Default   | Description                                                                                          |
|---------------------------------|------|-----------|------------------------------------------------------------------------------------------------------|
|                                 |      |           | string, see <code>cci_connect_with_url()</code> .                                                    |
| pool_size                       | int  | 10        | Maximum number of connections which a connection pool can have.                                      |
| max_pool_size                   | int  | pool_size | Total number of connections to create when creating an initial datasource. maximum value is INT_MAX. |
| max_wait                        | msec | 1000      | Maximum waiting time to get connection.                                                              |
| pool_prepared_state<br>ment     | bool | false     | Whether to enable statement pooling. true or false.                                                  |
| max_open_prepared<br>_statement | int  | 1000      | The maximum number of prepared statements to maintain in the statement pool.                         |
| login_timeout                   | msec | 0(inf.)   | Login timeout applied when you create a                                                              |

| Property name               | Type   | Default                                       | Description                                                                                                                               |
|-----------------------------|--------|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
|                             |        |                                               | datasource with <code>cci_datasource_create()</code> function or internal timeout occurs in prepare/execute function.                     |
| query_timeout               | msec   | 0(inf.)                                       | Query timeout.                                                                                                                            |
| disconnect_on_query_timeout | bool   | no                                            | Whether to terminate connection when execution is discarded due to query execution timeout. yes or no.                                    |
| default_autocommit          | bool   | CCI_DEFAULT_AUTO_COMMIT in cubrid_broker.conf | Auto-commit mode specified when a datasource is created by <code>cci_datasource_create()</code> function. true or false.                  |
| default_isolation           | string | isolation_level in cubrid.conf                | Transaction isolation level specified when a datasource is created by <code>cci_datasource_create()</code> function. See the below table. |
| default_lock_timeout        | msec   | lock_timeout in cubrid.conf                   | lock timeout specified when a datasource is                                                                                               |

| Property name | Type | Default | Description                                               |
|---------------|------|---------|-----------------------------------------------------------|
|               |      |         | created by <code>cci_datasource_create()</code> function. |

If the number of prepared statements exceeds **max\_open\_prepared\_statement** value, the oldest prepared statement is released from the statement pool. If you reuse it later, it is added to the statement pool again.

A number of connections which a connection pool can contain is changable by using `cci_datasource_change_property()` function when it's required, but it cannot exceed **max\_pool\_size**. You can change this number when you want to handle the limitation of the number of connections. For example, usually set the number less than **max\_pool\_size**; raise the number when more connections are required than expected; shrink the number again when many connections are not required.

The number of connections which a connection pool can contain is limited until **pool\_size**; it's maximum value is **max\_pool\_size**.

When you set **login\_timeout**, **default\_autocommit**, **default\_isolation** or **default\_lock\_timeout**, these specified values are used in a connection which is returned when calling `cci_datasource_borrow()` function.

**login\_timeout**, **default\_autocommit**, **default\_isolation** or **default\_lock\_timeout** can be changed even after calling `cci_datasource_borrow()` function. Regarding this, see `cci_set_login_timeout()`, `cci_set_autocommit()`, `cci_set_isolation_level()`, `cci_set_lock_timeout()`. Changed values by functions which the name starts with **cci\_set\_** are only applied to the changed connection objects, and after the connection is released, they are restored as the specified values by `cci_property_set()`. It is restored as the default value when there is no value specified by `cci_property_set()` function.

#### Note

- When specifying values together in `cci_property_set()` function and URL string, values specified in `cci_property_set()` function have the first priority.
- **login\_timeout** is applied when you create a DATASOURCE object and internal reconnection occurs in `cci_prepare()` or `cci_execute()` function. Internal reconnection occurs when you get the connection object from DATASOURCE and from `cci_connect()` / `cci_connect_with_url()` function.

- Creating time of a DATASOURCE object can take more than an internal reconnection time; therefore, you can consider to apply **login\_timeout** differently on these two cases. For example, if you want to set 5000(5 sec.) in the former and 2000(2 sec.) in the later, for the later, use `cci_set_login_timeout()` after creating a DATASOURCE.

**default\_isolation** has one of the following configuration values. For details on isolation level, see [SET TRANSACTION ISOLATION LEVEL](#).

| isolation_level | Configuration Value   |
|-----------------|-----------------------|
| SERIALIZABLE    | "TRAN_SERIALIZABLE"   |
| REPEATABLE READ | "TRAN_REP_READ"       |
| READ COMMITTED  | "TRAN_READ_COMMITTED" |

DB user's name and password can be specified by the setting of **user** and **password** directly, or by the setting of **user** and **password** in **url**.

The following shows how to work as the first priority if both are specified.

- If both are specified, the value of direct setting will be first.
- If one of them is NULL, the value which is not NULL is used.
- If both are NULL, they are used as NULL value.
- If the direct setting value of DB user is NULL then "public" is used, else if the direct setting value of the password is NULL then NULL is used.
- If the direct setting value of the password is NULL, it follows the setting of URL.

The following shows that the DB user's name becomes "dba" and the password becomes "cubridpwd".

```
cci_property_set(ps, "user", "dba");
cci_property_set(ps, "password", "cubridpwd");
...
cci_property_set(ps, "url", "cci:cubrid:
192.168.0.1:33000:demodb:public:mypwd:?
```

```
logSlowQueries=true&slowQueryThresholdMillis=1000&logTraceApi=true&logTraceNetwork=true");
```

### See also

```
cci_property_create(),    cci_property_destroy(),    cci_property_get(),    cci_property_set(),  
cci_datasource_create(), cci_datasource_destroy(), cci_datasource_release()
```

## cci\_query\_result\_free

int cci\_query\_result\_free(T\_CCI\_QUERY\_RESULT \*query\_result, int num\_query)

The **cci\_query\_result\_free** function releases query results created by `cci_execute_batch()`, `cci_execute_array()` or `cci_execute_result()` function from memory.

Parameters:

- **query\_result** – (IN) Query results to release from memory
- **num\_query** – (IN) The number of arrays in *query\_result*

Returns:

0: success

```
T_CCI_QUERY_RESULT *qr;  
char **sql_stmt;  
  
...  
res = cci_execute_array(conn, &qr, &err_buf);  
  
...  
cci_query_result_free(qr, res);
```

## CCI\_QUERY\_RESULT\_ERR\_NO

**CCI\_QUERY\_RESULT\_ERR\_NO(query\_result, index)**

Since query results performed by `cci_execute_batch()`, `cci_execute_array()`, or `cci_execute_result()` function are stored as an array of **T\_CCI\_QUERY\_RESULT** structure, you need to check the query result for each item of the array.

**CCI\_QUERY\_RESULT\_ERR\_NO** fetches the error number for the array item specified as *index*, if it is not an error, it returns 0.

#### Parameters:

- **query\_result** (T\_CCI\_QUERY\_RESULT\*) – (IN) Query result to retrieve
- **index** (int) – (IN) Index of the result array(base :1). It represents a specific location of the result array.

#### Returns:

Error number

## CCI\_QUERY\_RESULT\_ERR\_MSG

### CCI\_QUERY\_RESULT\_ERR\_MSG(query\_result, index)

The **CCI\_QUERY\_RESULT\_ERR\_MSG** macro gets error messages about query results executed by `cci_execute_batch()`, `cci_execute_array()` or `cci_execute_result()` function. If there is no error message, this macro returns ""(empty string). It does not check whether the specified argument, *query\_result*, is **NULL**, and whether *index* is valid.

#### Parameters:

- **query\_result** (T\_CCI\_QUERY\_RESULT\*) – (IN) Query results of to be executed
- **index** (int) – (IN) Column index (base: 1)

#### Returns:

Error message

## CCI\_QUERY\_RESULT\_RESULT

### CCI\_QUERY\_RESULT\_RESULT(query\_result, index)

The **CCI\_QUERY\_RESULT\_RESULT** macro gets the result count executed by `cci_execute_batch()`, `cci_execute_array()` or `cci_execute_result()` function. It does not check whether the specified argument, *query\_result*, is **NULL** and whether *index* is valid.

#### Parameters:

- **query\_result** (T\_CCI\_QUERY\_RESULT\*) – (IN) Query results to be retrieved
- **index** (int) – (IN) Column index (base: 1)

#### Returns:

result count

## CCI\_QUERY\_RESULT\_STMT\_TYPE

### CCI\_QUERY\_RESULT\_STMT\_TYPE(query\_result, index)

Since query results performed by `cci_execute_batch()`, `cci_execute_array()` or `cci_execute_result()` function are stored as an array of T\_CCI\_QUERY\_RESULT type, you need to check the query result for each item of the array.

The **CCI\_QUERY\_RESULT\_STMT\_TYPE** macro gets the statement type for the array items specified as *index*.

It does not check whether the specified argument, *query\_result*, is **NULL** and whether *index* is valid.

#### Parameters:

- **query\_result** (T\_CCI\_QUERY\_RESULT\*) – (IN) Query results to be retrieved
- **index** (int) – (IN) Column index (base: 1)

#### Returns:

statement type (T\_CCI\_CUBRID\_STMT)

## cci\_register\_out\_param

```
int cci_register_out_param(int req_handle, int index)
```

The **cci\_register\_out\_param** function is used to bind parameters as outbind in a stored procedure. The index value starts from 1. To call this function, **CCI\_PREPARE\_CALL** flag of **cci\_prepare** function should be specified.

Parameters:

- **req\_handle** – (IN) Request handle

Returns:

Error code

- **CCI\_ER\_BIND\_INDEX**
- **CCI\_ER\_REQ\_HANDLE**
- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

The following shows how to print the string “Hello, CUBRID” string using a stored procedure.

```
$ vi cubrid.conf

$ cubrid service start
$ cubrid server start demodb
```

Implement and compile the class to be used as a stored procedure.

```
public class SpCubrid{
    public static void outTest(String[] o) {
        o[0] = "Hello, CUBRID";
    }
}

%javac SpCubrid.java
```

Load the compiled Java class into CUBRID.

```
$ loadjava demodb SpCubrid.class
```

Register the loaded Java class.

```
-- csql>
```

```
CREATE PROCEDURE test_out(x OUT STRING)
AS LANGUAGE JAVA
NAME 'SpCubrid.outTest(java.lang.String[] o)';
```

**On** the CCI application program, specify **\*\*CCI\_PREPARE\_CALL\*\*** flag **into** the **\*\*cci\_prepare\*\* function**, **and** bring the fetching **result after** setting the **position of** the outbind **parameter by** calling **\*\*cci\_register\_out\_param\*\***.

```
// On Linux, compile with "gcc -g -o jsp jsp.c -I$CUBRID/
include/ -L$CUBRID/lib/ -lcascci -lpthread"

`cci_prepare()`

## cci\_row\_count

`int cci_row_count(int conn_handle, int *row_count, T_CCI_ERROR *err_buf)`

The **cci\_row\_count** function gets the number of rows affected by the last executed query.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **row\_count** – (OUT) The number of rows affected by the last executed query
- **err\_buf** – (OUT) Error buffer

Returns:

Error code

- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_LOGIN\_TIMEOUT**

- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_DBMS**

## cci\_savepoint

int cci\_savepoint(int conn\_handle, T\_CCI\_SAVEPOINT\_CMD cmd, char \*savepoint\_name, T\_CCI\_ERROR \*err\_buf)

The **cci\_savepoint** function configures savepoint or performs transaction rollback to a specified savepoint. If *cmd* is set to **CCI\_SP\_SET**, it configures savepoint and if it is set to **CCI\_SP\_ROLLBACK**, it rolls back transaction to specified savepoint.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **cmd** – (IN) CCI\_SP\_SET or CCI\_SP\_ROLLBACK
- **savepoint\_name** – (IN) Savepoint name
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_QUERY\_TIMEOUT**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_DBMS**

```
con = cci_connect( ... );
... /* query execute */

/* Sets the savepoint named "savepoint1" */
cci_savepoint(con, CCI_SP_SET, "savepoint1", err_buf);

... /* query execute */
```

```
/* Rolls back to specified savepoint,"savepoint1" */
cci_savepoint(con, CCI_SP_ROLLBACK, "savepoint1", err_buf);
```

## cci\_schema\_info

int cci\_schema\_info(int conn\_handle, T\_CCI\_SCHEMA\_TYPE type, char \*class\_name, char \*attr\_name, char flag, T\_CCI\_ERROR \*err\_buf)

The **cci\_schema\_info** function gets schema information. If it is performed successfully, the results are managed by the request handle and can be fetched by fetch and getdata. If you want to retrieve a *class\_name* and *attr\_name* by using pattern matching of the **LIKE** statement, you should configure *flag*.

### Parameters:

- **conn\_handle** – (IN) Connection handle
- **type** – (IN) Schema type
- **class\_name** – (IN) Class name or NULL
- **attr\_name** – (IN) Attribute name or NULL
- **flag** – (IN) Pattern matching flag  
(**CCI\_CLASS\_NAME\_PATTERN\_MATCH** or **CCI\_ATTR\_NAME\_PATTERN\_MATCH**)
- **err\_buf** – (OUT) Database error buffer

### Returns:

Success: Request handle, Failure: Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_CONNECT**

Two types of *flag* s, **CCI\_CLASS\_NAME\_PATTERN\_MATCH**, and **CCI\_ATTR\_NAME\_PATTERN\_MATCH**, are used for pattern matching; you can configure these two *flag* s by using the OR operator ( | ). To use pattern matching, search by using the **LIKE**

statement. For example, to search the information on a column whose *class\_name* is “athlete” and *attr\_name* is “code,” you can enter as follows (in the example, “%code” is entered in the value of *attr\_name*).

```
cci_schema_info(conn, CCI_SCH_ATTRIBUTE, "athlete", "%code",
CCI_ATTR_NAME_PATTERN_MATCH, &error);
```

The table below shows record type for each type.

### Record for Each Type

In the **cci\_schema\_info** function, the *type* argument supports the pattern matching of the **LIKE** statement for the *class\_name* and *attr\_name*.

**type, class\_name(table name), and attr\_name(column name) That Supports Pattern Matching**

| type                                | class_name     | attr_name      |
|-------------------------------------|----------------|----------------|
| CCI_SCH_CLASS (VCLASS)              | string or NULL | always NULL    |
| CCI_SCH_ATTRIBUTE (CLASS ATTRIBUTE) | string or NULL | string or NULL |
| CCI_SCH_CLASS_PRIVILEGE             | string or NULL | always NULL    |
| CCI_SCH_ATTR_PRIVILEGE              | always NULL    | string or NULL |
| CCI_SCH_PRIMARY_KEY                 | string or NULL | always NULL    |
| CCI_SCH_TRIGGER                     | string or NULL | always NULL    |

- The type with “NULL” in class\_name doesn’t support the pattern matching about the table name.
- The type with “NULL” in attr\_name doesn’t support the pattern matching about the column name.
- If the pattern *flag* is not configured, exact matching will be used for the given table and column names; in this case, no result will be returned if the value is **NULL**.
- If *flag* is configured and the value is **NULL**, the result will be the same as when “%” is given in the **LIKE** statement. In other words, the result about all tables or all columns will be returned.

#### Note

TYPE column of **CCI\_SCH\_CLASS** and **CCI\_SCH\_VCLASS**: The proxy type is added. When used in OLEDB, ODBC or PHP, vclass is represented without distinguishing between proxy and vclass.

```
// gcc -o schema_info schema_info.c -m64 -I${CUBRID}/include -
lnsl ${CUBRID}/lib/libcascci.so -lpthread
```

```

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#include "cas_cci.h"

```

## cci\_set\_allocators

int cci\_set\_allocators(CCI\_MALLOC\_FUNCTION malloc\_func, CCI\_FREE\_FUNCTION free\_func, CCI\_REALLOC\_FUNCTION realloc\_func, CCI\_CALLOC\_FUNCTION calloc\_func)

The **cci\_set\_allocators** function registers the memory allocation/release functions used by users. By executing this function, you can use user-defined functions for every memory allocation/release jobs being processed in CCI API. If you do not use this function, system functions (malloc, free, realloc, and calloc) are used.

### Note

This function can be used only on Linux, so cannot be used on Windows.

**Parameters:**

- **malloc\_func** – (IN) Pointer of externally defined function corresponding to malloc
- **free\_func** – (IN) Pointer of externally defined function corresponding to free
- **realloc\_func** – (IN) Pointer of externally defined function corresponding to realloc
- **calloc\_func** – Pointer of externally defined function corresponding to calloc

**Returns:**

Error code (0: success)

- **CCI\_ER\_NOT\_IMPLEMENTED**

```
/*

        return 1;
    }

    test_simple (con);
    return 0;
}

```

## cci\_set\_autocommit

`int cci_set_autocommit(int conn_handle, CCI_AUTOCOMMIT_MODE autocommit_mode)`

The **cci\_set\_autocommit** function configures the auto-commit mode of current database connection. It is only used to turn ON/OFF of auto-commit mode. When this function is called, every transaction being processed is committed regardless of configured mode.

### Note

**CCI\_DEFAULT\_AUTOCOMMIT** in **cubrid\_broker.conf** determines the default autocommit mode upon program startup.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **autocommit\_mode** – (IN) Configures the auto-commit mode. It has one of the following value: CCI\_AUTOCOMMIT\_FALSE or CCI\_AUTOCOMMIT\_TRUE

Returns:

Error code (0: success)

 **Note**

**CCI\_DEFAULT\_AUTOCOMMIT**, a broker parameter configured in the **cubrid\_broker.conf** file, determines whether it is in auto-commit mode upon program startup.

## cci\_set\_db\_parameter

```
int cci_set_db_parameter(int conn_handle, T_CCI_DB_PARAM param_name, void *value,  
T_CCI_ERROR *err_buf)
```

The **cci\_set\_db\_parameter** function configures a system parameter. For the type of *value* for *param\_name*, see `cci_get_db_parameter()`.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **param\_name** – (IN) System parameter name
- **value** – (IN) Parameter value
- **err\_buf** – (OUT) Database error buffer

Returns:

Error code (0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_PARAM\_NAME**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## cci\_set\_element\_type

int cci\_set\_element\_type(T\_CCI\_SET set)

The **cci\_set\_element\_type** function gets the element type of the **T\_CCI\_SET** type value.

Parameters:

- **set** – (IN) cci set pointer

Returns:

Type

## cci\_set\_free

void cci\_set\_free(T\_CCI\_SET set)

The **cci\_set\_free** function releases the memory allocated to the type value of **T\_CCI\_SET** fetched by **CCI\_A\_TYPE\_SET** with `cci_get_data()`. The **T\_CCI\_SET** type value can be created through fetching `cci_get_data()` or `cci_set_make()` function.

Parameters:

- **set** – (IN) cci set pointer

## cci\_set\_get

int cci\_set\_get(T\_CCI\_SET set, int index, T\_CCI\_A\_TYPE a\_type, void \*value, int \*indicator)

The **cci\_set\_get** function gets the *index* -th data for the type value of **T\_CCI\_SET**.

## Parameters:

- **set** – (IN) cci set pointer
- **index** – (IN) set index (base: 1)
- **a\_type** – (IN) Type
- **value** – (OUT) Result buffer
- **indicator** – (OUT) null indicator

## Returns:

## Error code

- **CCI\_ER\_SET\_INDEX**
- **CCI\_ER\_TYPE\_CONVERSION**
- **CCI\_ER\_NO\_MORE\_MEMORY**
- **CCI\_ER\_COMMUNICATION**

The data type of *value* for *a\_type* is shown in the table below.

| <b>a_type</b>            | <b>value type</b> |
|--------------------------|-------------------|
| <b>CCI_A_TYPE_STR</b>    | char **           |
| <b>CCI_A_TYPE_INT</b>    | int *             |
| <b>CCI_A_TYPE_FLOAT</b>  | float *           |
| <b>CCI_A_TYPE_DOUBLE</b> | double *          |
| <b>CCI_A_TYPE_BIT</b>    | T_CCI_BIT *       |
| <b>CCI_A_TYPE_DATE</b>   | T_CCI_DATE *      |

| a_type            | value type                         |
|-------------------|------------------------------------|
| CCI_A_TYPE_BIGINT | int64_t * (For Windows: __int64 *) |

## cci\_set\_holdability

int cci\_set\_holdability(int conn\_handle, int holdable)

Sets whether to enable or disable cursor holdability of the result set from the connection level. When it is 1, the connection is disconnected or the cursor is holdable until the result set is intentionally closed regardless of commit. When it is 0, the result set is closed when committed and the cursor is not holdable. For more details on cursor holdability, see [Cursor Holdability](#).

### Parameters:

- **conn\_handle** – (IN) Connection handle
- **holdable** – (IN) Cursor holdability setting value (0: not holdable, 1: holdable)

### Returns:

### Error Code

- **CCI\_ER\_INVALID\_HOLDABILITY**

## cci\_set\_isolation\_level

int cci\_set\_isolation\_level(int conn\_handle, T\_CCI\_TRAN\_ISOLATION new\_isolation\_level, T\_CCI\_ERROR \*err\_buf)

The **cci\_set\_isolation\_level** function sets the transaction isolation level of connections. All further transactions for the given connections work as *new\_isolation\_level*.

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **new\_isolation\_level** – (IN) Transaction isolation level
- **err\_buf** – (OUT) Database error buffer

#### Returns:

#### Error code

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_CONNECT**
- **CCI\_ER\_ISOLATION\_LEVEL**
- **CCI\_ER\_DBMS**

**Note** If the transaction isolation level is set by `cci_set_db_parameter()`, only the current transaction is affected. When the transaction is complete, the transaction isolation level returns to the one set by CAS. You must use **cci\_set\_isolation\_level** () to set the isolation level for the entire connection.

## cci\_set\_lock\_timeout

`int cci_set_lock_timeout(int conn_handle, int locktimeout, T_CCI_ERROR *err_buf)`

The **cci\_set\_lock\_timeout** function specifies the connection lock timeout as milliseconds. This is the same with calling **cci\_set\_db\_parameter** (conn\_id, CCI\_PARAM\_LOCK\_TIMEOUT, &val, err\_buf). See `cci_set_db_parameter()` .

#### Parameters:

- **conn\_handle** – (IN) Connection handle
- **locktimeout** – (IN) lock timeout value(Unit: milliseconds).

#### Returns:

Error code(0: success)

- **CCI\_ER\_CON\_HANDLE**

- **CCI\_ER\_PARAM\_NAME**
- **CCI\_ER\_DBMS**
- **CCI\_ER\_COMMUNICATION**
- **CCI\_ER\_CONNECT**

## cci\_set\_login\_timeout

int cci\_set\_login\_timeout(int conn\_handle, int timeout, T\_CCI\_ERROR \*err\_buf)

The **cci\_set\_login\_timeout** function specifies the login timeout as milliseconds. The login timeout is applied when an internal reconnection occurs as `cci_prepare()` or `cci_execute()` function is called. This change is only applied to the current connection.

Parameters:

- **conn\_handle** – (IN) Connection handle
- **timeout** – (IN) Login timeout(unit: milliseconds)
- **err\_buf** – (OUT) Error buffer

Returns:

Error code(0: success)

- **CCI\_ER\_CON\_HANDLE**
- **CCI\_ER\_USED\_CONNECTION**

## cci\_set\_make

int cci\_set\_make(T\_CCI\_SET \*set, T\_CCI\_U\_TYPE u\_type, int size, void \*value, int \*indicator)

The **cci\_set\_make** function makes a set of a new **CCI\_A\_TYPE\_SET** type. The created set is sent to the server as **CCI\_A\_TYPE\_SET** by `cci_bind_param()`. The memory for the set created by **cci\_set\_make()** must be freed by `cci_set_free()`. The type of *value* for *u\_type* is shown in the table below.

Parameters:

- **set** – (OUT) cci set pointer

- **u\_type** – (IN) Element type
- **size** – (IN) set size
- **value** – (IN) set element
- **indicator** – (IN) null indicator array

Returns:

Error code

## cci\_set\_max\_row

int cci\_set\_max\_row(int req\_handle, int max)

The **cci\_set\_max\_row** function configures the maximum number of records for the results of the **SELECT** statement executed by `cci_execute()`. If the *max* value is 0, it is the same as not setting the value.

Parameters:

- **req\_handle** – (IN) Connection handle
- **max** – (IN) The maximum number of rows

Returns:

Error code

```
req = cci_prepare( ... );
cci_set_max_row(req, 1);
cci_execute( ... );
```

## cci\_set\_query\_timeout

int cci\_set\_query\_timeout(int req\_handle, int milli\_sec)

The **cci\_set\_query\_timeout** function configures timeout value for query execution.

Parameters:

- **req\_handle** – (IN) Request handle

- **milli\_sec** – Timeout (unit: msec.)

#### Returns:

Success: Request handle ID (int), Failure: Error code

- CCI\_ER\_REQ\_HANDLE

The timeout value configured by **cci\_set\_query\_timeout** affects `cci_prepare()`, `cci_execute()`, `cci_execute_array()`, `cci_execute_batch()` functions. When timeout occurs in the function and if the **disconnect\_on\_query\_timeout** value configured in `cci_connect_with_url()` connection URL is yes, it returns the **CCI\_ER\_QUERY\_TIMEOUT** error.

These functions can return the **CCI\_ER\_LOGIN\_TIMEOUT** error if **login\_timeout** is configured in the connection URL, which is an argument of `cci_connect_with_url()` function; this means that login timeout happens between application client and CAS during re-connection.

It is going through the process of re-connection between application client and CAS when an application restarts or it is re-scheduled. Re-scheduling is a process that CAS chooses an application client, and starts and stops connection in the unit of transaction. If **KEEP\_CONNECTION**, broker parameter, is OFF, it always happens; if AUTO, it can happen depending on its situation. For details, see the description of **KEEP\_CONNECTION** in the [Parameter by Broker](#)

## cci\_set\_size

int cci\_set\_size(T\_CCI\_SET set)

The **cci\_set\_size** function gets the number of elements for the type value of **T\_CCI\_SET**.

#### Parameters:

- **set** – (IN) cci set pointer

#### Returns:

Size

## PHP Driver

CUBRID PHP driver implements an interface to enable access from application in PHP to CUBRID database. Every function offered by CUBRID PHP driver has a prefix **cubrid\_** such as `cubrid_connect()` and `cubrid_connect_with_url()`.

The official one is available as a PECL package. PECL is a repository for PHP extensions, providing a directory of all known extensions and holding facilities for downloading and development of PHP extensions. For more information about PECL, visit <https://pecl.php.net/> .

CUBRID PHP driver is written based on CCI API so affected by CCI configurations such as **CCI\_DEFAULT\_AUTOCOMMIT**.

## Installing and Configuring PHP

The easiest and fastest way to get all applications installed on your system is to install CUBRID, Apache web server, PHP, and CUBRID PHP driver at the same time.

For Linux

### Configuring the Environment

- Operating system: 32-bit or 64-bit Linux
- Web server: Apache
- PHP: version 5.x, or version 7.x (<https://www.php.net/downloads.php>)
- We refer to the latest PHP versions 5.6.x ,7.1.x and 7.4.x as a convenience.

### Installing CUBRID PHP Driver using PECL

If **PECL** package has been installed on your system, the installation of CUBRID PHP driver is straightforward. **PECL** will download and compile the driver for you.

1. Enter the following command to install the latest version of CUBRID PHP driver.

```
sudo pecl install cubrid
```

If you need earlier versions of the driver, you can install exact versions as follows:

```
sudo pecl install cubrid-10.1.0.0002
```

During the installation, you will be prompted to enter **CUBRID base install dir autodetect :**. Just to make sure your installation goes smoothly, enter the full path to the directory where you have installed CUBRID. For example, if CUBRID has been installed at **/home/cubridtest/CUBRID**, then enter **/home/cubridtest/CUBRID**.

2. Edit the configuration file.

If you are using CentOS 6.0 and later or Fedora 15 and later, create a file named **cubrid.ini**, enter a command line **extension=cubrid.so**, and store the file in the **/etc/php.d** directory.

If you are using earlier versions of CentOS 6.0 or Fedora 15, edit the **php.ini** file (default location: **/etc/php5/apache2/** or **/etc/**) and add the following two command lines at the end of the file.

```
[CUBRID]
extension=cubrid.so
```

3. Restart the web server to apply changes.

### Installing using apt-get on Ubuntu

1. If you do not have PHP itself installed, install it using the following command; if you have PHP installed on your system, skip this step.

```
sudo apt-get install php5

or for PHP version 7
sudo add-apt-repository ppa:ondrej/php
sudo apt-get update
sudo apt-get install php7.1
```

2. To install CUBRID PHP driver using **apt-get**, we need to add CUBRID's repository so that Ubuntu knows where to download the packages from and tell the operating system to update its indexes.

```
sudo add-apt-repository ppa:cubrid/cubrid
sudo apt-get update
```

3. Now install the driver.

```
sudo apt-get install php5-cubrid
```

To install earlier versions, indicate the version as:

```
sudo apt-get install php5-cubrid-9.3.1
```

This will copy the **cubrid.so** driver to **/usr/local/lib/php/\*** and add the following configuration lines to **/etc/php.ini**.

```
[PHP_CUBRID]
extension=cubrid.so
```

4. Restart the web server so that PHP can read the module.

```
service apache2 restart
```

## For Windows

### Requirements

- CUBRID: 9.3.x or later
- Operating system: 32-bit or 64 bit Windows
- Web server: Apache or IIS
- PHP: 5.6.x, 7.1.x or 7.4.x (<https://windows.php.net/download/>)
- For PHP 7.1.x or 7.4.x, you need to install Microsoft Visual C++ 2015 Redistributable Package for 32bit or 64bit.

### Using CUBRID PHP Driver Installer

The CUBRID PHP API Installer is a Windows installer which automatically detects the CUBRID and PHP version and installs the proper driver for you by copying it to the default PHP extensions directory and adding the extension load directives to the **php.ini** file. In this section, we will explain how to use the CUBRID PHP API Installer to install the CUBRID PHP extension on Windows.

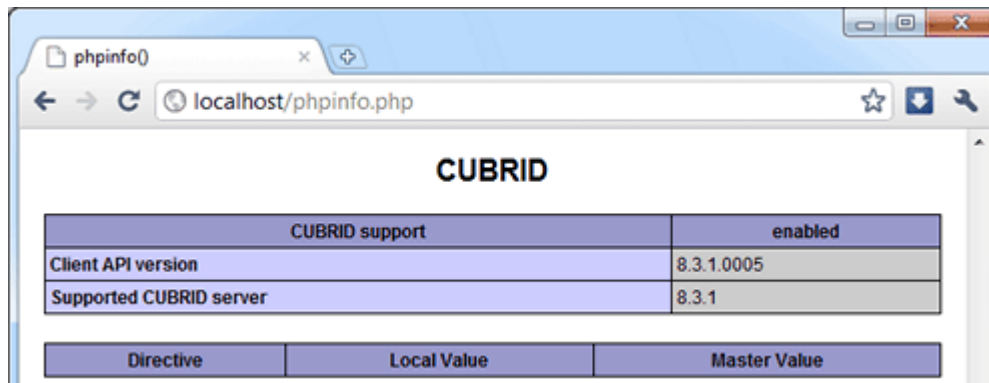

In case you want to remove the CUBRID PHP driver, you just have to run the CUBRID PHP API Installer again in uninstall mode (like any other un-installer on Windows) and it will reset all the changes made during installation.

Before you install CUBRID PHP driver, make sure that paths of PHP and CUBRID are added in the system variable, **Path**.

1. Download the CUBRID PHP API installer for Windows from the link below. The current installer includes the drivers for all CUBRID versions.

<https://www.cubrid.org/downloads#php>

2. To install the PHP extension, run the installer. Once the installer starts, click the [Next] button.
3. Agree with the BSD license terms and click the [Next] button.
4. Choose where you would like to install this CUBRID PHP API Installer and click the [Next] button. You should choose a new folder for this installer like **C:\Program Files\CUBRID PHP API**.
5. Give a folder name and click the [Install] button. If you fail installation, you should probably receive an error message. In this case, see “Configuring the environment” below.
6. If no error message is displayed, this should install the CUBRID PHP extension and update your **php.ini** file. Click [Finish] to close the installer.
7. For changes to take place, restart your web server and execute the phpinfo() to confirm CUBRID has successfully been installed.

## Configuring the environment

If you have received an error messages, follow the steps below; if you can see CUBRID in phpinfo(), you do not need to look further. By default, when you install CUBRID, it automatically adds its installation directory to the **Path** system environment variable. To verify the variable have been correctly configured, launch the command prompt ([Start] > [Programs] > [Accessories] > [Command Prompt]) and enter the following commands one by one.

1. Enter command below in the command prompt as follows.

```
php --version
```

You can see the PHP version like below if it is properly configured.

```
PHP 5.6.30 (cli) (built: Jun 13 2017 16:16:30)
or for version 7.1.x
PHP 7.1.7 (cli) (built: Aug 3 2017 10:59:35) ( NTS )
```

```
C:\Users\Administrator>php --version
PHP 5.6.30 (cli) (built: Jan 18 2017 19:47:28)
```

2. Enter command as follows.

```
cubrid --version
```

You can see the CUBRID version like below if it is properly configured.

```
C:\Users\Administrator>cubrid --version
cubrid.exe (CUBRID utilities)
      CUBRID 9.3 (9.3.8.0003) (64bit release build for
Windows_NT) (Apr 11 2017 11:54:08)
```

If you cannot get the result like above, it is highly likely that your PHP and CUBRID installations went wrong. Try to reinstall them and recheck again. If the path is not automatically specified even after you complete reinstallation, you can do it manually.

1. Right-click [My Computer] and select [Properties]. The [System Properties] dialog box will appear.
2. Go to [Advanced] tab and click on [Environment Variables].
3. Select the variable called **Path** in the [System variables] box and click [Edit] button. You will notice that the value of that variable contains system paths separated by semi-colon.
4. Add the paths for CUBRID and PHP in that variable. For example, if PHP is installed in **C:\Program Files\PHP** and also CUBRID in **C:\CUBRID\bin**, you will have to append (do not overwrite, just append) these values to the path like **C:\CUBRID\bin;C:\Program Files\PHP**.
5. Click [OK] to save and close the dialog box.
6. To confirm you have done everything correct, check the variable presence in the command prompt.

### Downloading and Installing Compiled CUBRID PHP Driver

First, download CUBRID PHP/PDO driver of which versions match the versions of your operating system and PHP installed from <https://www.cubrid.org/downloads#php>.

After you download the driver, you will see the **php\_cubrid.dll** file for CUBRID PHP driver or the **php\_pdo\_cubrid.dll** file for CUBRID PDO driver. Follow the steps below to install it.

1. Copy this driver to the default PHP extensions directory (usually located at **C:\Program Files\PHP\ext**).
2. Set your system environment. Check if the environment variable **PHPRC** is **C:\Program Files\PHP** and system variable path is added with **%PHPRC%** and **%PHPRC%\ext**.

3. Edit **php.ini** (**C:\Program Files\PHP\php.ini**) and add the following two command lines at the end of the **php.ini** file.

```
[PHP_CUBRID]
extension=php_cubrid.dll
```

For CUBRID PDO driver, add command lines below.

```
[PHP_PDO_CUBRID]
extension = php_pdo_cubrid.dll
```

4. Restart your web server to apply changes.

## Building CUBRID PHP Driver from Source Code

For Linux

In this section, we will introduce the way of building CUBRID PHP driver for Linux.

### Configuring the environment

- CUBRID: Install CUBRID. Make sure the environment variable **%CUBRID%** is defined in your system.
- PHP 5.6.x, 7.1.x or 7.4.x source code: You can download PHP source code from <https://www.php.net/downloads.php>.
- Apache 2: It can be used to test PHP.
- CUBRID PHP driver source code: You can download the source code from <https://www.cubrid.org/downloads#php>. Make sure that the version you download is the same as the version of CUBRID which has been installed on your system.
- If building CCI driver In Linux Or Mac, GNU Developer Toolset 8 or higher is required.

### Compiling CUBRID PHP driver

1. Download the CUBRID PHP driver, extract it, and enter the directory.

```
$> tar zxvf php-<version>.tar.gz (or tar jxvf php-<version>.tar.bz2)
$> cd php-<version>/ext
```

2. Run **phpize**. For more information about getting **phpize**, see [Remark](#).

```
cubrid-php> /usr/bin/phpize
```

3. Configure the project. It is recommended to execute **./configure -h** so that you can check the configuration options (we assume that Apache 2 has been installed in **/usr/local**).

```
cubrid-php>./configure --with-cubrid --with-php-config=/usr/local/bin/php-config
```

- `--with-cubrid=shared`: Includes CUBRID support.
- `--with-php-config=PATH`: Enters an absolute path of php-config including the file name.

4. Build the project. If it is successfully compiled, the **cubrid.so** file will be created in the **/modules** directory.

5. Copy the **cubrid.so** to the **/usr/local/php/lib/php/extensions** directory; the **/usr/local/php** is a PHP root directory.

```
cubrid-php> mkdir /usr/local/php/lib/php/extensions
cubrid-php> cp modules/cubrid.so /usr/local/php/lib/php/extensions
```

6. In the **php.ini** file, set the **extension\_dir** variable and add the CUBRID PHP driver to the **extension** variable as shown below.

```
extension_dir = "/usr/local/php/lib/php/extension/no-debug-zts-xxx"
extension = cubrid.so
```

## Testing CUBRID PHP driver installation

1. Create a **test.php** file as follows:

```
<?php phpinfo(); ?>
```

2. Use web browser to visit <http://localhost/test.php>. If you can see the following result, it means that installation is successfully completed.

| CUBRID  | Value       |
|---------|-------------|
| Version | 10.1.0.XXXX |

## Remark

**phpize** is a shell script to prepare the PHP extension for compiling. You can get it when you install PHP because it is automatically installed with PHP installation, in general. If it you do not have **phpize** installed on your system, you can get it by following the steps below.

1. Download the PHP source code. Make sure that the PHP version works with the PHP extension that you want to use. Extract PHP source code and enter its root directory.

```
$> tar zxvf php-<version>.tar.gz (or tar jxvf php-<version>.tar.bz2)
$> cd php-<version>
```

2. Configure the project, build, and install it. You can specify the directory you want install PHP by using the option, **--prefix**.

```
php-root> ./configure --prefix=prefix_dir; make; make install
```

3. You can find **phpize** in the **prefix\_dir/bin** directory.

## For Windows

In this section, we will introduce three ways of building CUBRID PHP driver for Windows. If you have no idea which version you choose, read the following contents first.

If you are using PHP as module with Apache builds from apache.org (not recommended) you need to use the older VC6 versions of PHP compiled with the legacy Visual Studio 6 compiler. Do NOT use VC11+ versions of PHP with the apache.org binaries.

With Apache you have to use the Thread Safe (TS) versions of PHP.

- If you are using PHP version 5.5.x or later, you should use the VC11 versions (Visual Studio 2012)
- If you are using PHP version 7.1.x or later, you should use the VC14 versions (Visual Studio 2015)

VC11 and VC14 versions are compiled with the Visual Studio 2012 and 2015 compiler respectively. The VC11 or VC14 versions have more improvements in performance and stability.

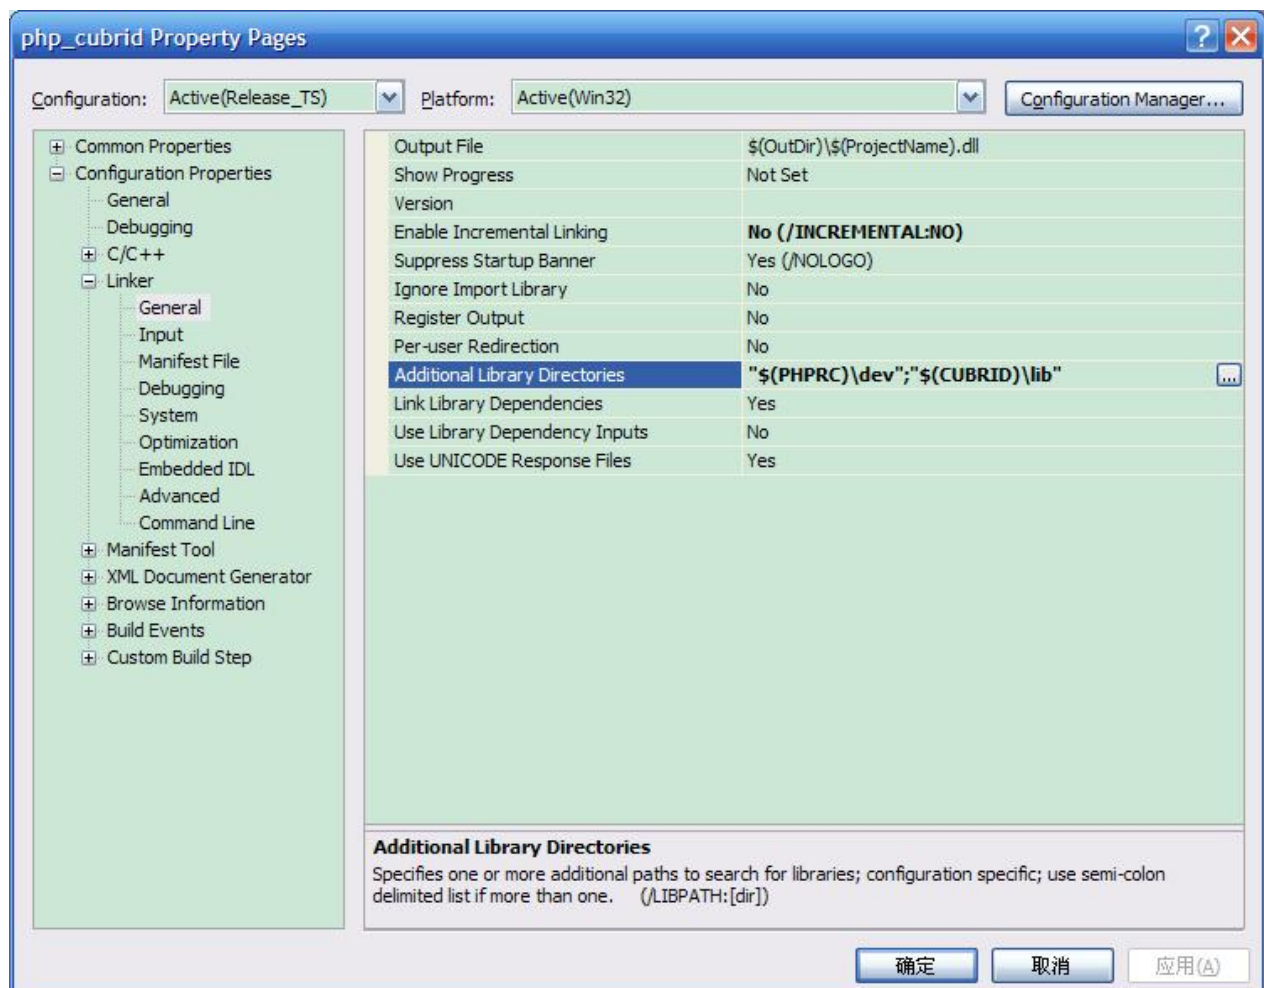

More recent versions of PHP are built with VC11, VC14 (Visual Studio 2012 or 2015 compiler respectively) and include improvements in performance and stability.

- The VC11 builds require to have the Visual C++ Redistributable for Visual Studio 2012 x86 or x64 installed
- The VC14 builds require to have the Visual C++ Redistributable for Visual Studio 2015 x86 or x64 installed

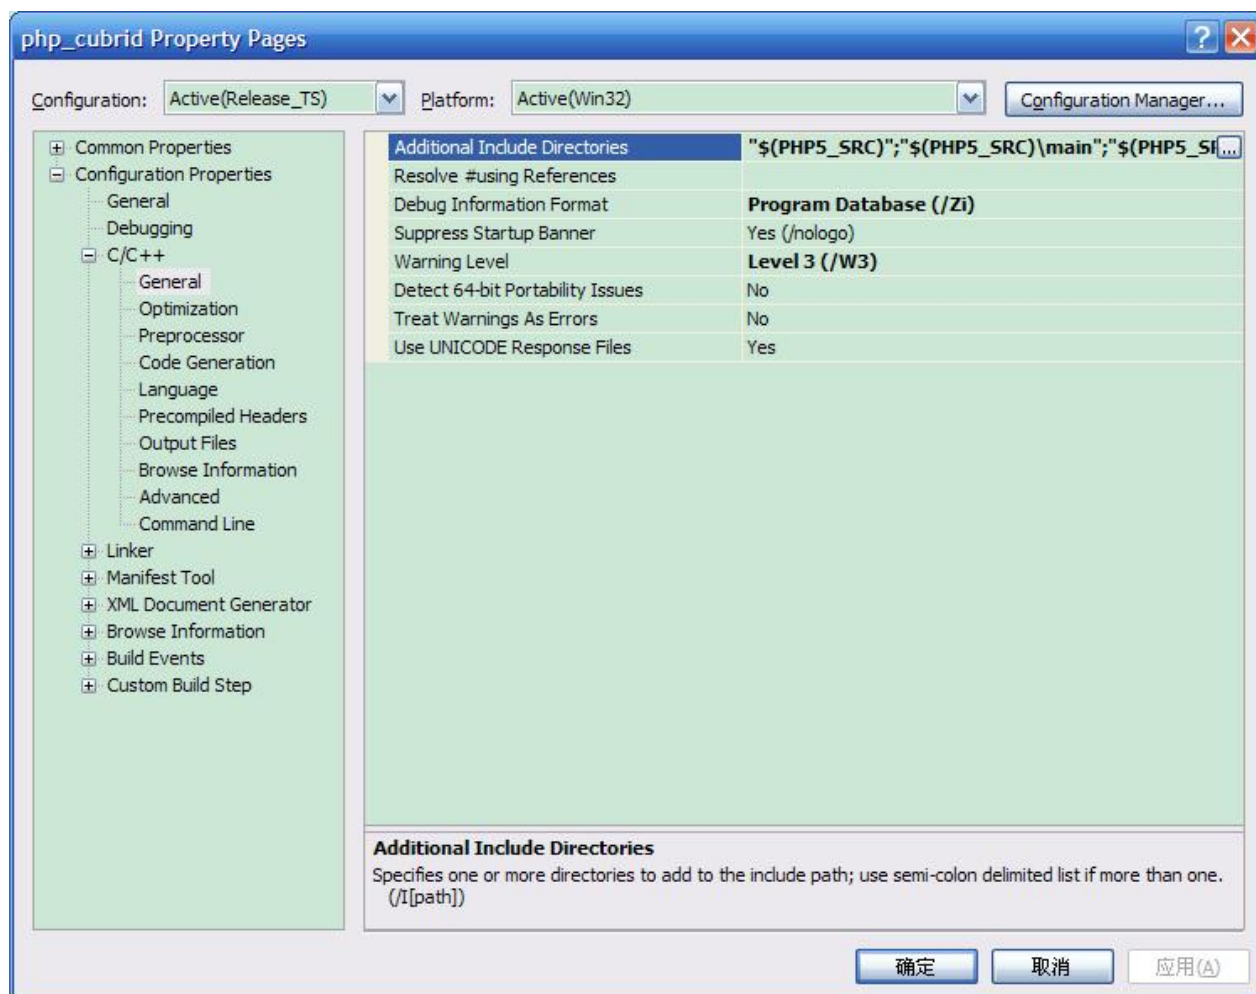

## Building CUBRID PHP Driver with VC11 for PHP 5.6.x

### Configuring the environment

- CUBRID: Install CUBRID. Make sure the environment variable **%CUBRID%** is defined in your system.
- Visual Studio 2012: You can alternately use the free Visual C++ Express Edition or the Visual C++ 11 compiler included in the Windows SDK if you are familiar with a makefile. Make sure that you have the Microsoft Visual C++ Redistributable Package installed on your system to use CUBRID PHP VC11 driver.
- PHP 5.6.x binaries: You can install VC11 x86 Non Thread Safe or VC11 x86 Thread Safe. Make sure that the **%PHPRC%** system environment variable is correctly set. In the [Property Pages] dialog box, select [General] under the [Linker] tree node. You can see **\$(PHPRC)** in [Additional Library Directories].

- PHP 5.6.x source code: Remember to get the source code that matches your binary version. After you extract the PHP 5.6.x source code, add the **%PHP5\_SRC%** system environment variable and set its value to the path of PHP 5.6.x source code. In the [Property Pages] dialog box, select [General] under the [C/C++] tree node. You can see **\$(PHP5\_SRC)** in [Additional Include Directories].

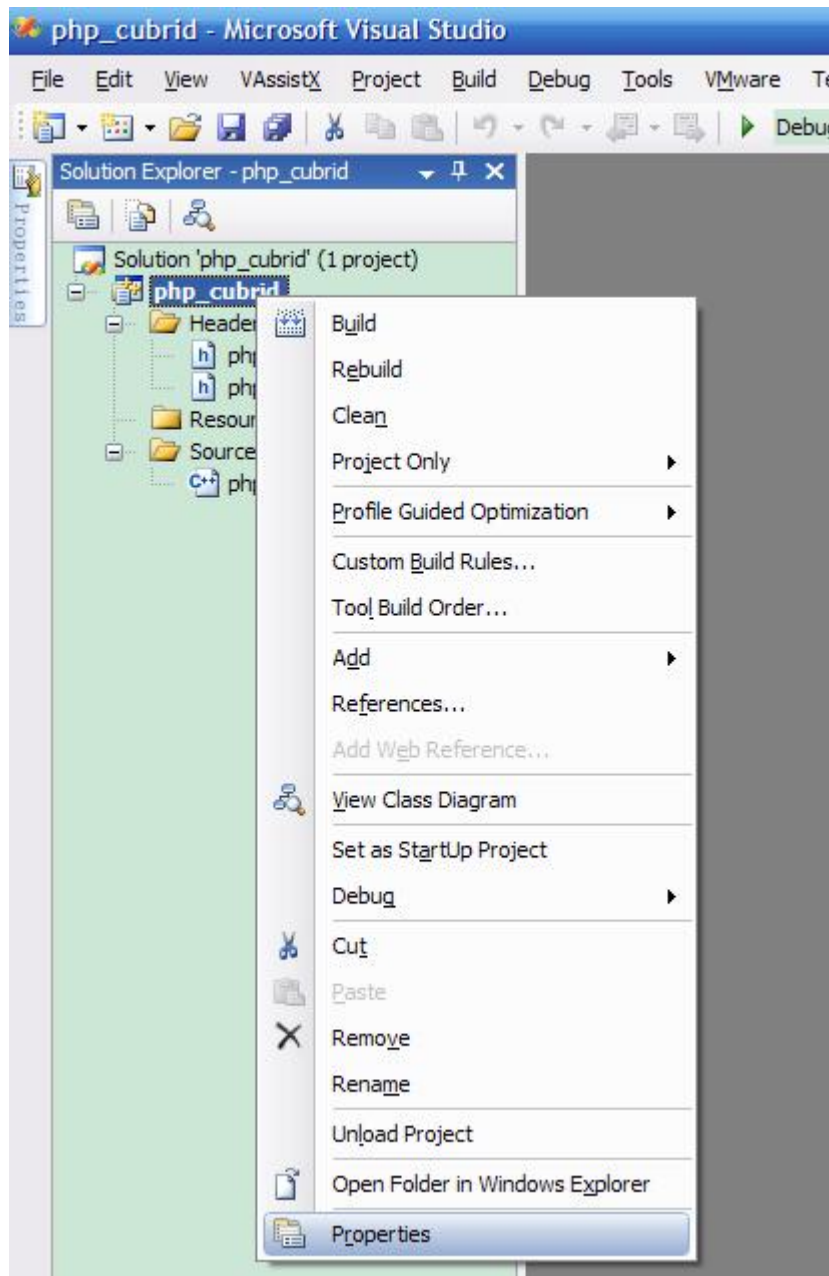

- CUBRID PHP driver source code: You can download CUBRID PHP driver source code of which the version is the same as the version of CUBRID that have been installed on your system. You can get it from <https://www.cubrid.org/downloads#php>.

### Note

You do not need to build PHP 5.6.x from source code but configuring a project is required. If you do not make configuration settings, you will get the message that a header file (**config.w32.h**) cannot be found. Read <https://wiki.php.net/internals/windows/stepbystepbuild> to get more detailed information.

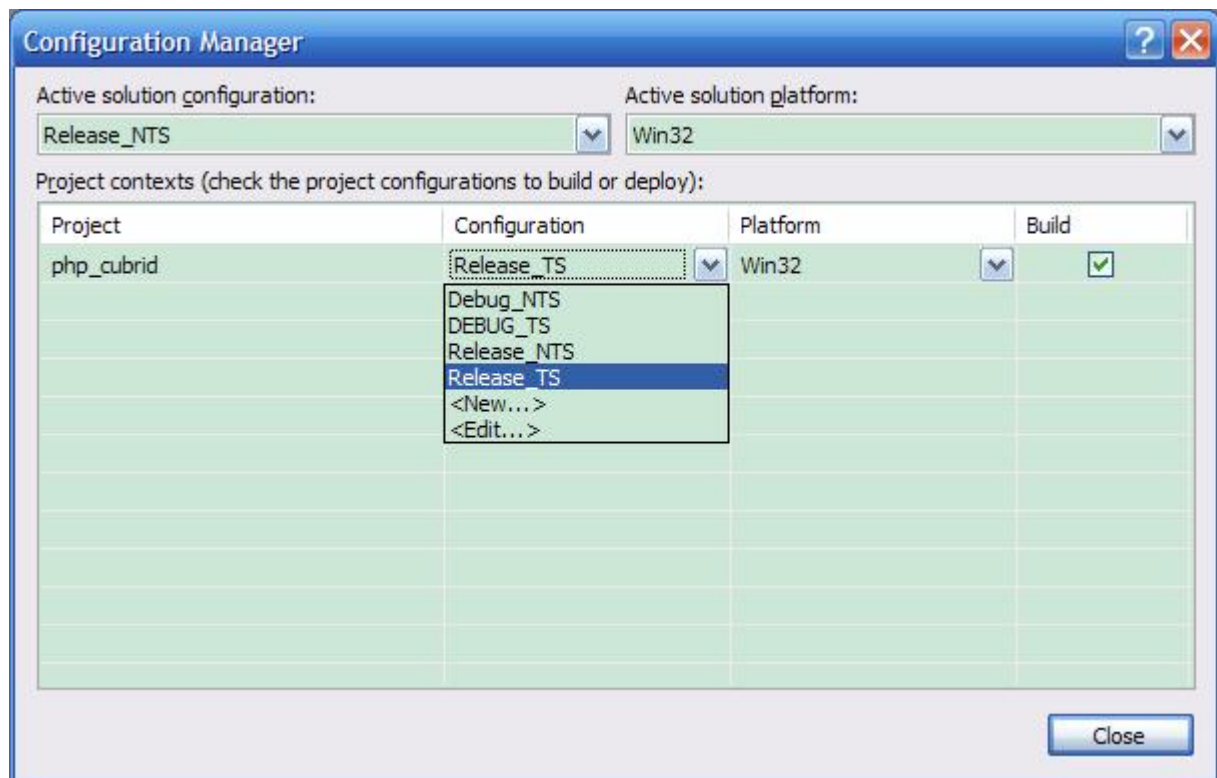

## Building CUBRID PHP driver

1. Open the **php\_cubrid.vcproj** file under the **\win** directory. In the [Solution Explorer] pane, right-click on the **php\_cubrid** (project name) and select [Properties].

2. In the [Property Page] dialog box, click the [Configuration Manager] button. Select one of four values among Release\_TS, Release\_NTS, Debug\_TS, and Debug\_NTS in [Configuration] of [Project contexts] and click the [Close] button.

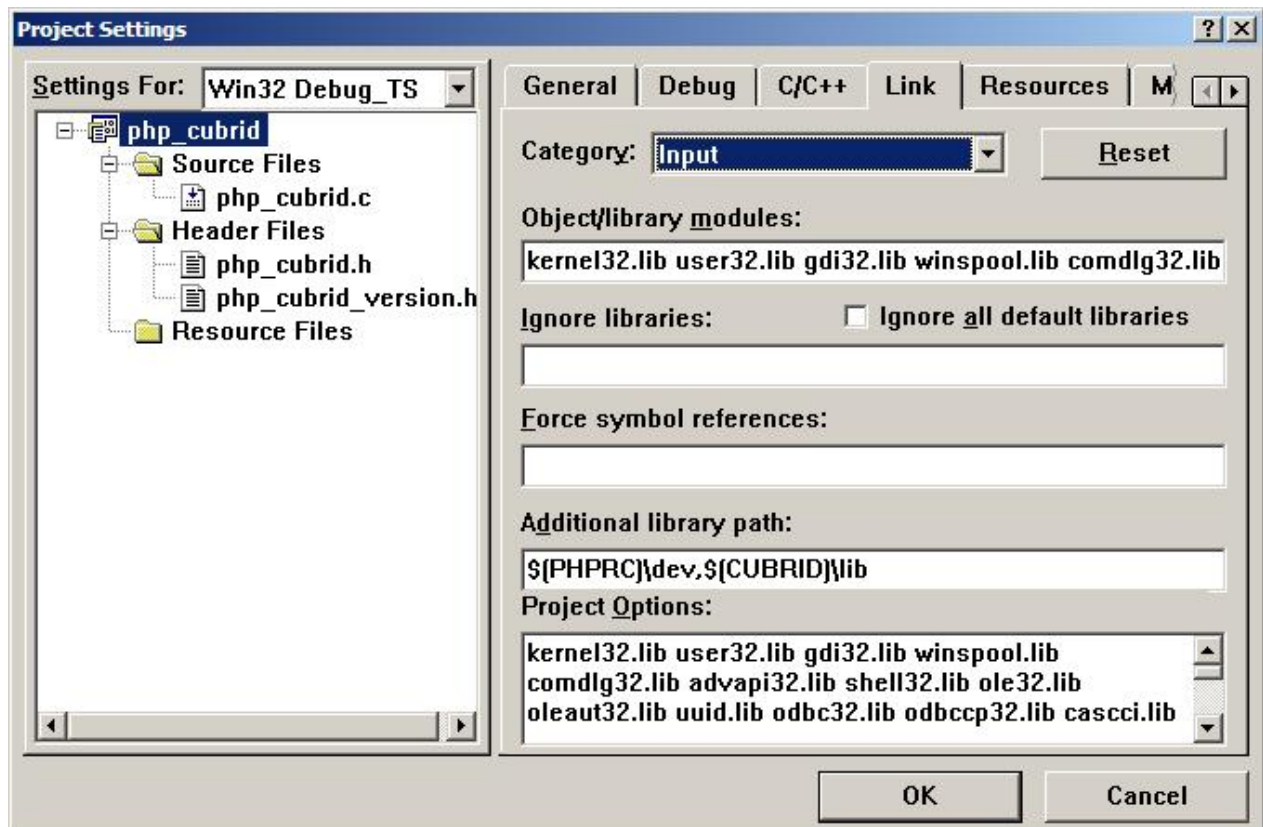

3. After you complete the properties modification, click the [OK] button and press the <F7> key to compile the driver. Then, we have the **php\_cubrid.dll** file built.
4. You need to make PHP recognize the **php\_cubrid.dll** file as an extension. To do this:
  - Create a new folder named **cubrid** where PHP has been installed and copy the **php\_cubrid.dll** file to the **cubrid** folder. You can also put the **php\_cubrid.dll** file in **%PHPRC%\ext** if this directory exists.
  - In the php.ini file, enter the path of the **php\_cubrid.dll** file as an extension\_dir variable value and enter **php\_cubrid.dll** as an extension value.

## Building CUBRID PHP Driver with VC14 for PHP 7.1.x

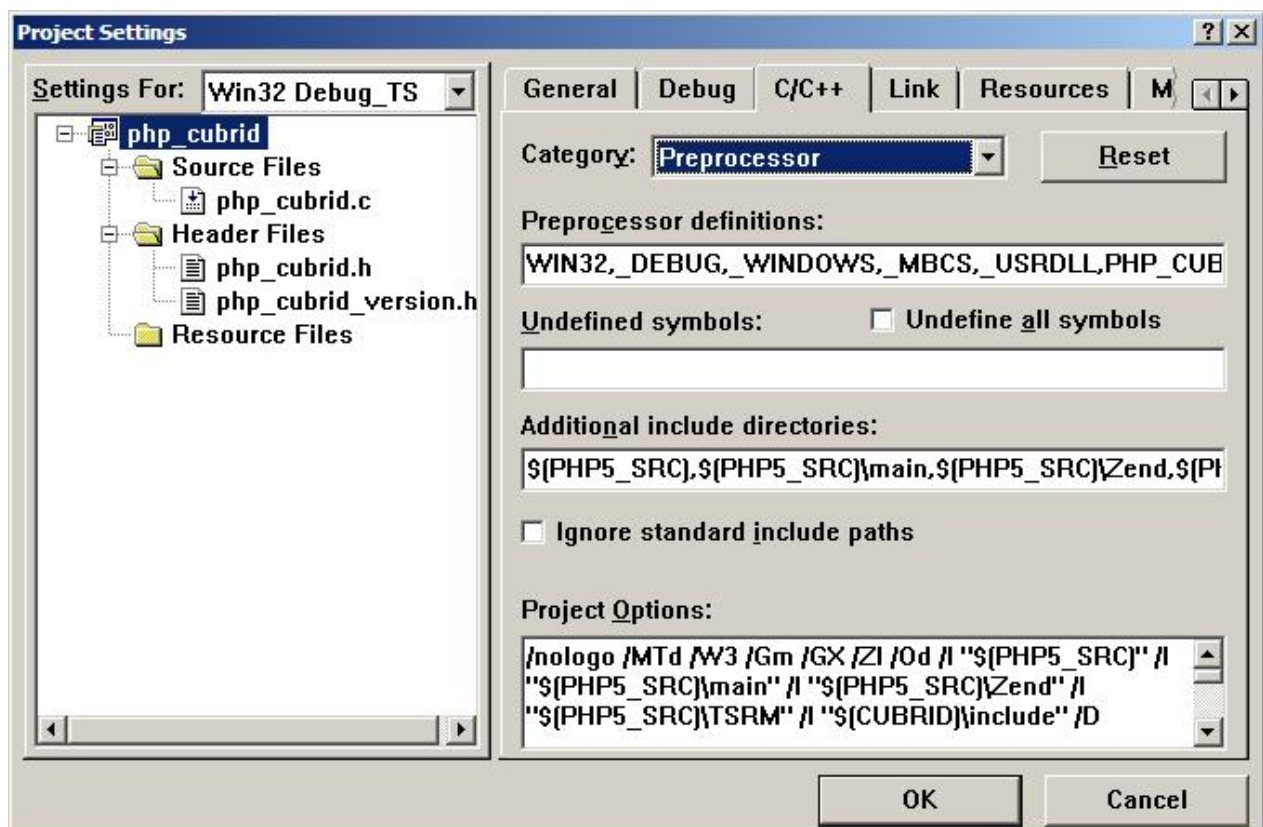

### Configuring the environment

- CUBRID: Install CUBRID. Make sure that the environment variable **%CUBRID%** is defined in your system.
- Visual Studio 2015: You can alternately use the free Visual C++ Express Edition or the Visual C++ 14 compiler included in the Windows SDK if you are familiar with a makefile. Make sure that you have the Microsoft Visual C++ Redistributable Package installed on your system to use CUBRID PHP VC14 driver.
- PHP 7.1.x binaries: You can install VC14 x86 Non Thread Safe or VC14 x86 Thread Safe. Make sure that the value of the **%PHPRC%** system environment variable is correctly set. In the [Project Settings] dialog box, you can find **\$(PHPRC)** in [Additional library path] of the [Link] tab.

- PHP 7.1.x source code: Remember to get the source that matches your binary version. After you extract the PHP 7.1.x source code, add the **%PHP7\_SRC%** system environment variable and set its value to the path of PHP 7.1.x source code. In the [Project Settings] dialog box of VC11 project, you can find **\$(PHP7\_SRC)** in [Additional include directories] of the [C/C++] tab.

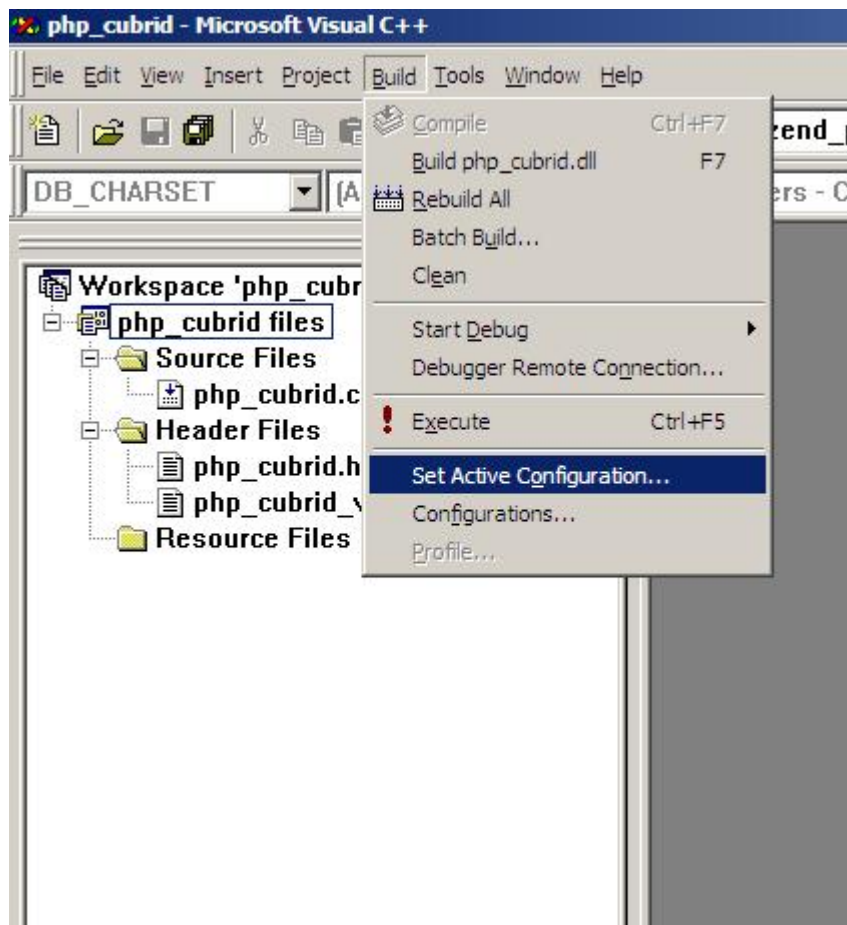

- CUBRID PHP driver source code: You can download CUBRID PHP driver source code of which the version is the same as the version of CUBRID that has been installed on your system. You can get it from <https://www.cubrid.org/downloads#php>.

### Note

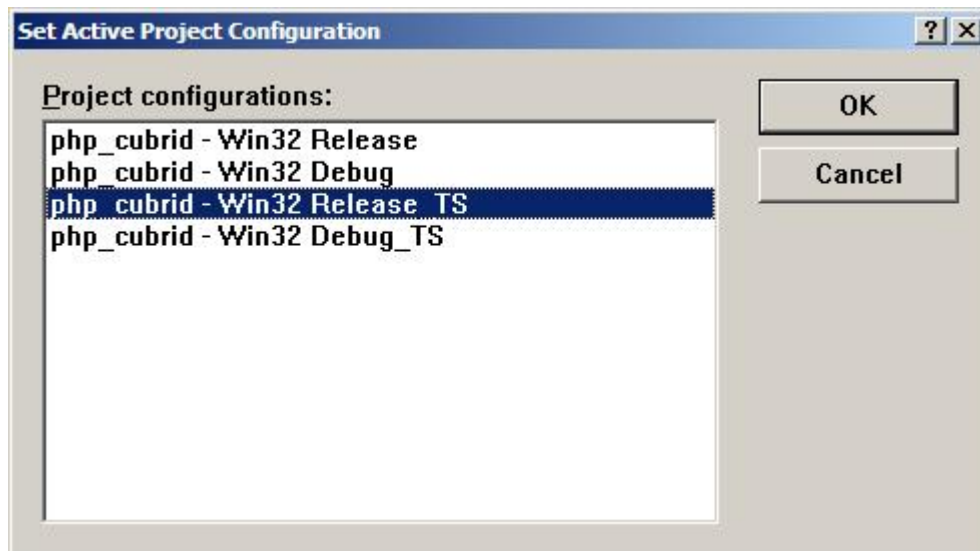

If you build CUBRID PHP driver with PHP 7.1.x source code, you need to make some configuration settings for PHP 7.1.x on Windows. If you do not make these settings, you will get the message that a header file (**config.w32.h**) cannot be found. Read <https://wiki.php.net/internals/windows/stepbystepbuild> to get more detailed information.

## Building CUBRID PHP driver

1. Open the project in the [Build] menu and then select [Set Active Configuration].

2. There are four types of configuration settings (Win32 Release\_TS, Win32 Release, Win32 Debug\_TS, and Win32 Debug). Select one of them depending on your system and then click the [OK] button.

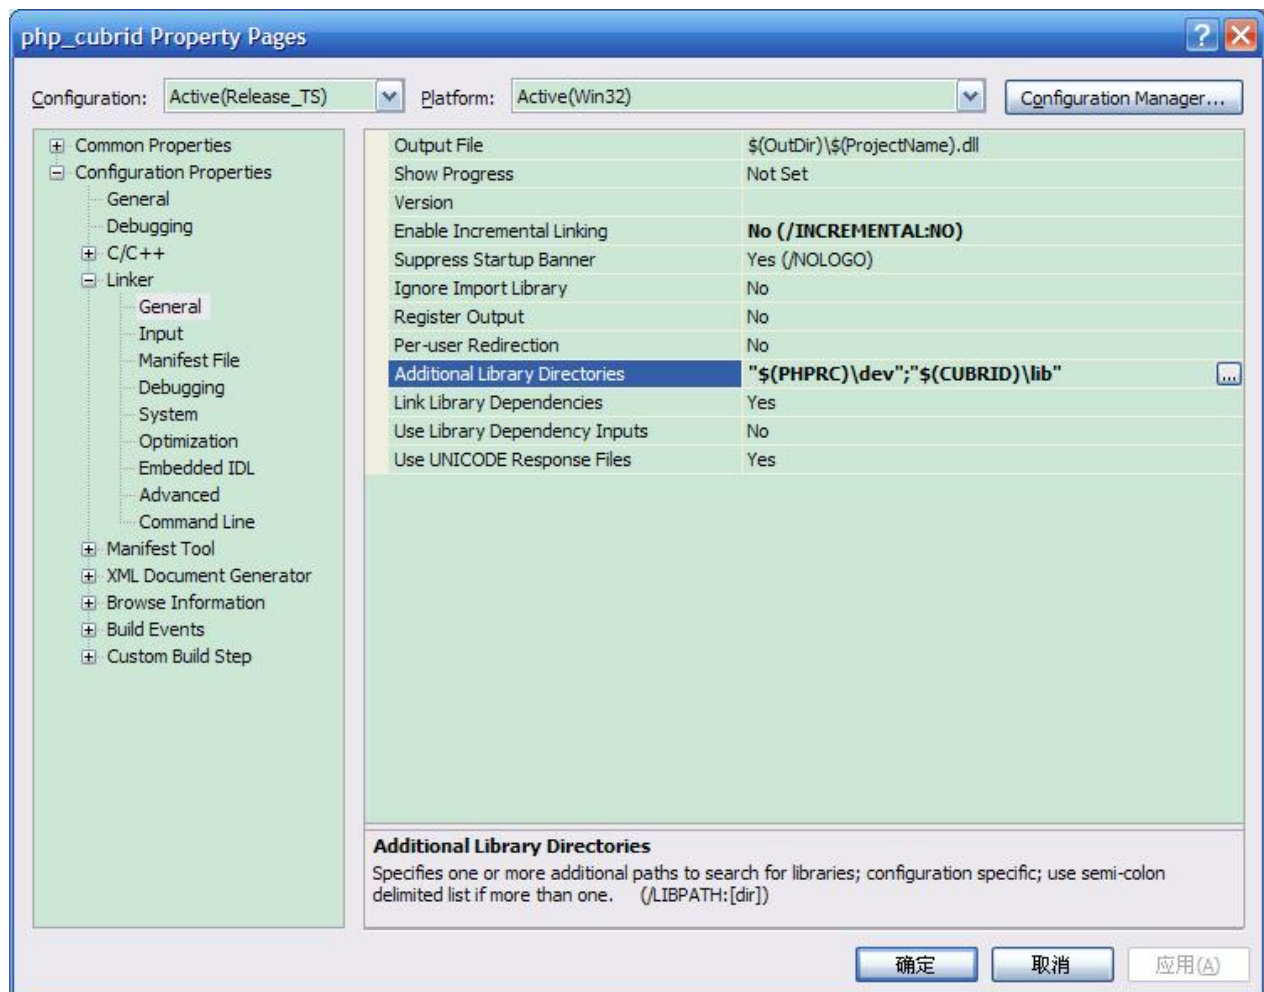

3. After you complete the properties modification, click the [OK] button and press the <F7> key to compile the driver. Then you have the **php\_cubrid.dll** file built.
4. You need to make PHP recognize the **php\_cubrid.dll** file as an extension. To do this:
  - Create a new folder named **cubrid** where PHP is installed and copy **php\_cubrid.dll** to the **cubrid** folder. You can also put **php\_cubrid.dll** in **%PHPRC%\ext** if this directory exists.
  - Set the **extension\_dir** variable and add CUBRID PHP driver to **extension** variable in the **php.ini** file.

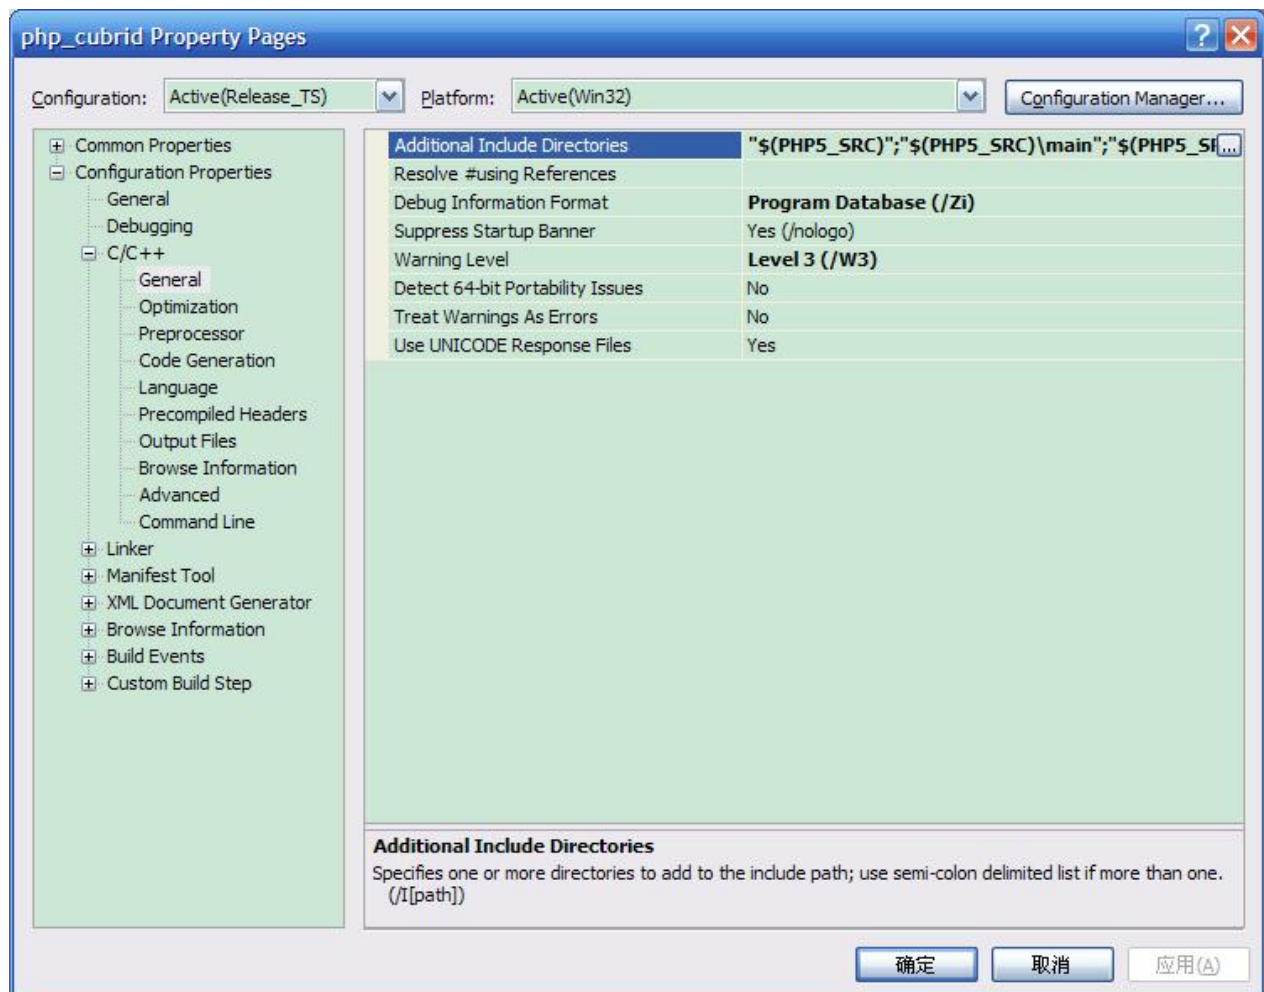

## Building CUBRID PHP Driver for 64-bit Windows

### PHP for 64-bit Windows

- PHP 5.6.x binaries: You can install VC11 x64 Non Thread Safe or VC11 x64 Thread Safe. Make sure that the **%PHPRC%** system environment variable is correctly set. In the [Property Pages] dialog box, select [General] under the [Linker] tree node. You can see **\$(PHPRC)** in [Additional Library Directories].

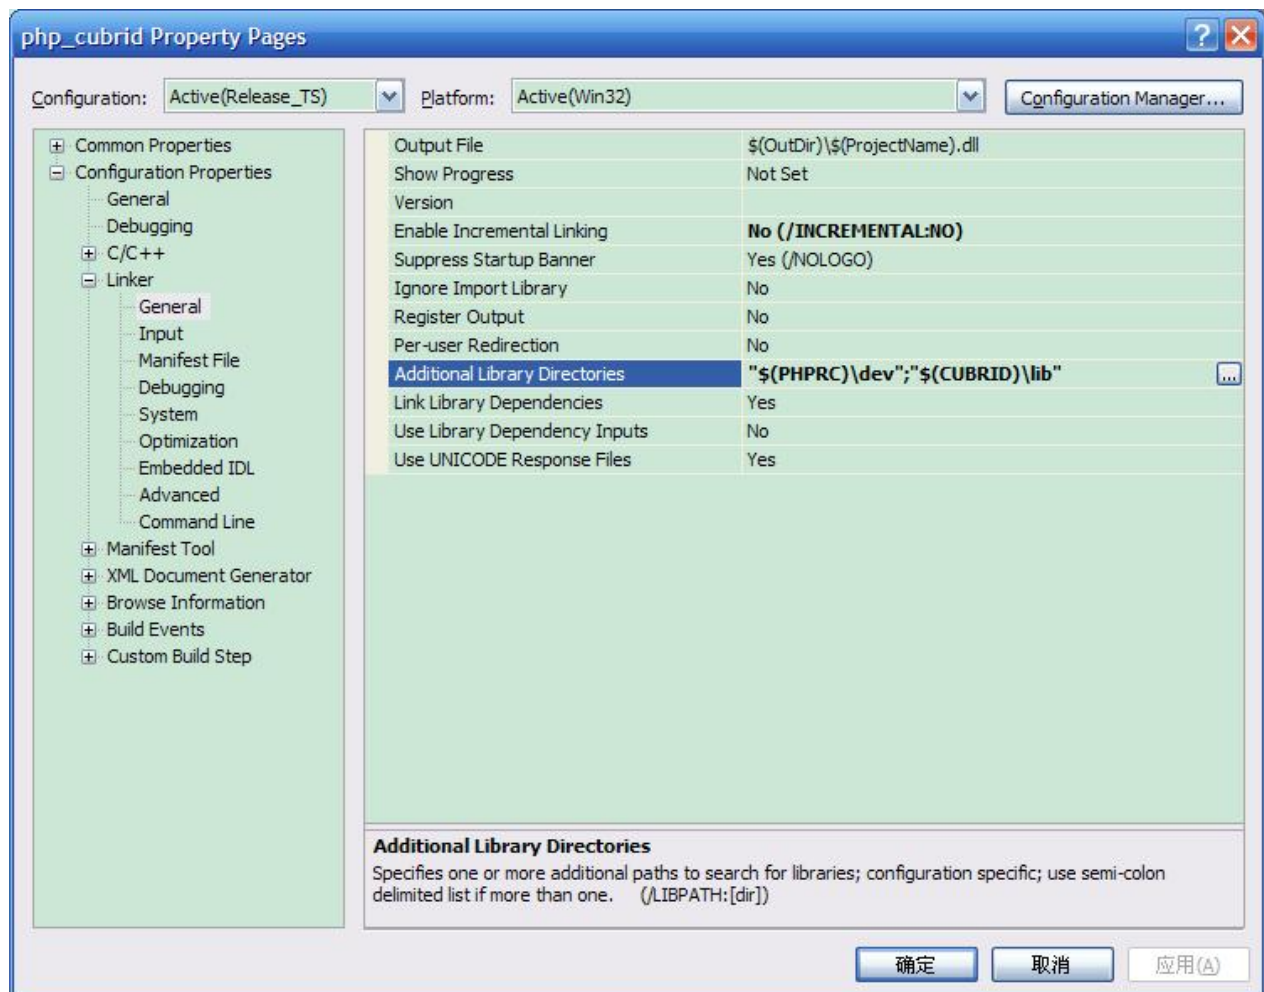

- PHP 5.6.x source code: Remember to get the source code that matches your binary version. After you extract the PHP 5.6.x source code, add the **%PHP5\_SRC%** system environment variable and set its value to the path of PHP 5.6.x source code. In the [Property Pages] dialog box, select [General] under the [C/C++] tree node. You can see **\$(PHP5\_SRC)** in [Additional Include Directories].

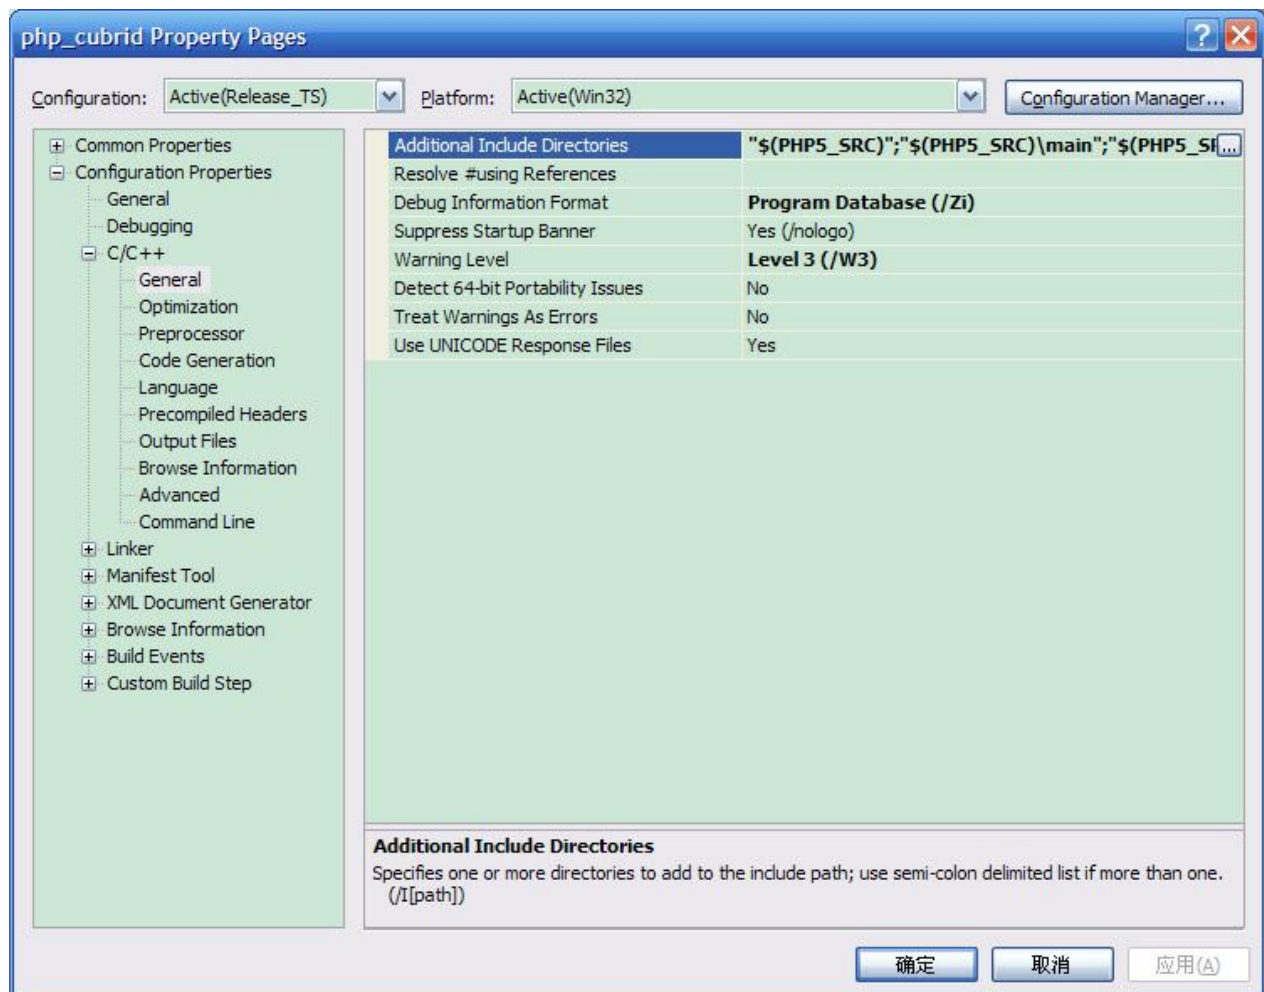

- PHP 7.1.x binaries: You can install VC14 x64 Non Thread Safe or VC14 x64 Thread Safe. Make sure that the **%PHPRC%** system environment variable is correctly set. In the [Property Pages] dialog box, select [General] under the [Linker] tree node. You can see **\$(PHPRC)** in [Additional Library Directories].

- PHP 7.1.x source code: Remember to get the source code that matches your binary version. After you extract the PHP 7.1.x source code, add the **%PHP7\_SRC%** system environment variable and set its value to the path of PHP 7.1.x source code. In the [Property Pages] dialog box, select [General] under the [C/C++] tree node. You can see **\$(PHP7\_SRC)** in [Additional Include Directories].

- You can find the supported compilers to build PHP on Windows at <https://wiki.php.net/internals/windows/compiler>. You can see that both Visual C++ 11 (2012) and Visual C++ 14 (2015) can be used to build 64-bit PHP.

## Apache for 64-bit Windows

- Apache Lounge has provided up-to-date Windows binaries including 64bit version. You can download the latest apache 2.2.34 64bit version on the following link.

<https://www.apachelounge.com/download/win64/binaries/httpd-2.2.34-win64.zip>

## Configuring the environment

- CUBRID for 64-bit Windows: You can install the latest version of CUBRID for 64-bit Windows. Make sure the environment variable **%CUBRID%** is defined in your system.
- Visual Studio 2012 or 2015: You can alternately use the free Visual C++ Express Edition or the Visual C++ compiler in the Windows SDK if you are familiar with a makefile.
- PHP 5.6.x or 7.1.x binaries for 64-bit Windows: You can build your own VC11 or VC14 x64 PHP. Both x64 Non Thread Safe and x64 Thread Safe are available. After you have installed it, check if the value of system environment variable **%PHPRC%** is correctly set.

- PHP 5.6.x source: Remember to get the src package that matches your binary version. After you extract the PHP 5.6.x src, add system environment variable **%PHP5\_SRC%** and set its value to the path of PHP 5.6.x source code. In the VC11 [Property Pages] dialog box, select [General] under the [C/C++] tree node. You can see **\$(PHP5\_SRC)** in [Additional Include Directories].
- PHP 7.1.x source: Remember to get the src package that matches your binary version. After you extract the PHP 7.1.x src, add system environment variable **%PHP7\_SRC%** and set its value to the path of PHP 7.1.s source code. In the VC14 [Property Pages] dialog box, select [General] under the [C/C++] tree node. You can see **\$(PHP7\_SRC)** in [Additional Include Directories].
- CUBRID PHP driver source code: You can download CUBRID PHP driver source code of which the version is the same as the version of CUBRID that is installed on your system. You can get it from <https://www.cubrid.org/downloads#php>.

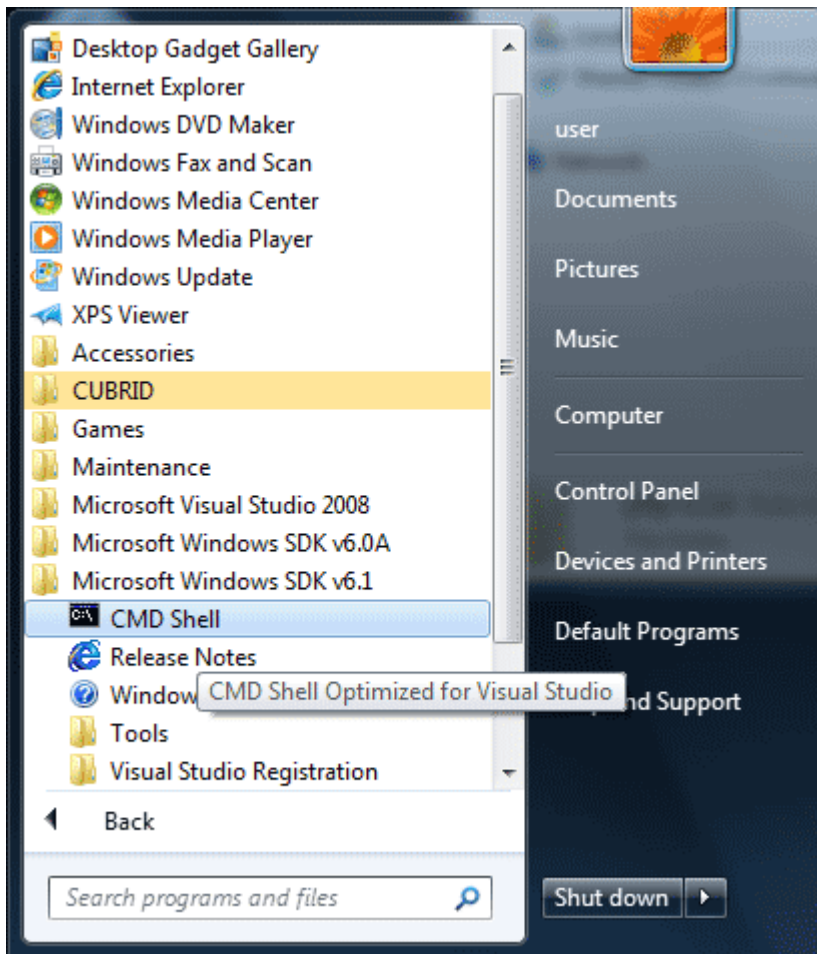

#### Note

You do not need to build PHP 5.6.x or 7.1.x from source code; however, configuring a project is required. If you do not make configuration settings, you will get the message that a header file (**config.w32.h**) cannot be found. Read <https://wiki.php.net/internals/windows/stepbystepbuild> to get more detailed information.

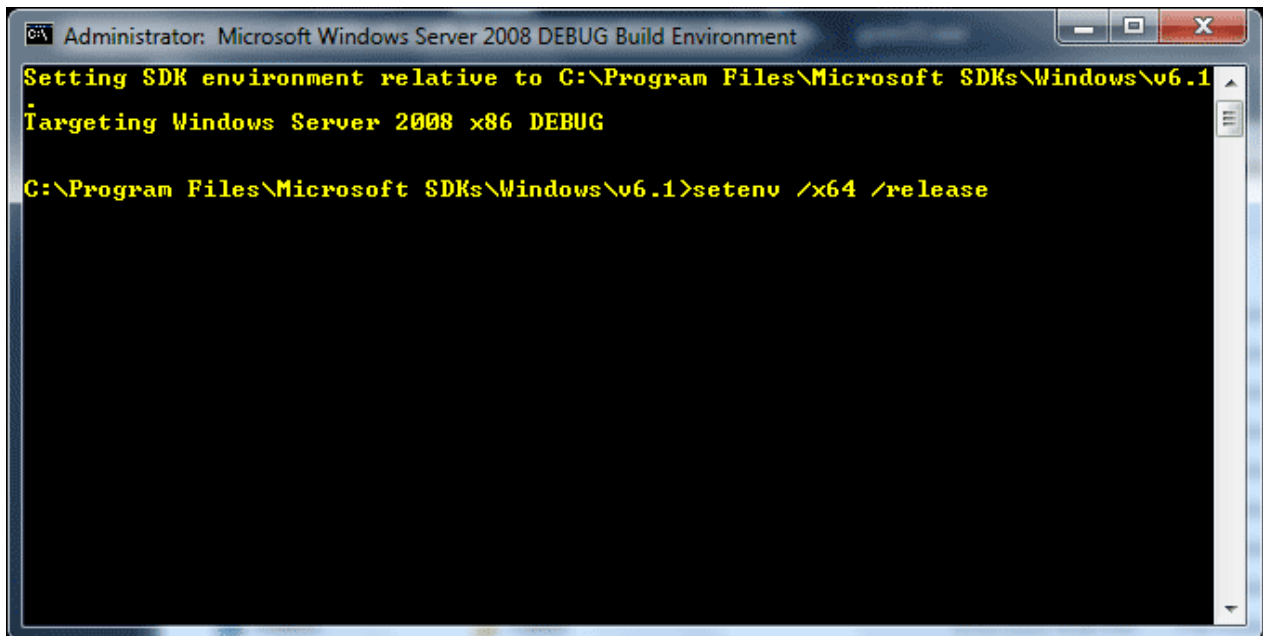

### Configuring PHP 5.6.x or 7.1.x

1. After you have installed SDK 6.1 or 8.1 later, click the [CMD Shell] shortcut under the [Microsoft Windows SDK v.x] folder (Windows Start menu).

2. Run **setenv /x64 /release**.

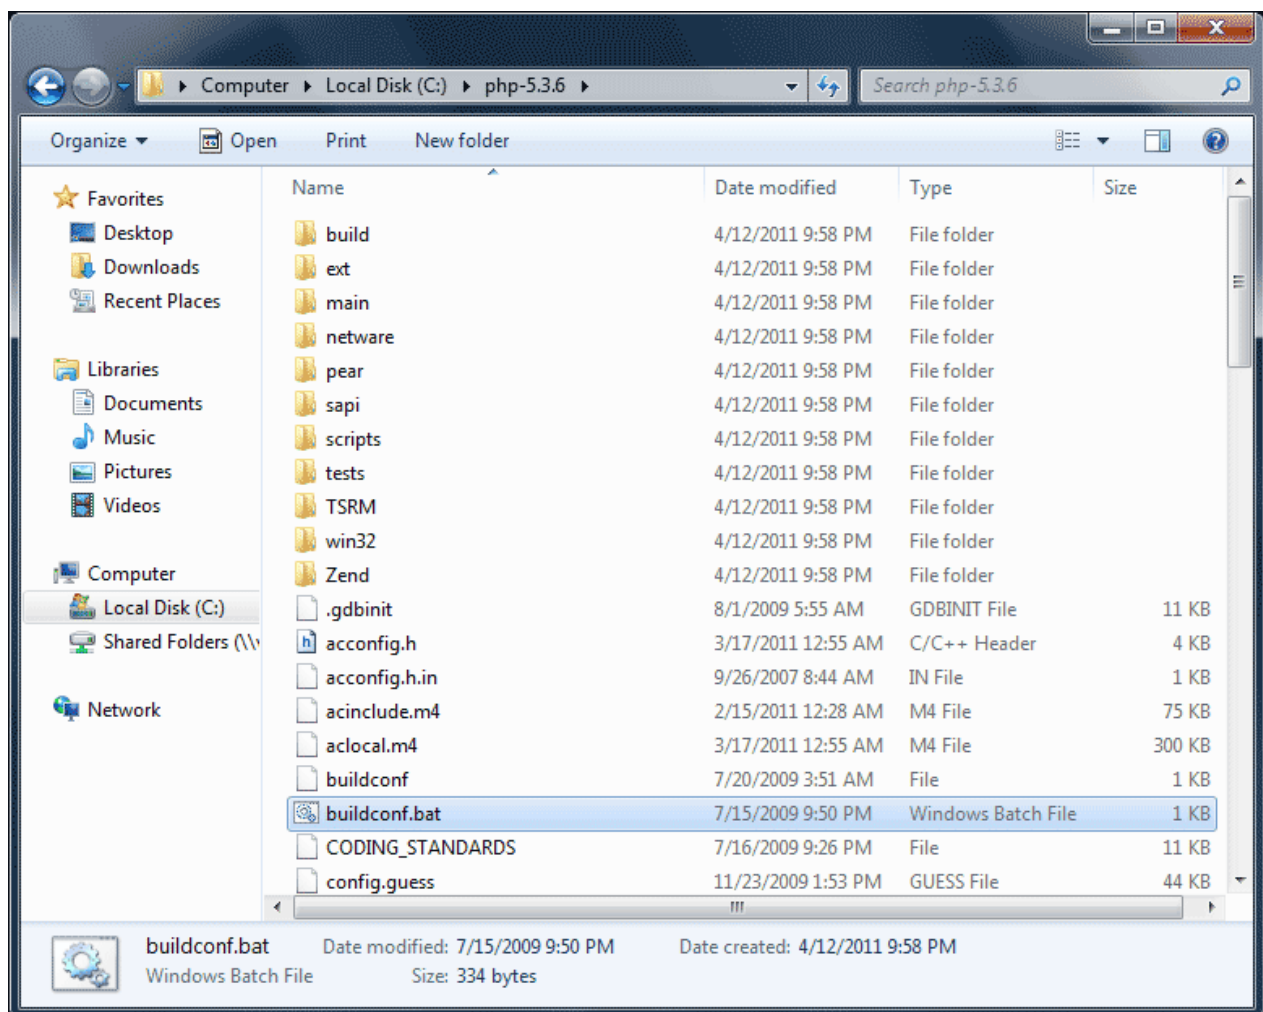

3. Enter PHP 5.6.x or 7.1.x source code directory in the command prompt and run **buildconf** to generate the **configure.js** file.

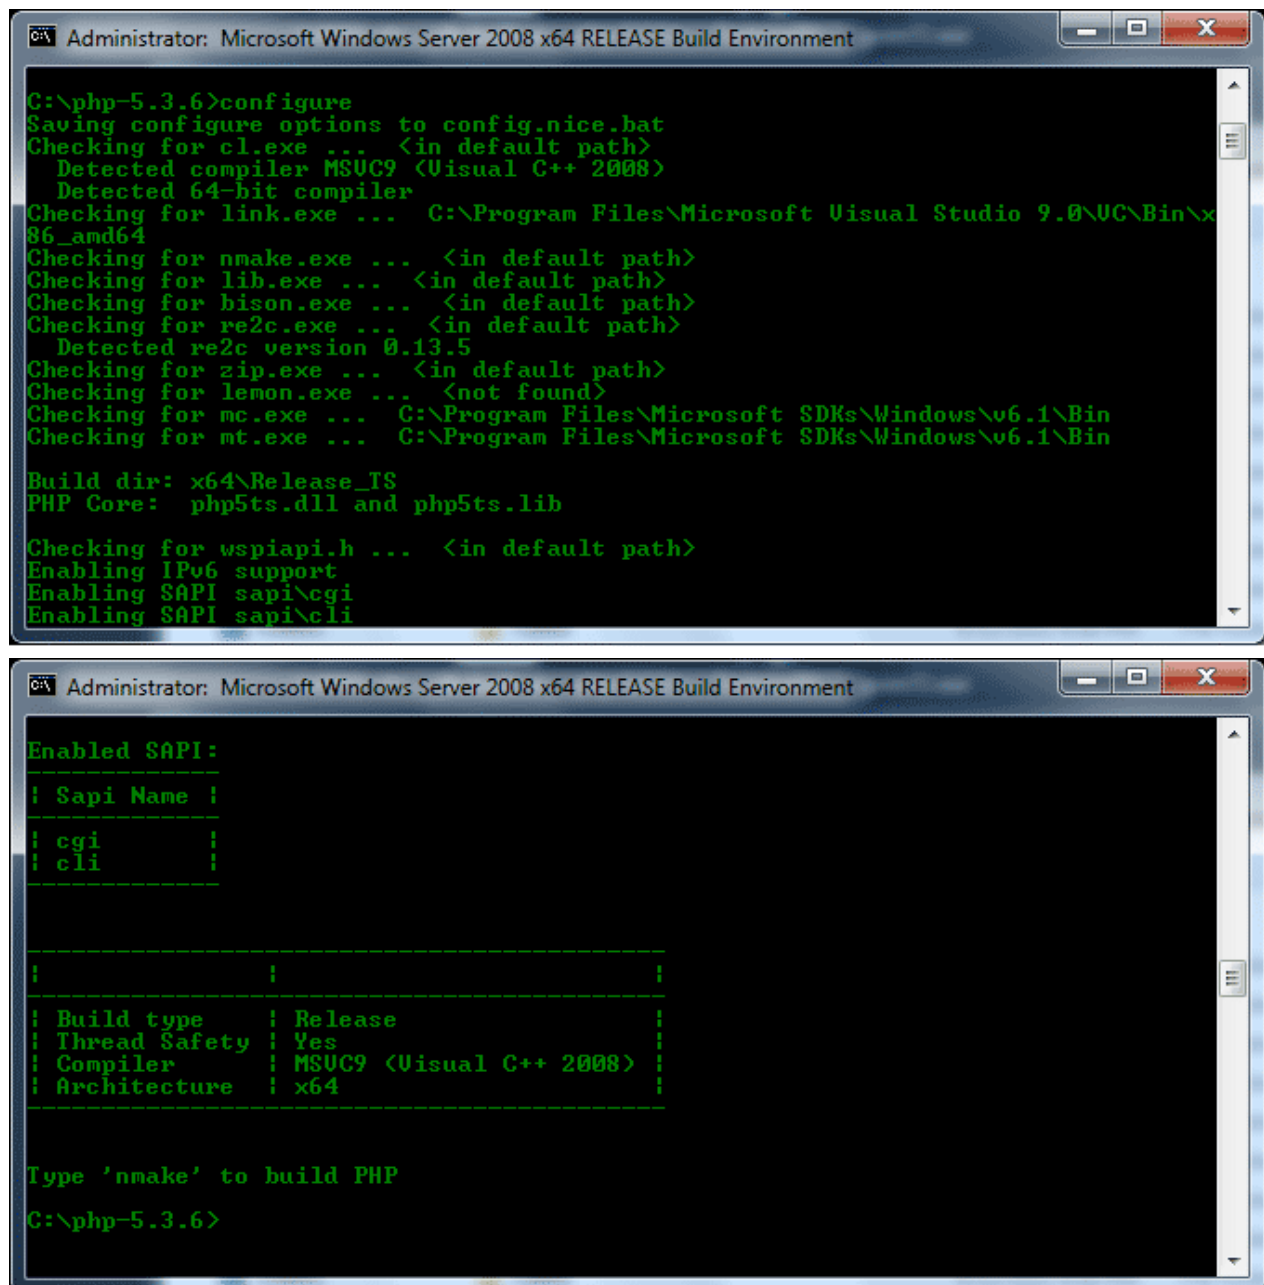

```
Administrator: Microsoft Windows Server 2008 x64 RELEASE Build Environment
Setting SDK environment relative to C:\Program Files\Microsoft SDKs\Windows\v6.1
Targeting Windows Server 2008 x64 RELEASE

C:\Program Files\Microsoft SDKs\Windows\v6.1>cd \
C:\>cd php-5.3.6
C:\php-5.3.6>buildconf
Rebuilding configure.js
Now run 'configure --help'
C:\php-5.3.6>_
```

Or you can also double-click the **buildconf.bat** file.

4. Run the **configure** command to configure the PHP project.

```

Administrator: Microsoft Windows Server 2008 x64 RELEASE Build Environment

C:\php-5.3.6>configure
Saving configure options to config.nice.bat
Checking for cl.exe ... <in default path>
  Detected compiler MSVC9 (Visual C++ 2008)

+-----+

Type 'nmake' to build PHP
C:\php-5.3.6>

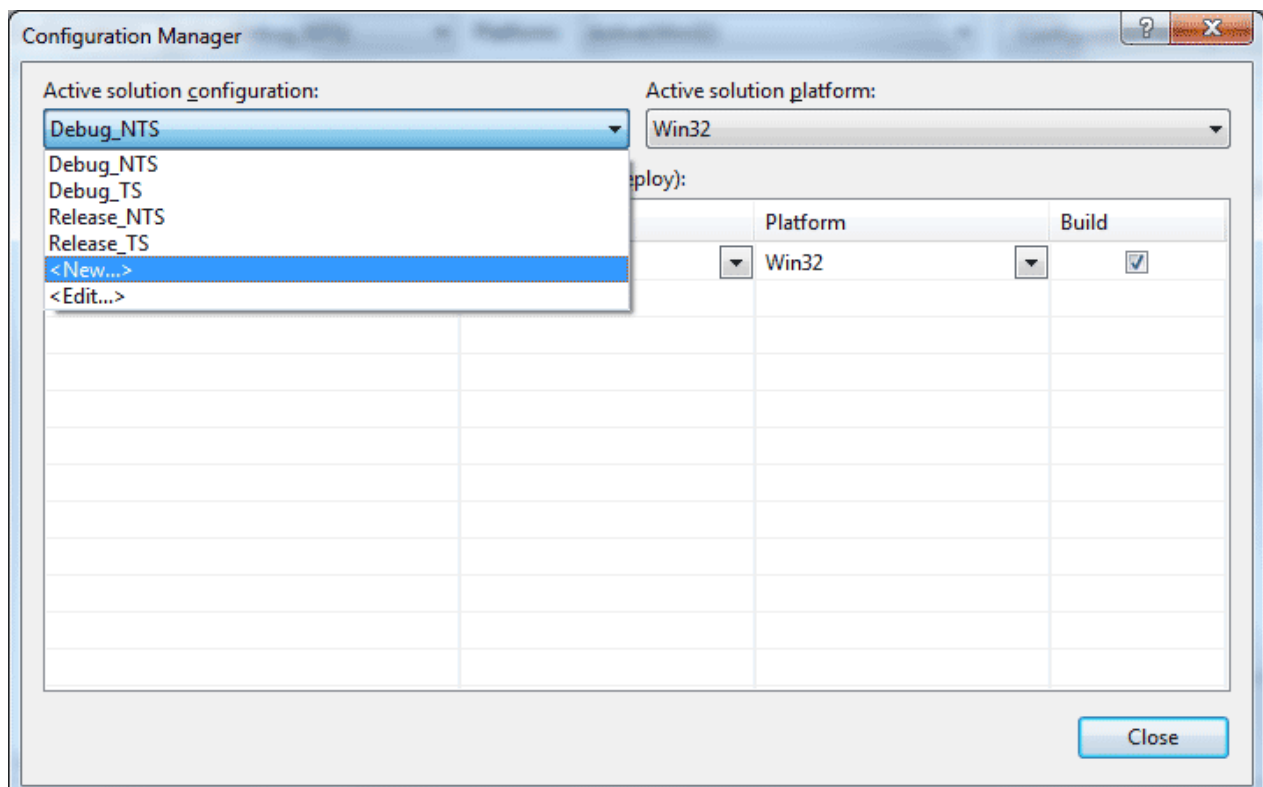

```

## Building CUBRID PHP dirver

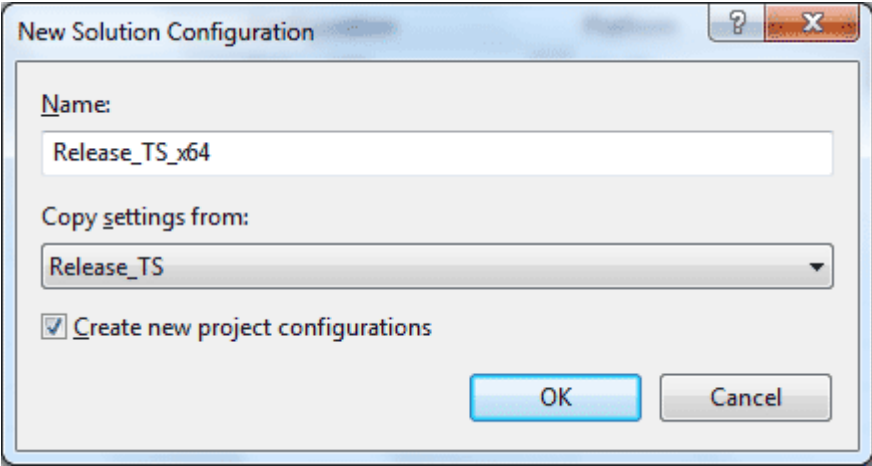

1. Open the **php\_cubrid.vcproj** file under the **\win** directory. In the [Solution Explorer] on the left, right-click on the **php\_cubrid** project name and select [Properties].
2. On the top right corner of the [Property Pages] dialog box, click [Configuration Manager].

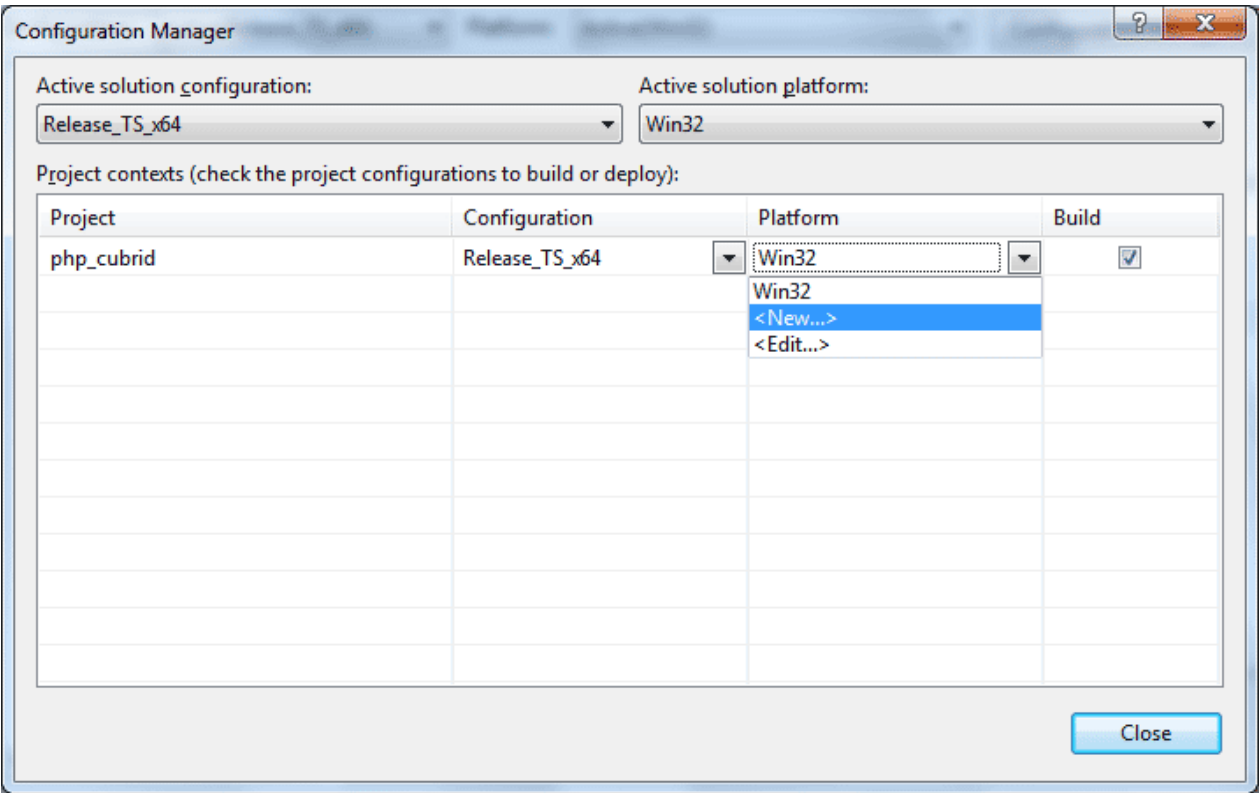

3. In the [Configuration Manager] dialog box, you can see four types of configurations (Release\_TS, Release\_NTS, Debug\_TS, and Debug\_NTS) in the [Active solution configuration] dropdown list. Select **New** in the dropdown list so that you can create a new one for your x64 build.

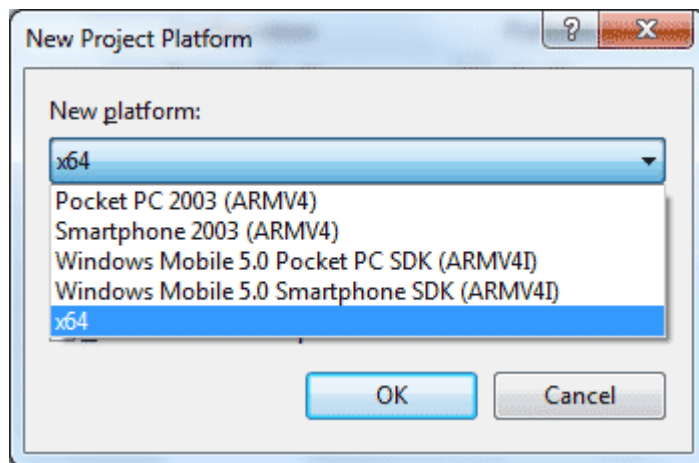

4. In the [New Solution Configuration] dialog box, enter a value in the **Name** box (e.g., **Release\_TS\_x64**). In the [Copy settings from] dropdown list, select the corresponding x86 configuration and click [OK].

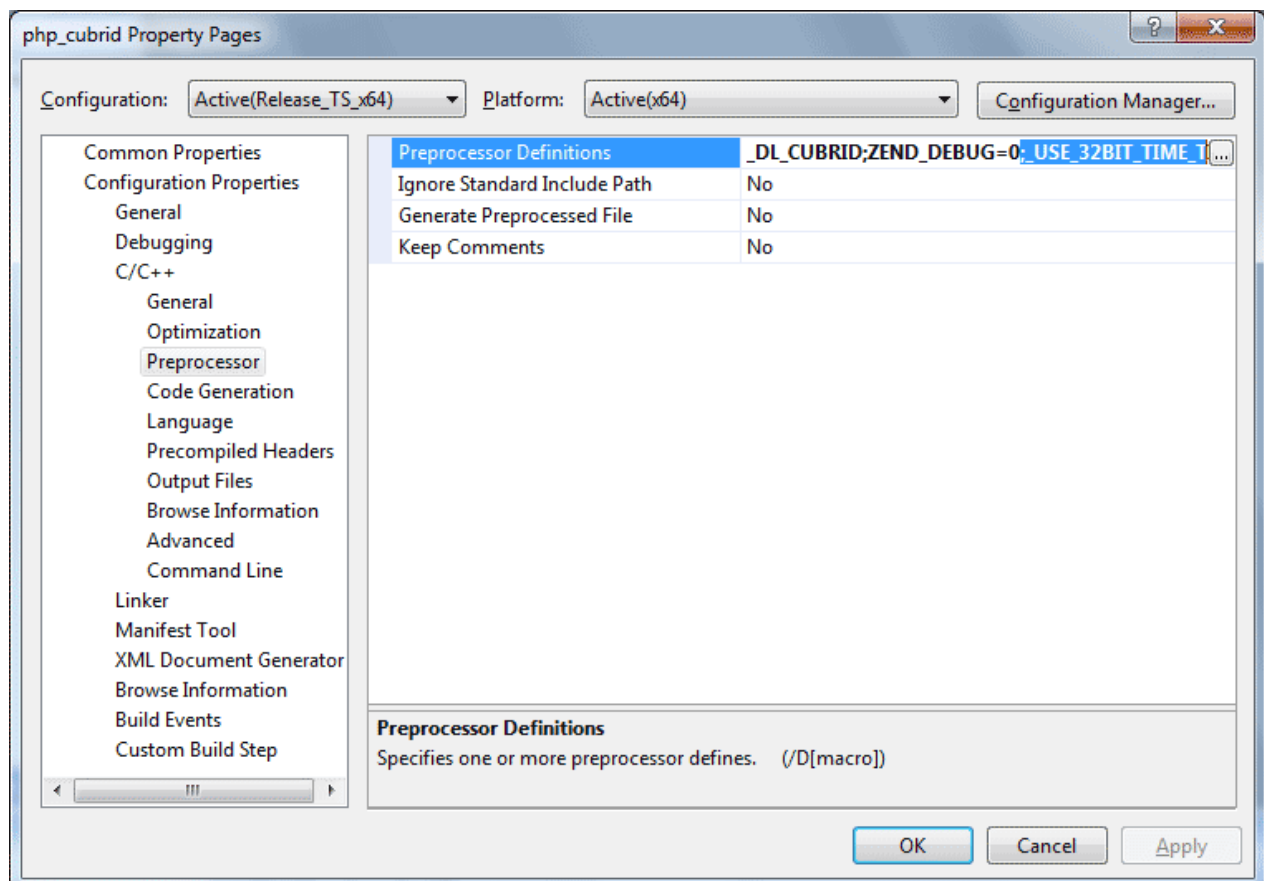

5. In the [Configuration Manager] dialog box, select the value **x64** in the [Platform] dropdown list. If it does not exist, select **New**.

- In the [New Project Platform] dialog box, select **x64** option in the [New platform] dropdown list.

6. In the [Property Pages] dialog box, select [Preprocessor] under the [C/C++] tree node. In [Preprocessor Definitions], delete `_USE_32BIT_TIME_T` and click [OK] to close the dialog box.

7. Press the <F7> key to compile. Now you will get the CUBRID PHP driver for 64-bit Windows.

## PHP Programming

### Connecting to a Database

The first step of database applications is to use `cubrid_connect()` or `cubrid_connect_with_url()` function which provides database connection. Once `cubrid_connect()` or `cubrid_connect_with_url()`

() function is executed successfully, you can use any functions available in the database. It is very important to call the `cubrid_disconnect ()` function before applications are terminated. The `cubrid_disconnect ()` function terminates the current transaction as well as the connection handle and all request handles created by the `cubrid_connect ()` function.

#### Note

- The database connection in thread-based programming must be used independently each other.
- In autocommit mode, the transaction is not committed if all results are not fetched after running the SELECT statement. Therefore, although in autocommit mode, you should end the transaction by executing COMMIT or ROLLBACK if some error occurs during fetching for the resultset.

## Transactions and Auto-Commit

CUBRID PHP supports transaction and auto-commit mode. Auto-commit mode means that every query that you run has its own implicit transaction. You can use the `cubrid_get_autocommit ()` function to get the status of current connection auto-commit mode and use the `cubrid_set_autocommit ()` function to enable/disable auto-commit mode of current connection. In auto-commit mode, any transactions being executed are committed regardless of whether it is set to **ON** or **OFF**.

The default value of auto-commit mode upon application startup is configured by the **CCI\_DEFAULT\_AUTOCOMMIT** (broker parameter). If the broker parameter value is not configured, the default value is set to **ON**.

If you set auto-commit mode to **OFF** in the `cubrid_set_autocommit ()` function, you can handle transactions by specifying a proper function; to commit transactions, use the `cubrid_commit ()` function and to roll back transactions, use the `cubrid_rollback ()` function. If you use the `cubrid_disconnect ()` function, transactions will be disconnected and jobs which have not been committed will be rolled back.

## Processing Queries

### Executing queries

The following are the basic steps to execute queries.

- Creating a connection handle
- Creating a request handle for an SQL query request

- Fetching result
- Disconnecting the request handle

```
$con = cubrid_connect("192.168.0.10", 33000, "demodb");
if($con) {
    $req = cubrid_execute($con, "select * from code");
    if($req) {
        while ($row = cubrid_fetch($req)) {
            echo $row["s_name"];
            echo $row["f_name"];
        }
        cubrid_close_request($req);
    }
    cubrid_disconnect($con);
}
```

### Column types and names of the query result

The `cubrid_column_types()` function is used to get arrays containing column types and the `cubrid_column_names()` function is used to get arrays containing column names.

```
$req = cubrid_execute($con, "select host_year, host_city from
olympic");
if($req) {
    $col_types = cubrid_column_types($req);
    $col_names = cubrid_column_names($req);

    while (list($key, $col_type) = each($col_types)) {
        echo $col_type;
    }
    while (list($key, $col_name) = each($col_names)) {
        echo $col_name;
    }
    cubrid_close_request($req);
}
```

### Controlling a cursor

The `cubrid_move_cursor()` function is used to move a cursor to a specified position from one of three points: beginning of the query result, current cursor position, or end of the query result).

```
$req = cubrid_execute($con, "select host_year, host_city from
olympic order by host_year");
if($req) {
    cubrid_move_cursor($req, 20, CUBRID_CURSOR_CURRENT)
    while ($row = cubrid_fetch($req, CUBRID_ASSOC)) {
        echo $row["host_year"]." ";
    }
}
```

```
        echo $row["host_city"]."\n";
    }
}
```

## Result array types

One of the following three types of arrays is used in the result of the `cubrid_fetch()` function. The array types can be determined when the `cubrid_fetch()` function is called. Of array types, the associative array uses string indexes and the numeric array uses number indexes. The last array includes both associative and numeric arrays.

- Numeric array

```
while (list($id, $name) = cubrid_fetch($req, CUBRID_NUM)) {
    echo $id;
    echo $name;
}
```

- Associative array

```
while ($row = cubrid_fetch($req, CUBRID_ASSOC)) {
    echo $row["id"];
    echo $row["name"];
}
```

## Catalog Operations

The `cubrid_schema()` function is used to get database schema information such as classes, virtual classes, attributes, methods, triggers, and constraints. The return value of the `cubrid_schema()` function is a two-dimensional array.

```
$pk = cubrid_schema($con, CUBRID_SCH_PRIMARY_KEY, "game");
if ($pk) {
    print_r($pk);
}

$fk = cubrid_schema($con, CUBRID_SCH_IMPORTED_KEYS, "game");
if ($fk) {
    print_r($fk);
}
```

## Error Handling

When an error occurs, most of PHP interfaces display error messages and return false or -1. The `cubrid_error_msg ()`, `cubrid_error_code ()` and `cubrid_error_code_facility ()` functions are used to check error messages, error codes, and error facility codes.

The return value of the `cubrid_error_code_facility ()` function is one of the following (**CUBRID\_FACILITY\_DBMS** (DBMS error), **CUBRID\_FACILITY\_CAS** (CAS server error), **CUBRID\_FACILITY\_CCI** (CCI error), or **CUBRID\_FACILITY\_CLIENT** (PHP module error)).

### Using OIDs

The OID value in the currently updated f record by using the `cubrid_current_oid` function if it is used together with query that can update the **CUBRID\_INCLUDE\_OID** option in the `cubrid_execute ()` function.

```
$req = cubrid_execute($con, "select * from person where id = 1",
CUBRID_INCLUDE_OID);
if ($req) {
    while ($row = cubrid_fetch($req)) {
        echo cubrid_current_oid($req);
        echo $row["id"];
        echo $row["name"];
    }
    cubrid_close_request($req);
}
```

Values in every attribute, specified attributes, or a single attribute of an instance can be obtained by using OIDs.

If any attributes are not specified in the `cubrid_get ()` function, values in every attribute are returned (a). If attributes is specified in the array data type, the array containing the specified attribute value is returned in the associative array (b). If a single attribute it is specified in the string type, a value of the attributed is returned (c).

```
$attrarray = cubrid_get ($con, $oid); // (a)
$attrarray = cubrid_get ($con, $oid, array("id", "name")); // (b)
$attrarray = cubrid_get ($con, $oid, "id"); // (c)
```

The attribute values of an instance can be updated by using OIDs. To update a single attribute value, specify attribute name and value in the string type (a). To update multiple attribute values, specify attribute names and values in the associative array (b).

```
$cubrid_put ($con, $oid, "id", 1); // (a)
$cubrid_put ($con, $oid, array("id"=>1, "name"=>"Tomas")); // (b)
```

### Using Collections

You can use the collection data types through PHP array data types or functions that support array data types. The following example shows how to fetch query result by using the `cubrid_fetch()` function.

```
$row = cubrid_fetch ($req);
$col = $row["customer"];
while (list ($key, $cust) = each ($col)) {
    echo $cust;
}
```

You can get values of collection attributes. The example shows how to get values of collection attributes by using the `cubrid_col_get()` function.

```
$tels = cubrid_col_get ($con, $oid, "tels");
while (list ($key, $tel) = each ($tels)) {
    echo $tel."\n";
}
```

You can directly update values of collection types by using `cubrid_set_add()` or `cubrid_set_drop()` function.

```
$tels = cubrid_col_get ($con, $oid, "tels");
while (list ($key, $tel) = each ($tels)) {
    $res = cubrid_set_drop ($con, $oid, "tel", $tel);
}

cubrid_commit ($con);
```

#### Note

If a string longer than defined max length is inserted (**INSERT**) or updated (**UPDATE**), the string will be truncated.

## PHP API

See [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/).

## PDO Driver

The official CUBRID PHP Data Objects (PDO) driver is available as a PECL package and it implements the PDO interface to enable access from PDO to CUBRID. PDO is available with PHP 5.1. For PHP 5.0, you can use it as a PECL extension. PDO cannot run with earlier versions of PHP 5.0 because it requires the new OO features in the core of PHP 5.0.

PDO provides a data-access abstraction layer, which means that, regardless of which database you are using, you use the same functions to issue queries and fetch data; PDO does not provide a database abstraction. Using PDO as a database interface layer can have important advantages over “direct” PHP database drivers as follows:

- Portable PHP code between different databases and database abstraction.
- Supports SQL parameters and bind.
- Safer SQLs (syntax verification, escaping, it helps protect against SQL injections etc.)
- Cleaner programming model

In particular, having a CUBRID PDO driver means that any application that uses PDO as a database interface should work with CUBRID.

CUBRID PDO driver is based on CCI API so affected by CCI configurations such as **CCI\_DEFAULT\_AUTOCOMMIT**.

## Installing and Configuring PDO

### Linux

#### Requirements

- Operating system: 32-bit or 64-bit Linux
- Web server: Apache
- PHP: 5.6.x, 7.1.x, or 7.4.x (<https://www.php.net/downloads.php>)

#### Installing CUBRID PHP Driver using PECL

If **PECL** package has been installed on your system, the installation of CUBRID PDO driver is straightforward. **PECL** will download and compile the driver for you.

1. Enter the following command to install the latest version of CUBRID PDO driver.

```
sudo pecl install pdo_cubrid
```

If you need earlier versions of the driver, you can install exact versions as follows:

```
sudo pecl install pdo_cubrid-8.3.1.0003
```

During the installation, you will be prompted to enter **CUBRID base install dir autodetect :**. Just to make sure your installation goes smoothly, enter the full path to the directory where you have CUBRID installed. For example, if CUBRID has been installed at **/home/cubridtest/CUBRID**, then enter **/home/cubridtest/CUBRID**.

## 2. Edit the configuration file.

- If you are using CentOS 6.0 and later or Fedora 15 and later, create a file named **pdo\_cubrid.ini**, enter a command line **extension=pdo\_cubrid.so**, and store the file in the **/etc/php.d** directory.
- If you are using earlier versions of CentOS or Fedora 15, edit the **php.ini** file (default location: **/etc/php5/apache2** or **/etc/**) and add the following two command lines at the end of the file.

```
[CUBRID]
extension=pdo_cubrid.so
```

## 3. Restart the web server to apply changes.

## Windows

### Requirements

- Operating system: 32-bit or 64-bit Windows
- Web server: Apache or IIS
- PHP: 5.6.x, 7.1.x, or 7.4.x (<https://windows.php.net/download/>)
- For PHP 7.1.x or 7.4.x, you need to install Microsoft Visual C++ 2015 Redistributable Package for 32bit or 64bit.

### Downloading and Installing Compiled CUBRID PDO Driver

First, download CUBRID PHP/PDO driver of which versions match the versions of your operating system and PHP installed at <https://www.cubrid.org/downloads#pdo>.

After you download the driver, you will see the **php\_cubrid.dll** file for CUBRID PHP driver or the **php\_pdo\_cubrid.dll** file for CUBRID PDO driver. Follow the steps below to install it.

1. Copy this driver to the default PHP extensions directory (usually located at **C:\Program Files\PHP\ext**).
2. Set your system environment. Check if the environment variable **PHPRC** is **C:\Program Files\PHP** and system variable path is added with **%PHPRC%** and **%PHPRC%\ext**.
3. Edit **php.ini** (**C:\Program Files\PHP\php.ini**) and add the following two lines at the end of the **php.ini** file.

```
[PHP_PDO_CUBRID]
extension=php_pdo_cubrid.dll
```

For CUBRID PHP driver, add command lines below.

```
[PHP_PDO_CUBRID]
extension = php_pdo_cubrid.dll
```

4. Restart your web server to apply changes.

## Building CUBRID PHP Driver from Source Code

Building CUBRID PDO driver and [Building CUBRID PHP driver from source code](#) are the same.

## PDO Programming

### Data Source Name (DSN)

The PDO\_CUBRID data source name (DSN) consists of the following elements:

| Element    | Description                                       |
|------------|---------------------------------------------------|
| DSN prefix | The DSN prefix is <b>cubrid</b> .                 |
| host       | The hostname on which the database server resides |

| Element | Description                                            |
|---------|--------------------------------------------------------|
| port    | The port number where the database server is listening |
| dbname  | The name of the database                               |

### Example

```
"cubrid:host=127.0.0.1;port=33000;dbname=demodb"
```

### Predefined Constants

The constants defined by CUBRID PDO driver are available only when the extension has been either compiled into PHP or dynamically loaded at runtime. In addition, these driver-specific constants should only be used if you are using PDO driver. Using driver-specific attributes with another driver may result in unexpected behavior.

The `PDO::getAttribute()` function may be used to obtain the **PDO\_ATTR\_DRIVER\_NAME** attribute value to check the driver if your code can run.

The constants below can be used with the `PDO::cubrid_schema` function to get schema information.

| Constant                       | Type    | Description                            |
|--------------------------------|---------|----------------------------------------|
| PDO::CUBRID_SCH_TABLE          | integer | Gets name and type of table in CUBRID. |
| PDO::CUBRID_SCH_VIEW           | integer | Gets name and type of view in CUBRID.  |
| PDO::CUBRID_SCH_QUERY_SPE<br>C | integer | Get the query definition of view.      |
| PDO::CUBRID_SCH_ATTRIBUTE      | integer |                                        |

| Constant                            | Type    | Description                                                                                                                                                                             |
|-------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     |         | Gets the attributes of table column.                                                                                                                                                    |
| PDO::CUBRID_SCH_TABLE_ATTR<br>IBUTE | integer | Gets the attributes of table.                                                                                                                                                           |
| PDO::CUBRID_SCH_TABLE_MET<br>HOD    | integer | Gets the instance method. The instance method is a method called by a class instance. It is used more often than the class method because most operations are executed in the instance. |
| PDO::CUBRID_SCH_METHOD_FI<br>LE     | integer | Gets the information of the file where the method of the table is defined.                                                                                                              |
| PDO::CUBRID_SCH_SUPER_TAB<br>LE     | integer | Gets the name and type of table which table inherits attributes from.                                                                                                                   |
| PDO::CUBRID_SCH_SUB_TABLE           | integer | Gets the name and type of table which inherits attributes from this table.                                                                                                              |
| PDO::CUBRID_SCH_CONSTRAIN<br>T      | integer | Gets the table constraints.                                                                                                                                                             |
| PDO::CUBRID_SCH_TRIGGER             | integer | Gets the table triggers.                                                                                                                                                                |
| PDO::CUBRID_SCH_TABLE_PRIV<br>ILEGE | integer | Gets the privilege information of table.                                                                                                                                                |

| Constant                           | Type    | Description                                |
|------------------------------------|---------|--------------------------------------------|
| PDO::CUBRID_SCH_COL_PRIVILEGE      | integer | Gets the privilege information of column.  |
| PDO::CUBRID_SCH_DIRECT_SUPER_TABLE | integer | Gets the direct super table of table.      |
| PDO::CUBRID_SCH_DIRECT_PRIMARY_KEY | integer | Gets the table primary key.                |
| PDO::CUBRID_SCH_IMPORTED_KEYS      | integer | Gets imported keys of table.               |
| PDO::CUBRID_SCH_EXPORTED_KEYS      | integer | Gets exported keys of table.               |
| PDO::CUBRID_SCH_CROSS_REFERENCE    | integer | Gets reference relationship of two tables. |

## PDO Sample Program

### Verifying CUBRID PDO Driver Version

If you want to verify that the CUBRID PDO driver is accessible, you can use the `PDO::getAvailableDrivers()` function.

```
<?php
echo 'PDO Drivers available:
';
foreach(PDO::getAvailableDrivers() as $driver)
{
if($driver == "cubrid"){
echo " - Driver: <b>".$driver."</b>
";
}else{
echo " - Driver: ".$driver.'
';

```

```
}  
}  
?>
```

This script will output all the currently installed PDO drivers:

```
PDO Drivers available:  
- Driver: mysql  
- Driver: pgsql  
- Driver: sqlite  
- Driver: sqlite2  
- Driver: cubrid
```

## Connecting to CUBRID

Use the data source name (DSN) to connect to the database server. For details about DSN, see [Data Source Name \(DSN\)](#).

Below is a simple PHP example script which performs a PDO connection to the CUBRID *demodb* database. You can notice that errors are handling in PDO by using a try-catch mechanism and the connection is closed by assigning **NULL** to the connection object.

```
<?php  
$database = "demodb";  
$host = "localhost";  
$port = "30000"; //use default value  
$username = "dba";  
$password = "";  
  
try{  
    //cubrid:host=localhost;port=33000;dbname=demodb  
    $conn_str = "cubrid:dbname=".$database.";host=".$host.";port=".$port;  
    echo "PDO connect string: ".$conn_str."  
    ";  
    $db = new PDO($conn_str, $username, $password );  
    echo "PDO connection created ok!."  
    ";  
    $db = null; //disconnect  
} catch(PDOException $e){  
    echo "Error: ".$e->getMessage()."  
    ";  
}  
?>
```

If connection succeeds, the output of this script is as follows:

```
PDO connect string: cubrid:dbname=demodb;host=localhost;port=30000
PDO connection created ok!
```

## Executing a SELECT Statement

In PDO, there is more than one way to execute SQL queries.

- Using the `query ()` function
- Using prepared statements (see `prepare ()` / `execute ()` functions)
- Using the `exec ()` function

The example script below shows the simplest one - using the `query ()` function. You can retrieve the return values from the resultset (a `PDOStatement` object) by using the column names, like `$rs["column_name"]`.

Note that when you use the `query ()` function, you must ensure that the query code is properly escaped. For information about escaping, see `PDO::quote ()` function.

```
<?php
include("_db_config.php");
include("_db_connect.php");

$sql = "SELECT * FROM code";
echo "Executing SQL: <b>".$sql."</b>";
';
echo '
';

try{
foreach($db->query($sql)as $row){
echo $row['s_name'].' - '. $row['f_name'].'
';
}
}catch(PDOException $e){
echo $e->getMessage();
}

$db = null;//disconnect
?>
```

The output of the script is as follows:

```
Executing SQL: SELECT * FROM code

X - Mixed
```

W - Woman  
M - Man  
B - Bronze  
S - Silver  
G - Gold

## Executing an UPDATE Statement

The following example shows how to execute an UPDATE statement by using a prepared statement and parameters. You can use the `exec()` function as an alternative.

```
<?php
include("_db_config.php");
include("_db_connect.php");

$s_name = 'X';
$f_name = 'test';
$sql = "UPDATE code SET f_name=:f_name WHERE s_name=:s_name";

echo "Executing SQL: <b>".$sql."</b>";
';
echo '
';

echo ":f_name: <b>".$f_name."</b>";
';
echo '
';
echo ":s_name: <b>".$s_name."</b>";
';
echo '
';

$qe = $db->prepare($sql);
$qe->execute(array(':s_name'=>$s_name, ':f_name'=>$f_name));

$sql = "SELECT * FROM code";
echo "Executing SQL: <b>".$sql."</b>";
';
echo '
';

try{
foreach($db->query($sql)as $row){
echo $row['s_name'].' - '. $row['f_name'].'
';
}
}catch(PDOException $e){
echo $e->getMessage();
```

```
}  
  
$db = null;//disconnect  
?>
```

The output of the script is as follows:

```
Executing SQL: UPDATE code SET f_name=:f_name WHERE s_name=:s_name  
  
:f_name: test  
  
:s_name: X  
  
Executing SQL: SELECT * FROM code  
  
X - test  
W - Woman  
M - Man  
B - Bronze  
S - Silver  
G - Gold
```

## Using prepare and bind

Prepared statements are one of the major features offered by PDO and you can take following benefits by using them.

- SQL prepared statements need to be parsed only once even if they are executed multiple times with different parameter values. Therefore, using a prepared statement minimizes the resources and, in general, the prepared statements run faster.
- It helps to prevent SQL injection attacks by eliminating the need to manually quote the parameters; however, if other parts of the SQL query are being built up with unescaped input, SQL injection is still possible.

The example script below shows how to retrieve data by using a prepared statement.

```
<?php  
include("_db_config.php");  
include("_db_connect.php");  
  
$sql ="SELECT * FROM code WHERE s_name NOT LIKE :s_name";  
echo"Executing SQL: <b>".$sql."</b>  
';  
  
$s_name ='xyz';  
echo":s_name: <b>".$s_name."</b>
```

```
';  
  
echo '  
';  
  
try{  
$stmt = $db->prepare($sql);  
  
$stmt->bindParam(':s_name', $s_name, PDO::PARAM_STR);  
$stmt->execute();  
  
$result = $stmt->fetchAll();  
foreach($result as $row)  
{  
echo $row['s_name'].' - '. $row['f_name'].'  
';  
}  
}catch(PDOException $e){  
echo $e->getMessage();  
}  
echo '  
';  
  
$sql ="SELECT * FROM code WHERE s_name NOT LIKE :s_name";  
echo "Executing SQL: <b>".$sql."</b>  
';  
  
$s_name = 'X';  
echo ":s_name: <b>".$s_name."</b>  
';  
  
echo '  
';  
  
try{  
$stmt = $db->prepare($sql);  
  
$stmt->bindParam(':s_name', $s_name, PDO::PARAM_STR);  
$stmt->execute();  
  
$result = $stmt->fetchAll();  
foreach($result as $row)  
{  
echo $row['s_name'].' - '. $row['f_name'].'  
';  
}  
$stmt->closeCursor();  
}catch(PDOException $e){  
echo $e->getMessage();  
}  
echo '  
';
```

```
$db = null;//disconnect  
?>
```

The output of the script is as follows:

```
Executing SQL: SELECT * FROM code WHERE s_name NOT LIKE :s_name  
:s_name: xyz
```

```
X - Mixed  
W - Woman  
M - Man  
B - Bronze  
S - Silver  
G - Gold
```

```
Executing SQL: SELECT * FROM code WHERE s_name NOT LIKE :s_name  
:s_name: X
```

```
W - Woman  
M - Man  
B - Bronze  
S - Silver  
G - Gold
```

## Using the PDO::getAttribute() Function

The `PDO::getAttribute()` function is very useful to retrieve the database connection attributes. For example,

- Driver name
- Database version
- Auto-commit state
- Error mode

Note that if you want to set attributes values (assuming that they are writable), you should use the `PDO::setAttribute()` function.

The following example script shows how to retrieve the current versions of client and server by using the `PDO::getAttribute()` function.

```
<?php  
include("_db_config.php");  
include("_db_connect.php");
```

```
echo"Driver name: <b>".$db->getAttribute(PDO::ATTR_DRIVER_NAME). "</b>";
echo"
";
echo"Client version: <b>".$db->getAttribute(PDO::ATTR_CLIENT_VERSION). "</b>";
echo"
";
echo"Server version: <b>".$db->getAttribute(PDO::ATTR_SERVER_VERSION). "</b>";
echo"
";

$db = null;//disconnect
?>
```

The output of the script is as follows:

```
Driver name: cubrid
Client version: 8.3.0
Server version: 8.3.0.0337
```

## CUBRID PDO Extensions

In CUBRID, the PDO::cubrid\_schema() function is offered as an extension; the function is used to retrieve the database schema and metadata information. Below is an example script that returns information about primary key for the *nation* table by using this function.

```
<?php
include("_db_config.php");
include("_db_connect.php");
try{
echo"Get PRIMARY KEY for table: <b>nation</b>:

";
$pk_list = $db->cubrid_schema(PDO::CUBRID_SCH_PRIMARY_KEY,"nation");
print_r($pk_list);
}catch(PDOException $e){
echo $e->getMessage();
}

$db = null;//disconnect
?>
```

The output of the script is as follows:

```
Get PRIMARY KEY for table: nation:
Array ( [0] => Array ( [CLASS_NAME] => nation [ATTR_NAME] => code
[KEY_SEQ] => 1 [KEY_NAME] => pk_nation_code ) )
```

## PDO API

For more information about PHP Data Objects (PDO) API, see <https://www.php.net/manual/en/book.pdo.php>. The API provided by CUBRID PDO driver is as follows:

For more information about CUBRID PDO API provides, see [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/PDO/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/PDO/).

## ODBC Driver

CUBRID ODBC driver supports ODBC version 3.52. It also ODBC core and some parts of Level 1 and Level 2 API. Because CUBRID ODBC driver has been developed based on the ODBC Spec 3.x, backward compatibility is not completely ensured for programs written based on the ODBC Spec 2.x.

CUBRID ODBC driver is written based on CCI API, but it's not affected by `CCI_DEFAULT_AUTOCOMMIT` exceptionally.

### Note

ODBC is not affected by `CCI_DEFAULT_AUTOCOMMIT` is from 9.3 version. In the previous versions, you should set `CCI_DEFAULT_AUTOCOMMIT` as OFF.

## Data Type Mapping Between CUBRID and ODBC

The following table shows the data type mapping relationship between CUBRID and ODBC.

| CUBRID Data Type | ODBC Data Type |
|------------------|----------------|
| CHAR             | SQL_CHAR       |
| VARCHAR          | SQL_VARCHAR    |

| CUBRID Data Type         | ODBC Data Type                 |
|--------------------------|--------------------------------|
| STRING                   | SQL_LONGVARCHAR                |

## Configuring and Environment ODBC

### Requirements

- CUBRID 2008 R4.4 (8.4.4) or later (32-bit or 64-bit)

### Configuring CUBRID ODBC Driver

CUBRID ODBC driver is automatically installed upon CUBRID installation. You can check whether it is properly installed in the [Control Panel] > [Administrative Tools] > [Data Source (ODBC)] > [Drivers] tab.

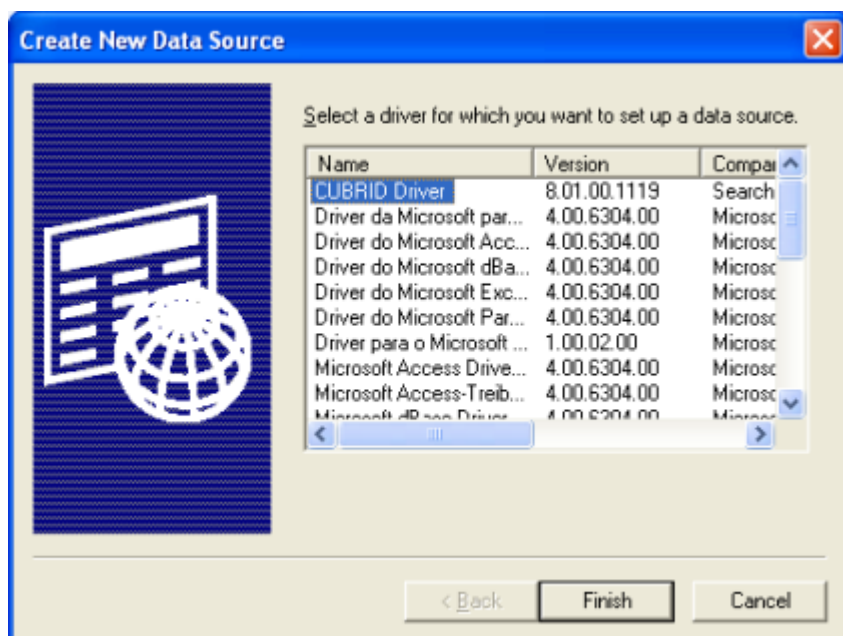

### Choosing 32-bit ODBC driver on 64-bit Windows

To run 32-bit application, 32-bit ODBC driver is required. If you have to choose 32-bit ODBC driver on 64-bit Windows, run C:WINDOWSSysWOW64odbcad32.exe .

Microsoft Windows 64-bit platform support the environment to run 32-bit application on 64-bit environment, which is called WOW64 (Windows-32-on-Windows-64). This environment maintains its own copy of the registry that is only for 32-bit applications.

### Configuring DSN

After you check the CUBRID ODBC driver installed, configure DSN as a database where the applications are trying to connect. To configure, click the [Add] button in the ODBC Data Source Administrator dialog box. Then, the following dialog box will appear. Select “CUBRID Driver” and then click the [Finish] button.

In the [Config CUBRID Data Sources] dialog box, enter information as follows:

Config CUBRID Data Sources

Data Source: CUBRID Driver

Description: CUBRID ODBC Driver

Database: demodb

User: dba

Password:

Server: localhost

Port: 33000

FETCH\_SIZE: 100

Charset: utf-8

Autocommit: on

Omit Schmea: no

OK Cancel

- **DSN** : The name of a source data
- **DB Name** : The name of a database to be connected

- **DB User** : The name of a database user
- **Password** : The password of a database user
- **Server Address** : The host address of a database. The value should be either localhost or the IP address of other server.
- **Server Port** : The number of a broker port. You can check the CUBRID broker port number in the **cubrid\_broker.conf** file. The default value is 33,000. To verify the port number, check the BROKER\_PORT value in the **cubrid\_broker.conf** file or enter the **cubrid service status** in the command prompt. The result will be displayed as follows:

```

Administrator: C:\Windows\system32\cmd.exe
Microsoft Windows [Version 6.1.7601]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

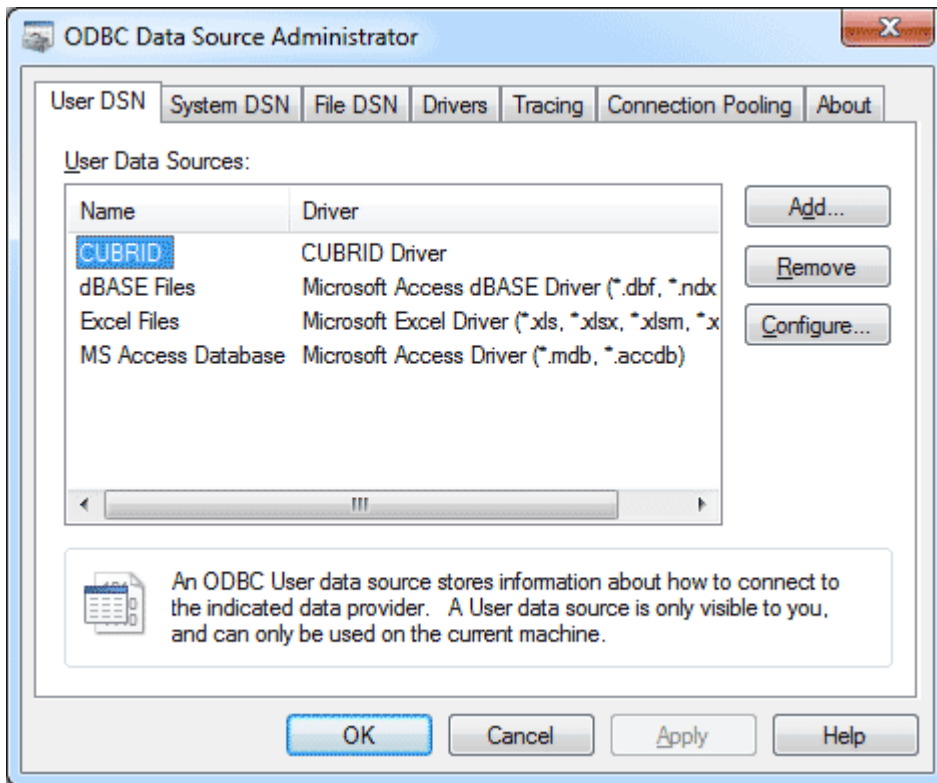

C:\Users\cub>cubrid service status
@cubrid master status
++ cubrid master is running.
@cubrid server status
@cubrid broker status
  NAME          PID  PORT  AS  JQ      REQ  TPS  QPS    LONG-T    LONG-Q  ERR-Q
=====
* broker1       2724 33000  5   0        0    0    0    0/0.0    0/0.0    0
* query_editor  3112 30000  5   0        0    0    0    0/0.0    0/0.0    0
@cubrid manager server status
++ cubrid manager server is running.
@cubrid replication status

C:\Users\cub>_

```

- **Charset** : The name of the database charset.
- **Autocommit** : Autocommit mode. Default is OFF.
- **Omit Schema** : This feature provides only the schema information created by the logged-in user when a user requests catalog information in a database server of version 11.2 or higher that supports the schema concept. This feature is required when **ERWin<sup>TM</sup>** uses CUBRID 11.2 or higher (omit\_schema=yes). If **YES**, only information on the Tables/Views/Primary Keys/Foreign Keys owned by the logged-in user are provided, and the owner's name is removed on these objects. Default is **NO**.
- **FETCH\_SIZE** : A value configures the number of records fetched from server whenever the **cci\_fetch ()** function of CCI library (which CUBRID ODBC driver internally uses) is called.

After you filled out every field, click the [OK] button. You will notice that data source is added in the [User Data Sources] as shown below.

### Connecting to a Database Directly without DSN

It is also possible to connect to a CUBRID database directly in the application source code by using the connecting string. Below shows the example of connection string.

```
conn = "driver={CUBRID
Driver};server=localhost;port=33000;uid=dba;pwd=;db_name=demodb;"
```

#### **Note**

Make sure that your database is running before you try to connect to a CUBRID database. Otherwise, you will receive an error indicating that ODBC call has failed. To start the database called demodb, enter **cubrid server start demodb** in the command prompt.

## ODBC Programming

### Configuring Connection String

When you are programming CUBRID ODBC, write the connection strings as follows:

| Category    | Example               | Description                                               |
|-------------|-----------------------|-----------------------------------------------------------|
| Driver      | CUBRID Driver Unicode | Driver name                                               |
| UID         | PUBLIC                | User ID                                                   |
| PWD         | xxx                   | Password                                                  |
| FETCH_SIZE  | 100                   | Fetch size                                                |
| PORT        | 33000                 | The broker port number                                    |
| SERVER      | 127.0.0.1             | The IP address or the host name of a CUBRID broker server |
| DB_NAME     | demodb                | Database name                                             |
| DESCRIPTION | cubrid_test           | Description                                               |
| CHARSET     | utf-8                 | Character set                                             |
| AUTOCOMMIT  | ON                    | Autocommit mode                                           |
| OMIT_SCHEMA | NO                    | Single Schema feature (applicable only 11.2 or higher)    |

The following shows the result of using connection strings above.

```
"DRIVER={CUBRID Driver
Unicode};UID=PUBLIC;PWD=xxx;FETCH_SIZE=100;PORT=33000;SERVER=127.0.0.
1;DB_NAME=demodb;DESCRIPTION=cubrid_test;CHARSET=utf-8;OMIT_SCHEMA=YE
S"
```

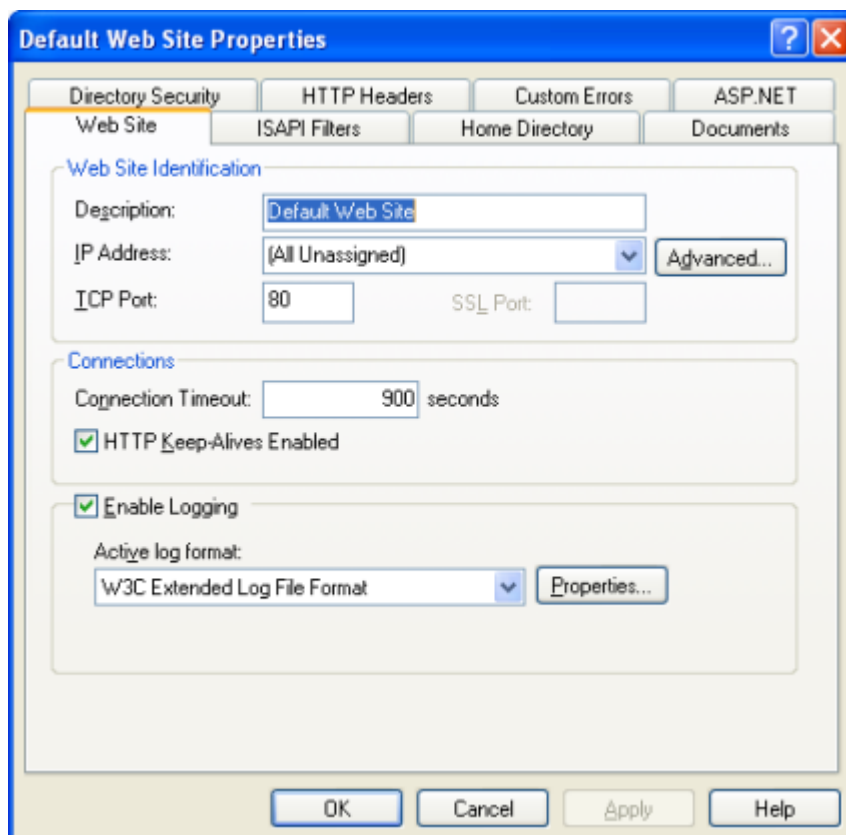

If you use UTF-8 unicode, install a driver for unicode and input the driver name in the connection string as “Driver={CUBRID Driver Unicode}”. Unicode is only supported in 9.3.0.0002 or higher version of CUBRID ODBC driver.

### Note

- Because a semi-colon (;) is used as a separator in URL string, it is not allowed to use a semi-colon as parts of a password (PWD) when specifying the password in connection strings.
- The database connection in thread-based programming must be used independently each other.
- In autocommit mode, the transaction is not committed if all results are not fetched after running the SELECT statement. Therefore, although in autocommit mode, you should end the transaction by executing COMMIT or ROLLBACK if some error occurs during fetching for the resultset.

## ASP Sample Program

In the virtual directory where the ASP sample program runs, right-click “Default Web Site” and click [Properties].

In the picture above, if you select **(All Unassigned)** from the [IP Address] dropdown list under [Web Site Identification], it is recognized as localhost. If you want to see the sample program through a specific IP address, make an IP address recognize a directory as a virtual directory and register the IP address in the registration information.

Create the below code as cubrid.asp and store it in a virtual directory.

```
<HTML>
  <HEAD>
    <meta http-equiv="Content-Type" content="text/html; charset=EUC-
KR">

## ADO.NET Driver

ADO.NET is a set of classes that expose data access services to the .NET programmer. ADO.NET provides a rich set of components for creating distributed, data-sharing applications. It is an integral part of the .NET Framework, providing access to relational, XML, and application data. ADO.NET supports a variety of development needs, including the creation of front-end database clients and middle-tier business objects used by applications, tools, languages, or Internet browsers.

## Installing and Configuring ADO.NET

### Requirements

- Windows (Windows Vista or Windows 7 recommended)
- .NET Framework 2.0 or later (4.0 or later versions recommended)

- Microsoft Visual Studio Express edition ( <https://visualstudio.microsoft.com/> )

## Installing and Configuring CUBRID ADO.NET Driver

Before you start developing .NET applications with CUBRID, you will need the CUBRID ADO.NET Data Provider library (**Cubrid.Data.dll**). You have the options to:

- Download the compiled library along with other files from:

<https://www.cubrid.org/downloads#adonet>

- Compile it yourself from source code. You can download the source code from GitHub.

<https://github.com/CUBRID/cubrid-adonet>

The CUBRID .NET Data Provider is 100% full-managed .NET code and it does not rely on any CUBRID library files. This means that the usage of the driver does not require any kind of CUBRID installation or files on the local machine.

The easiest way to install CUBRID ADO.NET Data Provider is to use the official installer. If you choose to install using the default option (x86), the driver will be installed in the **Program Files\CUBRID\CUBRID ADO.NET Data Provider 8.4.1** directory.

You can also choose to install the driver in GAC ( [https://en.wikipedia.org/wiki/Global\\_Assembly\\_Cache](https://en.wikipedia.org/wiki/Global_Assembly_Cache) ). The best way to install the driver is to use the tlbimp ( [https://learn.microsoft.com/en-us/previous-versions/dotnet/netframework-2.0/tt0cf3sx\(v=vs.80\)](https://learn.microsoft.com/en-us/previous-versions/dotnet/netframework-2.0/tt0cf3sx(v=vs.80)) ) tool. See the below to import the required namespaces.

```

33 | using System.Data.Common;
34 | using System.Diagnostics;
35 | using System.IO;
36 | using System.Reflection;
37 | using System.Text.RegularExpressions;
38 | using CUBRID.Data.CUBRIDClient;
39 |
40 | namespace CUBRID.ADO.NET.DataProvider.TestCases
41 | {
42 |     /// <summary>
43 |     /// Implementation of test cases for CUBRID ADO.NET Data
    .. | ..

```

## ADO.NET Programming

### A Simple Query/Retrieve Code

Let's take a look at a simple code which retrieves value from a CUBRID database table. Assume that the connection is already established.

```
String sql = "select * from nation order by `code` asc";

using (CUBRIDCommand cmd = new CUBRIDCommand(sql, conn))
{
    using (DbDataReader reader = cmd.ExecuteReader())
    {
        reader.Read();
        //(read the values using: reader.Get...() methods)
    }
}
```

Once you have created the **DbDataReader** object, all you have to do is to use the `Get...()` method to retrieve any column data. CUBRID ADO.NET driver implements all methods required to read any CUBRID data types.

```
reader.GetString(3)
reader.GetDecimal(1)
```

The `Get...()` method will use as an input parameter the 0-based index position of the retrieved column.

To retrieve specific CUBRID data types, you need to use **CUBRIDDataReader**, instead of the **DbDataReader** interface.

```
using (CUBRIDCommand cmd = new CUBRIDCommand("select * from t",
conn))
{
    CUBRIDDataReader reader = (CUBRIDDataReader)cmd.ExecuteReader();

    reader.Read();
    Debug.Assert(reader.GetDateTime(0) == new DateTime(2008, 10, 31,
10, 20, 30, 40));
    Debug.Assert(reader.GetDate(0) == "2008-10-31");
    Debug.Assert(reader.GetDate(0, "yy/MM/dd") == "08-10-31");
    Debug.Assert(reader.GetTime(0) == "10:20:30");
    Debug.Assert(reader.GetTime(0, "HH") == "10");
    Debug.Assert(reader.GetTimestamp(0) == "2008-10-31
10:20:30.040");
    Debug.Assert(reader.GetTimestamp(0, "yyyy HH") == "2008 10");
}
```

## batch Commands

When using CUBRID ADO.NET Data Provider library, you can execute more than one query against the data service in a single batch. For more information, see [https://learn.microsoft.com/en-us/previous-versions/dd744839\(v=vs.90\)](https://learn.microsoft.com/en-us/previous-versions/dd744839(v=vs.90)).

For example, in CUBRID, you can write the code like:

```
string[] sql_arr = newstring3;  
sql_arr0 = "insert into t values(1)";  
sql_arr1 = "insert into t values(2)";  
sql_arr2 = "insert into t values(3)";  
conn.BatchExecute(sql_arr);
```

or you can write as follows:

```
string[] sqls = newstring3;  
sqls0 = "create table t(id int)";  
sqls1 = "insert into t values(1)";  
sqls2 = "insert into t values(2)";  
  
conn.BatchExecuteNoQuery(sqls);
```

## Connection String

In order to establish a connection from .NET application to CUBRID, you must build the database connection string as the following format:

```
ConnectionString = "server=<server address>;database=<database  
name>;port=<port number to use for connection to broker>;user=<user  
name>;password=<user password>;"
```

All parameters are mandatory except for **port**. If you do not specify the broker port number, the default value is **30,000**.

The examples of connection string with different options are as follows:

- Connect to a local server, using the default *demodb* database.

```
ConnectionString =  
"server=127.0.0.1;database=demodb;port=30000;user=public;password="
```

- Connect to a remote server, using the default *demodb* database, as user **dba**.

```
ConnectionString =  
"server=10.50.88.1;database=demodb;user=dba;password="
```

- Connect to a remote server, using the default *demodb* database, as user **dba**, using password *secret*.

```
ConnectionString =  
"server=10.50.99.1;database=demodb;port=30000;user=dba;password=secret"
```

As an alternative, you can use the `CUBRIDConnectionStringBuilder` class to build easily a connection string in the correct format.

```
CUBRIDConnectionStringBuilder sb = new  
CUBRIDConnectionStringBuilder("localhost","33000","demodb","public","");  
using (CUBRIDConnection conn = new  
CUBRIDConnection(sb.GetConnectionString()))  
{  
    conn.Open();  
}
```

or you can write as follows:

```
sb = new CUBRIDConnectionStringBuilder();  
sb.User = "public" ;  
sb.Database = "demodb";  
sb.Port = "33000";  
sb.Server = "localhost";  
using (CUBRIDConnection conn = new  
CUBRIDConnection(sb.GetConnectionString()))  
{  
    conn.Open();  
}
```

#### Note

The database connection in thread-based programming must be used independently each other.

## CUBRID Collections

Collections are specific CUBRID data type. If you are not familiar with them, you can read information in [Collection Types](#). Because collections are not common to any database, the support for them is implemented in some specific CUBRID collection method.

```
public void AddElementToSet(CUBRIDoid oid, String attributeName,
Object value)
public void DropElementInSet(CUBRIDoid oid, String attributeName,
Object value)
public void UpdateElementInSequence(CUBRIDoid oid, String
attributeName, int index, Object value)
public void InsertElementInSequence(CUBRIDoid oid, String
attributeName, int index, Object value)
public void DropElementInSequence(CUBRIDoid oid, String
attributeName, int index)
public int GetCollectionSize(CUBRIDoid oid, String attributeName)
```

Here below are two examples of using these CUBRID extensions.

Reading values from a Collection data type:

```
using (CUBRIDCommand cmd = new CUBRIDCommand("SELECT * FROM t",
conn))
{
    using (DbDataReader reader = cmd.ExecuteReader())
    {
        while (reader.Read())
        {
            object[] o = (object[])reader[0];
            for (int i = 0; i < SeqSize; i++)
            {
                //...
            }
        }
    }
}
```

Updating a Collection data type:

```
conn.InsertElementInSequence(oid, attributeName, 5, value);
SeqSize = conn.GetCollectionSize(oid, attributeName);
using (CUBRIDCommand cmd = new CUBRIDCommand("SELECT * FROM t",
conn))
{
    using (DbDataReader reader = cmd.ExecuteReader())
    {
        while (reader.Read())
```

```

        {
            int[] expected = { 7, 1, 2, 3, 7, 4, 5, 6 };
            object[] o = (object[])reader0;
        }
    }
}
conn.DropElementInSequence(oid, attributeName, 5);
SeqSize = conn.GetCollectionSize(oid, attributeName);

```

## CUBRID BLOB/CLOB

Starting from CUBRID 2008 R4.0 (8.4.0), CUBRID deprecated the GLO data type and added support for LOB (BLOB, CLOB) data types. These data types are specific CUBRID data types so you need to use methods offered by CUBRID ADO.NET Data Provider.

Here are some basic source code examples.

Reading BLOB data:

```

CUBRIDCommand cmd = new CUBRIDCommand(sql, conn);
DbDataReader reader = cmd.ExecuteReader();

while (reader.Read())
{
    CUBRIDBlob bImage = (CUBRIDBlob)reader0;
    byte[] bytes = new byte[(int)bImage.BlobLength];
    bytes = bImage.getBytes(1, (int)bImage.BlobLength);
    //...
}

```

Updating CLOB data:

```

string sql = "UPDATE t SET c = ?";
CUBRIDCommand cmd = new CUBRIDCommand(sql, conn);

CUBRIDClob clob = new CUBRIDClob(conn);
str = conn.ConnectionString; //Use the ConnectionString for testing

clob.SetString(1, str);

CUBRIDParameter param = new CUBRIDParameter();

param.ParameterName = "?";
param.CUBRIDDataType = CUBRIDDataType.CCI_U_TYPE_CLOB;
param.Value = clob;

```

```
cmd.Parameters.Add(param);
cmd.ExecuteNonQuery();
```

## CUBRID Metadata Support

CUBRID ADO.NET Data Provider supports for database metadata. Most of these methods are implemented in the CUBRIDSchemaProvider class. ... code-block:: c#

```
public DataTable GetDatabases(string[] filters) public DataTable GetTables(string[]
filters) public DataTable GetViews(string[] filters) public DataTable
GetColumns(string[] filters) public DataTable GetIndexes(string[] filters) public
DataTable GetIndexColumns(string[] filters) public DataTable GetExportedKeys(string[]
filters) public DataTable GetCrossReferenceKeys(string[] filters) public DataTable
GetForeignKeys(string[] filters) public DataTable GetUsers(string[] filters) public
DataTable GetProcedures(string[] filters) public static DataTable GetDataTypes() public
static DataTable GetReservedWords() public static String[] GetNumericFunctions()
public static String[] GetStringFunctions() public DataTable GetSchema(string
collection, string[] filters)
```

The example below shows how to get the list of tables in the current CUBRID database.

```
CUBRIDSchemaProvider schema = new CUBRIDSchemaProvider(conn);
DataTable dt = schema.GetTables(newstring[] { "%" });
```

```
Debug.Assert(dt.Columns.Count == 3);
Debug.Assert(dt.Rows.Count == 10);
```

```
Debug.Assert(dt.Rows[0].ToString() == "demodb");
Debug.Assert(dt.Rows[1].ToString() == "demodb");
Debug.Assert(dt.Rows[2].ToString() == "stadium");
```

Get the list of Foreign Keys **in** a table:

```
CUBRIDSchemaProvider schema = new CUBRIDSchemaProvider(conn);
DataTable dt = schema.GetForeignKeys(newstring[] { "game" });
```

```
Debug.Assert(dt.Columns.Count == 9);
Debug.Assert(dt.Rows.Count == 2);
```

```
Debug.Assert(dt.Rows[0].ToString() == "athlete");
Debug.Assert(dt.Rows[1].ToString() == "code");
Debug.Assert(dt.Rows[2].ToString() == "game");
Debug.Assert(dt.Rows[3].ToString() == "athlete_code");
Debug.Assert(dt.Rows[4].ToString() == "1");
Debug.Assert(dt.Rows[5].ToString() == "1");
Debug.Assert(dt.Rows[6].ToString() == "1");
```

```
Debug.Assert(dt.Rows[7].ToString() == "fk_game_athlete_code");
Debug.Assert(dt.Rows[8].ToString() == "pk_athlete_code");
```

The example below shows how to get the list of indexes in a table.

```
CUBRIDSchemaProvider schema = new CUBRIDSchemaProvider(conn);
DataTable dt = schema.GetIndexes(newstring[] { "game" });

Debug.Assert(dt.Columns.Count == 9);
Debug.Assert(dt.Rows.Count == 5);

Debug.Assert(dt.Rows32.ToString() ==
"pk_game_host_year_event_code_athlete_code"); //Index name
Debug.Assert(dt.Rows34.ToString() == "True"); //Is it a PK?
```

## DataTable Support

The **DataTable** is a central object in the ADO.NET library and CUBRID ADO.NET Data Provider support the following features.

- **DataTable** populate
- Built-in commands: **INSERT**, **UPDATE**, and **DELETE**
- Column metadata/attributes
- **DataSet**, **DataView** inter-connection

The following example shows how to get columns attributes.

```
String sql = "select * from nation";
CUBRIDDataAdapter da = new CUBRIDDataAdapter();
da.SelectCommand = new CUBRIDCommand(sql, conn);
DataTable dt = new DataTable("nation");
da.FillSchema(dt, SchemaType.Source); //To retrieve all the column
properties you have to use the FillSchema() method

Debug.Assert(dt.Columns[0].ColumnName == "code");
Debug.Assert(dt.Columns[0].AllowDBNull == false);
Debug.Assert(dt.Columns[0].DefaultValue.ToString() == "");
Debug.Assert(dt.Columns[0].Unique == true);
Debug.Assert(dt.Columns[0].DataType == typeof(System.String));
Debug.Assert(dt.Columns[0].Ordinal == 0);
Debug.Assert(dt.Columns[0].Table == dt);
```

The following example shows how to insert values into a table by using the **INSERT** statement.

```
String sql = " select * from nation order by `code` asc";
using (CUBRIDDataAdapter da = new CUBRIDDataAdapter(sql, conn))
{
    using (CUBRIDDataAdapter daCmd = new CUBRIDDataAdapter(sql,
conn))
    {
        CUBRIDCommandBuilder cmdBuilder = new
CUBRIDCommandBuilder(daCmd);
        da.InsertCommand = cmdBuilder.GetInsertCommand();
    }

    DataTable dt = new DataTable("nation");
    da.Fill(dt);

    DataRow newRow = dt.NewRow();

    newRow["code"] = "ZZZ";
    newRow["name"] = "ABCDEF";
    newRow["capital"] = "MyXYZ";
    newRow["continent"] = "QWERTY";

    dt.Rows.Add(newRow);
    da.Update(dt);
}
```

## Transactions

CUBRID ADO.NET Data Provider implements support for transactions in a similar way with direct-SQL transactions support. Here is a code example showing how to use transactions.

```
conn.BeginTransaction();

string sql = "create table t(idx integer)";
using (CUBRIDCommand command = new CUBRIDCommand(sql, conn))
{
    command.ExecuteNonQuery();
}

conn.Rollback();

conn.BeginTransaction();

sql = "create table t(idx integer)";
using (CUBRIDCommand command = new CUBRIDCommand(sql, conn))
{
    command.ExecuteNonQuery();
}
```

```
conn.Commit();
```

## Working with Parameters

In CUBRID, there is no support for named parameters, but only for position-based parameters. Therefore, CUBRID ADO.NET Data Provider provides support for using position-based parameters. You can use any name you want as long as parameters are prefixed with the character a question mark (?). Remember that you must declare and initialize them in the correct order.

The example below shows how to execute SQL statements by using the parameters. The most important thing is the order in which the **Add ()** methods are called.

```
using (CUBRIDCommand cmd = new CUBRIDCommand("insert into t
values(?, ?)", conn))
{
    CUBRIDParameter p1 = new CUBRIDParameter("?p1",
CUBRIDDataType.CCI_U_TYPE_INT);
    p1.Value = 1;
    cmd.Parameters.Add(p1);

    CUBRIDParameter p2 = new CUBRIDParameter("?p2",
CUBRIDDataType.CCI_U_TYPE_STRING);
    p2.Value = "abc";
    cmd.Parameters.Add(p2);

    cmd.ExecuteNonQuery();
}
```

## Error Codes and Messages

The following list displays the error code and messages shown up when using CUBRID ADO.NET Data Provider.

| Code Number | Error Code    | Error Message                  |
|-------------|---------------|--------------------------------|
| 0           | ER_NO_ERROR   | "No Error"                     |
| 1           | ER_NOT_OBJECT | "Index's Column is Not Object" |

| Code Number | Error Code         | Error Message                                                         |
|-------------|--------------------|-----------------------------------------------------------------------|
| 2           | ER_DBMS            | "Server error"                                                        |
| 3           | ER_COMMUNICATION   | "Cannot communicate with the broker"                                  |
| 4           | ER_NO_MORE_DATA    | "Invalid dataReader position"                                         |
| 5           | ER_TYPE_CONVERSION | "DataType conversion error"                                           |
| 6           | ER_BIND_INDEX      | "Missing or invalid position of the bind variable provided"           |
| 7           | ER_NOT_BIND        | "Attempt to execute the query when not all the parameters are binded" |
| 8           | ER_WAS_NULL        | "Internal Error: NULL value"                                          |
| 9           | ER_COLUMN_INDEX    | "Column index is out of range"                                        |
| 10          | ER_TRUNCATE        | "Data is truncated because receive buffer is too small"               |
| 11          | ER_SCHEMA_TYPE     | "Internal error: Illegal schema paramCUBRIDDataType"                  |
| 12          | ER_FILE            | "File access failed"                                                  |

| Code Number | Error Code             | Error Message                                                   |

| 23          | ER_UNKNOWN             | “Error”                                                         |

## ADO.NET API

See [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/ADO.NET/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/ADO.NET/).

## Perl Driver

**DBD::cubrid** is a CUBRID Perl driver that implements Perl5 Database Interface (DBI) to enable access to CUBRID database server. It provides full API support.

CUBRID Perl driver is written based on CCI API so affected by CCI configurations such as **CCI\_DEFAULT\_AUTOCOMMIT**.

### Note

- The database connection in thread-based programming must be used independently each other.
- In autocommit mode, the transaction is not committed if all results are not fetched after running the SELECT statement. Therefore, although in autocommit mode, you should end the transaction by executing COMMIT or ROLLBACK if some error occurs during fetching for the resultset.

## Installing and Configuring Perl

### Requirements

- Perl: It is recommended to use an appropriate version of Perl based on your system environment. For example, all Linux and FreeBSD distributions come with Perl. For Windows, ActivePerl is recommended. For details, see <https://www.activestate.com/platform/supported-languages/perl/>.
- CUBRID: To build the CUBRID Perl driver, the CCI driver is needed. You can obtain it by installing the CUBRID Engine, which can be downloaded from <https://www.cubrid.org/downloads>. After downloading and installing a proper version of the CUBRID Engine, you can find the required CCI driver in the installed CUBRID Engine directory, \$CUBRID/cci.
- DBI: <https://metacpan.org/dist/DBI/>
- C compiler: In most cases, there are binary distributions of **DBD::cubrid** ( <https://www.cubrid.org/downloads#perl> ) available. However, if you want to build the driver from source code, a C compiler is required. Make sure to use the same C compiler that was used for

compiling Perl and CUBRID. Otherwise, you will encounter problems because of differences in the underlying C runtime libraries.

- For building CCI Driver In Linux, GNU Developer Toolset 8 or higher is required.

## Comprehensive Perl Archive Network (CPAN) Installation

You can automatically install the driver from source code by using the CPAN module.

```
cpan
install DBD::cubrid
```

If you are using the CPAN module for the first time, it is recommended to accept default settings.

If you are using an older version, you might enter the command line below, instead of command line above.

```
perl -MCPAN -e shell
install DBD::cubrid
```

## Manual Installation

If you cannot get the CPAN module, you should download the **DBD::cubrid** source code. The latest version is always available below:

<https://www.cubrid.org/downloads#perl>

The file name is typically something like this: **DBD-cubrid-X.X.X.tar.gz**. After extracting the archive, enter the command line below under the **DBD-cubrid-X.X.X** directory. (On Windows, you may need to replace **make** with **nmake** or **dmake**.)

```
Perl Makefile.PL
make
make test
```

If test seems to look fine, execute the command to build a driver.

```
make install
```

## Perl API

Currently, CUBRID Perl driver provides only basic features and does not support LOB type and column information verification.

If you want to get details about CUBRID Perl driver API, see [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/Perl/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/Perl/).

## Python Driver

**CUBRIDdb** is a Python extension package that implements Python Database API 2.0 compliant support for CUBRID. In addition to the minimal feature set of the standard Python DB API, CUBRID Python API also exposes nearly the entire native client API of the database engine in **`_cubrid`**.

CUBRID Python driver is written based on CCI API so affected by CCI configurations such as **`CCI_DEFAULT_AUTOCOMMIT`**.

## Installing and Configuring Python

### Linux/UNIX

There are three ways to install CUBRID Python driver on Linux, UNIX, and UNIX-like operating systems. You can find instructions for each of them below.

### Requirements

- Operating system: 32-bit or 64-bit Linux, UNIX, or UNIX-like operating systems
- Python: 2.4 or later (<https://www.python.org/downloads/>)

### Building CUBRID Python Driver from Source Code (Linux)

To install CUBRID Python driver by compiling source code, you should have Python Development Package installed on your system.

1. For building CCI Driver, GNU Developer Toolset 8 or higher is required.
2. Download the source code from <https://www.cubrid.org/downloads#python>.
3. Extract the archive to the desired location.

```
tar xvfz cubrid-python-11.2-latest.tar.gz
```

4. Navigate to the directory where you have extracted the source code.

```
cd RB-11.0.0
```

5. Build the driver. At this and next step, make sure you are still under the root user.

```
python setup.py build
```

6. Install the driver. Here you also need root privileges.

```
python setup.py install
```

### Using a Package Manager (EasyInstall) of CUBRID Python Driver (Linux)

EasyInstall is a Python module (**easy\_install**) bundled with **setuptools** that lets you automatically download, build, install, and manage Python packages. It gives you a quick way to install packages remotely by connecting to other websites via HTTP as well as connecting to the Package Index. It is somewhat analogous to the CPAN and PEAR tools for Perl and PHP, respectively. For more information about EasyInstall, see [https://setuptools.pypa.io/en/latest/deprecated/easy\\_install.html](https://setuptools.pypa.io/en/latest/deprecated/easy_install.html).

Enter the command below to install CUBRID Python driver by using EasyInstall.

```
easy_install CUBRID-Python
```

## Windows

To install CUBRID Python driver on Windows, first download CUBRID Python driver as follows:

- Visit the website below to download the driver. You will be given to select your operating system and Python version installed on your system.

<https://www.cubrid.org/downloads#python>

- Extract the archive you downloaded. You should see a folder and two files in the folder. Copy these files to the **Lib** folder where your Python has been installed; by default, it is **C:\Program Files\Python\Lib**.

## Python Programming

The CUBRIDdb package is supposed to have the following constants according to Python Database API 2.0.

| Name         | Value |
|--------------|-------|
| threadsafety | 2     |
| apilevel     | 2.0   |
| paramstyle   | qmark |

## Python Sample Program

This sample program will show steps that you need to perform in order to connect to the CUBRID database and run SQL statements from Python programming language. Enter the command line below to create a new table in your database.

```
csql -u dba -c "CREATE TABLE posts( id integer, title varchar(255),  
body string, last_updated timestamp );" demodb  
csql -u dba -c "grant ALL PRIVILEGES on posts to public;" demodb
```

### Connecting to demodb from Python

1. Open a new Python console and enter the command line below to import CUBRID Python driver.

```
import CUBRIDdb
```

2. Establish a connection to the *demodb* database located on localhost.

```
conn = CUBRIDdb.connect('CUBRID:localhost:33000:demodb::', 'dba',  
'')
```

For the *demodb* database, it is not required to enter any password. In a real-world scenario, you will have to provide the password to successfully connect. The syntax to use the `connect ()` function is as follows:

```
connect (url[,user[password]])
```

If the database has not started and you try to connect to it, you will receive an error such as this:

```
Traceback (most recent call last):
  File "tutorial.py", line 3, in <module>
    conn = CUBRIDdb.connect('CUBRID:localhost:30000:demodb:dba::')
  File "/usr/local/lib/python3.5/site-packages/CUBRIDdb/
__init__.py", line 61, in Connect
    return Connection(*args, **kwargs)
  File "/usr/local/lib/python3.5/site-packages/CUBRIDdb/
connections.py", line 22, in __init__
    self.connection = _cubrid.connect(*args, **kwargs2)
_cubrid.OperationalError: (-677, "ERROR: DBMS, -677, Failed to
connect to database server, 'demodb', on the following host(s):
localhost:localhost[CAS INFO-127.0.0.1:30000,0,0].")
```

If you provide wrong credentials, you will receive an error such as this:

```
Traceback (most recent call last):
  File "tutorial.py", line 3, in <module>
    con = CUBRIDdb.connect('CUBRID:localhost:
33000:demodb::','a','b')
  File "/usr/local/lib/python3.5/site-packages/CUBRIDdb/
__init__.py", line 61, in Connect
    return Connection(*args, **kwargs)
  File "/usr/local/lib/python3.5/site-packages/CUBRIDdb/
connections.py", line 22, in __init__
    self.connection = _cubrid.connect(*args, **kwargs2)
_cubrid.DatabaseError: (-165, 'ERROR: DBMS, -165, User "a" is
invalid.[CAS INFO-127.0.0.1:33000,0,0].')
```

## Executing an INSERT Statement

Now that the table is empty, insert data for the test. First, you have to obtain a cursor and then execute the **INSERT** statement.

```
cur = conn.cursor()
cur.execute("INSERT INTO posts (id, title, body, last_updated)
VALUES (1, 'Title 1', 'Test body #1', CURRENT_TIMESTAMP)")
conn.commit()
```

The auto-commit in CUBRID Python driver is disabled by default. Therefore, you have to manually perform commit by using the `commit()` function after executing any SQL statement. This is equivalent to executing `cur.execute("COMMIT")`. The opposite to executing `commit()` is executing `rollback()`, which aborts the current transaction.

Another way to insert data is to use prepared statements. You can safely insert data into the database by defining a row that contains the parameters and passing it to the `execute()` function.

```
args = (2, 'Title 2', 'Test body #2')
cur.execute("INSERT INTO posts (id, title, body, last_updated)
VALUES (?, ?, ?, CURRENT_TIMESTAMP)", args)
```

The entire script up to now looks like this:

```
import CUBRIDdb
conn = CUBRIDdb.connect('CUBRID:localhost:33000:demodb::', 'dba',
'')
cur = conn.cursor()

# Plain insert statement
cur.execute("INSERT INTO posts (id, title, body, last_updated)
VALUES (1, 'Title 1', 'Test body #1', CURRENT_TIMESTAMP)")

# Parameterized insert statement
args = (2, 'Title 2', 'Test body #2')
cur.execute("INSERT INTO posts (id, title, body, last_updated)
VALUES (?, ?, ?, CURRENT_TIMESTAMP)", args)

conn.commit()
```

### Fetching all records at a time

You can fetch entire records at a time by using the `fetchall()` function.

```
cur.execute("SELECT * FROM posts ORDER BY last_updated")
rows = cur.fetchall()
for row in rows:
    print (row)
```

This will return the two rows inserted earlier in the following form:

```
[1, 'Title 1', 'Test body #1', '2011-4-7 14:34:46']
[2, 'Title 2', 'Test body #2', '2010-4-7 14:34:46']
```

### Fetching a single record at a time

In a scenario where a lot of data must be returned into the cursor, you can fetch only one row at a time by using the `fetchone()` function.

```
cur.execute("SELECT * FROM posts")
row = cur.fetchone()
while row:
```

```
print (row)
row = cur.fetchone()
```

### Fetching as many as records desired at a time

You can fetch a specified number of records at a time by using the `fetchmany()` function.

```
cur.execute("SELECT * FROM posts")
rows = cur.fetchmany(3)
for row in rows:
    print (row)
```

### Accessing Metadata on the Returned Data

If it is necessary to get information about column attributes of the obtained records, you should call the `description` method.

```
for description in cur.description:
    print (description)
```

The output of the script is as follows:

```
('id', 8, 0, 0, 0, 0, 0)
('title', 2, 0, 0, 255, 0, 0)
('body', 2, 0, 0, 1073741823, 0, 0)
('last_updated', 15, 0, 0, 0, 0, 0)
```

Each of row has the following information.

```
(column_name, data_type, display_size, internal_size, precision,
scale, nullable)
```

For more information about numbers representing data types, see [https://pythonhosted.org/CUBRID-Python/toc-CUBRIDdb.FIELD\\_TYPE-module.html](https://pythonhosted.org/CUBRID-Python/toc-CUBRIDdb.FIELD_TYPE-module.html).

### Releasing Resource

After you have done using any cursor or connection to the database, you must release the resource by calling both object's `close()` function.

```
cur.close()
conn.close()
```

## Python API

Python Database API is composed of `connect()` module class, `Connection` object, `Cursor` object, and many other auxiliary functions. For more information, see Python DB API 2.0 Official Documentation at <https://peps.python.org/pep-0249/>.

You can find the information about CUBRID Python API at [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/Python/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/Python/).

## Ruby Driver

CUBRID Ruby driver implements the interface to enable access from applications in Ruby to CUBRID database server and official one is available as a RubyGem package.

CUBRID Ruby driver is written based on CCI API so affected by CCI configurations such as **CCI\_DEFAULT\_AUTOCOMMIT**.

## Installing and Configuring Ruby

### Requirements

- Ruby 1.8.7 or later
- CUBRID gem
- ActiveRecord gem

### Linux

You can install the CUBRID Connector through **gem**. Make sure that you add the **-E** option so that the environment path where CUBRID has been installed cannot be reset by the **sudo** command.

```
sudo -E gem install cubrid
```

### Windows

Enter the command line below to install the latest version of CUBRID Ruby driver.

```
gem install cubrid
```

## Ruby Sample Program

This section will explain how to use Ruby ActiveRecord adapter to work with CUBRID database. Create tables by executing the following SQL script.

```
CREATE TABLE countries(  
  id integer AUTO_INCREMENT,  
  code character varying(3) NOT NULL UNIQUE,  
  name character varying(40) NOT NULL UNIQUE,  
  record_date datetime DEFAULT sysdatetime NOT NULL,  
  CONSTRAINT pk_countries_id PRIMARY KEY(id)  
);  
  
CREATE TABLE cities(  
  id integer AUTO_INCREMENT NOT NULL UNIQUE,  
  name character varying(40) NOT NULL,  
  country_id integer NOT NULL,  
  record_date datetime DEFAULT sysdatetime NOT NULL,  
  FOREIGN KEY (country_id) REFERENCES countries(id) ON DELETE  
RESTRICT ON UPDATE RESTRICT,  
  CONSTRAINT pk_cities_id PRIMARY KEY(id)  
);
```

### Loading Library

Create a new file named *tutorial.rb* and add basic configuration.

```
require 'rubygems'  
require 'active_record'  
require 'pp'
```

### Establishing Database Connection

Define the connection parameters as follows:

```
ActiveRecord::Base.establish_connection(  
  :adapter => "cubrid",  
  :host => "localhost",  
  :database => "demodb" ,  
  :user => "dba"  
)
```

### Inserting Objects into a Database

Before starting to operate on tables, you must declare the two tables' mapping in the database as ActiveRecord classes.

```
class Country < ActiveRecord::Base
end

class City < ActiveRecord::Base
end

Country.create(:code => 'ROU', :name => 'Romania')
Country.create(:code => 'HUN', :name => 'Hungary')
Country.create(:code => 'DEU', :name => 'Germany')
Country.create(:code => 'FRA', :name => 'France')
Country.create(:code => 'ITA', :name => 'Italy', :record_date =>
Time.now)
Country.create(:code => 'SPN', :name => 'Spain')
```

### Selecting Records from a Database

Select records from a database as follows:

```
romania = Country.find(1)
pp(romania)

romania = Country.where(:code => 'ROU')
pp(romania)

Country.find_each do |country|
  pp(country)
end
```

### Updating Database Records

Change the *Spain* code from 'SPN' to 'ESP'.

```
Country.transaction do
  spain = Country.where(:code => 'SPN')[0]
  spain.code = 'ESP'
  spain.save
end
```

### Deleting Database Records

Delete records from a database as follows:

```
Country.transaction do
  spain = Country.where(:code => 'ESP')[0]
  spain.destroy
end
```

## Working with Associations

One method to add cities to a country would be to select the *Country* and assign the country code to a new *City* object.

```
romania = Country.where(:code => 'ROU')[0]
City.create(:country_id => romania.id, :name => 'Bucharest');
```

A more elegant solution would be to let ActiveRecord know about this relationship and declare it in the *Country* class.

```
class Country < ActiveRecord::Base
  has_many :cities, :dependent => :destroy
end

class City < ActiveRecord::Base
end
```

In the code above, it is declared that one country can have many cities. Now it will be very easy to add new city to a country.

```
italy = Country.where(:code => 'ITA')[0]
italy.cities.create(:name => 'Milano');
italy.cities.create(:name => 'Napoli');

pp (romania.cities)
pp (italy.cities)
```

This would be very helpful because when we access cities we get all the cities recorded for the referenced country. Another use is that when you delete the country, all its cities are removed. All is done in one statement.

```
romania.destroy
```

ActiveRecord also supports other relationship including one-to-one, many-to-many, etc.

## Working with Metadata

ActiveRecord enables the code to work with on different database backends without modifying the code.

## Defining a database structure

A new table can be defined using **ActiveRecord::Schema.define**. Let's create two tables: books and authors with a one-to-many relationship between *authors* and *books* (one-to-many).

```
ActiveRecord::Schema.define do
  create_table :books do |table|
    table.column :title, :string, :null => false
    table.column :price, :float, :null => false
    table.column :author_id, :integer, :null => false
  end

  create_table :authors do |table|
    table.column :name, :string, :null => false
    table.column :address, :string
    table.column :phone, :string
  end

  add_index :books, :author_id
end
```

CUBRID-supported column types are **:string**, **:text**, **:integer**, **:float**, **:decimal**, **:datetime**, **:timestamp**, **:time**, **:boolean**, **:bit**, **:smallint**, **:bigint**, and **:char**. Currently, **:binary** is not supported.

### Managing table columns

You can add, update, delete columns by using features from **ActiveRecord::Migration**.

```
ActiveRecord::Schema.define do
  create_table :todos do |table|
    table.column :title, :string
    table.column :description, :string
  end

  change_column :todos, :description, :string, :null => false
  add_column :todos, :created, :datetime, :default => Time.now
  rename_column :todos, :created, :record_date
  remove_column :todos, :record_date

end
```

### Dumping database schema

You can use **ActiveRecord::SchemaDumper.dump** to dump information for currently used schema. This is done into a platform independent format that is understood by Ruby ActiveRecord.

Note that if you are using custom column types database specific (**:bigint**, **:bit**), this may not work.

### Obtaining Server Capabilities

You can get database information extracted from the current connections as in the example below:

```
puts "Maximum column length      : " +
ActiveRecord::Base.connection.column_name_length.to_s
puts "SQL statement maximum length : " +
ActiveRecord::Base.connection.sql_query_length.to_s
puts "Quoting : ''test''         : " +
ActiveRecord::Base.connection.quote("''test''")
```

## Creating a schema

Due to the way CUBRID is functioning, you cannot programmatically create a schema as in the following example:

```
ActiveRecord::Schema.define do
  create_database('not_supported')
end
```

## Ruby API

See [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/Ruby/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/Ruby/).

## Node.js Driver

CUBRID Node.js driver is developed in 100% JavaScript and does not require specific platform compilation

Node.js is a platform built on [Chrome's JavaScript runtime](#).

Node.js has the following specifics.

- Event-driven, server-side JavaScript.
- Good at handling lots of different kinds of I/O at the same time.
- Non-blocking I/O model that makes it lightweight and efficient.

For more details, see <https://nodejs.org/en/>.

If you want to download CUBRID Node.js driver or find the recent information, see the following sites:

- source code main repository: <https://github.com/CUBRID/node-cubrid>

## Installing Node.js

### Requirements

- CUBRID 8.4.1 Patch 2 or higher
- [Node.js](#)

### Installation

You can install CUBRID Node.js driver with “npm(Node Packaged Modules) install” command, but firstly you need to install node.js on <https://nodejs.org/download/>.

```
npm install node-cubrid
```

If you uninstall CUBRID Node.js driver, do the following command.

```
npm uninstall node-cubrid
```

## CUBRID Node.js API

See [http://ftp.cubrid.org/CUBRID\\_Docs/Drivers/Node.js/](http://ftp.cubrid.org/CUBRID_Docs/Drivers/Node.js/).

## Release Notes

### 11.4 Release Notes

#### Contents

|                             |             |
|-----------------------------|-------------|
| <b>11.4 Release Notes</b>   | <b>2545</b> |
| ● Release Notes Information | 2557        |
| ● Overview                  | 634         |
| ● Driver Compatibility      | 2559        |

|                                                                                                    |      |
|----------------------------------------------------------------------------------------------------|------|
| ● 11.4 Changes                                                                                     | 2559 |
| ● New feature                                                                                      | 2559 |
| ● PL/CSQL                                                                                          | 1429 |
| ● SQL                                                                                              | 2559 |
| ● HASH JOIN Support                                                                                | 2559 |
| ● Support for Changing Owner of SERIAL SQL Syntax                                                  | 2559 |
| ● Support for SQL Statements to Add/Remove Members from a Created Group                            | 2560 |
| ● Extended Query Cache Support                                                                     | 2560 |
| ● Added <b>LEADING</b> Hint to Specify Join Order                                                  | 2561 |
| ● Utility                                                                                          | 2562 |
| ● Added Option to Delete Specific Plans in <code>cubrid plandump</code>                            | 2562 |
| ● Added Support for Separate loadjava Option for JNI-Based JavaSP                                  | 2562 |
| ● Added Memory Monitoring Featured utility                                                         | 2562 |
| ● Added support for the <code>diagdb -d 9</code> option to dump data from a specific class (table) | 2562 |
| ● Broker,CAS,CMS                                                                                   | 2563 |
| ● Added Parameter to Set the Size of Data Sent to Clients in the Broker                            | 2563 |
| ● Added Parameter to Set ACL(Access Control) for Each Broker                                       | 2563 |
| ● Others                                                                                           | 2564 |
| ● Support for Automatic Restart of Non-HA DB Server After Abnormal Termination                     | 2564 |
| ● Support for Script to Restore Backup as a New Database                                           | 2564 |

|                                                                                                                                 |      |
|---------------------------------------------------------------------------------------------------------------------------------|------|
| ● Specification Changes                                                                                                         | 2564 |
| ● SQL                                                                                                                           | 61   |
| ● Limit Maximum Number of Characters for CHAR Type to 2,048 (Previous Limit: 268,435,456)                                       | 2564 |
| ● LOB Locator Path Changed to Relative Path                                                                                     | 2565 |
| ● Restriction on Use of Analytic Functions in UPDATE JOIN Queries                                                               | 2565 |
| ● Restrict Use of <b>for update</b> clause on System Tables and Views                                                           | 2565 |
| ● Data Type Consistency Check Disabled During View Creation                                                                     | 2565 |
| ● Allow Use of NULL in SELECT Clause of View Query Specification                                                                | 2565 |
| ● Disallow Use of Both <b>AUTO_INCREMENT</b> and <b>DEFAULT</b> in TABLE Modification and Creation.                             | 2566 |
| ● Raise Error When Adding New Columns in <b>ALTER INDEX ... REBUILD</b>                                                         | 2566 |
| ● Raise Error When ROWNUM Value Exceeds NUMERIC Type Range                                                                      | 2566 |
| ● Utility                                                                                                                       | 61   |
| ● Recognize Session Commands While Writing SQL or PL/CSQL Statements(like create, body and etc) in <i>csql</i> Interactive Mode | 2566 |
| ● Suppress Plan Information Output Before Deletion in <code>cubrid plandump -d</code>                                           | 2566 |
| ● HA                                                                                                                            | 2566 |
| ● Raise Error When <code>ha_mode</code> is <b>on</b> and <b>myhost</b> is Included in <b>ha_node_list</b>                       | 2566 |
| ● Others                                                                                                                        | 63   |
| ● Column Name Changed in System Table <code>_db_serial</code> ( <code>att_name</code> → <code>attr_name</code> )                | 2566 |

|                                                                                                          |      |
|----------------------------------------------------------------------------------------------------------|------|
| ● Improvements (Including Performance Enhancements)                                                      | 2567 |
| ● SQL                                                                                                    | 63   |
| ● Performance Improvement with Caching for Correlated Subqueries                                         | 2567 |
| ● Enhancement of Sort-Limit Optimization When Bind Variables or Expressions Are Used in the LIMIT Clause | 2567 |
| ● PL(incl JavaSP)                                                                                        | 2568 |
| ● Improved Automatic Restart of JavaSP Server When JNI Program Encounters Segmentation Fault             | 2568 |
| ● Enhanced String Functionality to Support Multiple Character Encodings (euckr, utf8)                    | 2568 |
| ● Index                                                                                                  | 2568 |
| ● Removed Length Limitation on WHERE Clause When Creating Filter Indexes                                 | 2568 |
| ● Improved Index Scan Performance by Optimizing midxkey.buf Size Calculation for Multi-Column Indexes    | 2568 |
| ● Optimized Index Scan Performance by Reducing Unnecessary Calculations and Comparisons                  | 2568 |
| ● Optimizer                                                                                              | 2569 |
| ● Performance Improvement Through Overall Optimizer Enhancements                                         | 2569 |
| ● Improvement in Stored Procedure Execution Plans                                                        | 2570 |
| ● Improvement in Concurrency by Preventing Unnecessary X-LOCKS on Unneeded Rows                          | 2570 |
| ● Improvement in Index Scanning for LIKE Queries Using JavaSP Functions                                  | 2570 |
| ● Improvement in Range Index Scanning for Queries with $\leq$ and $\geq$ Conditions on Function Indexes  | 2571 |

|                                                                                                                                                   |      |
|---------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ● Utility                                                                                                                                         | 65   |
| ● Improvement to <code>unloaddb</code> in Databases Without Tables and Views to Extract Other Schemas(user, serial, sp, server, synonym, grant)   | 2571 |
| ● Performance Improvement in <code>unloaddb</code>                                                                                                | 2571 |
| ● Improvement in Clarity of <code>csql</code> Environment Variable Names                                                                          | 2571 |
| ● Improved the output of the <code>cubrid spacedb</code> command                                                                                  | 2571 |
| ● Broker,CAS,CMS                                                                                                                                  | 65   |
| ● Improvement in <code>cubrid spacedb</code> Output                                                                                               | 2572 |
| ● Error Occurrence for Incorrect ACL Settings for Improved User Awareness                                                                         | 2573 |
| ● Improvement to Allow TLS v1.2 Clients to Connect to CMS(CUBRID Manager Server)                                                                  | 2573 |
| ● Improvement to Prevent Zombie Processes When Broker/CAS Processes are Terminated Through CMS                                                    | 2573 |
| ● Improvement to CMS <code>getlogfileinfo()</code> API to Return SQL Log File Information Only Once                                               | 2573 |
| ● Improvement to <code>cms ha_status()</code> API to Display Replica Node Status in HA Environments with Master, Slave, and Replica Configuration | 2573 |
| ● HA                                                                                                                                              | 373  |
| ● Clear Error Message Display for Incorrect Settings in <b>ha_node_list</b> and <b>ha_replica_list</b> for Improved User Awareness                | 2573 |
| ● Clear Error Message Display for Failover and Failback Occurrences to Improve User Awareness                                                     | 2573 |
| ● Improvement to Prevent Incorrect Data Mismatch Error Message from Appearing When <b>restoreslave</b> is Executed on Slave Node                  | 2573 |
| ● Others                                                                                                                                          | 373  |
| ● Improvements to User Hosts ( <code>cubrid_host.conf</code> ) for User Convenience                                                               | 2573 |

|                                                                                                                                                                                                  |      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ● Improvements to DDL Audit Logs                                                                                                                                                                 | 2574 |
| ● Performance Improvement in REDO Recovery with Parallel Threads                                                                                                                                 | 2574 |
| ● Simplified Lock Information Logged in <b>dbname_latest.event</b> File During <b>Deadlock</b>                                                                                                   | 2574 |
| ● Performance Improvement in time_format() and date_format()                                                                                                                                     | 2574 |
| ● Query Performance Improvement with TRACE Enabled                                                                                                                                               | 2574 |
| ● Performance Improvement by Removing Unnecessary Length Checks on String Types                                                                                                                  | 2575 |
| ● Memory Usage Improvement by Limiting Lock Resource Retention to <b>lock_escalation</b> Setting                                                                                                 | 2575 |
| ● Improved User Awareness with Error Output for Invalid <b>optimization_level</b> Setting                                                                                                        | 2575 |
| ● Improvement in Checking DB Volume and Log Creation Times                                                                                                                                       | 2575 |
| ● Improvement in User Awareness by Adding Fence Key Information to <b>SHOW INDEX CAPACITY</b> and <b>diagdb</b>                                                                                  | 2575 |
| ● Bug Fixes                                                                                                                                                                                      | 2575 |
| ● SQL                                                                                                                                                                                            | 373  |
| ● Fixed an issue where referencing a remote server object without specifying the user schema could fail to resolve to the correct object if an object with the same name exists in another user. | 2577 |
| ● Fixed Hidden Column Handling in Scalar Subqueries with ORDER BY                                                                                                                                | 2577 |
| ● Fixed an issue where View Merging of Inline Views and Scalar Subqueries Containing ORDER BY Clauses, Where ROWNUM Was Incorrectly Rewritten as ORDER_BY_NUM()                                  | 2577 |
| ● Corrected an Issue When <b>oracle_style_empty_string=yes</b> is Set and The Result of The Expression 'null    string' Was Incorrectly Returned as NULL                                         | 2577 |
| ● Fixed NULL Output in REPLACE Function When <b>oracle_style_empty_string=yes</b>                                                                                                                | 2577 |

- 
- Fixed Incorrect Results in Covered Index Scans Using Function Indexes 2577

---

  - Fixed Segment Fault Errors in CTE Queries with Always False (or NULL) Conditions 2577

---

  - Fixed Segment Fault Errors in UNION ALL Queries Using Multiple Tables and Serial Next Values 2577

---

  - Fixed Segment Fault Errors in Queries Using Constants Over 255 Characters Without Aliases 2577

---

  - Fixed Errors During View Merging with OUTER JOIN 2577

---

  - Fixed Displaying Both User and Public Views With the Same Name in **SHOW CREATE VIEW** 2578

---

  - Fixed Missing Error Message and NULL Return in repeat() Function Exceeding string\_max\_size\_bytes Setting 2578

---

  - Fixed Incorrect Table Positioning During INNER JOIN Removal in Query Optimization 2578

---

  - Fixed Errors with Host Variables in PREPARE Statements Using Certain Built-in Functions 2578

---

  - Fixed Missing User Information Deletion in System Catalog Tables When Dropping Users by The **DROP USER** Clause 2578

---

  - Fixed Oracle-Style LEFT OUTER JOIN Not Rewriting to INNER JOIN When Using Host Variables in SP Call or WHERE Clause 2578

---

  - Fixed Incorrect Results in Subquery with **ORDERBY\_NUM()** During View Merging 2578

---

  - Fixed for Tables Without Join Relations Being Recognized as Join Tables During Query Optimization 2578

---

  - Fixed ROWNUM Values Being Printed as 0 When Using Equal Condition (=) in WHERE Clause and the Same Column in ORDER BY 2578

---

  - Fixed Errors That Occur When INNER JOIN and Oracle-Style OUTER JOIN Are Used Together and JOIN Condition Placement in WHERE Clause 2578

---

  - Corrected Incorrect Results in **INSERT INTO tbl ... SELECT ... FROM View ... ON DUPLICATE KEY UPDATE** Query 2578

|                                                                                                                                                                                                                                                  |      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ● Corrected Incorrect Column Order Numbers in Analytical Functions Inside Views                                                                                                                                                                  | 2579 |
| ● Resolved a Case Where Range Conditions Were Not Recognized as Range Items When Using The Pipe Operator (  )                                                                                                                                    | 2579 |
| ● Fixed An Error That Occurred When Handling NULL in Host Variables of DBLINK Statements                                                                                                                                                         | 2579 |
| ● Fixed Issue Where Korean Characters Were Corrupted When Inserting via Host Variables Using DBLINK on EUC-KR Oracle DB                                                                                                                          | 2579 |
| ● PL(JavaSP)                                                                                                                                                                                                                                     | 2579 |
| ● Resolved an Issue With Using DATETIMELTZ as a DATETIME Parameter in JavaSP                                                                                                                                                                     | 2579 |
| ● Fixed An Error That Occured Due to Space Between Declared Java Method Name and Opening Parenthesis in JavaSP                                                                                                                                   | 2579 |
| ● Fixed an Error that Occurred When Using Columns of Tables with Unsupported Types as Arguments in JavaSP                                                                                                                                        | 2579 |
| ● Fixed The <b>Cannot allocate query entry any more</b> Error in JavaSP                                                                                                                                                                          | 2579 |
| ● Utility                                                                                                                                                                                                                                        | 373  |
| ● Fixed The Exit Code Not Being Set to 3 When an Error Occurs During <code>loaddb</code> Execution                                                                                                                                               | 2580 |
| ● Fixed Incorrect <b>count(*)</b> Value Returned After Executing <code>loaddb</code> with <b>-no-logging</b>                                                                                                                                     | 2580 |
| ● Fixed Error That Occurred When Processing Serials Without Schema Names During <code>loaddb</code> Execution                                                                                                                                    | 2580 |
| ● Fixed an Issue Where <code>loaddb</code> Would Continue Execution Even After an Error Occurred                                                                                                                                                 | 2580 |
| ● Resolved an Error That Occurred When Processing a Synonym for System Tables During <code>loaddb</code> Execution                                                                                                                               | 2580 |
| ● Corrected an Issue Where the Schema Name Was Incorrectly Stored or Missing for Trigger System-Table Columns (condition, action_definition) During <code>loaddb</code> Execution Using <code>unloaddb</code> Files From Version 11.4 or Earlier | 2580 |

---

|                                                                                                                                                                                                                                                                    |      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ● Addressed a Case Where Reverse Unique-Index Comments Were Missing During <code>unloaddb</code> Execution                                                                                                                                                         | 2580 |
| ● Corrected an Issue Where the <b>auto_increment</b> Value Was Reset to 1 for PK Columns With <b>auto_increment</b> Set During <code>unloaddb</code> Execution                                                                                                     | 2580 |
| ● Resolved an Issue Where the <b>dbname_schema_uk</b> File Was Created Even When No Unique Index Existed During <code>unloaddb -split-schema-files</code> Execution                                                                                                | 2580 |
| ● Addressed a Case Where the <b>ALTER SERIAL</b> Statement Was Missing When Executing <code>unloaddb</code> With the <b>-i (-input-class-only)</b> Option                                                                                                          | 2580 |
| ● Resolved an Error That Occurred When <code>current_val</code> and <code>max_val</code> of a Serial Were Identical During <code>unloaddb</code> Execution                                                                                                         | 2581 |
| ● Corrected an Issue Where an Infinite Loop Occurred When Processing JSON Data Over 1MB During <code>unloaddb</code> Execution                                                                                                                                     | 2581 |
| ● Addressed a Case Where, When Running <code>unloaddb</code> as a Regular User, Schema Names Identical to the User Were Not Removed From the <code>query_spec</code> of Views                                                                                      | 2581 |
| ● Resolved a Case Where Schema Names for Serials and Triggers Were Missing When Executing <code>unloaddb</code> as <b>DBA</b> User                                                                                                                                 | 2581 |
| ● Corrected an Issue That Occured When Running <code>unloaddb</code> as a DBA User Without the <code>-as-dba</code> Option, Where Procedure Privileges Granted by Other Users (e.g., <code>GRANT ... ON PROCEDURE</code> ) Were Incorrectly Included in the Output | 2581 |
| ● Corrected an Issue That Occured When Running <code>unloaddb</code> as a Regular User, Where Schema Names Identical to the User Were Not Removed From the Condition and action_definition of Triggers                                                             | 2581 |
| ● Fixed for Unnecessary Archive Log Volumes Being Created During <code>backupdb</code> Execution                                                                                                                                                                   | 2581 |
| ● Fixed an Issue Where <code>flashback</code> Did Not Terminate Properly on Forced Exit (Ctrl+C)                                                                                                                                                                   | 2581 |
| ● Resolved a Case Where <code>backupdb</code> Could Hang in Certain Situations                                                                                                                                                                                     | 2581 |
| ● Broker,CAS, CMS                                                                                                                                                                                                                                                  | 374  |
| ● Fixed a Potential Memory Leak In the Processing of <code>addBatch()</code> and <code>executeBatch()</code> in Broker/CAS/CMS                                                                                                                                     | 2582 |

|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| ● | Corrected an Incorrect Output From the <i>getTransactionInfo()</i> Function Call                                                                                                                                                                                                                      | 2582    |
| ● | HA                                                                                                                                                                                                                                                                                                    | 374     |
| ● | Addressed a Case Where Replication Logs Were Not Deleted on a Replica Node When <i>ha_replica_delay</i> Was Set to 60 Seconds or More in an HA Environment With Master, Slave, and Replica Nodes                                                                                                      | 2582    |
| ● | Resolved an Issue Where the SQL Log File Was Not Automatically Deleted Under Certain Conditions During <code>applylogdb</code> Execution                                                                                                                                                              | 2582    |
| ● | Cautions                                                                                                                                                                                                                                                                                              | 1420    |
| ● | New Cautions                                                                                                                                                                                                                                                                                          | 2582    |
| ● | The database volume of CUBRID 11.4 is not compatible with that of CUBRID 11.3 and earlier versions.                                                                                                                                                                                                   | 2582    |
| ● | Existing Cautions                                                                                                                                                                                                                                                                                     | 2582    |
| ● | 11.3                                                                                                                                                                                                                                                                                                  | 374     |
| ● | The query optimizer's statistical information is not automatically updated when a DDL statement is executed; the user must manually execute the UPDATE STATISTICS statement to update the statistical information. (see Join Methods)                                                                 | 8352583 |
| ● | When changing the type of a column that has the AUTO_INCREMENT property or a default value in an ALTER TABLE statement, an error occurs if the new type cannot use AUTO_INCREMENT or if the existing default value is a type whose existing default value cannot be changed. (see :ref:change-column) | 2583    |
| ● | You cannot obtain a Connection object through <code>cubrid.jdbc.driver.CUBRIDDriver.getDefaultConnection()</code> from server-side JDBC. Instead, use <code>DriverManager.getConnection("jdbc:default:connection:")</code> . (see Creating Connection)                                                | 2583    |
| ● | If an invalid index name or table name is used in a USE INDEX (USING INDEX) statement, it is ignored instead of raising an error. (To record it in the log file, set the error_log warning parameter to yes.)                                                                                         | 2583    |
| ● | When writing a CREATE INDEX statement, the position of COMMENT has been moved to the end of the statement, after the WITH or INVISIBLE clause. (see INDEX DEFINITION STATEMENTS)                                                                                                                      | 2692583 |

|                                                                                                                                                                                                             |         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| ● 11.2                                                                                                                                                                                                      | 374     |
| ● The database volume of CUBRID 11.2 is not compatible with that of CUBRID 11.1 and earlier versions.                                                                                                       | 2583    |
| ● By introducing the concept of user schema, the same object name can be used for each user, and the behavior is changed as follows                                                                         | 2583    |
| ● The following functions and behavior changed when using “jdbc:default:connection:” or calling getDefaultConnection() in JavaSP. (see JavaSP Caution)                                                      | 2584    |
| ● The behavior of the TRUNCATE TABLE changed if there is set null or cascade of FK (see TRUNCATE)                                                                                                           | 8202584 |
| ● Column properties not written during alter change/modify are changed to be maintained, and auto_increment and on update properties cannot be removed with the alter statement (see CHANGE/MODIFY Clauses) | 2584    |
| ● Changed to handle an error if only the column name exists in the where clause                                                                                                                             | 2584    |
| ● Multiple SQL must be separated by semicolons                                                                                                                                                              | 2585    |
| ● The CCI Driver directory in the CUBRID package is changed from \$CUBRID/lib and \$CUBRID/include to \$CUBRID/cci/lib and \$CUBRID/cci/include, respectively (see CCI Overview)                            | 2585    |
| ● Changed Compression (-z, --compress) option to default on backup (see backupdb)                                                                                                                           | 2585    |
| ● 11.0                                                                                                                                                                                                      | 374     |
| ● The database volume of CUBRID 11.0 is not compatible with that of CUBRID 10.2 and earlier versions.                                                                                                       | 2586    |
| ● When creating a table without an option, it is created as a reuse_oid table.                                                                                                                              | 2586    |
| ● The maximum length of the CHAR data type has been changed to 256M character string.                                                                                                                       | 2586    |
| ● Modified to occur error when the input string length is longer than the set length of the string data type.                                                                                               | 2586    |

|                                                                                                                                                                                            |      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ● Modified to recognize the space character at the end of the string, it is recognized as a different character string according to the space character at the end of the string.          | 2586 |
| ● Due to the change in the statistics collection method, it is necessary to perform periodic statistics collection.                                                                        | 2586 |
| ● 10.2                                                                                                                                                                                     | 374  |
| ● The database volume of CUBRID 10.2 is not compatible with that of CUBRID 10.1 and earlier versions.                                                                                      | 2586 |
| ● 10.1                                                                                                                                                                                     | 2586 |
| ● The database volume of CUBRID 10.1 is not compatible with that of CUBRID 10.0 and earlier versions.                                                                                      | 2587 |
| ● Version 10.0 and earlier                                                                                                                                                                 | 2587 |
| ● The database volume of CUBRID 10.0 is not compatible with that of CUBRID 9.3 and earlier versions.                                                                                       | 2587 |
| ● Locale(language and charset) is specified when creating DB                                                                                                                               | 2587 |
| ● CUBRID_CHARSET environment variable is removed                                                                                                                                           | 2587 |
| ● [JDBC] Change zero date of TIMESTAMP into '1970-01-01 00:00:00'(GST) from '0001-01-01 00:00:00' when the value of zeroDateTimeBehavior in the connection URL is "round"(CUBRIDSUS-11612) | 2587 |
| ● Recommendation for installing CUBRID SH package in AIX(CUBRIDSUS-12251)                                                                                                                  | 2587 |
| ● CUBRID_LANG is removed, CUBRID_MSG_LANG is added                                                                                                                                         | 2588 |
| ● Modify how to process an error for the array of the result of executing several queries at once in the CCI application(CUBRIDSUS-9364)                                                   | 2588 |
| ● In java.sql.XAConnection interface, HOLD_CURSORS_OVER_COMMIT is not supported(CUBRIDSUS-10800)                                                                                           | 2590 |
| ● From 9.0, STRCMP behaves case-sensitively                                                                                                                                                | 2590 |

- 
- Since the 2008 R4.1 version, the Default value of CCI\_DEFAULT\_AUTOCOMMIT has been ON(CUBRIDSUS-5879) 2590
- 
- From the 2008 R4.0 version, the options and parameters that use the unit of pages were changed to use the unit of volume size(CUBRIDSUS-5136) 2591
- 
- Be cautious when setting db volume size if you are a user of a version before 2008 R4.0 Beta(CUBRIDSUS-4222) 2591
- 
- The change of the default value of some system parameters of the versions before 2008 R4.0(CUBRIDSUS-4095) 2591
- 
- Changed so that database services, utilities, and applications cannot be executed when the system parameter is incorrectly configured(CUBRIDSUS-5375) 2592
- 
- Database fails to start if the data\_buffer\_size is configured with a value that exceeds 2G in CUBRID 32-bit version(CUBRIDSUS-5349) 2592
- 
- Recommendations for controlling services with the CUBRID Utility in Windows Vista and higher(CUBRIDSUS-4186) 2593
- 
- A manager server process-related error occurs in the execution of the CUBRID source after its build(CUBRIDSUS-3553) 2593
- 
- GLO class which is used in 2008 r3.0 or before is not supported any longer(CUBRIDSUS-3826) 2593
- 
- Port configuration is required if the protocol between the master and server processes is changed, or if two versions are running at the same time(CUBRIDSUS-3564) 2595
- 
- Specifying a question mark when entering connection information as a URL string in JDBC(CUBRIDSUS-3217) 2595
- 
- Not allowed to include @ in a database name(CUBRIDSUS-2828) 2596
- 

## Release Notes Information

This document contains information about CUBRID 11.4 (Build Number 11.4.0.1778).

CUBRID 11.4 includes bug fixes and feature improvements found in CUBRID 11.3, as well as all bug fixes and feature enhancements applied in previous versions.

Information about CUBRID 11.3 can be found at [https://www.cubrid.org/manual/en/11.3/release\\_note/index.html](https://www.cubrid.org/manual/en/11.3/release_note/index.html).

Information about CUBRID 11.2 can be found at [https://www.cubrid.org/manual/en/11.2/release\\_note/index.html](https://www.cubrid.org/manual/en/11.2/release_note/index.html).

Information about CUBRID 11.0 can be found at [https://www.cubrid.org/manual/en/11.0/release\\_note/index.html](https://www.cubrid.org/manual/en/11.0/release_note/index.html).

Information about CUBRID 10.2 can be found at [https://www.cubrid.org/manual/en/10.2/release\\_note/index.html](https://www.cubrid.org/manual/en/10.2/release_note/index.html).

Information about CUBRID 10.1 can be found at [https://www.cubrid.org/manual/en/10.1/release\\_note/index.html](https://www.cubrid.org/manual/en/10.1/release_note/index.html).

Information about CUBRID 10.0 can be found at [https://www.cubrid.org/manual/en/10.0/release\\_note/index.html](https://www.cubrid.org/manual/en/10.0/release_note/index.html).

Information about CUBRID 9.3 can be found at [https://www.cubrid.org/manual/en/9.3.0/release\\_note/index.html](https://www.cubrid.org/manual/en/9.3.0/release_note/index.html).

## Overview

CUBRID 11.4 is the latest stable version that includes new features, significant changes, and improvements.

CUBRID 11.4 introduces:

1. **PL/CSQL support for Oracle compatibility**
2. **Addition of HASH JOIN for large-scale processing**
3. **Performance improvements through optimizer and index processing enhancements**
4. **Performance boost in data recovery through parallel processing**
5. **Performance enhancement by expanding result caching**
6. **Improved data dump performance**
7. **Addition of memory monitoring features**
8. **Enhanced access control functionality**
9. **Improved user convenience for backup and recovery operations**

These updates bring not only new features but also various performance improvements across multiple areas.

## Driver Compatibility

- CUBRID 11.4 ensures compatibility with earlier driver versions. To maximize the utilization of the advanced features introduced in this version, it is strongly recommended to adopt the latest driver.

## 11.4 Changes

### New feature

#### PL/CSQL

- CUBRID offers the PL/CSQL feature to ensure compatibility with ORACLE's PL/SQL.
- For syntax and usage details, please refer to the manual. ([CUBRID Procedural Language](#))

#### SQL

#### HASH JOIN Support

- HASH JOIN is now supported—a type of join processing method that creates a hash table based on the join condition column to efficiently execute the join.
- For the optimizer to apply a HASH JOIN, a join hint is required.
  - When `/*+ USE_HASH */` hint is added, HASH JOIN is considered.
  - When `/*+ NO_USE_HASH */` hint is added, HASH JOIN is not used.

#### Support for Changing Owner of SERIAL SQL Syntax

- Extended the **ALTER SERIAL** statement to support changing the owner of a SERIAL, which was previously only possible by calling the `call change_serial_owner()` method.

```
ALTER SERIAL serial_name OWNER TO user_name
```

- Only the DBA or members of the DBA group are allowed to change the owner of a SERIAL.

- An error is returned if the user does not have sufficient privileges or if the specified SERIAL does not exist.

## Support for SQL Statements to Add/Remove Members from a Created Group

- Extended the **ALTER USER** statement to support adding or removing users to/from a created group, which was previously only possible by calling `call add_member()` and `call drop_member()` methods.
- In HA environments, this enhancement simplifies user management by eliminating the need for separate operations on the master and slave nodes when modifying group membership.

```
ALTER USER user_name
[PASSWORD password] |
[ADD MEMBERS user_name {, user_name}...] |
[DROP MEMBERS user_name {, user_name}...]
[COMMENT 'comment_string']
```

- DBA/DBA Group Members
  - Add or remove members from the DBA group
  - Add or remove members from user-defined groups, including PUBLIC
- General Users
  - Can add or remove members only from their own groups

## Extended Query Cache Support

The query cache feature, which was previously available only at the full query level, has been extended to support subquery-level caching.

- Support query cache in CTE(Common Table Expressions).

```
with cte0 as (select /* query_cache */ count(*) from public.game
where host_year > 2000),
cte1 as (select /* query_cache */ count(*) from public.game where
host_year = 2004)
select * from cte1;
```

```
Trace Statistics:
SELECT (time: 0, fetch: 4, fetch_time: 0, ioread: 0)
  SCAN (temp time: 0, fetch: 4, ioread: 0, readrows: 1, rows: 1)
  SUBQUERY (uncorrelated)
```

```
CTE (non_recursive_part)
  SELECT (time: 0, fetch: 0, fetch_time: 0, ioread: 0)
  RESULT CACHE (reference count: 1)
CTE (non_recursive_part)
  SELECT (time: 0, fetch: 0, fetch_time: 0, ioread: 0)
  RESULT CACHE (reference count: 1)
```

- Support query cache in non-correlated subqueries.

```
select count(host_year)
from (select /*+ query_cache */ code from public.nation where code
like 'K%') n, public.game g
where n.code = g.nation_code;
```

```
Trace Statistics:
SELECT (time: 218, fetch: 872, fetch_time: 2, ioread: 0)
  SCAN (temp time: 0, fetch: 4, ioread: 0, readrows: 7, rows: 7)
    SCAN (table: public.game), (heap time: 215, fetch: 868, ioread:
0, readrows: 60571, rows: 386)
  SUBQUERY (uncorrelated)
    SELECT (time: 0, fetch: 0, fetch_time: 0, ioread: 0)
    RESULT CACHE (reference count: 3)
```

- Support displaying the reference count in trace information when executing queries that utilize the result cache by **RESULT CHACHE (reference count: number)**

## Added **LEADING** Hint to Specify Join Order

- The **LEADING** hint allows specifying a particular table or set of tables to be used as the prefix in the execution plan, enabling more flexible control over the table join order than the **ORDERED** hint.

```
SELECT /*+ LEADING(e j) */ *
FROM employees e, departments d, job_history j
WHERE e.department_id = d.department_id
AND e.hire_date = j.start_date;
```

- Conditions for Ignoring the LEADING Hint
  - Ignored when the ORDERED hint is present.
  - If multiple LEADING hints are used, only the first one is applied.
  - The hint is ignored if join graph dependencies prevent early joining of specified tables.

## Utility

### Added Option to Delete Specific Plans in `cubrid plandump`

- Option: `-s`

### Added Support for Separate `loadjava` Option for JNI-Based JavaSP

- Option: `-j` or `-jni`
- Not using the new `loadjava -j` option will now result in an error when a JNI-based JavaSP is executed.

### Added Memory Monitoring Featured utility

- The memory monitoring utility `cubrid memmon` retrieves and displays the following heap memory information from the server process (`cub_server`) memory management module.
  - Total heap memory usage allocated and currently in use by the server process.
  - Detailed memory allocation information based on the source code and line number where the memory allocation request was made.
- To use the server process memory management module, the system parameter `enable_memory_monitoring` must be set to “yes”, and the server needs to be restarted.
- For detailed usage and instructions, please refer to the manual. (`memmon`)

### Added support for the `diagdb -d 9` option to dump data from a specific class (table)

- Option: `-n class-name`
- In the case of partitioned tables, all partitions are dumped. For sub-partitioned tables, only the corresponding partition table is dumped.

## Broker,CAS,CMS

### Added Parameter to Set the Size of Data Sent to Clients in the Broker

- A new parameter, **NET\_BUF\_SIZE**, has been introduced to the Broker to control the size of the data transmitted to clients.
- The values that can be set for **NET\_BUF\_SIZE**
  - 16K(default)
  - 32K
  - 48K
  - 64K

### Added Parameter to Set ACL(Access Control) for Each Broker

- When using the broker's ACL (ACCESS\_CONTROL=ON), the ACCESS\_CONTROL\_DEFAULT\_POLICY parameter allows you to set the default action policy for brokers that are not specified in the ACCESS\_CONTROL\_FILE.
- Set the value of ACCESS\_CONTROL\_DEFAULT\_POLICY to **DENY** or **ALLOW** in the [broker] section of the `cubrid_broker.conf` file (default value is **DENY**).
  - If a broker is not specified in the ACCESS\_CONTROL\_FILE, and the default policy is ALLOW, all clients are allowed to connect; if the policy is DENY, connections are denied.

```
$ cubrid broker acl status
ACCESS_CONTROL=ON
ACCESS_CONTROL_DEFAULT_POLICY=DENY
ACCESS_CONTROL_FILE=cubrid_acl.conf

[%query_editor]
testdb:dba:acl_ip_list.conf

CLIENT IP LAST ACCESS TIME
=====
172.29.80.1
192.168.0.31
172.31.0.175

[%broker1]
```

```
++ cubrid broker acl: success
```

- **[%broker1]** does not have any client access information specified, all client connections are denied according to the default policy **DENY**.

## Others

### Support for Automatic Restart of Non-HA DB Server After Abnormal Termination

- When operating a non-HA DB server, a new feature enables automatic restart if the DB server is abnormally terminated, such as by the OOM killer.
- Notes
  - The server does not automatically restart after a normal shutdown.
  - This feature can be enabled or disabled using the `auto_restart_server` parameter.
  - Automatic restart is disabled if the server repeatedly terminates abnormally within a short period or fails to start successfully after a certain number of attempts.

### Support for Script to Restore Backup as a New Database

- When data recovery from a backup is needed on a production server, the `restore_to_newdb.sh` script allows restoring the backup as a new database without the need for additional steps such as creating new accounts or installing extra engine instances. For detailed usage and instructions, please refer to the manual ([restore\\_to\\_newdb.sh script](#))

## Specification Changes

### SQL

#### Limit Maximum Number of Characters for CHAR Type to 2,048 (Previous Limit: 268,435,456)

- To prevent potential issues such as memory allocation errors, the maximum number of characters allowed for the CHAR type has been reduced from 268,435,456 to 2,048.

- When migrating databases from versions prior to 11.4, any CHAR type columns exceeding 2,048 characters must be converted to VARCHAR.

### LOB Locator Path Changed to Relative Path

- To improve manageability and ease of moving LOB data files, the locator path for LOBs has been changed from an absolute path to a relative path.
- If the LOB directory location for a DB listed in databases.txt is changed, all existing LOB files in the previous directory must be moved or copied to the new LOB directory.

### Restriction on Use of Analytic Functions in UPDATE JOIN Queries

- To prevent unexpected behavior, the use of analytic functions in UPDATE JOIN queries involving two or more tables is now restricted.
- Queries using this pattern that were written in versions prior to 11.4 must be revised, as they will cause errors in version 11.4.

### Restrict Use of **for update** clause on System Tables and Views

- To prevent lock waits caused by X-LOCKS on system tables, the use of the **for update** clause on system tables and views now results in an error.

### Data Type Consistency Check Disabled During View Creation

- To improve Oracle compatibility, data type checks during view creation are no longer performed. Type consistency is now checked at runtime.
- If type conversion is not possible, an error will occur when the view is executed.

### Allow Use of NULL in SELECT Clause of View Query Specification

- To enhance Oracle compatibility, the use of NULL values in the SELECT clause of a view query specification is now allowed.

```
CREATE VIEW a_view( col1 ) AS select NULL as col1 from a_tbl;
```

## Disallow Use of Both **AUTO\_INCREMENT** and **DEFAULT** in TABLE Modification and Creation.

- When executing **CREATE TABLE** or **ALTER COLUMN** statements, an error will now be raised if both **AUTO\_INCREMENT** and **DEFAULT** attributes are specified together.

## Raise Error When Adding New Columns in **ALTER INDEX ... REBUILD**

- An error will now be raised if new columns are added during an ALTER INDEX ... REBUILD operation, as adding columns is not supported in this context.
- Queries written in versions prior to 11.4 using this pattern will cause errors in version 11.4 and must be revised.

## Raise Error When ROWNUM Value Exceeds NUMERIC Type Range

## Utility

## Recognize Session Commands While Writing SQL or PL/CSQL Statements(like create, body and etc) in *csql* Interactive Mode

## Suppress Plan Information Output Before Deletion in `cubrid plandump -d`

## HA

## Raise Error When `ha_mode` is **on** and **myhost** is Included in **ha\_node\_list**

- In previous versions, this configuration would automatically switch the server to replica mode.

## Others

## Column Name Changed in System Table `_db_serial` (`att_name` → `attr_name`)

- Queries that explicitly reference `att_name` in versions prior to 11.4 must be updated, as they will result in errors in version 11.4.

## Improvements (Including Performance Enhancements)

### SQL

#### Performance Improvement with Caching for Correlated Subqueries

- Correlated subqueries are executed individually for each row of the main query. When there are many repeated condition values, the same subquery can be executed multiple times, leading to performance degradation. By implementing caching, repeated executions of the same subquery for identical condition values are prevented, improving performance.

#### Enhancement of Sort-Limit Optimization When Bind Variables or Expressions Are Used in the LIMIT Clause

```
drop table if exists tbl1;
create table tbl1 (col1 int, col2 int);
insert into tbl1 select rownum, random() % 100000 +1 from db_class
a, db_class b, db_class c, db_class d limit 100000;
create index idx on tbl1(col1);

prepare stmt from
'SELECT a.col1, a.col2
FROM tbl1 a
      LEFT JOIN tbl1 b ON a.col1 = b.col1
      LEFT JOIN tbl1 c ON a.col1 = c.col1
ORDER BY a.col2,a.col1
LIMIT ?*10,?';

execute stmt using 10,10;
```

## PL(incl JavaSP)

### Improved Automatic Restart of JavaSP Server When JNI Program Encounters Segmentation Fault

### Enhanced String Functionality to Support Multiple Character Encodings (euckr, utf8)

- The string handling functionality has been improved to support various character encodings, such as euckr and utf8, by processing the encoding scheme of stored procedure strings as byte arrays.

## Index

### Removed Length Limitation on WHERE Clause When Creating Filter Indexes

### Improved Index Scan Performance by Optimizing midxkey.buf Size Calculation for Multi-Column Indexes

- In multi-column indexes, the previous method of repeatedly calculating the key length has been improved. Now, each column's **OFFSET** is directly referenced without needing calculations, which improves performance during **binary search, key filtering, and DML operations**.

### Optimized Index Scan Performance by Reducing Unnecessary Calculations and Comparisons

- The process of reading and processing keys during Range-Scan has been optimized to reduce unnecessary operations.
- Unnecessary comparisons with *upper\_key* during Range-Scan have been reduced, enhancing performance.
- Repetitive comparisons of index column IDs have been minimized, optimizing operations.
- Common prefix information has been added to leaf node headers, optimizing the processing of compressed leaf nodes by reducing repetitive comparisons and calculations.

## Optimizer

### Performance Improvement Through Overall Optimizer Enhancements

- The number of sampling pages has been increased to 5000 to improve the accuracy of collected statistics.
- Enhanced the method of collecting NDV(Number of Distinct Values), leading to more accurate statistics.
- Minimized Rule-Based Optimization (RBO) for Better Accuracy
  - Reduced the use of empirical weights (Heuristic Factor).
  - Removed RBO for cost differences within 1.x, transitioning to Cost-Based Optimization (CBO) for improved accuracy.
- Improved Cost Formula Calculation
  - **Reflected Index Filter Scan Selectivity**: Adjusted I/O cost calculation during index scan to account for selectivity.
  - Added selectivity for the *NOT LIKE* operator.
  - Added selectivity for **function-based indexes**.
  - Adjusted weight for **NDV**(Distinct Value Count) when duplicates are high: If the duplication rate in sampling data exceeds 1%, statistics weight is adjusted.
  - Introduced **SSCAN\_DEFAULT\_CARD**: Prevents inefficient plans in **NL JOIN**(Nested Loop Join) when cardinality estimation is too low.
  - Introduced cost and cardinality settings for the LIMIT clause to improve performance for small data retrievals, with **optimized LIMIT** and adjusted default cardinality values.
- Elimination of Redundant Conditions
  - Removed logically redundant predictable join conditions that were already evaluated.
  - Improved the removal of unnecessary INNER JOIN.
- Additional Improvements
  - Enhanced trace information by adding **fetch\_time** for better execution time tracking.
  - Improved **index skip scan** to be selected even without the `index_ss` hint.

- Enhanced the optimizer to choose a better index over the Primary Key.

## Improvement in Stored Procedure Execution Plans

- The execution plan processing for stored procedures has been modified to align with the execution plan of built-in functions.
- Improvements
  - Index scans are now supported.
  - Unnecessary joins have been eliminated.
  - **Result caching** is now available when using stored procedures in **correlated subqueries**.

## Improvement in Concurrency by Preventing Unnecessary X-LOCKS on Unneeded Rows

- In certain queries, locks were being created too early, causing unnecessary locks. The system has been improved to release unnecessary locks after all conditions have been evaluated.

## Improvement in Index Scanning for LIKE Queries Using JavaSP Functions

```
CREATE OR REPLACE FUNCTION stringTest(x String) RETURN String AS
LANGUAGE JAVA NAME 'SpTest.typeTestString(java.lang.String) return
java.lang.String';

CREATE TABLE tbl (ord INT, col_int INT, col_char char(1));
CREATE INDEX i_tbl ON tbl (ord);
CREATE INDEX i_tbl_char ON tbl (col_char);

INSERT INTO tbl VALUES (1,10,'a');
INSERT INTO tbl VALUES (2,10,'b');
INSERT INTO tbl VALUES (3,10,'c');
INSERT INTO tbl VALUES (4,10,'d');
INSERT INTO tbl VALUES (5,10,'e');

SELECT count(*) AS "like" FROM tbl WHERE col_char LIKE (SELECT
stringTest('a') FROM dual);
```

## Improvement in Range Index Scanning for Queries with `<=` and `>=` Conditions on Function Indexes

### Utility

## Improvement to `unloaddb` in Databases Without Tables and Views to Extract Other Schemas(user, serial, sp, server, synonym, grant)

### Performance Improvement in `unloaddb`

- Multi-threading has been implemented to significantly reduce data extraction time and improve overall performance.
- `unloaddb` options
  - **-thread-count**: Specifies the number of concurrent threads to execute (0-127).
  - **enhanced-estimates**: Provides more accurate record count estimation (for verbose mode only).

### Improvement in Clarity of `csql` Environment Variable Names

- To improve the clarity of CSQL environment variable names, the prefix CUBRID\_CSQL has been added to indicate that these environment variables are related to CUBRID.
- **Changes**
  - EDITOR → CUBRID\_CSQL\_EDITOR
  - SHELL → CUBRID\_CSQL\_SHELL
  - FORMATTER → CUBRID\_CSQL\_FORMATTER
- For backward compatibility, the original environment variable names can still be used.

### Improved the output of the `cubrid spacedb` command

- Improved the classification of overflow pages so that pages used by users are categorized as either INDEX or HEAP based on their purpose, instead of being incorrectly classified as SYSTEM pages.

Broker,CAS,CMS

## Improvement in cubrid spacedb Output

- Directory names used in configuration settings are now displayed as absolute paths.
- **ADMIN\_LOG\_FILE** display has been added.

Error Occurrence for Incorrect ACL Settings for Improved User Awareness

Improvement to Allow TLS v1.2 Clients to Connect to CMS(CUBRID Manager Server)

Improvement to Prevent Zombie Processes When Broker/CAS Processes are Terminated Through CMS

Improvement to CMS getlogfileinfo() API to Return SQL Log File Information Only Once

Improvement to cms ha\_status() API to Display Replica Node Status in HA Environments with Master, Slave, and Replica Configuration

HA

Clear Error Message Display for Incorrect Settings in **ha\_node\_list** and **ha\_replica\_list** for Improved User Awareness

Clear Error Message Display for Failover and Failback Occurrences to Improve User Awareness

Improvement to Prevent Incorrect Data Mismatch Error Message from Appearing When **restoreslave** is Executed on Slave Node

Others

Improvements to User Hosts (cubrid\_host.conf) for User Convenience

- Added “0.0.0.0 your\_hostname” entry.
- Improved functionality to allow hostnames to be used without case sensitivity.

- Validation has been added for IP addresses and hostnames; errors will occur if invalid entries are detected.

## Improvements to DDL Audit Logs

- Added the 'DB Name' to the DDL audit log file generated by CAS, enabling identification of which database the operation was performed on in environments with multiple databases.
- Modified the DDL audit log to record an ABORT log even if the transaction ends without a commit or rollback.
- Improved handling of multiple DDL statements executed in a single transaction with SetAutocommit(false) by ensuring a commit or rollback statement is recorded between commands.

## Performance Improvement in REDO Recovery with Parallel Threads

- Applied parallel threads for page-by-page recovery during the REDO recovery process, which does not require synchronization for data consistency, improving recovery performance.
- The improvement in performance is most noticeable when the REDO operation takes up a significant portion of the recovery process and the parallel index is high.

## Simplified Lock Information Logged in **dbname\_latest.event** File During **Deadlock**

- When a deadlock occurs, the server log file (dbname\_latest.event) now **only logs the lock information directly contributing to the deadlock**, simplifying the output.

## Performance Improvement in time\_format() and date\_format()

- Removed unnecessary string operation function calls to improve performance.

## Query Performance Improvement with TRACE Enabled

- When executing a query with `set trace on`, the performance was significantly worse compared to executing the same query with `set trace off`. This has been improved by reducing high-cost operations caused by TRACE's statistics gathering overhead, minimizing the performance degradation.

## Performance Improvement by Removing Unnecessary Length Checks on String Types

## Memory Usage Improvement by Limiting Lock Resource Retention to **lock\_escalation** Setting

## Improved User Awareness with Error Output for Invalid **optimization\_level** Setting

## Improvement in Checking DB Volume and Log Creation Times

- The `SHOW VOLUME HEADER`, `SHOW LOG HEADER`, and `SHOW ARCHIVE LOG HEADER` commands have been enhanced to display the **Creation\_time**, allowing users to easily check the volume creation time.
- The `diagdb` utility has been improved to allow users to view the creation times of each volume.
- Modification to applyinfo Utility to Display added Volume Creation Time in Log Volume Header

## Improvement in User Awareness by Adding Fence Key Information to **SHOW INDEX CAPACITY** and `diagdb`

- Information regarding the fence key used during leaf node key compression is now displayed separately from general key information, improving user awareness.

## Bug Fixes

## SQL

Fixed an issue where referencing a remote server object without specifying the user schema could fail to resolve to the correct object if an object with the same name exists in another user.

Fixed Hidden Column Handling in Scalar Subqueries with ORDER BY

Fixed an issue where View Merging of Inline Views and Scalar Subqueries Containing ORDER BY Clauses, Where ROWNUM Was Incorrectly Rewritten as ORDER\_BY\_NUM()

Corrected an Issue When **oracle\_style\_empty\_string=yes** is Set and The Result of The Expression 'null || string' Was Incorrectly Returned as NULL

Fixed NULL Output in REPLACE Function When **oracle\_style\_empty\_string=yes**

Fixed Incorrect Results in Covered Index Scans Using Function Indexes

Fixed Segment Fault Errors in CTE Queries with Always False (or NULL) Conditions

Fixed Segment Fault Errors in UNION ALL Queries Using Multiple Tables and Serial Next Values

Fixed Segment Fault Errors in Queries Using Constants Over 255 Characters Without Aliases

Fixed Errors During View Merging with OUTER JOIN

Fixed Displaying Both User and Public Views With the Same Name in **SHOW CREATE VIEW**

Fixed Missing Error Message and NULL Return in repeat() Function Exceeding string\_max\_size\_bytes Setting

Fixed Incorrect Table Positioning During INNER JOIN Removal in Query Optimization

Fixed Errors with Host Variables in PREPARE Statements Using Certain Built-in Functions

Fixed Missing User Information Deletion in System Catalog Tables When Dropping Users by The **DROP USER** Clause

Fixed Oracle-Style LEFT OUTER JOIN Not Rewriting to INNER JOIN When Using Host Variables in SP Call or WHERE Clause

Fixed Incorrect Results in Subquery with **ORDERBY\_NUM()** During View Merging

Fixed for Tables Without Join Relations Being Recognized as Join Tables During Query Optimization

Fixed ROWNUM Values Being Printed as 0 When Using Equal Condition (=) in WHERE Clause and the Same Column in ORDER BY

Fixed Errors That Occur When INNER JOIN and Oracle-Style OUTER JOIN Are Used Together and JOIN Condition Placement in WHERE Clause

Corrected Incorrect Results in **INSERT INTO tbl ... SELECT ... FROM View ... ON DUPLICATE KEY UPDATE** Query

Corrected Incorrect Column Order Numbers in Analytical Functions Inside Views

Resolved a Case Where Range Conditions Were Not Recognized as Range Items When Using The Pipe Operator (||)

Fixed An Error That Occurred When Handling NULL in Host Variables of DBLINK Statements

Fixed Issue Where Korean Characters Were Corrupted When Inserting via Host Variables Using DBLINK on EUC-KR Oracle DB

PL(JavaSP)

Resolved an Issue With Using DATETIMELTZ as a DATETIME Parameter in JavaSP

Fixed An Error That Occured Due to Space Between Declared Java Method Name and Opening Parenthesis in JavaSP

Fixed an Error that Occurred When Using Columns of Tables with Unsupported Types as Arguments in JavaSP

Fixed The **Cannot allocate query entry any more** Error in JavaSP

## Utility

Fixed The Exit Code Not Being Set to 3 When an Error Occurs During `loaddb` Execution

Fixed Incorrect **count(\*)** Value Returned After Executing `loaddb` with **-no-logging**

Fixed Error That Occurred When Processing Serials Without Schema Names During `loaddb` Execution

Fixed an Issue Where `loaddb` Would Continue Execution Even After an Error Occurred

Resolved an Error That Occurred When Processing a Synonym for System Tables During `loaddb` Execution

Corrected an Issue Where the Schema Name Was Incorrectly Stored or Missing for Trigger System-Table Columns (condition, action\_definition) During `loaddb` Execution Using `unloaddb` Files From Version 11.4 or Earlier

Addressed a Case Where Reverse Unique-Index Comments Were Missing During `unloaddb` Execution

Corrected an Issue Where the **auto\_increment** Value Was Reset to 1 for PK Columns With **auto\_increment** Set During `unloaddb` Execution

Resolved an Issue Where the **dbname\_schema\_uk** File Was Created Even When No Unique Index Existed During `unloaddb -split-schema-files` Execution

Addressed a Case Where the **ALTER SERIAL** Statement Was Missing When Executing `unloaddb` With the **-i (-input-class-only)** Option

Resolved an Error That Occurred When `current_val` and `max_val` of a Serial Were Identical During `unloaddb` Execution

Corrected an Issue Where an Infinite Loop Occurred When Processing JSON Data Over 1MB During `unloaddb` Execution

Addressed a Case Where, When Running `unloaddb` as a Regular User, Schema Names Identical to the User Were Not Removed From the `query_spec` of Views

Resolved a Case Where Schema Names for Serials and Triggers Were Missing When Executing `unloaddb` as **DBA** User

Corrected an Issue That Occured When Running `unloaddb` as a DBA User Without the `-as-dba` Option, Where Procedure Privileges Granted by Other Users (e.g., `GRANT ... ON PROCEDURE`) Were Incorrectly Included in the Output

Corrected an Issue That Occured When Running `unloaddb` as a Regular User, Where Schema Names Identical to the User Were Not Removed From the Condition and `action_definition` of Triggers

Fixed for Unnecessary Archive Log Volumes Being Created During `backupdb` Execution

Fixed an Issue Where `flashback` Did Not Terminate Properly on Forced Exit (Ctrl+C)

Resolved a Case Where `backupdb` Could Hang in Certain Situations

## Broker,CAS, CMS

Fixed a Potential Memory Leak In the Processing of *addBatch()* and *executeBatch()* in Broker/CAS/CMS

Corrected an Incorrect Output From the *getTransactionInfo()* Function Call

## HA

Addressed a Case Where Replication Logs Were Not Deleted on a Replica Node When *ha\_replica\_delay* Was Set to 60 Seconds or More in an HA Environment With Master, Slave, and Replica Nodes

Resolved an Issue Where the SQL Log File Was Not Automatically Deleted Under Certain Conditions During `applylogdb` Execution

## Cautions

### New Cautions

The database volume of CUBRID 11.4 is not compatible with that of CUBRID 11.3 and earlier versions.

- Due to the addition of new features, system catalog information has been modified or added (System Catalog). For other new precautions, please refer to [Specification Changes](#).

### Existing Cautions

## 11.3

The query optimizer's statistical information is not automatically updated when a DDL statement is executed; the user must manually execute the UPDATE STATISTICS statement to update the statistical information. (see Join Methods)

When changing the type of a column that has the AUTO\_INCREMENT property or a default value in an ALTER TABLE statement, an error occurs if the new type cannot use AUTO\_INCREMENT or if the existing default value is a type whose existing default value cannot be changed. (see :ref:change-column)

You cannot obtain a Connection object through `cubrid.jdbc.driver.CUBRIDDriver.getDefaultConnection()` from server-side JDBC. Instead, use `DriverManager.getConnection("jdbc:default:connection:")`. (see Creating Connection)

If an invalid index name or table name is used in a USE INDEX (USING INDEX) statement, it is ignored instead of raising an error. (To record it in the log file, set the `error_log` warning parameter to yes.)

When writing a CREATE INDEX statement, the position of COMMENT has been moved to the end of the statement, after the WITH or INVISIBLE clause. (see INDEX DEFINITION STATEMENTS)

## 11.2

The database volume of CUBRID 11.2 is not compatible with that of CUBRID 11.1 and earlier versions.

By introducing the concept of user schema, the same object name can be used for each user, and the behavior is changed as follows

- "." (dot) is not allowed in the object name.

- When using a query or utility command, it must be used as “[user name].object name”. (However, the user name can be omitted when querying the object of the logged-in user) (see [User Schema](#))
- Changed to include user name in info schema and show full tables results. (see [SHOW](#))
- The loaddb file prior to 11.2 must be modified to “user name.table name” so that it can be executed in 11.2, or loaddb can be executed by setting the --no-user-specified-name option. (see [loaddb](#))

The following functions and behavior changed when using “jdbc:default:connection:” or calling getDefaultConnection() in JavaSP. (see [JavaSP Caution](#))

- All functions of java.sql.DatabaseMetaData are not supported.
- createClob() and createBlob() of java.sql.Connection are not supported.
- addBatch(), clearBatch(), executeBatch(), setMaxRows() and cancel() of java.sql.Statement are not supported.
- Multiple SQL is not supported for one prepare (or execute).
- The cursor is changed to non-holdable.
- The ResultSet is changed to non-scrollable, non-sensitive and non-updatable.

The behavior of the TRUNCATE TABLE changed if there is set null or cascade of FK (see [TRUNCATE](#))

Column properties not written during alter change/modify are changed to be maintained, and auto\_increment and on update properties cannot be removed with the alter statement (see [CHANGE/MODIFY Clauses](#))

Changed to handle an error if only the column name exists in the where clause

- If used in the form of UPDATE t1 SET c1 = 9 WHERE c1; , an error occurs.

## Multiple SQL must be separated by semicolons

The CCI Driver directory in the CUBRID package is changed from \$CUBRID/lib and \$CUBRID/include to \$CUBRID/cci/lib and \$CUBRID/cci/include, respectively (see [CCI Overview](#))

- When using CCI, \$CUBRID/cci/lib must be added to LD\_LIBRARY\_PATH in the environment variable.

## Changed Compression (-z, --compress) option to default on backup (see [backupdb](#))

- System catalog information changed or added due to the addition of new features (see [System Catalog](#))

## 11.0

The database volume of CUBRID 11.0 is not compatible with that of CUBRID 10.2 and earlier versions.

When creating a table without an option, it is created as a reuse\_oid table.

The maximum length of the CHAR data type has been changed to 256M character string.

Modified to occur error when the input string length is longer than the set length of the string data type.

Modified to recognize the space character at the end of the string, it is recognized as a different character string according to the space character at the end of the string.

Due to the change in the statistics collection method, it is necessary to perform periodic statistics collection.

## 10.2

The database volume of CUBRID 10.2 is not compatible with that of CUBRID 10.1 and earlier versions.

## 10.1

The database volume of CUBRID 10.1 is not compatible with that of CUBRID 10.0 and earlier versions.

### Version 10.0 and earlier

The database volume of CUBRID 10.0 is not compatible with that of CUBRID 9.3 and earlier versions.

Locale(language and charset) is specified when creating DB

- It is changed as locale is specified when creating DB.

### CUBRID\_CHARSET environment variable is removed

- As locale(language and charset) is specified when creating DB from 9.2 version, CUBRID\_CHARSET is not used anymore.

[JDBC] Change zero date of TIMESTAMP into '1970-01-01 00:00:00'(GST) from '0001-01-01 00:00:00' when the value of zeroDateTimeBehavior in the connection URL is "round"(CUBRIDSUS-11612)

- From 2008 R4.4, when the value of the property "zeroDateTimeBehavior" in the connection URL is "round", the zero date value of TIMESTAMP is changed into '1970-01-01 00:00:00'(GST) from '0001-01-01 00:00:00'. You should be cautious when using zero date in your application.

### Recommendation for installing CUBRID SH package in AIX(CUBRIDSUS-12251)

- If you install CUBRID SH package by using ksh in AIX OS, it fails with the following error.

```
0403-065 An incomplete or invalid multibyte character encountered.
```

- Therefore, it is recommended to use ksh93 or bash instead of ksh.

```
$ ksh93 ./CUBRID-9.2.0.0146-AIX-ppc64.sh
$ bash ./CUBRID-9.2.0.0146-AIX-ppc64.sh
```

## CUBRID\_LANG is removed, CUBRID\_MSG\_LANG is added

- From version 9.1, CUBRID\_LANG environment variable is no longer used.
- To output the utility message and the error message, the CUBRID\_MSG\_LANG environment variable is used.

## Modify how to process an error for the array of the result of executing several queries at once in the CCI application(CUBRIDSUS-9364)

- When executing several queries at once in the CCI application, if an error has occurs from at least one query among the results of executing queries by using the cci\_execute\_array function, the cci\_execute\_batch function, the error code of the corresponding query was returned from 2008 R3.0 to 2008 R4.1. This problem has been fixed to return the number of the entire queries and check the error of each query by using the CCI\_QUERY\_RESULT\_\* macros from 2008 R4.3 and 9.1.
- In earlier versions of this modification, there is no way to know whether each query in the array is success or failure when an error occurs; therefore, it it requires certain conditions.

```
...
char *query = "INSERT INTO test_data (id, ndata, cdata, sdata,
ldata) VALUES (?, ?, 'A', 'ABCD', 1234)";
...
req = cci_prepare (con, query, 0, &cci_error);
...
error = cci_bind_param_array_size (req, 3);
...
error = cci_bind_param_array (req, 1, CCI_A_TYPE_INT, co_ex,
null_ind, CCI_U_TYPE_INT);
...
n_executed = cci_execute_array (req, &result, &cci_error);

if (n_executed < 0)
{
    printf ("execute error: %d, %s\n", cci_error.err_code,
cci_error.err_msg);

    for (i = 1; i <= 3; i++)
    {
        printf ("query %d\n", i);
    }
}
```

```

        printf ("result count = %d\n", CCI_QUERY_RESULT_RESULT
(result, i));
        printf ("error message = %s\n", CCI_QUERY_RESULT_ERR_MSG
(result, i));
        printf ("statement type = %d\n", CCI_QUERY_RESULT_STMT_TYPE
(result, i));
    }
}
...

```

- From the modified version, entire queries are regarded as failure if an error occurs. In case that no error occurred, it is determined whether each query in the array succeeds or not.

```

...
char *query = "INSERT INTO test_data (id, ndata, cdata, sdata,
ldata) VALUES (?, ?, 'A', 'ABCD', 1234)";
...
req = cci_prepare (con, query, 0, &cci_error);
...
error = cci_bind_param_array_size (req, 3);
...
error = cci_bind_param_array (req, 1, CCI_A_TYPE_INT, co_ex,
null_ind, CCI_U_TYPE_INT);
...
n_executed = cci_execute_array (req, &result, &cci_error);
if (n_executed < 0)
{
    printf ("execute error: %d, %s\n", cci_error.err_code,
cci_error.err_msg);
}
else
{
    for (i = 1; i <= 3; i++)
    {
        printf ("query %d\n", i);
        printf ("result count = %d\n", CCI_QUERY_RESULT_RESULT
(result, i));
        printf ("error message = %s\n", CCI_QUERY_RESULT_ERR_MSG
(result, i));
        printf ("statement type = %d\n", CCI_QUERY_RESULT_STMT_TYPE
(result, i));
    }
}
...

```

## In java.sql.XAConnection interface, HOLD\_CURSORS\_OVER\_COMMIT is not supported(CUBRIDSUS-10800)

- Current CUBRID does not support ResultSet.HOLD\_CURSORS\_OVER\_COMMIT in java.sql.XAConnection interface.

## From 9.0, STRCMP behaves case-sensitively

- Until the previous version of 9.0, STRCMP did not distinguish an uppercase and a lowercase. From 9.0, it compares the strings case-sensitively.
- To make STRCMP case-insensitive, you should use case-insensitive collation(e.g.: utf8\_en\_ci).

```
-- In previous version of 9.0 STRCMP works case-insensitively
SELECT STRCMP ('ABC','abc');
0

-- From 9.0 version, STRCMP distinguish the uppercase and the
lowercase when the collation is case-sensitive.
export CUBRID_CHARSET=en_US.iso88591

SELECT STRCMP ('ABC','abc');
-1

-- If the collation is case-insensitive, it distinguish the
uppercase and the lowercase.
export CUBRID_CHARSET=en_US.iso88591

SELECT STRCMP ('ABC' COLLATE utf8_en_ci , 'abc' COLLATE utf8_en_ci);
0
```

## Since the 2008 R4.1 version, the Default value of CCI\_DEFAULT\_AUTOCOMMIT has been ON(CUBRIDSUS-5879)

- The default value for the CCI\_DEFAULT\_AUTOCOMMIT broker parameter, which affects the auto commit mode for applications developed with CCI interface, has been changed to ON since CUBRID 2008 R4.1. As a result of this change, CCI and CCI-based interface (PHP, ODBC, OLE DB etc.) users should check whether or not the application's auto commit mode is suitable for this.

## From the 2008 R4.0 version, the options and parameters that use the unit of pages were changed to use the unit of volume size(CUBRIDSUS-5136)

- The options (-p, -l, -s), which use page units to specify the database volume size and log volume size of the cubrid createdb utility, will be removed. Instead, the new options, added after 2008 R4.0 Beta (-db-volume-size, -log-volume-size, -db-page-size, -log-page-size), are used.
- To specify the database volume size of the cubrid addvoldb utility, use the newly-added option (-db-volume-size) after 2008 R4.0 Beta instead of using the page unit.
- It is recommended to use the new system parameters in bytes because the page-unit system parameters will be removed. For details on the related system parameters, see the below.

## Be cautious when setting db volume size if you are a user of a version before 2008 R4.0 Beta(CUBRIDSUS-4222)

- From the 2008 R4.0 Beta version, the default value of data page size and log page size in creating the database was changed from 4 KB to 16 KB. If you specify the database volume to the page count, the byte size of the volume may differ from your expectations. If you did not set any options, 100MB-database volume with 4KB-page size was created in the previous version. However, starting from the 2008 R4.0, 512MB-database volume with 16KB-page size is created.
- In addition, the minimum size of the available database volume is limited to 20 MB. Therefore, a database volume less than this size cannot be created.

## The change of the default value of some system parameters of the versions before 2008 R4.0(CUBRIDSUS-4095)

- Starting from 2008 R4.0, the default values of some system parameters have been changed.
- Now, the default value of max\_clients, which specifies the number of concurrent connections allowed by a DB server, and the default value of index\_unfill\_factor that specifies the ratio of reserved space for future updates while creating an index page, have been changed. Furthermore, the default values of the system parameters in bytes now use more memory when they exceed the default values of the previous system parameters per page.

| Previous Parameter          | System | Added Parameter            | System | Previous Value     | Default | Changed Value (unit: byte) | Default |
|-----------------------------|--------|----------------------------|--------|--------------------|---------|----------------------------|---------|
| max_clients                 |        | None                       |        | 50                 |         | 100                        |         |
| index_unfill_factor         |        | None                       |        | 0.2                |         | 0.05                       |         |
| data_buffer_pages           |        | data_buffer_size           |        | 100M(page size=4K) |         | 512M                       |         |
| log_buffer_pages            |        | log_buffer_size            |        | 200K(page size=4K) |         | 4M                         |         |
| sort_buffer_pages           |        | sort_buffer_size           |        | 64K(page size=4K)  |         | 2M                         |         |
| index_scan_oid_buffer_pages |        | index_scan_oid_buffer_size |        | 16K(page size=4K)  |         | 64K                        |         |

- In addition, when a database is created using cubrid createdb, the minimum value of the data page size and the log page size has been changed from 1K to 4K.

### Changed so that database services, utilities, and applications cannot be executed when the system parameter is incorrectly configured(CUBRIDSUS-5375)

- It has been changed so that now the related database services, utilities, and applications are not executed when configuring system parameters that are not defined in cubrid.conf or cubrid\_ha.conf, when the value of system parameters exceed the threshold, or when the system parameters per page and the system parameters in bytes are used simultaneously.

### Database fails to start if the data\_buffer\_size is configured with a value that exceeds 2G in CUBRID 32-bit version(CUBRIDSUS-5349)

- In the CUBRID 32-bit version, if the value of data\_buffer\_size exceeds 2G, the running database fails. Note that the configuration value cannot exceed 2G in the 32-bit version because of the OS limit.

## Recommendations for controlling services with the CUBRID Utility in Windows Vista and higher(CUBRIDSUS-4186)

- To control services using cubrid utility from Windows Vista and higher, it is recommended to start the command prompt window with administrative privileges.
- If you don't start the command prompt window with administrative privileges and use the cubrid utility, you can still execute it with administrative privileges through the User Account Control (UAC) dialog box, but you will not be able to verify the resulting messages.

The procedures for starting the command prompt window as an administrator in Windows Vista and higher are as follows:

- Right-click [Start > All Programs > Accessories > Command Prompt].
- When [Execute as an administrator (A)] is selected, a dialog box to verify the privilege escalation is activated. Click "YES" to start with administrative privileges.

## A manager server process-related error occurs in the execution of the CUBRID source after its build(CUBRIDSUS-3553)

- If users want to build the CUBRID source and install it themselves, they must build and install CUBRID and the CUBRID Manager respectively. If you check out only CUBRID source and run cubrid service start or cubrid manager start after build, the error "cubrid manager server is not installed" will occur.

## GLO class which is used in 2008 r3.0 or before is not supported any longer(CUBRIDSUS-3826)

- CUBRID 2008 R3.0 and earlier versions processed Large Objects with the Generalized Large Object glo class, but the glo class has been removed from CUBRID 2008 R3.1 and later versions. Instead, they support BLOB and CLOB (LOB from this point forward) data types. (See [BLOB/CLOB Data Types](#) for more information about LOB data types).
- glo class users are recommended to carry out tasks as follows:
  - After saving GLO data as a file, modify to not use GLO in any application and DB schema.
  - Implement DB migration by using the unloaddb and loaddb utilities.
  - Perform tasks to load files into LOB data according to the modified application.
  - Verify the application that you modified operates normally.

- For reference, if the cubrid loaddb utility loads a table that inherits the GLO class or has the GLO class type, it stops the data from loading by displaying an error message, “Error occurred during schema loading.”
- With the discontinued support of GLO class, the deleted functions for each interface are as follows:

| Interface | Deleted Functions                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCI       | <code>cci_glo_append_data</code><br><code>cci_glo_compress_data</code><br><code>cci_glo_data_size</code><br><code>cci_glo_delete_data</code><br><code>cci_glo_destroy_data</code><br><code>cci_glo_insert_data</code><br><code>cci_glo_load</code><br><code>cci_glo_new</code><br><code>cci_glo_read_data</code><br><code>cci_glo_save</code><br><code>cci_glo_truncate_data</code><br><code>cci_glo_write_data</code> |
| JDBC      | <code>CUBRIDConnection.getNewGLO</code><br><code>CUBRIDOID.loadGLO</code><br><code>CUBRIDOID.saveGLO</code>                                                                                                                                                                                                                                                                                                            |

| Interface | Deleted Functions                                                               |
|-----------|---------------------------------------------------------------------------------|
| PHP       | cubrid_new_glo<br>cubrid_save_to_glo<br>cubrid_load_from_glo<br>cubrid_send_glo |

Port configuration is required if the protocol between the master and server processes is changed, or if two versions are running at the same time(CUBRIDSUS-3564)

- Because the communication protocol between a master process (cub\_master) and a server process (cub\_server) has been changed, the master process of CUBRID 2008 R3.0 or later cannot communicate with the server process of a lower version, and the master process of a lower version cannot communicate with a server process of 2008 R3.0 version or later. Therefore, if you run two versions of CUBRID at the same time by adding a new version in an environment where a lower version has already been installed, you should modify the cubrid\_port\_id system parameter of cubrid.conf so that different ports are used by the different versions.

Specifying a question mark when entering connection information as a URL string in JDBC(CUBRIDSUS-3217)

- When entering connection information as a URL string in JDBC, property information was applied even if you did not enter a question mark (?) in the earlier version. However, you must specify a question mark depending on syntax in this CUBRID 2008 R3.0 version. If not, an error is displayed. In addition, you must specify colon (:) even if there is no username or password in the connection information.

```
URL=jdbc:CUBRID:
127.0.0.1:31000:db1:::altHosts=127.0.0.2:31000,127.0.0.3:31000 --
Error
URL=jdbc:CUBRID:127.0.0.1:31000:db1:::?
altHosts=127.0.0.2:31000,127.0.0.3:31000 -- Normal
```

## Not allowed to include @ in a database name(CUBRIDSUS-2828)

- If @ is included in a database name, it can be interpreted that a host name has been specified. To prevent this, a revision has been made so that @ cannot be included in a database name when running cubrid createdb, cubrid renamedb and cubrid copydb utilities.

## General Information

### Revision history

| Revision Date | Description                  |
|---------------|------------------------------|
| Mar 2025      | CUBRID 11.4 Release (11.4.0) |

### Bug Reports and User Feedback

CUBRID welcomes your active participation in bug reporting and looks forward to your feedback. You can register your bug reports and feedback on the following Websites:

### License

The Apache license 2.0 applies to the CUBRID server engine, and the BSD license applies to CUBRID MANAGER and interfaces (APIs). For more information, see the License Policy on <https://www.cubrid.org/license>.

### Additional Information

Regarding CUBRID upgrade and migration, see [Upgrade](#).

Regarding the recent CUBRID sources, visit <https://github.com/CUBRID/cubrid> and <https://github.com/CUBRID>.

## Note on Drivers

Currently, CUBRID supports the following drivers: JDBC, CCI(CUBRID C API), Node.js, PHP, PDO, Python, Perl, Ruby, ADO.NET, ODBC, OLE DB. These drivers except JDBC, Node.js and ADO.NET are developed on top of CCI. Therefore, CCI changes can affect CCI-based drivers.
